The innate immune system cells are the first to respond, these include the following types of leukocytes: mast cells, macrophages, natural killer cells, dendritic cells, monocytes, neutrophils, basophils, and eosinophils (described in Figure 11.?). Cells of the adaptive immune system are classified as lymphocytes (a type of leukocyte) and include two main types: T-cells and B-cells (the letters denote 'thymus' and 'bone marrow', the tissues where each of these leukocytes mature).

Cell type	Characteristics	Location	Image
Mast cell	Dilates blood vessels and induces inflammation through release of histamines and heparin. Recruits macrophages and neutrophils. Involved in wound healing and defense against pathogens but can also be responsible for allergic reactions.	Connective tissues, mucous membranes	
Macrophage	Phagocytic cell that consumes foreign pathogens and cancer cells. Stimulates response of other immune cells.	Migrates from blood vessels into tissues.	
Natural killer cell	Kills tumor cells and virus-infected cells.	Circulates in blood and migrates into tissues.	
Dendritic cell	Presents antigens on its surface, thereby triggering adaptive immunity.	Present in epithelial tissue, including skin, lung and tissues of the digestive tract. Migrates to lymph nodes upon activation.	
Monocyte	Differentiates into macrophages and dendritic cells in response to inflammation.	Stored in spleen, moves through blood vessels to infected tissues.	
Neutrophil	First responders at the site of infection or trauma, this abundant phagocytic cell represents 50-60 percent of all leukocytes. Releases toxins that kill or inhibit bacteria and fungi and recruits other immune cells to the site of infection.	Migrates from blood vessels into tissues.	
Basophil	Responsible for defense against parasites. Releases histamines that cause inflammation and may be responsible for allergic reactions.	Circulates in blood and migrates to tissues.	
Eosinophil	Releases toxins that kill bacteria and parasites but also causes tissue damage.	Circulates in blood and migrates to tissues.	

Figure 16.1.4.1.4: The characteristics and location of cells involved in the innate immune system

Steps to the The Immune System Battle:

- The cellular immune response begins when a pathogen gets through the bodies physical and chemical barriers.
- If a pathogen gets past the hosts defenses it will attempt to infect the host and begin replicating itself. The subsequent battle between the germs and the body's immune system will cause the symptoms of illness.
- The first immune cells to respond to the invading pathogen are the innate immune cells: mast cells, macrophages, natural killer cells, dendritic cells, monocytes, neutrophils, basophils, and eosinophils. These cells are always ready to fight off pathogens and work hard to destroy the foreign invaders.
- Actions of the innate immune system cells
    - Dendritic Cells: Ingest pathogen and help activate the adaptive immune system by presenting their antigen to Helping T-Cells and killer T-Cells.

    - Neutrophils: Migrate from the bloodstream to ingest and kill bacteria and fungi and recruit more immune cells.
    - Macrophages: Known as the “big eaters”, they ingest pathogens and dead cells and help activate the adaptive immune system by presenting their antigen. They also recruit more immune cells.
    - Mast Cells: launch inflammatory response and recruit macrophages and neutrophils.
    - Natural Killer cells: Detect and kill tumor or virus infected cells.
    - Basophils: Defend against parasites and contribute to inflammatory response.
    - Eosinophils: Kill bacteria and parasites.
- The innate immune cells alert the whole body that there is a problem by activating the inflammatory response and initiating the adaptive immune system.
- The inflammatory response brings swelling, pain and higher temperature, which attracts more cells to the site of infection. This means more immune cells join the fight to destroy the pathogen.

- The innate immune cells provide important information to the adaptive immune cells to “train” the adaptive immune cells how to destroy the pathogen.
- Training the adaptive immune cells is done in two ways, by releasing cytokines and displaying the pathogens antigens.
    - Cytokines are signals that tell cells what to do and where to go. Your body responds to threats in different ways depending on the cytokine signal released by your immune cells.
    - The antigen is displayed when the innate immune cells capture and breakdown the invader.
    - Together, the cytokines and antigens train individual adaptive immune cells to recognize and destroy specific patterns of each foreign invader.
- The Adaptive Immune System Cells
    - Helper and killer T-Cells are activated after the Dendritic cells engulf the pathogen.
    - When the helper T-Cells create B-Cells they are initiating the adaptive immune system.
    - Antibodies, B Cells, are then produced that attach to the pathogen.
    - The B Cells divide to produce plasma and memory cells.
    - If the same pathogen invades again, the memory cells help the immune system activate much quicker.
- When the adaptive cells are “trained” how to fight a specific antigen, they remember how to fight it, thus the next time that this pathogen tries to infect you your adaptive immune cells will remember it and destroy it quickly.
- The ability of the immune system to remember previous pathogens is commonly called adaptive or acquired immunity and is the basis for vaccines.
- However, pathogens really want to live and they can be tricky. Some pathogens, including those that cause flu, strep throat, and malaria, can mutate and change the way they look to your immune system over time by changing their antigen markers thus disguising themselves marking it harder for your immune system to recognize the mutated germs even though you’ve been exposed to them before. This is why you can get sick from flu, strep throat, or COVID multiple times.

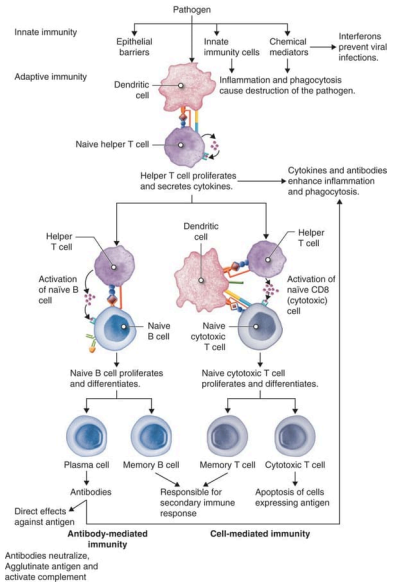

Figure 16.1.4.1.5 : Overview of Innate and Adaptive Immunity

Vaccines

It is possible to acquire adaptive immunity naturally or artificially. Natural immunity results from natural exposure to an antigen.

For example, someone sneezes the influenza virus into the air and then it is breathed into another person's nasal passageway. However, artificial immunity refers to deliberately introducing an antigen into an individual to stimulate an immune response, known as a vaccine. Whether you have been introduced to a pathogen naturally or artificially the end result is the same, to develop memory cells to acquire immunity against the pathogen.

If the immune system did not have the ability to remember pathogens then vaccines would not work; vaccines are effective because of memory cells. The mechanism underlying vaccination is that exposure of the adaptive immune system to a small dose of an antigen will produce an initial immune response. More importantly, this small dose of antigen establishes a population of memory T and B cells that will live long-term in the body. When that antigen is encountered again, the immune system is already primed. Upon a subsequent exposure, a more robust and faster response is established and the pathogen is destroyed faster. Vaccines can either prevent or decrease the severity of infections.

There are several different types of vaccines and even more types of vaccines in development. Each type is designed to teach your immune system how to fight off certain kinds of germs—and the serious diseases they cause. When scientists create vaccines, they consider how your immune system responds to the germ, who needs to be vaccinated against the germ, and the best technology or approach to create the vaccine.

Table 16.1.4.1.3 *: Vaccine Types, Characteristics, and Protections from Disease*

Vaccine Type	Characteristics	Vaccine Protects against
Inactivated vaccines	• Inactivated vaccines use the killed version of the germ that causes a disease. • Inactivated vaccines usually don't provide immunity (protection) that's as strong as live vaccines. So you may need several doses over time (booster shots) in order to get ongoing immunity against diseases.	• Hepatitis A • Flu (shot only) • Polio • (shot only)Rabies
Live-attenuated vaccines	• Live vaccines use a weakened (or attenuated) form of the germ that causes a disease. • Because these vaccines are so similar to the natural infection that they help prevent, they create a strong and long-lasting immune response. Just 1 or 2 doses of most live vaccines can give you a lifetime of protection against a germ and the disease it causes. • But live vaccines also have some limitations. For example: ◦ Because they contain a small amount of the weakened live virus, some people should talk to their health care provider before receiving them, such as people with weakened immune systems, long-term health problems, or people who've had an organ transplant. ◦ They need to be kept cool, so they don't travel well. That means they can't be used in countries with limited access to refrigerators.	• Measles, mumps, rubella (MMR combined vaccine) • Rotavirus • Smallpox • Chickenpox • Yellow fever
Messenger RNA (mRNA) vaccines	• Researchers have been studying and working with mRNA vaccines for decades and this technology was used to make some of the COVID-19 vaccines. • mRNA vaccines make proteins in order to trigger an immune response. • mRNA vaccines have several benefits compared to other types of vaccines, including shorter manufacturing times and, because they do not contain a live virus, no risk of causing disease in the person getting vaccinated.	• COVID-19

Vaccine Type	Characteristics	Vaccine Protects against
Subunit, recombinant, polysaccharide, and conjugate vaccines	• Subunit, recombinant, polysaccharide, and conjugate vaccines use specific pieces of the germ—like its protein, sugar, or capsid (a casing around the germ). • Because these vaccines use only specific pieces of the germ, they give a very strong immune response that's targeted to key parts of the germ. They can also be used on almost everyone who needs them, including people with weakened immune systems and long-term health problems. • One limitation of these vaccines is that you may need booster shots to get ongoing protection against diseases.	• Hib (Haemophilus influenzae type b) disease • Hepatitis BHPV (Human papillomavirus) • Whooping cough (part of the DTaP combined vaccine) • Pneumococcal disease • Meningococcal disease • Shingles
Toxoid vaccines	• Toxoid vaccines use a toxin (harmful product) made by the germ that causes a disease. They create immunity to the parts of the germ that cause a disease instead of the germ itself. That means the immune response is targeted to the toxin instead of the whole germ.Like some other types of vaccines, you may need booster shots to get ongoing	• Diphtheria • Tetanus
Viral vector vaccines	• For decades, scientists studied viral vector vaccines. Some vaccines recently used for Ebola outbreaks have used viral vector technology, and a number of studies have focused on viral vector vaccines against other infectious diseases such as Zika, flu, and HIV. Scientists used this technology to make COVID-19 vaccines as well. • Viral vector vaccines use a modified version of a different virus as a vector to deliver protection. Several different viruses have been used as vectors, including influenza, vesicular stomatitis virus (VSV), measles virus, and adenovirus, which causes the common cold. Adenovirus is one of the viral vectors used in some COVID-19 vaccines being studied in clinical trials.	• Ebola • COVID-19
DNA vaccines	• In development. • Easy and inexpensive to make—and they produce strong, long-term immunity.	In development. No vaccines available yet.
Recombinant vector vaccines (platform-based vaccines)	• In development • Act like a natural infection, so they're especially good at teaching the immune system how to fight germs.	In development. No vaccines available yet.

There is another way to get temporary immunity and that is called passive immunity, which is when antibodies are provided to the person from a donor recipient, for example from a mother to child as antibodies move across the placenta before birth. Passive immunity is not long-lasting because the individual does not produce memory cells.

This page titled 16.1.4.1: The Immune System is shared under a CC BY-NC 4.0 license and was authored, remixed, and/or curated by Manomita Patra and Yeny Pena-Grafton.

- 11.6: Fermentation has no license indicated.

16.1.4.2: Sexually Transmitted Diseases (STD'S)

There are approximately 20 different infections that are known to be transmitted through sexual contact. One in five people in the U.S. has an STD. While sexually transmitted diseases (STDs) affect individuals of all ages, STDs take a particularly heavy toll on young people. CDC estimates that youth ages 15-24 account for almost half of the 26 million new sexually transmitted infections that occurred in the United States in 2018.

Many cases of chlamydia, gonorrhea, and syphilis continue to go undiagnosed and unreported, and data on several additional STDs — such as human papillomavirus, herpes simplex virus, and trichomoniasis — are not routinely reported to CDC. Many STD's are asymptomatic, meaning they do not show any symptoms, yet can still be spread to sexual partners. As a result, the CDC data on rates of STD's only captures a fraction of the true burden of STDs in America. However, it provides important insights into the scope, distribution, and trends in STD diagnoses in the country.

Table

Year			
Rate of Syphilis	**Rate of Chlamydia**	**Rater of Gonorrhea**	
1985	28.4	17.4	383
1990	54.3	160.2	276.4
1995	26	187.8	147.5
2000	11.2	251.4	128.7
2005	11.2	329.4	114.6
2010	14.8	423.6	100.2
2015	23.2	475	123
2020	40.8	481.3	206.5

It is important to understand the risk factors and symptoms of STD's in order to protect yourself and your partners. It is also important to understand the impacts to your health if you do not get treatment.

Women who do not get treatment for STD's can get Pelvic Inflammatory Disease (PID). PID is a serious condition which left untreated can cause scar tissue and abscesses to develop in the reproductive tract which can lead to permanent damage to the reproductive organs. PID can cause ectopic pregnancy (in which the fetus develops in abnormal places outside of the womb, a condition that can be life-threatening) and infertility.

For more detailed information, review the CDC fact sheet for Pelvic Inflammatory Disease (PID

Partners who do not get treated for an STD can be at an increased risk of contracting or spreading HIV/AIDS. If you get an STD and you have a sore or break in the skin from the STD, this may allow HIV to more easily enter your body and people who have HIV are more likely to spread HIV if they have an STD. The same behaviors and circumstances that may put you at risk for getting an STD also can put you at greater risk for getting HIV. In addition, having a sore or break in the skin from an STD may allow HIV to more easily enter your body. If you are sexually active, get tested for STDs and HIV regularly, even if you don't have symptoms.

For more detailed information, review the CDC fact sheet for HIV/AIDS & STDs

Bacterial Vaginosis

Bacterial vaginosis (BV) is a condition that happens when there is too much of certain bacteria in the vagina. This changes the normal balance of bacteria in the vagina. BV is the most common vaginal condition in women ages 15-44.

Researchers do not know the cause of BV. However, we do know the condition most often occurs in those who are sexually active. BV is a result of an imbalance of "good" and "harmful" bacteria in a vagina. Douching, not using condoms, and having new or

multiple sex partners can upset the normal balance of vaginal bacteria, increasing your risk for getting BV.

We also do not know how sex causes BV. There also is no research to show that treating a sex partner affects whether someone gets BV. Having BV can increase your chances of getting other STDs.

BV rarely affects those who have never had sex.

You cannot get BV from toilet seats, bedding, or swimming pools.

Many people with BV do not have symptoms. If you do have symptoms, you may notice:

- A thin white or gray vaginal discharge;
- Pain, itching, or burning in the vagina;
- A strong fish-like odor, especially after sex;
- Burning when peeing; and
- Itching around the outside of the vagina.

For more detailed information, review the CDC fact sheet for Bacterial Vaginosis (BV)

Chlamydia

Chlamydia is a common bacterial STD that can cause infection among both men and women. It can cause permanent damage to a woman's reproductive system. This can make it difficult or impossible to get pregnant later. Chlamydia can also cause a potentially fatal ectopic pregnancy (pregnancy that occurs outside the womb).

You can get chlamydia by having vaginal, anal, or oral sex with someone who has chlamydia. Also, you can still get chlamydia even if your sex partner does not ejaculate (cum). A pregnant person with chlamydia can give the infection to their baby during childbirth.

Chlamydia often has no symptoms, but it can cause serious health problems, even without symptoms. If symptoms occur, they may not appear until several weeks after having sex with a partner who has chlamydia.

Even when chlamydia has no symptoms, it can damage a woman's reproductive system.

Women with symptoms may notice:

- An abnormal vaginal discharge; and
- A burning sensation when peeing.

Symptoms in men can include:

- A discharge from their penis;
- A burning sensation when peeing; and
- Pain and swelling in one or both testicles (although this is less common).

Men and women can also get chlamydia in their rectum. This happens either by having receptive anal sex, or by spread from another infected site (such as the vagina). While these infections often cause no symptoms, they can cause

- Rectal pain;
- Discharge; and
- Bleeding.

See a healthcare provider if you notice any of these symptoms. You should also see a provider if your partner has an STD or symptoms of one. Symptoms can include

- An unusual sore;
- A smelly discharge;
- Burning when peeing; or
- Bleeding between periods.

For more detailed information, review the CDC fact sheet for Chlamydia

Gonorrhea

Gonorrhea is is a common bacterial STD that can cause infection in the genitals, rectum, and throat. It is very common, especially among young people ages 15-24 years.

You can get gonorrhea by having vaginal, anal, or oral sex with someone who has gonorrhea. A pregnant person with gonorrhea can give the infection to their baby during childbirth.

Gonorrhea often has no symptoms, but it can cause serious health problems, even without symptoms.

Most women with gonorrhea do not have any symptoms. Even when a woman has symptoms, they are often mild and can be mistaken for a bladder or vaginal infection.

Symptoms in women can include:

- Painful or burning sensation when peeing;
- Increased vaginal discharge; and
- Vaginal bleeding between periods.

Men who do have symptoms may have:

- A burning sensation when peeing;
- A white, yellow, or green discharge from the penis; and
- Painful or swollen testicles (although this is less common).

Rectal infections may either cause no symptoms or cause symptoms in both men and women that may include:

- Discharge;
- Anal itching;
- Soreness;
- Bleeding; and
- Painful bowel movements.

See your healthcare provider if you notice any of these symptoms. You should also see a provider if your partner has an STD or symptoms of one. Symptoms can include an unusual sore, a smelly discharge, burning when peeing, or bleeding between periods.

For more detailed information, review the CDC fact sheet for Gonorrhea

Genital Herpes

Genital herpes is common viral STD in the United States. In 2018, CDC estimates show there were 572,000 new genital herpes infections in the United States among people aged 14 to 49.

HSV-1 often causes oral herpes, which can result in cold sores or fever blisters on or around the mouth. HSV-1 is typically acquired during childhood, is very common, and often has no symptoms. HSV-2 is a sexually transmitted disease that causes genital herpes. Oral herpes caused by HSV-1 can spread from the mouth to the genitals through oral sex, thus Genital herpes is an STD that can be caused by two types of viruses – herpes simplex virus type 1 (HSV-1) and herpes simplex virus type 2 (HSV-2).

You can get genital herpes by having vaginal, anal, or oral sex with someone who has the infection. You can get herpes if you have contact with:

- A herpes sore;
- Saliva from a partner with an oral herpes infection;
- Genital fluids from a partner with a genital herpes infection;
- Skin in the oral area of a partner with oral herpes; or
- Skin in the genital area of a partner with genital herpes.

You also can get genital herpes from a sex partner who does not have a visible sore or is unaware of their infection. It is also possible to get genital herpes if you receive oral sex from a partner with oral herpes.

You will not get herpes from toilet seats, bedding, or swimming pools. You also will not get it from touching objects, such as silverware, soap, or towels.

Most people with genital herpes have no symptoms or have very mild symptoms. Mild symptoms may go unnoticed or be mistaken for other skin conditions like a pimple or ingrown hair. Because of this, most people do not know they have a herpes infection.

Herpes sores usually appear as one or more blisters on or around the genitals, rectum or mouth. This is known as having an "outbreak". The blisters break and leave painful sores that may take a week or more to heal. Flu-like symptoms (e.g., fever, body aches, or swollen glands) also may occur during the first outbreak.

For more detailed information, review the CDC fact sheet for Genital Herpes

Hepatitis

Hepatitis means inflammation of the liver. The liver is a vital organ that processes nutrients, filters the blood, and fights infections. When the liver is inflamed or damaged, its function can be affected. Heavy alcohol use, toxins, some medications, and certain medical conditions can cause hepatitis. However, hepatitis is often caused by a virus. In the United States, the most common types of viral hepatitis are hepatitis A, hepatitis B, and hepatitis C (there is also Hepatitis D and E).

Hepatitis A and B can be transmitted through sexual activity, it is less common to be infected with Hepatitis C through sexual intercourse.

For more detailed information, review the CDC fact sheet for Hepatitis

Human Papillomavirus Virus (HPV)- Genital Warts

HPV is a viral STD and the most common STD/STI. There were about 43 million HPV infections in 2018, many among people in their late teens and early 20s. There are many different types of HPV. Some types can cause health problems, including genital warts and cancers. But there are vaccines that can stop these health problems from happening. HPV is a different virus than HIV and HSV (herpes).

You can get HPV by having vaginal, anal, or oral sex with someone who has the virus. It is most commonly spread during vaginal or anal sex. It also spreads through close skin-to-skin touching during sex. A person with HPV can pass the infection to someone even when they have no signs or symptoms. If you are sexually active, you can get HPV, even if you have had sex with only one person. You also can develop symptoms years after having sex with someone who has the infection. This makes it hard to know when you first got it.

HPV can cause cervical and other cancers, including cancer of the vulva, vagina, penis, or anus. It can also cause cancer in the back of the throat (called oropharyngeal cancer). This can include the base of the tongue and tonsils. Cancer often takes years, even decades, to develop after a person gets HPV. Genital warts and cancers result from different types of HPV.

There is no test to find out a person's "HPV status." Also, there is no approved HPV test to find HPV in the mouth or throat. However, there are HPV tests that can screen for cervical cancer. Most people with HPV do not know they have the infection. They never develop symptoms or health problems from it. Some people find out they have HPV when they get genital warts. Women may find out they have HPV when they get an abnormal Pap test result (during cervical cancer screening). Others may only find out once they've developed more serious problems from HPV, such as cancers.

There is a vaccine available to prevent new HPV infections. The HPV vaccine is recommended for routine vaccination starting at age 11 or 12 years (can be started at age 9). Vaccination is not recommended for everyone older than age 26 years, however adults ages 27 through 45 years might decide to get the HPV vaccine based on discussion with their clinician, if they did not get adequately vaccinated when they were younger.

For more detailed information, review the CDC fact sheet for Human Papillomavirus (HPV

Syphilis

Syphilis is a bacterial sexually transmitted infection (STI) that can cause serious health problems without treatment. Infection develops in stages (primary, secondary, latent, and tertiary). Each stage can have different signs and symptoms.

You can get syphilis by direct contact with a syphilis sore during vaginal, anal, or oral sex. You cannot get syphilis through casual contact with objects, such as toilet seats or doorknobs.

Syphilis can spread from a mother with syphilis to her unborn baby.

There are four stages of syphilis (primary, secondary, latent, and tertiary). Each stage has different signs and symptoms. Without treatment, syphilis can spread to the brain and nervous system (neurosyphilis), the eye (ocular syphilis), or the ear (otosyphilis) during any of the four stages.

- Primary Stage
  - During the first (primary) stage of syphilis, you may notice a single sore or multiple sores. The sore is the location where syphilis entered your body. These sores usually occur in, on, or around the penis, vagina, anus, rectum, or mouth.
  - Sores are usually (but not always) firm, round, and painless. Because the sore is painless, you may not notice it. The sore usually lasts 3 to 6 weeks and heals regardless of whether you receive treatment.
  - Even after the sore goes away, you must still receive treatment. This will stop your infection from moving to the secondary stage.
- Secondary Stage
  - During the secondary stage, you may have skin rashes and/or sores in your mouth, vagina, or anus.
  - This stage usually starts with a rash on one or more areas of your body. The rash can show up when your primary sore is healing or several weeks after the sore has healed. The rash usually won't itch and can be on the palms of your hands and/or the bottoms of your feet and look rough, red, or reddish-brown.
  - Other symptoms may include fever, swollen lymph nodes, sore throat, patchy hair loss, headaches, weight loss, muscle aches, and fatigue.
  - The symptoms from this stage will go not away unless you receive treatment. Without the right treatment, your infection will move to the latent and possibly tertiary stages of syphilis.
- Latent Stage
  - The latent stage of syphilis is a period when there are no visible signs or symptoms. Without treatment, you can continue to have syphilis in your body for years.
- Tertiary Stage
  - Most people with untreated syphilis do not develop tertiary syphilis. However, when it does happen, it can affect many different organ systems. These include the heart and blood vessels, and the brain and nervous system. Tertiary syphilis is very serious and would occur 10–30 years after your infection began. In tertiary syphilis, the disease damages your internal organs and can result in death. A healthcare provider can usually diagnose tertiary syphilis with the help of multiple tests.

For more detailed information, review the CDC fact sheet for Syphilis

Trichomoniasis

Trichomoniasis (or "trich") is a very common STD caused by infection with Trichomonas vaginalis (a protozoan parasite). Although symptoms vary, most people who have trich cannot tell they have it.

Sexually active people can get trich by having sex without a condom with a partner who has trich.

In women, the infection is most commonly found in the lower genital tract (vulva, vagina, cervix, or urethra). In men, the infection is most commonly found inside the penis (urethra). During sex, the parasite usually spreads from a penis to a vagina, or from a vagina to a penis. It can also spread from a vagina to another vagina.

It is not common for the parasite to infect other body parts, like the hands, mouth, or anus. It is unclear why some people with the infection get symptoms while others do not. It probably depends on factors like a person's age and overall health. People with trich can pass the infection to others, even if they do not have symptoms.

About 70% of people with the infection do not have any signs or symptoms. When trich does cause symptoms, they can range

from mild irritation to severe inflammation. Some people get symptoms within 5 to 28 days after getting the infection. Others do not develop symptoms until much later. Symptoms can come and go.

Men with trich may notice:

- Itching or irritation inside the penis;
- Burning after peeing or ejaculating; and
- Discharge from the penis.

Women with trich may notice:

- Itching, burning, redness or soreness of the genitals;
- Discomfort when peeing; and
- A clear, white, yellowish, or greenish vaginal discharge (i.e., thin discharge or increased volume) with a fishy smell.

Having trich can make sex feel unpleasant. Without treatment, the infection can last for months or even years.

For more detailed information, review the CDC fact sheet for Trichomoniasis

16.1.4.3: End-of-Chapter Material

Key takeaways for this Chapter

- The immune system is constantly working to keep you healthy.
- There are about 1,400 known pathogens that cause disease in humans.
- There are steps you can take to break the chain of infection and stop disease transmission.
- The bodies first barrier to disease are the physical and chemical barriers.
- The innate and adaptive immune system work in tandem to protect you.
- The immune system has an incredible ability to remember past infections.
- The ability to remember pathogens is the foundation for Vaccines
- There are several different types of vaccines.
- STD's are very common
- Most STDs are asymptomatic.

16.1.4.4: Protecting Health- Optional Continued Learning

The videos below provide an opportunity to expand on your learning from the chapter. As you watch the video, make a list of what you notice and what you wonder. This is a great strategy to listen purposefully, engage with the content, and look for deeper opportunities for self growth, self-reflection, and learning.

What do you **notice**?

- How does this topic support, expand, or challenge the content in the chapter?
- How does this topic connect to health topics from other chapters?
- How does this topic connect with your prior learning, your experiences, your work, your family, or your life in general?
- How does this topic help you to more fully understand health and wellness?

What do you **wonder**?

- How has this topic sparked your curiosity?
- What would you like to know more about?
- What questions did you have as you reviewed the topic?
- What other popular and scholarly sources support or refute this topic?

Videos for continued learning and application

Note: These videos are intended to more fully reflect on health. You might agree or disagree with the videos and that is ok! Utilize these videos to critically think through the topics and identify other sources, both scholarly and popular, to convey your learning.

Can you actually boost your immune system? Here's the truth

16.1.5.1: Environmental Nutrient Cycling and Human Health

Environmental Nutrient Cycling and Human Health

The importance of microorganisms is unquestionable in regard to how nutrients circulate throughout each ecosystem. There are direct and indirect links between Earth's ecosystems and human health, though like other microbial networks, they are sometimes unfathomably complex.

Climate change may be the most obvious association between environmental and human health, however, the solution to balance is not one likely easily achieved. Each type of ecosystem is unique, and reflects different changes to anthropogenic activity. Global soil microbiomes and organic foliar litter have great impact on worldwide biogeochemical cycling, plant health, and bioremediation, where environmental changes can disrupt microbial taxonomic distribution and functional profiles (Albright et al., 2020, Naylor et al., 2020). The ocean microbiome is vast considering it is the largest ecosystem on the planet, and plays a tremendous part in biogeochemical cycling, ecosystem dynamics, and response to climate change(Moran, 2015, Acinas et al., 2019, Marz et al., 2021). Also, since much of the ocean microbiome is uncharted, it could also serve as a major untapped reservoir for novel and progressive biosynthetic products (Paoli et al., 2021). Other aquatic environments such rivers, lakes, wetlands, and freshwater systems and their interaction with sediments and plants greatly influence carbon and other nutrient cycles in their respective ecosystems (Amado and Roland, 2017, Avila et al., 2019, Trevathan-Tackett et al., 2021).

View this YouTube Video online

In a cyclic manner, climate change can also greatly affect microbiome dynamics of large ecosystems like glaciers, tundra, permafrost, and even dry deserts, which can further exacerbate disturbances in that region and beyond. (Hamilton et al., 2013, Tripathi et al., 2019, Vigneron et al., 2019, Hough et al., 2020, Ray et al., 2020). These environments harbor several dormant microorganisms that can produce greenhouse gases like carbon dioxide and methane, and if they become metabolically active en masse, this could drastically increase contribution to climate change (Feng et al., 2020). Not only can ecosystem biodiversity be affected, but these changes can impact human society and health. Thus, it is important to consider analytical strategies to better understand global change so future actions can be coordinated to mitigate any negative consequences, and evaluating microbiomes may be part of the solution.

Global Change and the Soil Microbiome: A Human-Health Perspective

Article by Ochoa-Hueso, 2017 licensed under the terms of the Creative Commons Attribution License (CC BY).

The importance of the gut and the soil microbiomes as determinants of human and ecosystem health, respectively, is gaining rapid acceptation in the medical and ecological literatures. This suggests that there is a wealth of highly transferable knowledge about the microbial ecology of human and non-human ecosystems that is currently being generated in parallel, but mostly in isolation from one another. I suggest that effectively sharing this knowledge could greatly help at more efficiently understanding and restoring human health and the functioning of ecosystems, which are currently under wide-spread pressure. I illustrate this by comparing the effects of nitrogen deposition on ecosystem carbon sequestration with unhealthy dietary habits and human disease. The deposition of N, a key nutrient for plant growth, may increase carbon sequestration (equivalent to obesity) through several mechanisms, including a reduction in the ability of soil microbes to process organic matter, which some argue could help mitigate climate change. However, this usually results in a degradation of ecosystem health and, thus, cannot represent a real solution. Similarly, human obesity is linked to an alteration of the composition and functioning of microbial communities

inhabiting the gut, which is often attributed to unhealthy dietary habits, including ingesting high amounts of simple sugars and processed foods. Finally, I advocate for the explicit recognition of the many commonalities between the functioning of the gut and ecosystems and a broader multidisciplinary collaboration among experts in ecology and human health, including the engineering of soil microbial communities designed *ad-hoc* to restore ecosystem health.

Nitrogen Deposition and Carbon Sequestration in a Changing Climate

It has been widely proposed that atmospheric nitrogen (N) deposition could help mitigate climate change by increasing the rates of carbon (C) sequestration in terrestrial ecosystems (Knorr et al., 2005; Reich et al., 2006; Yue et al., 2016). Two commonly observed responses are typically proposed as mechanisms: first, a greater amount of N usually implies a higher capacity for plant growth, which would result in a greater amount of C retained within the system (Magnani et al., 2007; de Vries et al., 2009; Laubhann et al., 2009). Of course, for this to be true, it is necessary that the increase in the rates of C uptake and accumulation exceed the C emission rates, whatever the main route by which the latter happens, including plant and/or microbial respiration and changes in fire dynamics due to an excess of biomass accumulation (Dezi et al., 2010; Fenn et al., 2010). The second main mechanism is linked to a reduction in decomposition rates, particularly of recalcitrant organic matter, which would, therefore, accumulate within the system (Knorr et al., 2005; Waldrop and Zak, 2006). Otherwise, this accumulated C may be lost to the atmosphere in the form of CO_2 after being respired by soil microorganisms (Janssens et al., 2010). Of course, the relative importance of these mechanisms depend on how plant communities and soil microorganisms respond, directly and indirectly, to the additional inputs of N which, in any case, usually ends up resulting in a disruption of the interaction between these two key components of the ecosystem (Liu et al., 2014).

The Need for a New Perspective

In this article, I will adopt a human health perspective, hardly used in the discipline of global change ecology, to substantiate why atmospheric N deposition cannot represent a positive (i.e., healthy) alternative to mitigate climate change. In the medical literature, it is now widely recognized that human beings are like ecosystems (in fact, some consider us as living ecosystems) in which the eukaryotic cells that form part of our bodies and the prokaryotic cells that live in and on us are deeply interconnected, whereas the enormous importance of our microbiome to human health is also increasingly gaining acceptation (Bengmark, 1998; Berendsen et al., 2012; Ha et al., 2014; Alivisatos et al., 2015; Tilg and Adolph, 2015; Blaser, 2016; Blaser et al., 2016). The fact that many modern diseases, including conditions of the nervous and circulatory systems, skin and heart and allergies (including atopic dermatitis and food allergies), are directly caused by alterations in the microbial communities that live in our interior and exterior is also gaining rapid acceptation (Ha et al., 2014; Tilg and Adolph, 2015; Chang et al., 2016; Tang and Lodge, 2016). In this sense, the word ecosystem is widely used in the current literature of integrative medicine and gastroenterology. However, the opposite does not frequently happen in ecology [i.e., (cautiously) comparing ecosystems with the human body], despite the wealth of knowledge in the medical and human health literature that we, as ecologists, could apply in, for example, issues related to understanding the functioning (i.e., metabolism) of ecosystems and plant-soil-microbe interactions subjected to human pressure (Berendsen et al., 2012; Blaser et al., 2016; Table 1; Figure 1). Therefore, I will finally defend the need to approach problems in ecology from a more multidisciplinary, fresher perspective.

Characteristics associated with a healthy gut	Impacts associated with an unhealthy diet	References	Characteristics of healthy soils and ecosystems	Impacts associated with nitrogen deposition	References
Higher bacterial diversity and abundance that are able to metabolize more food sources and provide essential molecules such as vitamins, hormones, etc.	Functionally and compositionally impoverished gut communities	Thomas et al., 2014	Higher microbial diversity and abundance	Functionally and compositionally impoverished soil communities	Leff et al., 2015; Berg et al., 2017
Protection against disease through the stimulation of the immune system. More longevous individuals	Disease (obesity, diabetes, depression, inflammation etc.). People die younger	Berendsen et al., 2012; Ha et al., 2014; Thomas et al., 2014; Alivisatos et al., 2015; Tilg and Adolph, 2015; Xu et al., 2015; Blaser, 2016	Higher stability and resistance to disturbance	Die-back due to long-term N toxicity, altered fire regimes, pest outbreaks, less tolerance to frost, heat waves, etc.	Bobbink et al., 2010
Lean phenotype	Obese phenotype	Joyce and Gahan, 2014	Rapid processing, transformation and stabilization of litter inputs in the long-term soil pool	Accumulation of intact and partially decomposed leaf litter (i.e., carbon accumulation)	Knorr et al., 2005
High-energy feeling	Low-energy feeling	Umu et al., 2013	Higher ecosystem functionality and supply of key services such as air and water purification, food resources for pollinators, protections against extreme events such as floods, heat waves, etc.	Lower functionality and reduced supply of key services	Costanza et al., 1997; Jones et al., 2014
Well-trained immune system. No medication required. This is also associated with a smaller social cost	Weak immune system. Medication is very often required to treat diverse conditions. Development of drug-resistant strains. Higher social cost	Round and Mazmanian, 2009; Blaser, 2016	High ability to self-regenerate. No or very little management required. No extra cost involved	Management required, including applying herbicides, weeding, etc. High monetary cost	Costanza et al., 1997; Chiquoine et al., 2016
Higher Bacteroidetes to Firmicutes ratio	Lower Bacteroidetes to Firmicutes ratio	Mathur and Barlow, 2015	Higher fungal to bacterial biomass and activity ratio. Higher abundance and diversity of mutualistic mycorrhizal strains	Lower fungal to bacterial ratio. Less mutualistic mycorrhizal strains	Frey et al., 2004; Treseder, 2004; Waldrop et al., 2004; de Vries et al., 2006; Wallenstein et al., 2006

Table 1. The importance of the gut and the soil microbiomes as determinants of human and ecosystem health, respectively, is gaining rapid acceptation in the medical and ecological literatures.

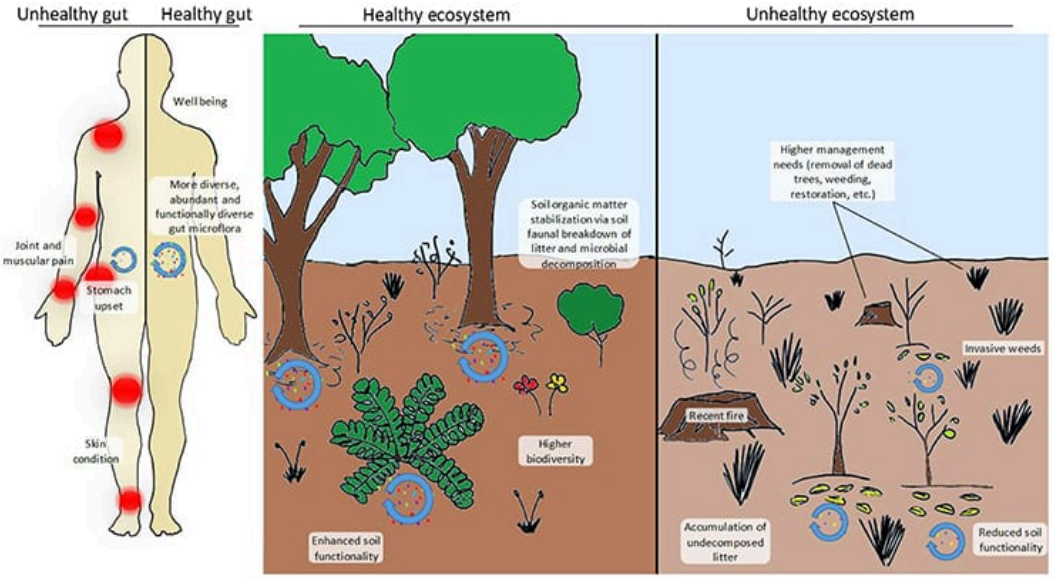

Figure 1. Comparison between a healthy and an unhealthy gut (left-hand side panel) and a healthy and an unhealthy ecosystem (right-hand side panel). In the case of the human individual, his/her gut microbiota is less diverse ("red" microbes are completely absent), less abundant and contains more pathogenic taxa ("yellow" microbes). The individual with the healthy gut has a more functional and more abundant microbiota that provides him/her with essential nutrients, hormones, amino acids, etc. and stimulates his/her immune system. A healthy gut is also less prone to become infected by pathogens and can process toxic compounds (i.e., detoxify) more easily. The disturbed (i.e., unhealthy) ecosystem shown here has recently been affected by a devastating fire fuelled by the accumulation of N-loving exotic grasses that have altered the natural fire dynamics of the system. Facilitated by the altered fire dynamics, the system has also become chronically dominated by weedy grasses, therefore requiring intensive (and costly) management practices (dead tree removal, weeding and restoration), also posing a threat to nearby human populations and their properties. Biodiversity (in terms of microbial, faunal and plant communities) is remarkably higher in the healthy ecosystem, which also has a higher potential to process organic matter inputs and stabilize them in the long-term soil pool. In contrast, undecomposed or partially decomposed litter accumulates on the functionally impoverished soil of the unhealthy ecosystem. This pattern is in agreement with reported observations of higher soil carbon sequestration under increased nitrogen deposition scenarios due to the inhibition of soil enzymes and the reduction of microbial biomass but poses relevant questions such as: Is this type of N deposition-induced carbon sequestration desirable? And, does it really represent a long-term (or even short-term) solution?

Why Nitrogen Deposition Cannot be the Solution to Climate Change

The reason why I think that a temporary, N deposition-induced increase in the rate of C sequestration will not contribute to mitigating climate change in the long term is equivalent to the reason of those that argue that an increase in obesity rates

in human populations derived from a diet rich in simple sugars and processed food and the consequent alteration of their microbiome will not successfully and permanently solve any public health problem of today's societies. Ingesting large amounts of simple sugars, processed foods, sugary drinks and saturated fats is definitely better than starving, but that does not mean that it is a healthy practice. And the same happens with N deposition and C sequestration. In ecosystems where N is still a limiting nutrient, which is quite common worldwide (LeBauer and Treseder, 2008), an increase in the availability of N can increase ecosystem productivity to levels comparable to human obesity (Tian et al., 2016), but that does not mean that the ecosystem is healthier and, therefore, that this will result in a long-term benefit (Bobbink et al., 2010; Jones et al., 2014). In this sense, a healthy ecosystem may be defined here as a highly multifunctional ecosystem that can maintain an adequate supply of services, at least as compared to a previously defined reference state.

In medicine, the term dysbiosis refers to changes in the composition of the microbiome that are not beneficial to the individuals, including a loss of abundance and diversity of beneficial microorganisms and increased number of pathogens, and that result in the development of a condition (Ha et al., 2014; Tilg and Adolph, 2015). This term could also be used to describe ecosystems that are dysfunctional due to alterations of their microbial communities. In this sense, it has been repeatedly shown through experimental studies and meta-analyses that increased N deposition is typically associated with changes in soil microbial communities (usually related to a decrease in abundance and biodiversity; Treseder, 2004, 2008; Ramirez et al., 2010; Zeng et al., 2015), reduced ecosystem functionality (alterations of energy metabolism; Waldrop and Zak, 2006; Treseder, 2008; Liu et al., 2014) and short- to mid-term increases in C sequestration, especially in aboveground biomass, but also in the soil and roots (comparable to obesity, as previously mentioned; Xia and Wan, 2008; Yue et al., 2016). Given that metabolic disorders and obesity in humans are clearly associated with a deterioration in the health status of individuals that may even result in cases of fatality due to chronic diseases, sudden death or, quite commonly in the natural world, to increased sensitivity to other environmental stresses (Mathur and Barlow, 2015; Monteiro et al., 2015), I think that we would do well to be cautious when we consider, perhaps naively, the potential benefits of a N that, after all, is the result of the atmospheric pollution derived from our activities (Gruber and Galloway, 2008).

The "Deceptively Simple" Solution

The connections between human health, disease, and the microbiome, especially in the case of the gut, are becoming increasingly apparent and are attracting the public attention, especially because of the high social cost of unhealthy dietary habits and lifestyles and the "deceptively simple" solution of the problem (Mathur and Barlow, 2015; Tilg and Adolph, 2015; Blaser, 2016). In the case of both people and ecosystems, (i) ensuring a healthy supply of nutrients derived from the breakdown and cycling of unprocessed food/organic matter, (ii) minimizing the use of antibiotics (particularly those associated with the livestock industry in the case of ecosystems; Park and Choi, 2008) and chemicals (including herbicides and pesticides in the case of ecosystems) that destroy the microbiome, unless this is strictly necessary, and (iii) promoting practices that favor the system's ability to self-regenerate, something that living systems do wonderfully well, and that increase its resilience against pathogens and extreme events could be part of the solution, if not all, of the problem.

Of course, there are opportunities to aid in the recovery of our damaged and degraded ecosystems as well as there are possibilities to recover the lost or damaged intestinal flora (Brudnak, 2002; Sheth et al., 2016). This can be achieved by the use of properly designed probiotics or fecal transplants or, in the case of ecosystems, inocula assembled in the lab from pure cultures or soil samples obtained in the field from healthy ecosystems (Bowker, 2007; Chiquoine et al., 2016; Wubs et al., 2016) in conjunction with a balanced nutrient supply (i.e., organic matter inputs, the equivalent to prebiotics; Mathur and Barlow, 2015; Sheth et al., 2016). In this sense, the concept of synbiotics (i.e., synchronous administration of probiotics and prebiotics) could represent a particularly promising benchmark borrowed from the human health literature to successfully restore degraded ecosystems (Tang and Lodge, 2016) and, thus, the human probiotics industry has an opportunity to play a key role in this development.

Concluding Remarks

Recognizing and understanding the similarities and deep connections between the gut and the belowground world, where roots are the equivalent to our gut and the rhizosphere is the gut microflora (Berendsen et al., 2012) can help us advance the understanding of ecosystems by leaps and bounds through the search of similar microbial indicators of disease (e.g., Bacteroidetes to Firmicutes ratio in humans; Mathur and Barlow, 2015) and, therefore, to implement quick and successful measures in ecosystem management rather than relying, perhaps naively, on that the very same thing that caused climate change (i.e., pollutant emissions to the atmosphere) will also be part of the solution. From here, I advocate for the development of a new field of research that specifically aims at recognizing and make practical use of the profound links between the functioning of the gut and the ecosystems that extend beyond our bodies and that benefits from a truly multidisciplinary collaboration among experts in the areas of global change ecology and human health.

16.1.5.2: The Ocean Microbiome and Marine Life

The Ocean Microbiome and Marine Life

The ocean is teeming with life, both macro and micro, where their adaptation and success are dependent on both a local and global scale. Oceanic microorganisms have major roles in nutrient cycling, ecological interactions, and influence and respond to environmental changes (Doney et al., 2012). Temperature is the strongest factor that determines microbial community composition, which parallels depth stratification, and these communities can serve as indicators for anthropogenically-induced climate changes (Sunagawa et al., 2015). It is predicted that carbon fixation by microbial primary producers will decrease which will have downstream effects on ocean microbiome structure and overall trophic level interactions (Moran, 2015).

While free-living marine microorganisms can provide relevant information and predictive models about the ocean, those host-associated microbes can also give environmental insight into the largest ecosystem on the planet.

Marine Animal Microbiomes: Toward Understanding Host–Microbiome Interactions in a Changing Ocean

Article by Apprill, 2017 licensed under the terms of the Creative Commons Attribution License (CC BY).

All animals on Earth form associations with microorganisms, including protists, bacteria, archaea, fungi, and viruses. In the ocean, animal–microbial relationships were historically explored in single host–symbiont systems. However, new explorations into the diversity of microorganisms associating with diverse marine animal hosts is moving the field into studies that address interactions between the animal host and a more multi-member microbiome. The potential for microbiomes to influence the health, physiology, behavior, and ecology of marine animals could alter current understandings of how marine animals adapt to change, and especially the growing climate-related and anthropogenic-induced changes already impacting the ocean environment. This review explores the nature of marine animal–microbiome relationships and interactions, and possible factors that may shift associations from symbiotic to dissociated states. I present a brief review of current microbiome research and opportunities, using examples of select marine animals that span diverse phyla within the Animalia, including systems that are more and less developed for symbiosis research, including two represented in my own research program. Lastly, I consider challenges and emerging solutions for moving these and other study systems into a more detailed understanding of host–microbiome interactions within a changing ocean.

Introduction

Marine animals are the icons of life in the oceans. They represent about two million species (Mora et al., 2011) and include a wide range of body designs, from the highly simplistic sponges lacking true tissues and organs to the complex vertebrates containing specialized tissues and organs, such as fish and marine mammals, with some iconic representatives presented in Figure 1. The bodies of marine animals span several orders of magnitude in size, from the abundant planktonic copepod (1–2 mm) to the highly mobile blue whale (30 m), the largest animal on Earth. Marine animals are key members of ocean ecosystems and serve as both prey of and predators for other animals within the complex ocean food web. In contrast to terrestrial animals, marine animals have developed strategies for osmoregulation as well as highly specialized approaches for maintaining homeostasis within diverse temperature, oxygen and pressure gradients of the ocean (Graham, 1990; Knoll and Carroll, 1999). Marine animals also possess sophisticated specializations and functions that promote their success on or within their benthic or pelagic habitats, including specializations for living or enduring depths (outlined in Figure 1) that vary widely in factors such as light availability, access to food and predator exposure.

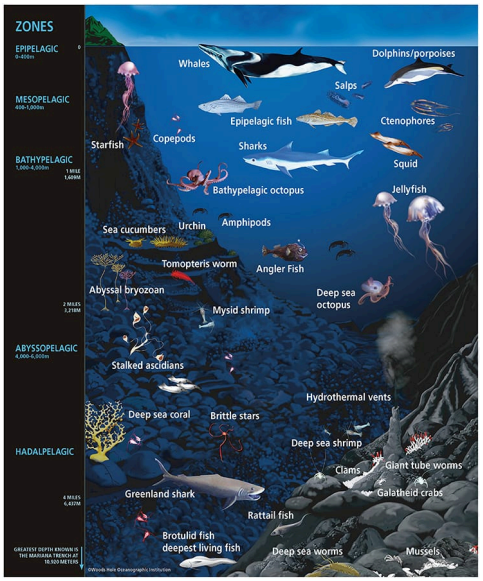

Figure 1. Illustration and common names of representative ocean animal life within their approximate depth-defined ecological habitats. Microorganisms exist on the surfaces and within the tissues and organs of the diverse life inhabiting the ocean, across all ocean habitats. Animals are not drawn to scale.

Marine animals share the sea with a vast diversity of microorganisms, including protists, bacteria, archaea, fungi, and viruses which comprise millions of cells in each milliliter of the 1.3 billion km^3 of water comprising the oceans (Eakins and Sharman, 2010). These microorganisms are several micrometers or smaller in size, but collectively their roles in oxygen production, nutrient cycling, and organic matter degradation provide critical functions to the oceans and Earth (Arrigo, 2005; Falkowski et al., 2008). Microorganisms that associate with marine animals are part of the animal's microbiome, or collection of microorganisms that reside on or within the animal. Some of the microorganisms comprising the microbiomes of marine animals are thought to originate from this surrounding supply of seawater-associated cells (e.g., Nussbaumer et al., 2006), while other cells appear to have strict inheritance patterns, passed on through generations from the host (Sharp et al., 2007).

Over the past two decades, the widespread application of genomic and more integrative microbiological approaches have advanced our understanding of animal microbiomes (reviewed within McFall-Ngai et al., 2013). Symbiotic relationships between microorganisms and marine animals have been studied for decades, but technological advancements are providing new insights into the sheer diversity of microbial life in association with animals in the sea (Smith, 2001; Douglas, 2010). For example, reef-building corals are acknowledged as the icons of animal–microbial symbiosis in the sea, with corals hosting photosynthetic symbionts that make critical contributions to host nutrition (Muscatine et al., 1981). New reports of diverse protists, bacteria, archaea, and viruses in association with corals provide insights into the role of these cells for fulfilling diverse functional processes within the different niches of the coral host (reviewed within Thompson et al., 2015; Bourne et al., 2016). In fact, for many terrestrial animals, new reports of microbial symbioses provide insights into the variety of genetic and biochemical interactions and the ways that microorganisms contribute to animal health, behavior, and ecology (e.g., Ley, 2010; Cho and Blaser, 2012).

Understanding the microbiomes of marine animals is a growing research area within the field of marine science. Currently, the science is heavily focused on identifying consistent or "core" microbial members of the microbiome (Shade and Handelsman, 2012). After first gaining an understanding of "who's there" generally using diversity-based surveys targeting the small subunit (SSU) ribosomal RNA (rRNA) gene, these microbiomes are then often examined as a whole or in smaller units to understand the function of the cells, the nature of the associations and ultimately gain insight into the role of the microbiome in animal health, physiology, ecology, and behavior (Ezenwa et al., 2012; McFall-Ngai et al., 2013). Additionally, the ocean environment is changing at unprecedented rates due to climate-related and anthropogenic-induced impacts (Halpern et al., 2008; Doney et al., 2012), and the microbiome is also being investigated for its possible role as a sentinel of a changing host (Ainsworth and Gates, 2016).

How environmental changes and animal life history events affect the microbiomes of marine animals is growing area of research, and there is an emerging focus on better understanding interactions between the animal, microbiome, and ocean environment, including the elements that may define their exchanges (e.g., Meron et al., 2011; Lesser et al., 2016; Webster et al., 2016). Therefore, this review considers the symbiosis and dissociated stages of animal–microbiome associations, and discusses factors and causes that may alter interactions between animals and their microbiome. Next, this review discusses current research examining animal–microbiome relationships and interactions, by focusing on select systems that represent

diverse marine animal phyla and which span the range of being more to less developed for microbiome research. Two of these systems, corals and marine mammals, are represented in my own research program. Lastly, this review concludes with a discussion of challenges in marine animal–microbiome research and opportunities available to further advance knowledge of animal–microbiome interactions in the ocean.

Conceptual Model of Factors Contributing to Host-Microbiome Interactions

Host–microbiome dynamics are generally described as falling into two main categories: symbiosis, in which the organisms are involved in a normal metabolic and immune signaling interactions, and secondly dysbiosis, in which the relationship or interactions are heavily altered, possibly related to a major stress or infection event. While host–microbiome symbiosis and dysbiosis has been mostly considered in humans and humanized models (Hamdi et al., 2011; Nicholson et al., 2012; Scharschmidt and Fischbach, 2013), many of the same concepts are applicable to organisms in the sea (Egan and Gardiner, 2016), and are being explored in various systems (discussed below). The exact factors and mechanisms tipping the scale between symbiosis and dysbiosis will probably vary with complexity of the host anatomy and immune functioning (e.g., simplistic sponges and corals compared to more complex fish and sharks) as well as with the complexity of interactions that may occur between the members of the microbiome.

A normal animal–microbiome relationship in the ocean could be referred to as a “symbiotic” state, although the exact nature of the relationship may vary for each cell in the association. For example, cells residing on the surface or within the gut cavity of an animal are physically associated, yet do not share as intimate of an association as those microbes residing intracellularly with the host’s cells. This normal symbiotic state is subject to a variety of environmental fluctuations, which are generally defined by the characteristics of the habitat (Figure 1). For example, in the ocean’s upper photic zone, animals are exposed to variations in temperature and light, and host–symbiont interactions, especially in ectothermal animals, could alter on cycles such as seasons that generally control the temperature and light environment. Normal fluctuations in animal-specific patterns could also alter host–microbiome relationships. For example, changes in diet, possibly due to short-term prey availability, can alter gut microbiota and host–microbiome metabolic exchanges in other systems (e.g., David et al., 2014), and similar diet trends may also affect marine animals. Stress is another factor more complex animals encounter on a daily basis (e.g., squid, crabs, fish), which could be related to social/territorial encounters or chasing or fleeing from prey, and the short-term production of stress hormones such as cortisol can influence host–microbiome relationships (e.g., Moloney et al., 2014).

There are also normal animal life events that occur on longer time frames or that are more drastic in scope, such as animal development, aging, and reproduction. In non-marine animals, these factors have been shown to cause alterations in animal-microbial relationships (e.g., Heintz and Mair, 2014). These changes can be drastic enough to cause a state of “altered symbiosis” that could extend for short or longer term. For example, the gut microbiome of women generally becomes altered during pregnancy (Koren et al., 2012). Events resulting in normal animal stress may also lead to a more altered symbiotic state, for example if social conflict was more chronic, perhaps due to the pressures of a particular habitat. Data from humans and humanized models suggests that the microbial community and associated genes do fluctuate with the normal variations and animal life events, and both may be considered “healthy” fluctuations (Nicholson et al., 2012). However, how these fluctuations affect exchanges between the host and microbiome is much less understood.

If symbiosis and altered symbiosis are considered as normal host–microbiome variations throughout an organism’s life, dysbiosis is the breakdown in the relationship, generally related to one or more major stressors, and can greatly alter host health and lead to a disease state (Holmes et al., 2011). The stressor may come from an external source, such as a pollutant, infective agent, or a longer-term natural environmental change—and there are probably countless other factors that could fit this category (Figure 2). For example, one of the most visible signs of host–microbiome dysbiosis is with scleractinian corals, whose relationship with unicellular algae breaks down after long-term yet small increases in seawater temperature, causing the coral to become “bleached” (Brown, 1997). In humanized models, major stressors such as malnutrition are related to less physically visible changes in innate immunity, which are linked to microbial ecology (Hashimoto et al., 2012). Understanding the relationship between symbiosis, dysbiosis and host health and functioning are general topics of research in most host–microbiome studies, but the environmental changes occurring in the ocean environment have made this area of research more pressing for marine animals. Overall, the concepts behind the model presented in Figure 2, as well as variations of this model, are generally driving much of the current research examining animal-microbial relationships in the ocean.

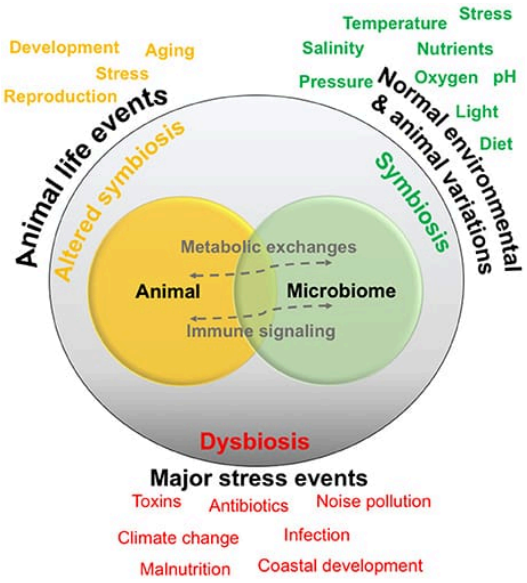

Figure 2. Conceptual diagram of a host-microbiome relationship. Relationships are generally thought to exist in a symbiotic state, and are normally exposed to environmental and animal-specific factors that may cause natural variations. Some events may change the relationship into a functioning but altered symbiotic state, whereas extreme stress events may cause dysbiosis or a breakdown of the relationship and interactions.

Overview of Diverse and Emerging Animal-Microbiome Study Systems

The microbiomes of diverse marine animals are currently under study, from simplistic organisms including sponges (e.g., Webster et al., 2010) and ctenophores (Daniels and Breitbart, 2012) to more complex organisms such as sea squirts (Blasiak et al., 2014) and sharks (Givens et al., 2015). Below I present some of the current study systems that represent a diverse cross-section of marine animal phyla, and trends of research in these systems including focus on symbiosis and dysbiosis. The organisms are generally presented in order from increasing to decreasing knowledge about the host-microbiome relationship.

The relationship between the Hawaiian bobtail squid *Euprymna scolopes* (phylum Mollusca) and the bioluminescent bacterium *Vibrio fisheri* (also recognized as *Aliivibrio fisheri*) is one of the best studied symbiotic relationships in the sea and is a choice system for general symbiosis research (Figures 3A,B). The *E. scolopes*-*V. fisheri* relationship has provided insight into fundamental processes in animal-microbial symbioses, and especially biochemical interactions and signaling between the host and bacterium (McFall-Ngai, 2000, 2014). Much of this research focuses on establishment of the symbiosis, with less focus on dysbiosis. Additionally, because *V. fisheri* exists in the light organ, these studies have been primarily limited to this one isolated relationship, with the remainder of the squid's microbiome virtually unstudied (but see Barbieri et al., 2001; Collins et al., 2012). The *E. scolopes*–*V. fisheri* system offers simplicity for the study of host–microbial interactions and numerous helpful developments in animal husbandry, genomic tools, and experimental design that could be applied to ask more comprehensive questions about squid–microbiome interactions, including the conditions leading to dysbiosis of relationships.

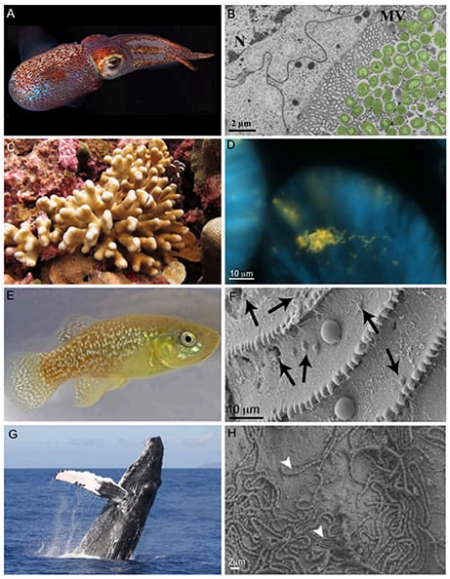

Figure 3. Photographs of marine animals and their associated microbiomes from select study systems. Photographs include: the Hawaiian bobtail squid Euprymna scolopes (A) and a transmission electron micrograph of Vibrio fisheri cells associating with dense microvilli (MV) and in proximity to the epithelial nucleus (N) within the light organ (B); the reef-building coral Stylophora pistillata (C) and a microscopy image of Endozoicomonas cells (probed yellow using in situ hybridization) within the tentacles of a S. pistillata host (D); the Atlantic killifish (Fundulus heteroclitus) (E) and a scanning electron microscopy (SEM) image of the surface and scales of the fish, with arrows pointing to bacterial-sized cells and larger cells (which are not noted) are presumably phytoplankton (F); a humpback whale (Megaptera novaeangliae) breaching (G) and a scanning electron microscopy image of a humpback's skin surface associated bacteria, with arrows indicating two different cell morphologies (H). Photographs (A,B) were produced by M. McFall-Ngai and were previously published photographs (McFall-Ngai, 2014), (C,H) were previously published by the author Neave et al. (2016) and Apprill et al. (2014), photograph (D) was taken by Liping Xun and photograph (E) by Evan D'Alessandro.

Similar to *E. scolope*, the gutless marine oligochaete worm *Olavius algarvensis* (phylum Annelida) is another relatively well-studied marine host to microbes. One major difference is that it has been studied within the context of a larger consortium of microorganisms compared to *E. scolope*. These 3 cm long worms reside within shallow marine sediments of the Mediterranean Sea. The worms do not contain a mouth or a digestive or excretory system, but are instead nourished with the help of a suite of extracellular bacterial endosymbionts that reside upon coordinated use of sulfur present in the environment (Dubilier et al., 2001). This system has benefited from some of the most sophisticated 'omics and visualization tools (Woyke et al., 2006). For example, multi-labeled probing has improved visualization of the microbiome (Schimak et al., 2016) and transcriptomics and proteomics have been applied to examine host–microbiome interactions, including energy transfer between the host and microbes (Kleiner et al., 2012) and recognition of the consortia by the worm's innate immune system (Wippler et al., 2016). The major strength of this system is that it does offer the ability to study host–microbiome interactions with a low diversity microbial consortium, and it also offers a number of host and microbial genomic resources (e.g., Woyke et al., 2006; Ruehland et al., 2008). Dysbiosis has not been heavily investigated in this system, and given the growing knowledge of host–microbial interactions, *O. algarvensis* could be an imperative animal for dysbiosis research.

As mentioned above, corals (phylum Cnidaria) (Figure 3C) are one of the most common examples of an animal host whose symbiosis with microalgae can turn to dysbiosis, and is visibly detected as bleaching. Coral microbiomes have been examined in a variety of studies, which demonstrate how variations in the ocean environment, most notably temperature, light, and inorganic nutrients, affect the abundance and performance of the microalgal symbionts, as well as calcification and physiology of the host (Dubinsky and Jokiel, 1994; Anthony et al., 2008). Studies have also suggested that resident bacteria, archaea, and fungi additionally contribute to nutrient and organic matter cycling within the coral, with viruses also possibly playing a role in structuring the composition of these members, thus providing one of the first glimpses at a multi-domain marine animal symbiosis (reviewed in Bourne et al., 2016). The gammaproteobacterium *Endozoicomonas* is emerging as a central member of the coral's microbiome, with flexibility in its lifestyle (Figure 3D) (Neave et al., 2016, 2017). Ocean disturbances including elevated temperature and ocean acidification have been shown to disrupt the coral's associated bacteria (Thurber et al., 2009; Meron et al., 2011), including relationships with *Endozoicomonas* (Morrow et al., 2015). However, some members of this microbiome appear to be stable across large environmental gradients (Hernandez-Agreda et al., 2016). In addition to nutrition, the microbiome plays a role in coral health and stress. Temperature and light stress to corals can result in overproduction of reactive oxygen species (ROS), which can be detrimental to *Symbiodinium* and result in bleaching, but the associated bacteria have also recently been shown to contribute extracellular ROS (Diaz et al., 2016; Zhang et al., 2016), which could play a signaling role with the host or

within the microbiome. Given the recent mass bleaching occurring on reefs (Hughes et al., 2017), corals will likely continue to be a useful and popular system for symbiosis and dysbiosis research. There are number of resources available to further promote study of the coral microbiome, including integrated databases (Franklin et al., 2012; Madin et al., 2016), a growing number of host and microbial genomes (Shinzato et al., 2011; Bayer et al., 2012; Neave et al., 2017), and laboratory amendable "model" systems (Weis et al., 2008; Baumgarten et al., 2015).

Sponges (phylum Porifera) are common members of the ocean's diverse benthic habitats and their abundance and ability to filter large volumes of seawater have led to the awareness that these organisms play critical roles in influencing benthic and pelagic processes in the ocean (Bell, 2008). They are one of the oldest lineages of animals, and have a relatively simple body plan that commonly associates with bacteria, archaea, algal protists, fungi, and viruses (reviewed within Webster and Thomas, 2016). Sponge microbiomes are composed of specialists and generalists, and complexity of their microbiome appears to be shaped by host phylogeny (Thomas et al., 2016). Studies have shown that the sponge microbiome contributes to nitrogen cycling in the oceans, especially through the oxidation of ammonia by archaea and bacteria (Bayer et al., 2008; Radax et al., 2012). Most recently, microbial symbionts of tropical sponges were shown to produce and store polyphosphate granules (Zhang et al., 2015), perhaps enabling the host to survive periods of phosphate depletion in oligotrophic marine environments (Colman, 2015). The microbiomes of some sponge species do appear to change in community structure in response to changing environmental conditions, including temperature (Simister et al., 2012a) and ocean acidification (Morrow et al., 2015; Ribes et al., 2016), as well as synergistic impacts (Lesser et al., 2016). Understanding the effect of these altered host–microbiome interactions on sponge growth and ecology are topics for further research. As such, there are a number of resources to support research on sponges including a curated database of sponge–microbial sequences (Simister et al., 2012b), cultivated microbial isolates and sponge cell cultures from some species (Taylor et al., 2007) to facilitate investigations.

Atlantic killifish, (*Fundulus* spp., Phylum Chordata) (Figure 3E) are one of the most abundant estuarine fishes in North America, and are related to other families with more global distributions in coastal areas (Fritz et al., 1975; Lotrich, 1975). The killifish have a broad North American geographic distribution yet limited subpopulation movement, and thus the Atlantic killifish have become a useful field-residing model species for examining biological and ecological responses to natural environment conditions (salinity, oxygen, pH, and temperature) as well as chemical pollutants (Burnett et al., 2007). While the killifish microbiome (Figure 3F) has not been extensively studied, there is work examining the influence of pollutants on the skin and mucus of the fish, which suggests that this skin microbial community is relatively resistant to change (Larsen et al., 2015). Populations of the fish offer a unique host genetic resistance to toxicity (Hahn et al., 2004), and it is possible that this resistance is also facilitated by features of the microbiome. The Atlantic killifish appear to be an ideal study species for microbiome investigations and especially the response of the host–microbiome symbiosis to changing ocean conditions. Specifically, the killifish can be maintained in laboratory aquaria, they are hardy and amendable to experimental manipulation, and spawning material can be acquired for developmental (Burnett et al., 2007).

The microbiomes of marine mammals (phylum Chordata) (Figure 3G) have recently been investigated and offer a comparative study system to terrestrial mammals (reviewed within Nelson et al., 2015). Marine mammals are often viewed as sentinel species of the ocean, because they appear to rapidly respond to ocean conditions, disturbances, and pathogens similarly to humans (Bossart, 2011). Several studies have examined the skin (Figure 3H), gut and respiratory microbiomes of diverse marine mammal species, and describe species-specific relationships (Johnson et al., 2009; Apprill et al., 2014; Bik et al., 2016). Connections between the community composition of the microbiome and animal health (Apprill et al., 2014) and diet (Nelson et al., 2013; Sanders et al., 2015) have been made, and more detailed studies are needed to understand these specific connections. While there are very limited resources available for studying host–microbiome interactions in marine mammals, there are some animals in captivity as well as well-studied populations that will heighten investigations of host–microbiome symbiosis and dysbiosis in these sentinel species.

Challenges and Emerging Solutions to Studying Animal–Microbiome Interactions

A number of the systems highlighted above are currently examining animal–microbiome interactions, but these are generally most developed in systems such as *O. algarvensis* that offer lower complexity microbiomes, or within the single host–symbiont relationship between *E. scolopes* and *V. fisheri*. As such, a major challenge to the field is exploring host–microbiome interactions within the context of a diverse microbiome, and especially if the microbiome includes members such a uncharacterized protists, fungi, and viruses, which have generally not been described in most marine animal systems. Therefore, a through description of the microbiome is a first necessity, but this still presents many challenges on a variety of levels. For example, amplifying or shotgun sequencing microbial DNA with the presence of abundant host cells often requires optimization or high sequencing output (e.g., Rocha et al., 2014; Weber et al., 2017). Taxonomic databases generally contain few microbial sequences from many of these animals, and therefore simple tasks such as assigning taxonomy can be challenging. Developing animal-specific databases (Simister et al., 2012b), which include the next-generation supplied sequences generally not available in curated taxonomic

databases, could help alleviate this problem. There are also a number of new tools for metagenomics-based analysis, including advancements in binning genomes from complex samples (Kang et al., 2015; Graham et al., 2017) as well as new visualization methods for comparing genomes (Eren et al., 2015; Wagner et al., 2017). A challenging issue that has received less attention is how to gain information from unknown genes and gene families, which can make up over half of the environmental microbial genomes. Algorithms utilizing gene function predictions do provide some assistance with this problem (Mi et al., 2015), and these tools may improve as more environmental microbial genomes are available. Lastly, computational tools are emerging to facilitate identifying associations between host genetic variation and microbiome composition (Lynch et al., 2016).

Once some of these hurdles are overcome and a comprehensive view of the microbiome is available, researchers can then explore the nature of the host–microbiome relationship. Visualization using a variety of different microscopy-based techniques is a powerful tool to recognize the physical relationship between a host and the microbiome, as well as the organization of cells within the microbiome. Electron microscopy provides the most detailed information about this organization, but this is less useful for complex microbiomes because taxonomically distinct microbial cells with similar appearances cannot be distinguished. Fluorescent *in situ* hybridization (FISH), and especially using a multi-taxonomic, simultaneous probing technique such as Combinatorial Labeling and Spectral Imaging FISH (CLASI-FISH) (Valm et al., 2011) can provide significant insight into host–microbe and microbe–microbe interactions. FISH techniques do require optimization for some animal systems, such as corals that possess autofluorescent host tissues (Wada et al., 2016). Visualization techniques can also be paired with isotope probing, to provide opportunities to trace the transfer of specific molecules between the host and microbiome, as well as within the microbiome using Nano-SIMS and Nano-SIP approaches (Musat et al., 2016). There have also been many recent instrumental and database advances in the field of metabolomics (Beisken et al., 2015), and this approach is beginning to be applied to examine host–microbiome interactions (Gomez et al., 2015; Sogin et al., 2016). An understanding of specific microbial metabolites will help facilitate targeted investigations of how these products affect the host nutritional and immune systems.

Lastly, experimental manipulation is a challenge to the study of host–microbial interactions in the ocean. Studying the animals in their natural environment is the most ideal approach because it ensures that the surrounding seawater microbial community is maintained. However, natural experiments are only as helpful as the natural variability in the host-microbe system, and generally only afford the opportunity to study events such as seasonality, animal growth or other life history events. Artificial systems such as aquaria or mesocosms offer opportunities to manipulate environmental conditions or expose the animal to antibiotics or other molecules that are difficult to dose in the wild. However, not all animals are ideal for these systems (e.g., large whales, hydrothermal vent worms), and it can be challenging to reproduce some environmental conditions. Advances in aquaria design that offer consistency in environmental conditions and the ability to manipulate complex environmental interactions, such as the Australian Institute of Marine Science's National Sea Simulator, provide opportunities to conduct more realistic experiments. As the need to understand how host–microbiome interactions will alter with the forecasted changes in ocean temperature and pH, facilities such as this will become critical to animal–microbiome research in the ocean.

While studies of marine animal–microbiome interactions are certainly plagued by a number of challenges, the future is also very bright for this emerging field. Many of the new bioinformatics and methodological advancements now available to marine biologists stem from the biomedical field, and thus marine animal microbiome research, as well as other environmental-based fields, are profiting from the elevation in microbiome research funding and attention. There could also be growing interest in using marine animals as models for examining resilience, promoted by the fact that alterations in the ocean conditions are often outpacing those in terrestrial environments. Given the phylogenetic breath of animals in the ocean, coupled with the many diverse ocean environments, there is certainly a wealth of research opportunities available to study host–microbiome interactions in the ocean.

Author Contributions

The author confirms being the sole contributor of this work and approved it for publication.

Funding

Funding was provided by the WHOI's Andrew W. Mellon Foundation Endowed Fund for Innovative Research.

Conflict of Interest Statement

The author declares that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

Acknowledgments

Many thanks to Margaret McFall-Ngai and Evan D'Alessandro for use of images and to Laura Weber for early comments on this review.

View this Interactive Content online

Prevalence of certain marine topics appearing in combination with the term holobiont in the title, abstract, and/or keywords of scientific publications from 1990 to February 2021 (N = 1269). Bars indicate the percentage of publications that contain terms related to a certain marine topic (cnidarians, corals, sponges, etc.). It is important to note that the different topics may overlap in several publications. For example, many publications treat of the topics of coral and sponge holobionts together. Data retrieved from the curated citation and abstract database Scopus on the date 10/03/2021. (Stevenne et al., 2021)

Check your Understanding

- Which environmental factor is the biggest driver of change for the community composition of free-living oceanic microbes?
- What factors affect the normal symbiotic state between marine host and their microbiome?
- Describe one well-studied marine animal-microbial symbiosis and its importance.
- What are some challenges to studying marine host-associated microbiomes?

16.1.5.3: Soil Microbiomes

Soil Microbiomes

The terrestrial landscape on Earth harbors countless microbes that have major responsibilities in shaping their surrounding environment. One gram of soil can contain up to 10 billion microorganisms and consist of thousands of different species. Each ecosystem has unique soil properties that cultivate a diverse array of microbial communities, which are primarily composed of bacteria, however archaea, protists, fungi, viruses, and other microscopic organisms can be found in varying abundances too. The composition and health of the surrounding environment and its macro inhabitants are dependent on their soil borne microbial partners, and a disturbance in the balance of the soil microbiome can have far-reaching effects (Omotayo and Babalola, 2021).

Environmental and agricultural sustainability is important in a number of regards, especially maintaining biodiversity, plant and animal health, ecosystem homeostasis, and even human health. Anthropogenic effects on the climate and environment have become abundantly apparent, and it is imperative to adjust mindsets to become more environmentally conscious, not only to preserve aspects of nature, but to accommodate an increasing human population. The soil is foundational to agricultural practices, and therefore food production, and so a better understanding of various soil microbiomes could serve to benefit future applications and practices (Tosi et al., 2020). One possibility, is to become less reliant on synthetic nitrogen fertilizers for soil, and utilize symbiotic nitrogen-fixing bacteria as sources for plant nitrogen.

Microbe to Microbiome: A Paradigm Shift in the Application of Microorganisms for Sustainable Agriculture

Article by Ray et al., 2020 licensed under the terms of the Creative Commons Attribution License (CC BY).

Light, water and healthy soil are three essential natural resources required for agricultural productivity. Industrialization of agriculture has resulted in intensification of cropping practices using enormous amounts of chemical pesticides and fertilizers that damage these natural resources. Therefore, there is a need to embrace agriculture practices that do not depend on greater use of fertilizers and water to meet the growing demand of global food requirements. Plants and soil harbor millions of microorganisms, which collectively form a microbial community known as the microbiome. An effective microbiome can offer benefits to its host, including plant growth promotion, nutrient use efficiency, and control of pests and phytopathogens. Therefore, there is an immediate need to bring functional potential of plant-associated microbiome and its innovation into crop production. In addition to that, new scientific methodologies that can track the nutrient flux through the plant, its resident microbiome and surrounding soil, will offer new opportunities for the design of more efficient microbial consortia design. It is now increasingly acknowledged that the diversity of a microbial inoculum is as important as its plant growth promoting ability. Not surprisingly, outcomes from such plant and soil microbiome studies have resulted in a paradigm shift away from single, specific soil microbes to a more holistic microbiome approach for enhancing crop productivity and the restoration of soil health. Herein, we have reviewed this paradigm shift and discussed various aspects of benign microbiome-based approaches for sustainable agriculture.

Introduction

The health of soil plays an essential role in the ability of plants to produce food, fuel, and fiber for a growing world population. To

keep pace, the total area of cultivated land worldwide has increased over 500% in the last five decades with a 700% increase in fertilizer use and a several-fold increase in pesticide use (Banerjee et al., 2019). In addition to being the world's largest agricultural producers and exporters, the EU, Brazil, United States, and China also are some of the world's largest pesticide users – each using 827 million, 831 million, 1.2 billion, and 3.9 billion pounds of pesticides, respectively, in 2016 (Donley, 2019). However, these numbers are not sustainable from either a supply-chain or environmental perspective. Thus, because natural resources are limited and their overuse pollutes the environment, the continued use of fertilizers and water to meet the demand of future global food requirements is not sustainable. Of relevance here is that agricultural intensification with high resource use and low crop diversity can negatively affect soil- and plant-associated microbiota (the so-called "phytobiome") with subsequent impacts on critical ecosystem services (Matson et al., 1997).

There is growing evidence that aboveground plant diversity supports belowground microbial biodiversity, primarily through root exudation and rhizo-deposition (Bais et al., 2006; Eisenhauer et al., 2017; Morella et al., 2020). These more simple carbohydrates released into the soil primarily feed bacteria (Gunina and Kuzyakov, 2015) and are the most abundant near the root surface and diffuse along a gradient as distance from the root increases (Gao et al., 2011). The microbial composition is more abundant and complex in the rhizosphere, the narrow zone surrounding plant roots, with up to 10^9 cells per gram in typical rhizospheric soil, comprising up to 10^6 taxa (Lakshmanan et al., 2017). The more complex carbohydrates (e.g., lignin, cellulose) are largely degraded by decomposer fungi that break down these recalcitrant compounds into forms that can be used by other microbes. This conversion is largely decoupled from conventional agricultural practices, wherein the organic matter content is often lost to the system (Craven and Ray, 2019), and the carbon flux is at least partially unregulated in this regard. Again, defining nutrient fluxes with techniques like Stable Isotope Labeling (SIP) holds great potential to define and construct resilient, functioning and beneficial microbiomes that can contribute to future holistic agriculture. Thus, applying an efficient and diverse soil microbiome backed by these new technologies can facilitate and promote sustainable agriculture and can effectively contribute to meet the triple requirements of economic, social and environmental sustainability (Ray and Craven, 2016).

Historically, microorganisms that promote plant growth and nutrient acquisition have been used largely as single strains in agriculture to offset such fertilizer inputs as nitrogen and phosphorous. However, studies of natural populations suggest that groups of microbes with distinct function niches play pivotal roles in adhering and desorbing inorganic nutrients to physical surfaces, as well as breaking down organic residues and incorporating them into the soil (Lakshmanan et al., 2014; Finkel et al., 2017; Kumar and Dubey, 2020). Conceptually, such observations support the idea of the microbiome as a second genome or an extended genome of the plant (Vandenkoornhuyse et al., 2015). It is now evident that improving plant performance in a sustainable manner is beyond the binary interaction between a specific microbe or a consortium of beneficial microbes and a targeted host plant. This is a much more complex set of interactions than previously thought that requires modeling for improving predictable outcomes. In this review, we will highlight the current state of the art for the incorporation of specific plant growth-promoting microorganisms and discuss the principles and management practices for next-generation, microbiome-based approaches for sustainable agriculture.

Application of Beneficial Microbes in Sustainable Agriculture: Past, Present and Future

Since the early 1800s, the United States Department of Agriculture has recommended the use of certain rhizobacteria to improve nitrogen fertility in leguminous crops (Schneider, 1892). Since that time, a great deal of research has been conducted on this relationship between legumes and these bacteria, now termed rhizobia, that inhabit unique structures, the nodules, that form on the roots. Rhizobia infecting these nodules are now capable of "biological nitrogen fixation," whereby di-nitrogen is fixed into forms that can be used by the plant. Symbiotically, the bacteria trade these nitrogenous compounds to the host plant in exchange for photosynthetically derived carbon. Despite these limited applications, much remains to be learned regarding both the functional and taxonomic diversity of these symbiotic bacteria and their host plants, the role they play in the global nitrogen cycle, and ultimately, how they can best be harnessed for improving plant productivity. This is particularly true for marginal lands that are not suited for row crop production but will need to be incorporated into global food and forage production approaches moving forward. Further, such degraded lands must but regenerated with the goal of restoring soil health and productivity. Any successful endeavor in this regard must include a characterization of the soil microbiome, both taxonomically and functionally. Attempts currently are underway to fix nitrogen in such non-legumes as wheat, corn and other staple crops that produce the bulk of human food by engineering symbiotic relationships using synthetic biology approaches (Rogers and Oldroyd, 2014; Ryu et al., 2020). Such approaches would significantly impact global food supplies, and may function adequately to reduce the arable land required to meet productivity goals.

Plant growth-promoting microbes not only play critical and diverse roles in growth promotion *per se*, but also in improving various aspects of plant resilience against a wide array of biotic and abiotic stresses (Arnold et al., 2003; Sun et al., 2010; Agler et

al., 2016; Azad and Kaminskyj, 2016; Singh, 2016; Oleńska et al., 2020; Rai et al., 2020). In this context, researchers globally have worked over the last several decades on plant growth-promoting microorganisms, such as root-associated mycorrhizal fungi, across a broad range of crops and encompassing a wide range of agro-climatic conditions. For perspective, Brundrett and Tedersoo (2018) recently reviewed 135 years of mycorrhizal research and reported that merely 8% of the vascular plants are non-mycorrhizal, suggesting that plant families associating with mycorrhizae have been very successful over the evolution of the plant kingdom.

Traditionally, agricultural application of beneficial microorganisms involves a few types of well-characterized microbes, such as mycorrhizal fungi or rhizobia bacteria, for which the mechanisms underlying the plant growth promotion effects are well understood. Further, most of these studies focused solely on the ability of the applied microorganisms to facilitate such specific plant growth-promoting traits as phosphate solubilization, nitrogen fixation, ACC deaminase production (Sarkar et al., 2018), siderophore production, biofilm formation, plant hormone production, biotic, and abiotic stress tolerance or resistance, among others (Weyens et al., 2009; Bhattacharyya and Jha, 2012; Singh et al., 2019). While these beneficial microorganisms can impart considerable benefits to plant growth and fitness, they are typically documented in simple, one-on-one studies, often conducted in sterile soils in greenhouse conditions. As a consequence, the effects found in such simplified conditions often fail to translate to more complex field situations (Chutia et al., 2007; Nicot et al., 2011; Parnell et al., 2016). Soil in field plots have more complex microbial environments that are presumably adapted to the local eco-environment.

In recent years, next-generation sequencing has revolutionized our understanding of microbial community composition and function, and together with improved culturing methodologies has greatly facilitated the use of biologicals in the field (Schweitzer et al., 2008; Panke-Buisse et al., 2014; Mueller and Sachs, 2015). Specifically, metagenomics-based approaches have uncovered vast, previously unrecognized populations of microbes that may have new or enhanced properties that could be used for agriculture, bioremediation, and human health. For example, comparative analyses of rhizosphere metagenomes from resistant and susceptible tomato plants enabled the identification and assembly of a flavobacterial genome that was far more abundant in the resistant plant rhizosphere microbiome than in that of the susceptible plants. Such findings certainly reveal a role for native microbiota in protecting plants from phytopathogens, and pave a way forward for the development of probiotics to ameliorate plant diseases akin to human health (Kwak et al., 2018). In another study, a 16S rRNA gene amplicon sequencing analysis of maize root microbiome led to the identification of bacteria that promote growth under low temperature conditions (Beirinckx et al., 2020). Additionally, principles of consortium design that rely on cross-talk, cross-feeding and/or substrate channeling between different microorganisms offer new opportunities for “intelligent” consortia design (Calvo et al., 2014; Vorholt et al., 2017; Paredes et al., 2018). We propose that the manipulation of the plant microbiome holds tremendous potential for agricultural improvement (Table 1). Through recent years of research, it is elucidated how microbes worked in nature before, and how decades of chemical fertilizer use have silenced their ability to improve plant fitness and soil health. Therefore, designing a microbial consortium that carefully weighs and evaluates the relationship between inoculants and the resident microbiome would substantially improve the plant growth-promoting potential and resilience of agricultural biologicals to boost plant growth. In this review, we will discuss the key considerations that would improve the likelihood of microbial products to improve crop yield, decrease disease severity and/or ameliorate abiotic stress response. Further, it is likely that such considerations would reduce the inconsistency between the performances of beneficial microbes from controlled greenhouse conditions and more natural environments.

Category	Salient findings	Reference
Plant growth promotion	Chilling temperatures critically affects growth of Maize in N. hemisphere. This study reported enrichment of *Comamonadaceae* and the *Pseudomonadaceae* in the root endosphere of maize grown under chilling conditions. Additionally two bacterial strains were identified from the root endosphere that could boost maize growth under chilling conditions.	Beirinckx et al., 2020
	A root endophytic bacteria Sphingomonas sp. Cra20 improved growth of *Arabidopsis thaliana* under drought stress by stimulating the growth of lateral roots and root hairs. Additionally, the relative abundance of Sphingomonas increased in the rhizosphere bacterial community in the water-deficit treatment, suggesting the role of Sphingomonas sp. Cra20 in alleviating drought induced stress.	Luo et al., 2019
	A community-based culture collection (CBC) approach was undertaken to isolate bacteria from the stalks and rhizosphere of Sugarcane. Subsequently, a synthetic community was designed by cross-referencing the CBC with the sugarcane microbiome profile that comprised of highly abundant bacterial groups from roots and stalks. The synthetic community could successfully improve the biomass of sugarcane, and was found to displace the native rhizosphere bacteria community.	Armanhi et al., 2018
	Willows (Salix spp.) were grown in gamma-irradiated petroleum-contaminated soils. Plants were inoculated with contaminated rhizosphere soil from a willow that grew well, or with contaminated bulk soil in which the plants had died. Willows inoculated with bulk soil performed better than those inoculated with rhizosphere soil. Microbiomes of different treatments were divergent at the beginning, but had converged at the end of the study, suggesting lasting effect of inoculated microbiome on plant growth, but not on the rhizosphere microbiome.	Yergeau et al., 2015
Plant defense response	Microbiome structure of Banana endosphere in the roots and shoot tips were investigated during plant growth and wilting processes. The keystone bacterial species belonging to the family *Enterobacteriaceae* family were isolated and further engineered to express ACC deaminase. Plants inoculated with engineered *Enterobacteriaceae* strains increased resistance to the Fusarium wilt disease. The findings illustrate that the keystone species in the banana microbiome plays functional role in the wilt resistance.	Liu et al., 2019
	Composts represent a sustainable way to suppress diseases and improve plant growth. Compost derived microbial communities enriched in the rhizosphere of Tomato were analyzed for antifungal activity against soil-borne fungal pathogens. Subsequently, microbial synthetic communities (SynComs) were designed with an overarching aim to improve plant fitness. SynComs were found to promote tomato growth as well as suppressed Fusarium wilt symptoms in controlled conditions.	Tsolakidou et al., 2019
	Tomato variety Hawaii 7996 is resistant to the soil-borne pathogen *Ralstonia solanacearum*, whereas the Moneymaker variety is susceptible to the pathogen. Rhizosphere microbiome analysis revealed clear differences in community profile of these two varieties. Transplantation of rhizosphere microbiota from resistant plants suppressed disease symptoms in susceptible plants. Additionally, a flavobacterium strain isolated from resistant plant rhizosphere microbiome was found to suppress R. solanacearum in susceptible plants.	Kwak et al., 2018
	A simplified synthetic bacterial community based on maize rhizosphere microbiome was designed representing most dominant phyla to study their functional attributes in maize seedlings. This synthetic community inhibited the phytopathogenic fungus *Fusarium verticillioides*, both *in planta* and *in vitro*. This study indicates how community profile information can be utilized to design beneficial microbial consortia for improving plant fitness and productivity	Niu et al., 2017
Abiotic stress response and nutrient use efficiency	Recognition of microbes by plant immune system mediated by phosphate stress was investigated. A representative synthetic bacterial community (SynCom) was designed that comprised of 35 bacteria isolated from the roots of Brassicaceae. SynCom enhanced the activity of PHR1, the master transcriptional regulator of the PSR, in Arabidopsis thaliana grown under limited phosphate. Additionally PHR1, repressed plant's immune system in phosphorous starved regime, validating plant's prioritization of nutritional stress over defense.	Castrillo et al., 2017
	Nitrogen-use efficiency of indica varieties of rice is superior to that of japonica varieties. Root microbiome analysis of these two varieties revealed that microbiota of indica and japonica highly distinct. Further, it was found that this distinctness was associated with a rice nitrate transporter and sensor NRT1.1B. Based on microbiome analysis, microbial synthetic communities (SynComs) were designed. It was found that indica-enriched SynCom improved rice growth in organic nitrogen conditions compared with a japonica-enriched SynCom.	Zhang et al., 2019
	Root associated microbiome of drought-sensitive pepper plant (*Capsicum annuum* L.) were analyzed focusing on role of microbes conferring plant growth under water limitation. Subsequently pepper root associated culturable bacteria were isolated and evaluated for plant growth promotion and drought tolerance abilities. The composition of the cultivable community associated to rhizosphere and root surrounding soil fractions shared a high similarity. Most of these isolates were able to promote plant growth and alleviate drought-induced stress with enhanced abilities observed in *Bacillus* and the *Rhizobacteria* strains.	Marasco et al., 2012
	Community profiling microbiome associated with superior halo-tolerant seepweed Suaeda salsa revealed that rhizospheric and endophytic bacterial community were enriched in genes responsible for salt stress acclimatization. This suggest that S. salsa preferentially recruit halotolerant taxa to confront soil salinity. Based on root endosphere core microbiota, halotolerant bacterial and fungal strains belonging to Pseudomonadales and Montagnulaceae were isolated. It was demonstrated that these core microbiome members were successfully able to improve growth and salt tolerance in the non-host rice plant.	Yuan et al., 2016

Table 1. List of recent publications in plant and soil microbiome focusing on plant fitness and productivity.

Microbes for Plant Growth Promotion: A Reductionist Approach

Sustainable agriculture primarily focuses on reducing the dependency of plants on chemical fertilizers and improving their ability to grow on marginal soil types. For such purposes, individual microorganisms for plant growth-promotion have largely focused on those that facilitate growth and development by enhancing acquisition of nutrient resources from the environment, including fixed nitrogen, iron and phosphate, or modulating growth by altering plant hormone levels (Figure 1) (Hayat et al., 2010). Another approach aimed at reducing yield losses to disease relies on microbes that decrease or prevent the deleterious effects of plant pathogens by several different mechanisms (Glick, 2012), i.e., by acting as a biocontrol agent. Microbe-based plant growth-promoting products, more popularly marketed as biofertilizer, has been commercially available in many countries since the 1950s (Timmusk et al., 2017). Application of such plant growth-promoting microbes in agricultural context and more specifically as inoculants has been nicely reviewed by Souza et al. (2015). However, under certain cases, the results obtained in the laboratory could not be reproduced in the field primarily due to the presence of many crop species and crop varieties, variable environmental conditions between fields, (Timmusk et al., 2017; Saad et al., 2020), occasionally due to the low quality of the inocula, and their inability to compete with the indigenous population. In that context, it is important to consider the fact that there is always greater likelihood of success by introducing mixed cultures of compatible microorganisms, rather than single, pure cultures. This is simply because each strain in the multi-strain consortium can compete effectively with the indigenous rhizosphere population and enhance plant growth with its partners. For example, sequential inoculation of nitrogen fixing bacterium *Azotobacter vinelandii*, followed by plant growth-promoting root-endophytic fungus *Serendipita indica* demonstrated better growth in rice (Dabral et al., 2020). Dual inoculation of *S. indica* and *Mycolicibacterium* strains boosted the beneficial effects in tomato (del Barrio-Duque et al., 2019) and that of arbuscular mycorrhizal fungus with plant growth-promoting bacteria *Bacillus subtilis* demonstrated better growth in wheat (Yadav et al., 2020) as compared to the singly inoculated plants. There also are numerous other reports that showed two strains used in a consortium promoted plant growth in a more effective manner (Nadeem et al., 2013; Fatnassi et al., 2015; Priyadharsini and Muthukumar, 2016). Nevertheless, to unlock the full potential of soil microbes for such nutrient cycling as nitrogen or phosphorus and providing plant protection against biotic and abiotic stress microbiomes, it is necessary to develop strategies to comprehend the functional capabilities of soil microbial communities. Irrespective of the approach, persistence is the first and foremost principle underlying the design of a successful microbial consortium for conferring plant growth promotion. This is not surprising, as the survival and activity of microbes in any soil system face a monumental task of competing with the myriad of microbes naturally adapted to that same soil. Thus, in addition to establishment of a compatible interaction with the host, a successful microbial inoculant has to subsequently compete and persist in the context of indigenous microbes as well as local abiotic conditions (Finkel et al., 2017). It has been reported that bacterial inoculations can persist in soil up to 7 weeks, but whether this inoculum also can provide plant growth benefits is not clear (Schreiter et al., 2014). While persistence or resilience of any microbial inoculum is more dependent on biotic components of a specific soil type, their persistence can be improved by inoculating crops with consortia rather than single strains (Verbruggen et al., 2012; Nemergut et al., 2013). Thus, it can arguably be stated that the diversity of a microbial inoculum, in addition to its plant growth-promoting traits, is critical for enhancing productivity and longevity (Cordero and Polz, 2014).

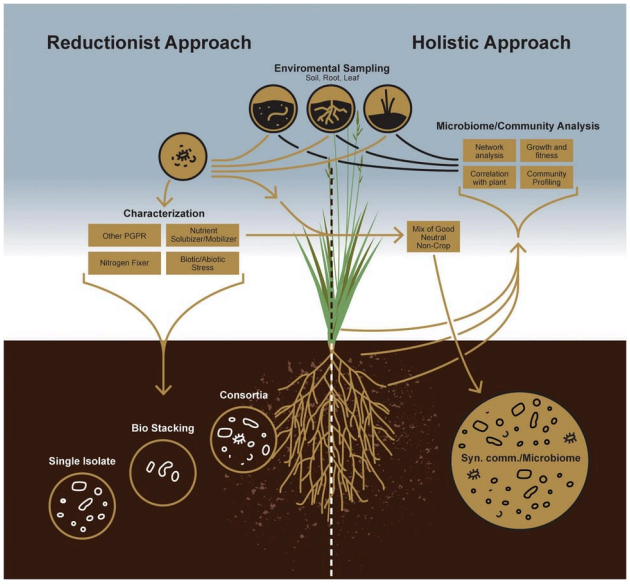

Figure 1. A schematic comparison between individual microorganism-based reductionist approach and microbial community-based holistic approach.

To improve the likelihood of success for such a management strategy, *a priori* knowledge of indigenous microbial populations competing with the introduced plant growth-promoting agent(s) is critical. While a reductionist approach can define the currency of individual plant-microbe interactions, the concepts of microbial community survival and functioning require, a more holistic, microbiome-based approach empowered by next-generation sequencing technology to study plant-microbe interactions at the community level (Figure 2). Indeed, this will enable researchers to design more robust, synthetic microbial consortia capable of reliably enhancing agricultural productivity.

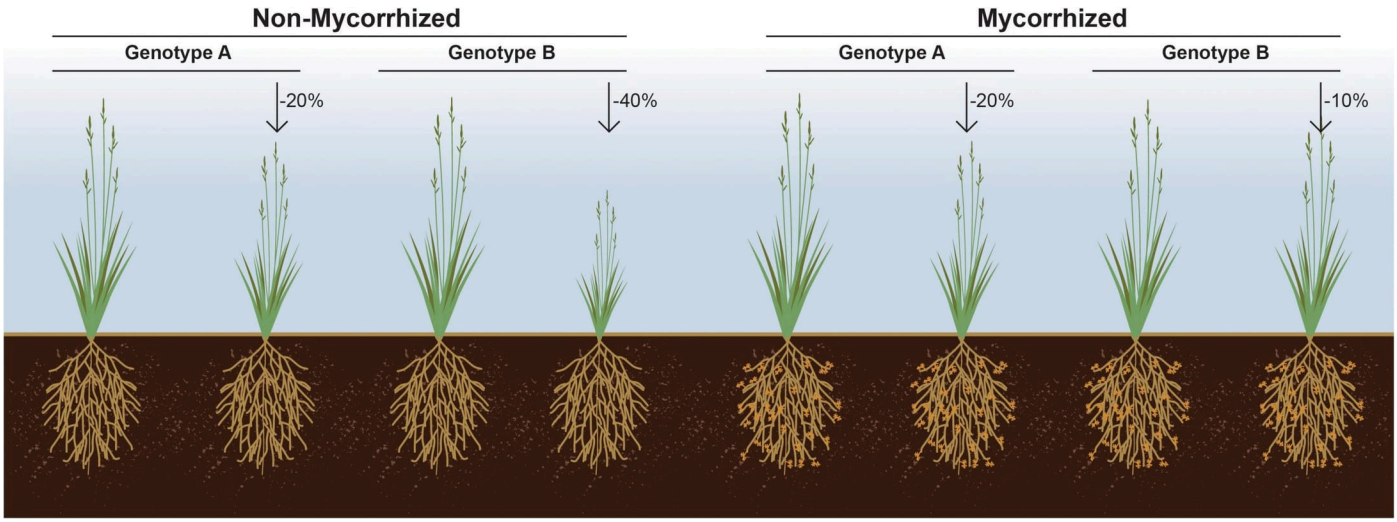

Figure 2. Responsiveness as the% gain in plant fitness attribute in response to symbiosis over un-colonized cohorts. This figure illustrates a hypothetical situation wherein genotype A loses less biomass (–20%) in response to soil nutrient limitation than does genotype B (–40%). However, if genotype B for its inherently associated rhizosphere microbiome responds optimally to a mycorrhizal symbiont, then it may be that it loses the least biomass (–10%) due to soil nutrient limitation, if the symbiont is present.% denotes loss in biomass due to soil nutrient limitation.

Microbiomes for Plant Growth Promotion: The Holistic Approach

Soil is a vastly heterogeneous growth medium, providing a wide spectrum of ecological niches for microorganisms that enable diverse strains to coexist and form complex microbial communities. When the earliest plants extended their roots into primordial soils, they encountered a habitat already teeming with bacterial and fungal life (Bulgarelli et al., 2013; Kemen, 2014). Since that early time, plants have interacted with rhizosphere microbes, evolving strategies to forge beneficial alliances with some while keeping others at bay. Such early associations certainly had consequences on plant growth and development. Therefore, a more holistic approach is needed to understand better these microbes and the roles they play in the overall health of plant and soil (Figure 1). Again, recent advances in next-generation sequencing technology and the decreasing costs associated with that technology now allow us to evaluate how microbial populations fluctuate in both space and time or to identify core microbiomes that appear conserved among host genotypes or species (Sergaki et al., 2018). Thus, although culture-independent methods have contributed tremendously to our understanding of plant-associated fungal and bacterial community structures, the study of microbiome functions remains challenging because of the inherent noise of plant-associated microbial communities. It is now well known that there are core sets of microbes that, depending on the host, are recognized as keystone taxa that consistently associate with healthy plants (Banerjee et al., 2018). Consequently, researchers working with specific plant-microbe interactions have increasingly acknowledged the mitigating impact these larger microbial communities have on individual plant-microbe outcomes for plant growth promotion or fitness. Now, plant-associated fungal and bacterial stains from various plant species are being isolated, which will provide in the near future an inestimable resource for assembling taxonomically defined microbial communities with increasing complexity. Therefore, it is now imperative to take advantage of this knowledge to design consortia of microbes to maintain a sustainable rhizosphere community, with key functional properties that include plant protection, nutrient acquisition, and alleviating biotic and abiotic stress responses. From that perspective, synthetic community (SynCom) approaches can provide functional and mechanistic insights into how plants regulate their microbiomes (Figure 1). Not surprisingly, recent culture-independent analyses thus have paved the way for developing SynComs more often (Bodenhausen et al., 2014; Armanhi et al., 2018; Carlström et al., 2019).

Mycorrhizal fungi, at least the arbuscular type, were early symbiotic partners of most land plant species, improving nutritional conditions through soil exploration and pathogen resistance of host plants (Klironomos et al., 2000). In reward for the essential physiological services, they receive ca. 20% of net photosynthetic products from plants (HoÈgberg et al., 2001). Other mycorrhizal

systems may have different nutritional benefits and costs, as has been proposed for the serendipitous system (Craven and Ray, 2019). Additionally, third-party partners can modulate the outcome of the tripartite interaction, such as the case of mycorrhizal helper bacteria (Frey-Klett et al., 2007), fungal endobacteria (Bonfante and Desirò, 2017; Bonfante et al., 2019) like *Candidatus Moeniiplasma glomeromycotorum* within the spores and hyphae of Glomeromycotina (Naito et al., 2017), *Rhizobium radiobacter* within *Serendipita indica* (Guo et al., 2017), and N_2-fixing endobacteria *Pseudomonas stutzeri* inside basidiomycetes yeast endophyte *Rhodotorula mucilaginosa* (Paul et al., 2020). Hence, it is imperative to consider the composition and functioning of these microbe–microbe interactions to understand plant–microbiome associations in a holistic manner.

Principles and Management of Rhizosphere Microbiomes for Sustainable Agriculture

Competence and Resilience of the Rhizosphere Microbiome: Impact of Introduced Microbes on Native Microbiomes

In 1904, the German agronomist and plant physiologist Lorenz Hiltner coined the term *rhizosphere* (Hartmann et al., 2008) to describe the area around a plant root inhabited by a unique population of microorganisms. Since then, numerous studies have been undertaken to decipher the interplay between plants and rhizosphere microorganisms, encompassing a wide variety of plant growth-promoting bacteria, fungi, insects, protozoans, viruses, etc. (Marschner, 2012; McNear, 2013). The majority of these studies have traditionally followed a simple principle for maximizing successful host infection by pre-inoculation onto the targeted crop of choice to provide a competitive advantage for a desired microbe. Conceptually, this increases the relative abundance of a given beneficial microbe in the rhizosphere, at least temporarily, to achieve the desired benefit. Such studies typically take place in a controlled, artificial condition, such as a defined growth medium in a greenhouse, where competition from a native rhizosphere community is relatively low or non-existent. As mentioned above, this approach occasionally has failed once field application is attempted or the benefits are dramatically reduced in amplitude and/or endurance.

As an example, Lekberg and Helgason (2018) conducted a literature survey of research papers published on mycorrhizal functioning spanning a 30-year period (1987–2017). The most striking finding of this survey was that less than 5% of the work scientifically manipulated mycorrhizal abundance in the field. While we are not arguing the merit of greenhouse-based studies where the number of variables can be controlled and accounted for, yield gains in field conditions will continue to be modest with such an approach. Rhizosphere competence must be evaluated in a field situation if the true power of this approach is to be realized.

Over the last few decades, mycorrhiza-based bio-fertilizers containing one or several species of fungi were developed in forestry and agriculture (Jeffries and Rhodes, 1987; Baraza et al., 2016; Igiehon and Babalola, 2017). These inoculants are generally effective in plant growth promotion under controlled lab and greenhouse conditions. However, few targeted efforts have been made to measure interactions between the introduced microbe(s) and the native mycorrhizal community, let alone the more complex rhizosphere microbiome (Svenningsen et al., 2018; Turrini et al., 2018). To optimize outcomes from these interactions, targeted research must be undertaken to understand how such mycorrhiza-based biofertilizer integrate themselves within the context of the native microbiome.

Integration of Rhizosphere Microbiomes in Plant-Microbe-Nutrient Relationships

The soil microbial community often assists plants by weathering minerals from rock surfaces and degrading recalcitrant soil organic matter whereby soil microbes break down soluble and insoluble organic matter and convert it into inorganic, plant-available forms. Soil organic matter turnover is thus considered a net positive, as it liberates the nutrients locked up in organic matter. For this reason, conventional farming has always relied heavily on soil tillage, along with such other intensive agricultural practices as usage of inorganic fertilizers, herbicides and pesticides. However, it is already clear that such practices have negative consequences on the functional diversity of soil microbiomes. Long-term chemical fertilization has been shown to dramatically decrease the soil pH, which leads to a decrease in bacterial diversity and other changes in microbial community structure (Sun et al., 2015). This was well documented in the work of Kumar et al. (2017), who showed that long-term application of high doses of inorganic nitrogenous fertilizers severely reduces relative abundance, diversity and structure of diazotrophs, which play a key role in converting atmospheric N_2 to plant-available ammonium.

As mentioned above, soil bacterial communities play a pivotal role in soil organic matter decomposition. In particular, soil carbon and nitrogen are critical factors for bacteria that rely on soil organic C and N decomposition to obtain energy (Chen et al., 2014; Wild et al., 2014; Tian et al., 2018). Further, different types of soil C selectively manipulate soil microbial community

composition, resulting in changes in such belowground ecosystem functions as decomposition and nutrient transfer and creating feedbacks that may affect overall plant growth and productivity (Orwin et al., 2006). For example, bacteria belonging to the genera *Chloroflexi*, *Nitrospirae*, and *Planctomycetes* preferentially feed on recalcitrant organic C, whereas *Proteobacteria* and *Bacteroidetes* prefer labile organic C present in the soil (Nie et al., 2018). For this reason, amending the soil with such organic fertilizers as compost or manure contributes to higher microbial diversity and biomass compared to mineral-fertilized soils, which in turn positively impacts soil health (Schmid et al., 2018; Banerjee et al., 2019). Unfortunately, only a few agroecosystem experiments exist that compare organic and conventional management strategies over an extended period for evaluation of impact on soil health and restoration (Raupp et al., 2006; Khatoon et al., 2020). Hartmann et al. (2015) took a metagenomics approach to assess microbial diversity of soil in response to more than 20 years of continuous organic and conventional farming. Not surprisingly, they found that organic farming increased richness, decreased evenness, and shifted the structure of the soil microbiota when compared with conventionally managed soils under mineral fertilization (Hartman et al., 2018; Li et al., 2020b). There also are reports of significant alterations in the microbial community composition of both summer maize and winter wheat in response to increased nitrogen fertilization dose (Wang et al., 2018; Li et al., 2020a). Clearly, a better understanding of the interactions between the soil microbiome and conventional agricultural practices is crucial for the development of sustainable management of soil fertility and crop production.

Managing the Rhizosphere Microbiome to Induce Disease Suppression in Soil

Disease suppressive soils were originally defined by Baker and Cook (1974) as “soils in which the pathogen does not establish or persist, establishes but causes little or no damage, or establishes and causes disease for a while but thereafter the disease is less important, although the pathogen may persist in the soil.” Disease suppressive soils are the best examples of microbiome-mediated protection of plants against root infections by soil-borne pathogens. Such disease-suppressive soils have been described for various soil-borne pathogens, including fungi, bacteria, oomycetes, and nematodes (Mazzola, 2007; Kwak et al., 2018). To date, several microbial genera have been proposed as key players in disease suppressiveness of soils, but the complexity of the microbiome, as well as the underlying mechanisms and microbial traits, remain elusive for most disease suppressive soils (Toyota and Shirai, 2018).

Recently, Carrión et al. (2019) showed that upon pathogen invasion, members of the *Chitinophagaceae* and *Flavobacteriaceae* became enriched within the plant endosphere. They proposed that this bacterial population shift led to the induction of enzymatic activities associated with fungal cell-wall degradation, as well as secondary metabolite biosynthesis, all aimed at accelerating and augmenting the plant defense response(s). Although the disease suppressive abilities of certain soils can be at least partially attributed to their physico-chemical properties, the capacity of a soil to suppress disease progression is more often attributed to agri-management practices and crop rotation (Weller et al., 2002). In classic studies by Gerlagh (1968) and Shipton et al. (1973), the authors have shown soil to become disease suppressive after mono-culturing wheat over time. More recently, a comparative metatranscriptome analysis of wheat rhizosphere microbiome grown in fields suppressive and non-suppressive to the plant pathogen *R. solani* AG8 clearly revealed distinct dominant taxa in these two soil types. Additionally, suppressive samples showed greater expression of polyketide cyclase, terpenoid biosynthesis, and cold shock proteins (Hayden et al., 2018). While development of probiotics for the human gut microbiome has already been an established field of research, the use of probiotics that comprises naturally occurring bacterial antagonists and competitors that suppress pathogens has recently emerged as a promising strategy for disease suppression in soil. A study on application of probiotic consortia that comprised predefined *Pseudomonas* species reported suppression of the bacterial plant pathogen *Ralstonia solanacearum* in the tomato rhizosphere microbiome (Hu et al., 2016). In another study, amendment of *Metarhizium*, an insect-pathogenic fungus that is commonly employed as biological control agents against crop pests, in the rhizosphere of common bean (*Phaseolus vulgaris*) significantly increased the relative abundance of plant growth promoting such taxa as *Bradyrhizobium*, *Flavobacterium*, *Chaetomium*, and *Trichoderma* while suppressing the root rot disease symptoms *Fusarium solani* (Barelli et al., 2020). Soil suppressive properties are mostly derived from the biological functions of soils. Therefore, elucidation of microbial functions in suppressive soils by a next-generation sequencing approach will facilitate the development of effective, consistent and durable disease management tools.

Impact of Agriculture Management Practices on the Soil Microbiome

One important context for plant-microbe interactions is soil structure, as it can vary greatly depending on land-use history, plant species composition and successional stage (Erktan et al., 2016). Besides playing pivotal roles in soil organic matter decomposition, carbon cycling, nutrient mobilization, etc., saprotrophic fungi also are involved in creating soil structure through the secretion of extracellular compounds and physical binding of soil via hyphal networks (Bergmann et al., 2016). Interestingly, studies on the impact of tillage on the soil fungal communities have shown mixed results. Reports in no-till systems have varied from increased ratios of fungal to bacterial biomass (Acosta-Martínez et al., 2010) to decreased ratios (Mbuthia et al., 2015),

as well as no change at all (Mathew et al., 2012). More recent studies have shown that soil fungal communities are negatively impacted by tillage, as they typically would be responsible for degrading crop residue left on the surface with no-till (Yin et al., 2017). More specifically, soil bacterial communities were primarily found to be structured by tillage, whereas soil fungal communities responded mainly to management type with additional effects by tillage (Hartman et al., 2018). Additionally, it is acknowledged that organically managed systems increased taxonomic and phylogenetic richness, diversity and heterogeneity of the soil microbiota when compared with conventional farming systems (Lupatini et al., 2017). In a simple definition, organic farming system consists of low-input agro-ecosystem farms in which plant productivity and ecosystem functionality are based on the natural availability of plant nutrients (Lammerts van Bueren et al., 2002). A study aimed at comparing the soil microbiome in conventional and organic farming systems in central Europe revealed no major differences among the main phyla of bacteria between the two farming styles (Armalytë et al., 2019), whereas another study that investigated the effects of 12 years of organic farming on soil microbiomes in northern China reported shifting of the community composition of dominant phyla and significant alterations of functional groups associated with ammonia oxidation, denitrification and phosphorus recycling when compared to conventional farming systems (Ding et al., 2019).

In addition to tillage, crop rotation also plays a pivotal role in increasing belowground microbial diversity compared to intensive mono-cropping practices. Although the United States Department of Agriculture has advocated [via the Conservation Reserve Program (CRP)] crop rotation to improve eroded land as early as 1985 (Allen and Vandever, 2005), its benefit on soil health has only been recognized recently. Several studies reported increases in such soil quality parameters as organic matter content, microbial biomass and respiration under crop rotation management when compared with a mono-cropping system (Campbell et al., 1991; Luce et al., 2013). A meta-analysis of 122 studies that examined crop rotation revealed similar findings, namely that adding one or more crops in rotation to a monoculture substantially increased the soil microbial biomass along with increases in total soil C and N, respectively (McDaniel et al., 2014). In another study, soil microbial communities of corn and switchgrass in mono-cropping systems when compared with mixed prairie grasses demonstrated that bacterial and fungal biomass, especially arbuscular mycorrhizal fungi, were higher in plots with mixed prairie grasses (Jesus et al., 2016). A 16S amplicon-based metagenomic analysis of an almost 20-year-old field trial in Bernburg, Germany revealed a significant effect of tillage practice and the preceding crop on prokaryotic community structures (Babin et al., 2019)

Cover crops are typically unharvested crops planted between cash crops that augment C provisioning to the soil system not only via unharvested residues, but also as root exudates that can support many rhizosphere microbes during the active growing season of the cover crop. Other benefits attributed to cover cropping include improved N fertility by incorporating legumes as a cover crop, reduced soil compaction via deep-rooted plants, and reduced erosion by keeping a plant and its root system in the field year round (Fernandez et al., 2016). Of various crop rotation management practices, those that include cover crops sustain soil quality and productivity by enhancing soil C, N and microbial biomass (Kim et al., 2020), making them a cornerstone for sustainable agroecosystems. Nonetheless, very few studies have assessed the relationship between cover crop stands and their associated belowground microbial communities. Early research in unfertilized grasslands demonstrated that fungal communities respond positively to plant-derived C inputs, suggesting that inclusion of cover crops in a rotation may promote fungal community development (Denef et al., 2009). More recently, a field study tested this hypothesis by specifically examining the impact on soil microbial communities of eight fall-sown cover crop species grown singly and in multispecies mixtures following a spring oats (*Avena sativa* L.) cropping season and found that certain cover crops selectively favored particular microbial functional groups. Arbuscular mycorrhizal fungi were more abundant beneath oat and cereal rye (*Secale cereale* L.) cover crops, while non-AM fungi were positively associated with hairy vetch (*Vicia villosa* L.) (Finney et al., 2017). Beyond positively affecting soil C and increasing the diversity of such beneficial fungi as arbuscular mycorrhiza, clover as a cover crop is often reported to suppress the relative abundance of pathogenic fungi (Benitez et al., 2016). Contrarily, in a 2-year field study, cover crops reportedly increased overall phylogenetic diversity of fungi but did not change the relative abundance of saprophytes, symbionts or pathogens, implying that cover cropping does not always appear to contribute to functional changes in the fungal community (Schmidt et al., 2019).

Reassessment of Plant Responsiveness to Symbiosis

It is now increasingly evident that plants employ fine-tuned mechanisms to shape the structure and function of their microbiome, with different genotypes of the same plant species growing in the same soil yet associating with distinct microbial communities (Berendsen et al., 2012). This is demonstrated in the findings of Bazghaleh et al. (2015), who clearly demonstrated the importance of intraspecific host variation in the association of chickpea cultivars with AM and non-AM fungi. Therefore, specific traits of a plant that modulate its microbiome should be considered as a trait for plant breeding (Wallenstein, 2017).

Despite the obvious importance of beneficial microorganisms for plant growth and fitness, and the impact of plant genotype on shaping their microbiome composition, plant germplasm is typically screened in the absence of microbes, and the selection of best breeding lines made solely based on the interaction between plant genotype and performance under various abiotic factors. We propose that an *a priori* examination of the interaction between a plant genotype(s) and the symbiotic microbes

upon which it likely depends is an important factor in the selection of plant breeding lines. It seems very likely that a subset of rejected germplasm could outperform others, but only when coupled with a beneficial microbe or microbiome (Figure 2). Arguably, current breeding and selection efforts most likely result in decoupling of the soil microbiome from plant fitness. As a result, modern varieties may have lost their ability to support diverse microbiomes and thus, fail to gain the most from these interactions (Wallenstein, 2017).

It is now acknowledged that transitioning from a highly intensive mono-cropping system to a more diversified cropping system consisting of multiple host genotypes leads to increased bacterial and fungal diversity (Calderon et al., 2016). Hence, future plant breeding efforts should incorporate plant characteristics that are related to microbiome diversity. For example, efforts focusing on manipulating plant root exudates likely play a critical role in selective recruitment of the rhizosphere microbiome (Bakker et al., 2012). In support of this notion, it has been shown that plants can select which microbial populations receive the lion's share of root exudates, demonstrating a capacity by the host to refine its microbial composition. Hence, an unbiased screening of plant genotypes for responsiveness in the presence of a beneficial microbe or microbiome can set forth a new and potentially transformative paradigm in selecting microbes for plant growth promotion (Figure 2).

Significance of Mycorrhizas: A Critical Component of Healthy Soil Rhizospheres

Mycorrhizae are mutualistic associations between soil fungi and plant roots that gradually evolved to be reciprocally beneficial to both partners (Brundrett, 2002). The benefits are generally assumed to involve an exchange of photosynthetically derived carbon from the host plant in exchange for soil nutrients provided by the foraging mycorrhiza. While likely true of arum-type arbuscular types of mycorrhizae, there are other types that can derive carbon from organic matter in the soil, or even "steal" it from one host plant to supply to another (Allen and Allen, 1991). A recent study has reported that in contrast to *Arum maculatum*, in which carbon is entirely derived from photo-assimilation, the green leaves of *Paris quadrifolia* contain a striking 50% carbon of fungal origin. Such partial mycoheterotrophy could thus potentially be widespread among the roughly 100,000 plant species that are known to develop a Paris-type AM, with far-reaching implications for our understanding of C trading in plant-microbe communities (Giesemann et al., 2019). Exactly what the mycorrhiza gains from this interaction is still under debate, but benefits may involve a safe haven from the open, more competitive soil space and a second, more reliable carbon source (Sapp, 2004).

Mycorrhizae not only shape plant communities, but they also affect the functional diversity of their cohabitants in the rhizospheric microbiome. The mycelium of mycorrhizal fungi transports plant-derived carbon into the soil in the form of sugars, amino acids and polyols to help sustain the microbiome (Tarkka et al., 2018). More recent studies focusing on soil microbial ecology revealed that mycorrhizal fungi mediate many diverse interactions within the soil "mycorrhizosphere," including pathogens and mutualists that fix atmospheric nitrogen, take up phosphorus, produce vitamins, and/or protect against antagonists (Buée et al., 2009; Tedersoo et al., 2020). The "ectomycorrhizosphere," which forms a very specific interface between soil and many trees, hosts a large and diverse community of microorganisms that likely play roles in mineral weathering and solubilization processes (Uroz et al., 2007). This carbon-rich mycorrhizosphere also supports large communities of root-associated microorganisms that further accelerate weathering of minerals by excreting organic acids, phenolic compounds, protons, and siderophores (Drever and Vance, 1994; Illmer et al., 1995).

Similarly, the extraradical hyphae of arbuscular mycorrhiza provide a direct pathway for the translocation of photosynthetically derived carbon to the soil, leading to the development of nutrient-rich niches for other soil microorganisms, particularly bacteria. A quantitative real-time PCR method detected significantly higher 16S rDNA abundance in both the bulk and the rhizosphere soils of zucchini (*Cucurbita pepo* L.) inoculated with *Acaulospora laevis* and *Glomus mosseae* (Qin et al., 2014). Additionally, arbuscular mycorrhizae have been reported to increase the relative abundance of *Firmicutes*, *Streptomycetes*, *Comamonadaceae*, and *Oxalobacteraceae* inhabiting the mycorrhizosphere (Offre et al., 2007; Nuccio et al., 2013). While there is clear evidence that microbial communities in the rhizosphere function cohesively with their mycorrhizal partner in nutrient mobilization from soil minerals, nitrogen cycling and protection of plants against root pathogens, such bidirectional synergy is not always universal. There are reports that indicate suppressive effects of bacterial communities on mycorrhizal functioning and vice versa. While one study reported (Svenningsen et al., 2018) that soil with a higher abundance of *Acidobacteria* suppresses the normal functioning of extra-radical mycelium in arbuscular mycorrhizae, another study found that *Glomus intraradices* and *Glomus mosseae* suppressed most of the associated soil microbial community (Welc et al., 2010).

A Novel Type of Endophytic Symbiont: The *Serendipitaceae*

A diverse group of fungi in the Basidiomycota, the *Serendipitaceae* (formerly Sebacinales Group B) (Oberwinkler et al., 2014) encompasses endophytes and lineages that repeatedly evolved ericoid, orchid and ectomycorrhizal types. Accordingly, in many natural ecosystems these fungi form mycorrhizal symbioses with an astounding variety of host plants – every mycorrhizal type, in

fact, except for arbuscular. Previous research performed in our lab with a strain of this group, *Serendipita vermifera*, demonstrated plant growth-promoting properties in a variety of plants (Ghimire and Craven, 2011; Ray et al., 2015; Ray and Craven, 2016; Ray et al., 2020). Unfortunately, the agronomic utility of these fungi is hampered by the paucity of strains available, the large majority isolated from Australian orchids. We have begun to address this constraint by isolating the first North American strain of *Serendipita*, named *Serendipita vermifera* subsp. *bescii* NFPB0129, from the roots of a switchgrass plant in Ardmore, Oklahoma (Craven and Ray, 2017; Ray et al., 2018).

As mentioned above, soil organic matter has a tremendous influence on the biological, chemical, and physical properties of soils, making it a vital component of healthy agricultural systems. Whether a natural soil or an agricultural one, the release of the nutrients locked within SOM requires decomposers, primarily insects, fungi, and bacteria, to secrete organic acids and enzymes that can loosen and break down the cellulose and the recalcitrant lignin into nutritive forms that can be used by other microbes and plants. Unlike arbuscular mycorrhizae, which exchange inorganic, mineralized nutrients mined from the soil for carbon derived from host photosynthesis, members of the *Serendipitaceae* studied thus far have a complete arsenal of carbohydrate-active enzymes (CAZymes), representing approximately 4% of the entire gene set and rivaling the more well-studied saprophytic white and brown wood rotters, and much more than other symbiotic fungi. Additionally, genome analysis of *S. bescii* and *S. vermifera* suggests that *Serendipitaceae* fungi have the metabolic capacity to assimilate N from organic forms of N-containing compounds (Ray et al., 2019). We hypothesize that this carbohydrate-degrading enzyme complement endows these *Serendipitaceae* fungi with saprotrophic abilities (Craven and Ray, 2019). Unlike free-living decomposers that maintain a solitary lifestyle, seeking only dead or dying plant tissues as their source of subsistence, *Serendipitaceae* fungi seem to maintain a largely symbiotic lifestyle with the roots of living host plants. It currently is unclear whether there is expression of CAZymes while strains of *Serendipita* are in symbiosis with host plants, and if so, whether there is spatial or temporal separation from more mutualistic traits. Still, the capacity of some strains to form mycorrhizal relationships with orchids, where the seeds require carbon from the fungus for germination and often well into the plant's lifespan, suggests that these *Serendipitaceae* symbionts may be less of a carbon cost to their host plant. Presumably, this saved carbon could potentially be used for other symbiotic relationships or developmental processes. In any case, these intriguing fungi and their seemingly unlimited host range provide a novel symbiosis that could be used in a broad variety of cropping systems.

Conclusion

Soil-dwelling microorganisms are critical components of soil health, itself a determinant of plant productivity and stress tolerance. Deploying microbes to improve agriculture productivity is an extremely attractive approach that is non-transgenic and can be viewed collectively as the extended plant genome. Because these same microbes can contribute to restoring soil health and productivity, they have a bright future in low-input, sustainable agriculture that extends beyond more classically defined plant-microbe symbioses.

Author Contributions

PR and KC conceived and planned the overall idea of the review manuscript. PR, VL, JL, and KC wrote the manuscript. All authors contributed to the article and approved the submitted version.

Funding

This work was supported by the Center for Bioenergy Innovation (CBI) project. The Center for Bioenergy Innovation (CBI) was a United States Department of Energy (DOE) Bioenergy Research Center supported by the Office of Biological and Environmental Research (OBER) in the DOE Office of Science.

Conflict of Interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

16.1.5.4: Plant Microbiomes

Plant Microbiomes

Plant health is influenced by a variety of environmental factors, and though the soil content (including the microbial community present) is a major element, the distinct plant microbiome serves an important role. Similar to organ systems in the human body (e.g. skin, gut, etc.), the components of various plants (e.g. internal tissues, leaves, roots, etc.) can have unique microbial communities that contribute to its respective and overall vitality. A better understanding of the corresponding roles of plant microbiomes can be combined in a synergistic effort with other environmental microbiomes to maintain and promote sustainable agricultural practices, ecosystem biodiversity, and research model studies.

Plant microbiome–an account of the factors that shape community composition and diversity

Article by Dastogeer et al., 2020 licensed under the terms of the Creative Commons Attribution License (CC BY).

Abstract

Plants live in association with diverse microorganisms, collectively called the microbiome. These microbes live either inside (endosphere) or outside (episphere) of plant tissues. Microbes play important roles in the ecology and physiology of plants. Significant progress has been made in revealing structure and dynamics of plant microbiome in the last few years. Various factors related to host, microbes as well as environment influence the community composition and diversity of plant microbiome. This review aimed to provide a general account of the factors (host, microbe and environment) that drive the microbial community composition in plant. First, we gave an overview of the aboveground and belowground plant microbiomes. Next, we discussed which host factors are involved in variation in plants followed by importance of microbe-microbe interactions and the elements of environment that influence composition and community structuring of plant microbiomes.

Introduction

A diverse kind of microorganisms associated with a higher organism (human, animal, plants etc.) is together defined as its microbiome. All higher organisms examined to date, including plants, insects, fish, rats, apes, and humans, harbor microbiomes [1,2]. Research on the human microbiome has progressed very quickly. Recently, researchers have also paid much attention to elucidating the composition and functions of plant and soil microbiomes. It is now believed that plants are not separate entities, but rather they live in association with a large variety of microbes. These microbes live either inside (endosphere) or outside (episphere) of plant tissues. Among these microorganisms, bacteria and fungi are predominant. About a few thousand bacterial and fungal taxa have been reported from plant tissues [3,4]. They play important roles such as increased nutrient availability, uptake by plants and increased plant stress tolerance. Thus, plant fitness (growth and survival) is the result of physical and physiological functions of the plant *per se* as well as the associated microbiome, which together are known as a plant holobiont [5].

The study of the association of plants with microorganisms precedes that of the animal and human microbiomes, notably the

roles of microbes in nitrogen and phosphorus uptake. The most notable examples are plant root-arbuscular mycorrhizal (AM) and legume-rhizobial symbioses, both of which greatly influence the ability of roots to uptake various nutrients from the soil. Some of these microbes cannot survive in the absence of the plant host (the 'obligate symbionts' including viruses, some bacteria and fungi), which provides space, oxygen, proteins, and carbohydrates to the microorganisms. The association of AM fungi with plants has been known since 1842, and over 80 % of land plants are found associated with them [6]. It is thought that AM fungi helped in the domestication of plants [7]. Traditionally, culturable microbes have been used for plant-microbe interaction studies with the enormous unculturable microbes remain uninvestigated and consequently, our knowledge of the roles of these unculturable microbes remains largely unknown.

Unraveling the types and outcomes of plant-microbe interactions has received considerable interest among ecologists, evolutionary biologists, plant biologists, and agronomists [4,8,9]. Recent developments in meta-omics and the establishment of large collections of microorganisms have dramatically increased our knowledge of the plant microbiome composition and diversity. The sequencing of marker genes of entire microbial communities, referred to as metagenomics, sheds light on the phylogenetic diversity of the microbiomes of plants. It also adds to the knowledge of the major biotic and abiotic factors responsible for shaping plant microbiome community assemblages [8].

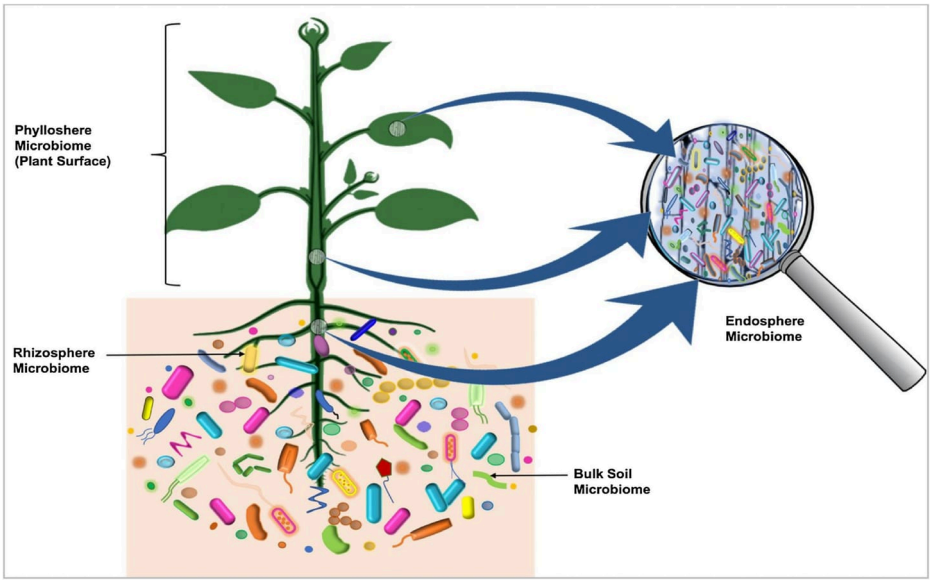
However, our understanding on the roles of microbiomes, with respect to their impact on plant ecology and physiology, is still far from complete, and we are at the beginning of knowing their functions [10]. The outcome of this improved knowledge will have significant bearings on a variety of experiments and applications, such as development of biofertilizer and biopesticides for sustainable agricultural production with less reliance on agrochemicals, while augmenting yield and nutritional value [11].

In this review, we will present an account of recent studies and prospects of studying the plant microbiome. Firstly, we will present an overview of aboveground and belowground plant microbiomes. Next, we will discuss the factors driving the composition and community structuring of plant microbiomes. We will not address plant pathogenic microbes, although inclusion of this fraction of microbiome would make sense from a broader and more holistic viewpoint.

Rhizosphere microbiome

The rhizosphere comprises the 1–10 mm zone of soil immediately surrounding the roots that is under the influence of the plant through its deposition of root exudates, mucilage and dead plant cells [12]. A diverse array of organisms specialize in living in the rhizosphere, including bacteria, fungi, oomycetes, nematodes, algae, protozoa, viruses, and archaea [13]. The most frequently studied beneficial rhizosphere organisms are mycorrhizae, rhizobium bacteria, plant growth promoting rhizobacteria (PGPR), and biocontrol microbes. Gans, Wolinsky [14] projected that one gram of soil could harbor more than a million distinct bacterial genomes. İnceoğlu, Al-Soud [15] reported 55,121 OTUs (operational taxonomic unites) from the potato rhizosphere. Among the prokaryotes in the rhizosphere, the most frequent bacteria are within the Acidobacteria, Proteobacteria, Planctomycetes, Actinobacteria, Bacteroidetes, and Firmicutes [3,16]. In some studies, no significant differences were reported in the microbial community composition between the bulk soil (soil not attached to the plant root) and rhizosphere soil [17,18]. Certain bacterial groups (e. g. Actinobacteria, Xanthomonadaceae) are less abundant in the rhizosphere than in nearby bulk soil [3].

Mycorrhizal fungi are abundant members of the rhizosphere community, and have been found in over 200,000 plant species, and are estimated to associate with over 80 % of all plants [19]. These mycorrhizae–root associations play profound roles in land ecosystems by regulating nutrient and carbon cycles. Mycorrhizae are integral to plant health because they provide up to 80 % of N and P requirements. In return, the fungi obtain carbohydrates and lipids from host plants [20]. Recent studies of arbuscular mycorrhizal fungi using sequencing technologies show greater between-species and within-species diversity than previously known [21].

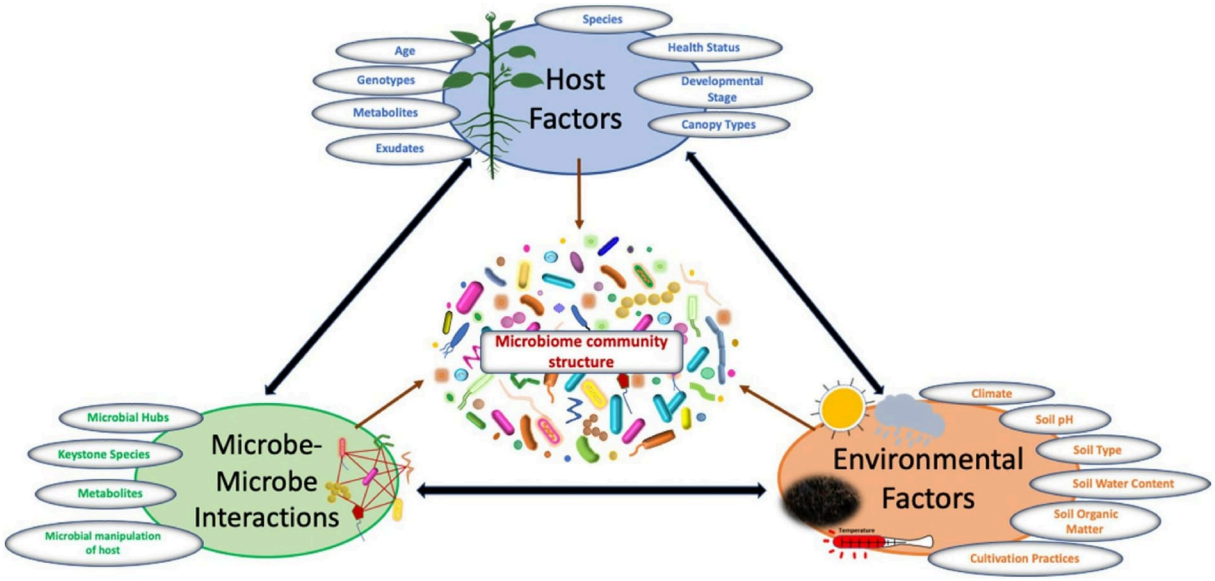


Phyllosphere microbiome

The aerial surface of a plant (stem, leaf, flower, fruit) is called the phyllosphere and is considered comparatively nutrient poor when compared to the rhizosphere and endosphere. The environment in the phyllosphere is more dynamic than the rhizosphere and endosphere environments. Microbial colonizers are subjected to diurnal and seasonal fluctuations of heat, moisture, and radiation. In addition, these environmental elements affect plant physiology (such as photosynthesis, respiration, water uptake etc.) and indirectly influence microbiome composition. Rain and wind also cause temporal variation to the phyllosphere microbiome [22]. Overall, there remains high species richness in phyllosphere communities. Fungal communities are highly variable in the phyllosphere of temperate regions and are more diverse than in tropical regions [23]. There can be up to 10^7 microbes per cm^2 present on leaf surfaces of plants, and thus the bacterial population of the phyllosphere on a global scale is estimated to be 10^{26} cells [24]. The population size of the fungal phyllosphere is likely to be smaller [25]. Phyllosphere

microbes from different plants appear to be somewhat similar at high levels of taxa, but at the lower levels taxa there remain significant differences. This indicates that microorganisms may need finely tuned metabolic adjustment to survive in phyllosphere environment [24]. Proteobacteria seems to be the dominant colonizers, with Bacteroidetes and Actinobacteria also predominant in phyllospheres [26]. Although there are similarities between the rhizosphere and soil microbial communities, very low similarity has been reported between phyllosphere communities and those in open air [27].

Endosphere microbiome



Some microorganisms, such as endophytes, penetrate and occupy the plant internal tissues, forming the endospheric microbiome (Fig. 1). The AM and other endophytic fungi are the dominant colonizers of the endosphere [28]. Bacteria, and to some degree Archaea, are important members of endosphere communities. Some of these endophytic microbes interact with their host and provide obvious benefits to plants [[29], [30], [31]]. Unlike the rhizosphere and the rhizoplane, the endospheres harbor highly specific microbial communities. The root endophytic community can be very distinct from that of the adjacent soil community. In general, diversity of the endophytic community is lower than the diversity of the microbial community outside the plant [18]. The identity and diversity of the endophytic microbiome of above-and below-ground tissues may also differ within the plant [28].

The ‘Plant Microbiome’ consists of diverse microbial communities on the outside surface and in internal tissues of the host plant. The rhizosphere, endosphere, and phyllosphere constitute the major compartments of plant microbiome. The soil microbiome is an important source of the plant microbiome.

Drivers of plant microbiome composition

Plant microbiome structure is influenced by complex interactions between hosts, microbes, and associated environmental factors such as climate, soil, cultivation practices etc. (Fig. 2). Below, we provide an assessment of current knowledge of these factors, providing insight to plant-microbe interactions in a broader-sense.

A simple schematic representation of various factors that shape microbiome community structures. The host, microbe, and environment all factors are interconnected and together build the microbiome community in plants.

Host factors that influence plant microbiome community composition

Plant species

The identity of the host plant has a significant influence on the identity of its microbiome. Different plant species growing adjacent to one another can harbor distinct microbiomes. A comparative survey of root microbiomes in maize, sorghum, and wheat showed different community composition among these plants [32]. Samad et al. [33] investigated the microbiome compositions of roots and rhizospheres using 16S rRNA gene from grapevines and some weed species growing in the same field, and their findings suggested that these species hosted significantly different microbiomes in the roots and rhizosphere, with the more pronounced difference in the root communities. Plants that are distantly-related phylogenetically show greater variation in associated microbiome compositions, suggesting a role of plant phylogeny in structuring root microbiomes [32]. Plant species also influences the identity and diversity of endophytic communities. Manter et al. [34] reported differences in endophytic community composition in potato and *Eucalyptus* plants. The most abundant bacterial root endophytes in potato were rare or absent in *Eucalyptus* and vice-versa [34] suggesting that the host plant selects its endophytic microbes. Analysis of endophytic fungi of three native Australian *Nicotiana* species revealed that they are host-specific but not plant organ- or host location-specific [28]. In addition to the rhizospheric and endophytic microbiomes, phyllosphere community composition also depends on plant identity [24]. Kembel et al. [35] showed that the leaf microbiome community is highly correlated with plant evolutionary relatedness similar to the endospheric microbiome.

The effects of host plant species in recruiting microbes from the surrounding environment indicate that plants have evolved traits that govern root microbiome assemblages [36]. For example, endosphere, rhizosphere community composition are correlated with host taxonomy [36]. Xiao et al. [37] found that the rhizosphere and root microbiomes are mostly influenced by soil type, and the nodule and root endophytes are influenced by plant species. Differential microbiome assembly in different plant species is attributed to variation in plant resource consumption [36]. Plant traits such as leaf permeability, wettability and topography and physicochemical properties, cuticle chemistry, root exudates, antibiotic production, and inherent plant immunity to invasion by microbes may also to play a role.

Plant genotypes

Evidence suggests a difference in microbe community composition between genotypes of a particular species [17,26,38]. Genetics of the host is one of the factors that shape the plant-microbiome structure. For example, OTUs in three different potato varieties were cultivar-specific [36]. Similarly, cultivar-dependent effects have been reported for the bacterial communities in young potato rhizospheres [15]. Peiffer et al. [39] demonstrated that OTU richness and β-diversity are influenced by plant genotypes in maize. Bulgarelli et al. [38] reported that genotype contributed to about 6% of the variation of the microbiome composition in the rhizosphere region. A larger influence of host genotype on community composition has been reported [40].

Genotype-dependent microbiome community structuring has been reported for sweet potato, wheat, pea, and oat [9,41]. Bacteria such as *Acinetobacter, Chryseobacterium, Pseudomonas, Sphingobium,* and *Stenotrophomonas* were more abundant in low-starch cultivars than those having high-starch contents [41]. The rhizosphere communities of different genetic clones of wild-type and transgenic lines have been reported to be distinct in *Populus* [42]. Within-species genetic variability can influence microbiome composition in leaf tissues [43]. Wagner et al. [44] conducted an extensive field experiment to unravel drivers of community composition of bacteria associated with leaves and roots of *Boechera stricta*. Their findings suggested that the host genotype influences leaf community, but the root microbiome was variable at different collection sites.

Agler et al. [45] proposed that host genotype influences on keystone microbes, which then pass these effects onto the total microbiome by changing microbe–microbe interactions and altering plant fitness [3]. The host specificity of plant microbiome could also be attributed to the nutrient preferences of plants [46]. However, whether the observed host influences are heritable, how strong the effect is, and whether these associations will be actionable for plant breeding is yet to be established.

Plant organ

Different plant tissues host distinct microbiome communities. Edwards et al. [47] demonstrated that each surface and internal tissue of plants may harbor distinct microbial communities and that the role of tissue-type was greater than host type and the microbiome of the soil. This may be because the adaptation strategies of various tissues may affect the microbes in colonizing them for community composition. For instance, surface tissues are exposed to constant fluctuations of weather and have relatively poor nutritional status compared to the root or internal tissues. Therefore, microbes colonizing the leaf surface need to be adapted in these conditions [25]. Other studies found very little or no effect of plant organ in community composition of fungi and bacteria [28].

Study with agaves determined that prokaryotes are largely influenced by the plant compartment, whereas the rhizosphere, the phyllosphere, and endosphere communities are clearly different from each other and from adjacent soils [48]. Many studies have reported that fungal communities show a different pattern, where the biogeography of host were the major influencing factor [48]. This may be explained by the dispersal limitation in fungi [49], because fungi are eukaryotes like plants and animals, but bacteria are different in this respect.

Plant age and developmental stage

In the cases of interactions between plants and pathogens, ontogenic resistance (age-related resistance) is widely reported and correlated with plant developmental stage [50]. Symbiosis research has also indicated that plant age and developmental stage are important factors affecting microbial communities [51]. Analysis of the bacterial rhizosphere community of *Arabidopsis* revealed that the seedling stage selects distinct microbiomes at developmental time points. Plants produce mixtures of compounds and specific phytochemicals in the root exudates. Some of these chemicals are indeed distinct at plant developmental stages and appear to shape microbiome community assemblages [52]. The effect of the plant age on microbiome using DGGE fingerprint analysis revealed that it significantly influences bacterial community composition of all groups investigated for all three sweet potato cultivars [41]. The effect of plant age on the composition of bacterial microbiome in the rhizosphere has been demonstrated in potato, maize and soybean [15,53,54]. Age-related microbiome differentiation may be associated with root growth, physiology, root architecture, root morphology, root exudate, and its composition [51,52]. However, further research is needed on the identity and effect of root exudates at different plant developmental stages to determine how plants communicate in the rhizosphere. This knowledge might offer a basis for augmenting agricultural crops by the application of rhizosphere microbes.

Plant canopy type

Plant canopy type also influences microbiome community composition. For example, bacterial communities in sugar maple leaf samples are correlated with canopy composition [55]. The microbial migration through rain runoff may be an important factor for variation in microbial colonization in different canopy types. Canopy structure influences the composition of endophytic community but not the rhizospheric community, indicating less effect of rain runoff, and there may be other mechanisms such as soil factors or some unknown factors involved in this variation [55].

Plant immunity and signaling

Plant health status may influence microbiome composition. Plants employ two layers of defense against pathogens: pattern-

triggered immunity (PTI), which is triggered by conserved molecular structures such as microbe/pathogen-associated molecular patterns (MAMPs/PAMPs), and damage-associated molecular patterns, which are recognized by plasma membrane-localized pattern recognition receptors [56]. It is unknown whether plants recognize non-pathogenic microbes in the similar way as they recognize pathogens and modulate their response. When plants are challenged with herbivory or pathogens they release hormones and exogenous volatiles that alter the composition of root exudates (for review, see [57]), and these in turn modify the microbiome community. Aphid infestation and pathogenic microbial infection increaseed populations of the non-pathogenic rhizobacterium *Bacillus subtilis* in the sweet pepper rhizosphere [58]. In *Arabidopsis thaliana* plants infected by *Pseudomonas syringae*, the expression of root malate transporter is altered, indicating a change in secretion of malic acid that increased the number of the beneficial rhizobacterium *Bacillus subtilis* [59,60]. Cucumber roots infected by *Fusarium oxysporum* f. sp. *cucumerinum* exhibited augmented secretion of fumaric and citric acid, which led to the formation of biofilms (aggregates of living bacteria in a slimy extracellular polymeric substances) of *Bacillus amyloliquefaciens*. Most investigations, however, have focused on one-to-one interactions (plant-microbe), although in reality, plants are subjected to attack by numerous microbial pathogens and insect pests. Therefore, it would be interesting to see how multiple herbivory and/or pathogens modify the community composition of plant microbiomes. Recent studies have reported a change in rhizosphere microbiome community composition as influenced by specific compounds such as sugars, sugar alcohols, or mixtures of various chemical compounds in root exudates [52]. Plants use various strategies in response to pathogenic infection and insect attack. One of them is activation of defense responses in roots, which may influence microbiome composition in the rhizosphere and roots [61]. When aphids feed on foliage both SAR (Systemic Acquired Resistance) and ISR (Induced Systemic Resistance) signaling are activated throughout the plants, which elicits sweet pepper plants to attract *B. subtilis* in the rhizosphere [58]. Again, increased JA signaling in plant either by injury or exogenously in *Medicago truncatula* caused higher colonization of beneficial mycorrhizae [62]. Different root and phyllosphere endophyte microbial communities have been reported when altered SA signaling was induced [63]. Plants lacking in jasmonate-mediated defense have shown more diverse epiphytic colonization [64]. It is evident from these studies that the role of plant defense systems on the microbial composition are inconstant, and that SAR is an important factor in regulating some bacterial community composition. Chemical signals released by plants for example, flavonoids, activate varied responses in plant rhizosphere microbiomes [65]. Branching in mycorrhizal hyphae is affected by strigolactones, which enhance and promote seed germination by parasitic plants [66].

Plant derived compounds

A diverse array of antimicrobial compounds are produced in plants [67]. Some of them, such as different alkaloids, phenolics, and terpenoids, are common in plants. Some are specific to particular groups [68], for instance, Brassicales produce glucosinolates. It was found that transgenic *Arabidopsis* producing an exogenous glucosinolate had different microbiomes in the rhizosphere and root tissues [69]. Voges et al. 2018 reported a significant role of plant derived coumarins in structuring the rhizosphere community. They suggested that iron-mobilizing coumarins are involved in redox reactions that can mobilize ferric iron and generate reactive oxygen species (ROS) with detrimental effects on microbial proliferation and thus selectively inhibit certain microbial growth while allowing proliferation other more beneficial partners. Triterpenoid saponins, which are known as avenacins, are found in oat (*Avena strigosa*), and have antifungal properties [70]. Oat plants lacking avenacin production attracted different culturable fungi in roots [71] and were more vulnerable to pathogenic infections than wild-type oat [72]. Interestingly, however, a recent comprehensive analysis of the rhizosphere community of these two genotypes reported little difference between the fungal communities. The effect of avenacins on the Amoebozoa and Alveolata was profound but has not been reported for bacterial communities [73]. This revealed that a small difference in plant genotype might exert multifaceted and unpredicted effects on the plant microbiome composition and diversity. These plants derived compound may affect microbiome assembly in different ways. For example, root exudates may be specific for host plant and can modulate rhizosphere community as well as selects specific root microbiome and thus contributing host specific plant microbiome. Also, antimicrobial compound may selectively enhance microbial growth by restricting certain microbes which is a kind of ‘balance’ in mutualism.

Microbial factors in shaping plant microbiome structure

Microorganisms play important roles in shaping microbial community structures in plants. However, our knowledge on how microorganisms influence microbiome structuring is limited.

Microbial manipulation of hosts

Microorganisms can affect host plants, for example host root exudations, which in turn affect the permeability of roots and root metabolism. Some microbes in soil where the plant if growing can also absorb certain compounds in root exudates and excrete other compounds. Soil microbes can produce compounds that affect plant signaling and metabolism, which lead to production of microbe-derived compounds in plants. Some microbes produce antibiotics (e.g., penicillin and polymyxin) which increase

the exudation of organic materials, altered cell permeability, and increased leakage [74] and results in a variable microbiome assembly.

Microbe-microbe interaction

The extent to which microbe–microbe interactions can play roles in the microbiome composition is not well understood. The outcome of microbe-microbe interactions could be explained as cooperation, parasitism, and competition. In cooperation, at least one species benefits, while others are not harmed. When both species benefit, the term mutualism is used, whereas, when one partner benefits while the other is not affected, the term commensalism is used. In contrast, parasitism and competition are harmful for at least one species [75].

We know from recent studies that microbial communities harbor highly connected taxa called keystone taxa [76]. These taxa independently or in a group show a substantial effect on microbiome composition and functions regardless of their spatial and temporal dynamics. They play a unique and vital role on microbiomes, and their absence could cause a significant alterations in microbiome composition and functioning [76]. They use various strategies to impact on host microbiome. For instance, they might cause changes in intermediate or effector groups which in turn regulate microbiome community composition and functioning [77]. Production of a secondary metabolite (2,4-diacetyl phloroglucinol) was reported for some strains of *Pseudomonas fluorescens* that suppress *Gaeumannomyces graminis* var. *tritici*, responsible for wheat take-all [78]. Similarly, many fungi (e.g. *Trichoderma* and bacteria (e.g. *Bacillus*) produce various secondary metabolites that suppress microbial growth [79,80]. The keystone taxa may produce bacteriocins to shift microbiota structure selectively. Again, by synergism, keystone taxa may alter the abundance of their partners, and influence community structure and performance. For example, certain species of *Burkholderia* are symbiotic with arbuscular mycorrhizae and may change abundance and community composition of AM fungi, thereby influencing plant community richness, diversity, and production [19]. Agler et al. [45] studied the roles of microorganisms (bacteria, fungi and oomycetes) in the community composition of phyllosphere microbiomes of Arabidopsis thaliana using a systems biology approach. They described an interkingdom interactions network with a profound influence on community structure. They identified a few taxa, termed “microbial hubs’, which are highly interlinked and have a significant impact on communities. They used two “hub” microbes (Albugo, an oomycete pathogen and Dioszegia, a basidiomycete yeast) in detail. Albugo strongly affected epiphytic and endophytic bacterial colonization. Many symbiotic microbes (including pathogens) produce effector proteins to suppress, activate, or alter host defense mechanisms [81], and some can entirely reprogram the host metabolism [82]. These host adjustments can lead to alterations of microbiome composition because some microorganisms and not others can benefit from altered conditions. Actually, the niches of some microorganisms is dependent on others. For instance, primary colonizers can aid subsequent colonizers against hazardous abiotic factors [83] or can enhance the competitive ability of following colonizers by producing secondary metabolic compounds [84]. There can be direct microbe-microbe interactions, such as the hyper-parasitism (parasite of parasite) of primary colonizers [85] and opportunists that utilize host’s compromised plant defenses to colonize them [86]. Such phenomena point out why some colonizers can affect the development of microbes on the host even if they may be distantly related [84] and highlight a crucial functions of such interactions in shaping microbiome composition and structure.

One of the major strategies by which PGPR augments plant growth is by its influence on rhizosphere microbes. For example, *Pseudomonas* sp. DSMZ 13134 alters the composition of dominant bacteria in barley roots [87]. In some cases, however, the effects of PGPRs on resident microbiome may not be prominent. For example, no substantial changes in rhizosphere community were noticed after the application of *Bacillus amyloliquefaciens* FZB42 [88]. Supporting results have also been reported in soybean with the application of *B. amylolique faciens* BNM122 [89]. The recent investigation on the effect of *B. amyloli quefaciens* on the lettuce microbiome using 454-amplicon sequencing revealed no or only transient and minor effects in the rhizosphere zone [90]. Interestingly, a decrease in the bacterial number was reported. In the field only 55 % of the inoculated bacterial DNA could be traced after a month [91]. The effects of *Bacillus subtilis* strain PTS-394 on the rhizosphere microbiome has been examined by metagenomic profiling. Similar to the results above for *B. amyloliquefaciens* FZB42 [90,91], only a minor effect on the composition was reported. However, up until now, the impact of *Bacillus* PGPR on other plant microbiota, such as fungi, has not been investigated, and investigation on this could reveal a more general effect of inoculated bacteria on resident microbiota and thus on host physiology and ecology.

Environmental factors as drivers of plant microbiome assembly

Environmental elements, such as soils, climatic conditions, geography, farming activities, and plant domestication, could result in the differences of plant associated microbial community composition [92]. A change in an environmental component results in plant phenotypic changes (e.g., [93], which consequently also change the assemblage of distinct microbiomes harboring plant compartments [94]. Plants grown under controlled conditions provide specific environments for microorganisms. For instance,

when lettuce was grown under a glasshouse, a distinct bacterial signature was found from those grown in open fields [95]. Whitaker, Reynolds et al. [96] reported the community composition of endophytic fungi local environment (i.e., site), but not by host ecotype, pointing that environmental factors are major drivers of the endophytic mycobiome of switchgrass.

Soil

Plants recruit root microbes mainly from the soils where they grow. Various soil factors viz. soil types, soil pH, and the C/N ratio, as well as available P and K are frequently reported to be the determinants of root microbial community composition by affecting plant growth and immunity [8,9]. Innumerable studies using high throughput sequencing have proved that soil type is a major factor for root microbiome structure, which is evident from the differential initial microbial inocula present in different soil types [18,47]. Dombrowski et al. [97] collected the arctic-alpine *Arabis alpine* samples from the native location as well as from those grown under controlled conditions and investigated the root microbiome by 16S rRNA amplicon sequencing analysis. They reported that soil type and length of time the plants remained in the soil are the most important drivers, causing variation of up to 15 % of root microbiota. In addition, in the same soil, the root microbiome of perennial *A. alpina* was similar to *A. thaliana* and *Cardamine hirsuta,* the annual relatives of *A. alpina*. The root microbiome communities are strongly influenced by the composition of the soil microbiome close to roots. A strong correlation between the soil and root bacterial communities in *A. thaliana* has been reported by various authors [3,18]. Similarly, the structure of fungal communities is influenced more predominately by soil type than by host plant [98]. The type of soil influenced the rhizosphere bacterial microbiota composition in lettuce [99], oak [16], *Arabidopsis* [3], and maize [100].

Several studies have shown that environmental variability, such as soil pH, C: N ratio, soil carbon, water content and biogeography may influence the microbiota composition [39]. Lauber et al. [101] described that the impact of soil pH on total community composition was obvious even at a very high taxonomic level. Analyses revealed that pH has substantial correlation with the structure of these microbiome phyla in all soil types studied. The effects of soil pH on soil bacterial community composition has also been reported in other studies using various methods [102]. Zarraonaindia et al. [103] reported that the composition of soil and root microbiome of grapevine significantly influenced by soil pH and C:N ratio but leaf- and grape-associated microbiota were mostly influenced by soil carbon. Hartman, Richardson et al. [104] reported from their study that pH was the most important factor in predicting the alteration of soil bacterial communities, and they detected changes in phylum-level abundances across the pH levels. However, contrasting results have been reported by Fierer et al. [105], where they noted soil carbon was more important than soil pH for Bacteroidetes, Betaproteobacteria, and Acidobacteria. This difference of the findings was possibly linked to sample sizes and number of soil types investigated as well as to differences in methodologies. The exact mechanism(s) of the role of soil pH on microbial community composition and diversity is unknown. Two general explanations have been given [101]. Firstly, soil pH may indirectly alter bacterial community structure with its influences on soil characteristics. Secondly, soil pH may directly impose a physiological limit on soil bacteria, changing outcomes of competition or reducing survival of taxa intolerable to condition. In addition, we hypothesize that soil pH may alter plant microbiome by its influence on plant growth and physiology, which also may influence soil microbiome composition. Other soil properties, for example soil temperature and contaminants in the soil, also influence microbiome composition. Heat disturbance of soil results in a shift in rhizobacterial microbiome composition [106]. Heat disturbances due to natural wildfires can cause a decrease in microbial activity and significant alterations in microbial communities [107]. Increasing petroleum hydrocarbon contamination levels results in the alteration of willow microbiome structure. These alterations were less extreme in the rhizosphere and plant tissues, but they were prominent in the bulk soil. These could be because plants provide more controlled conditions and shield microbes against an enhanced contamination gradient [108].

Cultivation practices

Land use and cultivation practices are the most important causes of declines in biodiversity, leading to undesirable consequences for the environment [109]. Changes in the vegetation influence the diversity and structure of soil microbiomes. Agricultural activities do not necessarily have negative consequences in soil bacterial community diversity and structure, but they may have positive or neutral feedback (effect not perceived) [110]. For example, the intensity of land use (LUI) has been reported to influence the pattern of bacterial communities. Estendorfer et al. [111] found that under low LUI, there remains a strong interaction between plants and adjacent soil. In contrast, no influence of LUI on microbial diversity has been found in the rhizosphere, which indicates that plant species have much more influence on the rhizosphere community than soil properties do [112]. However, Suleiman et al. [113] reported that plants may have robust core microbiome compositions that are less prone to alteration due to variation of land use, soil type or edaphic factors. It was found that microbiome of in relatively untouched deciduous forest and long-term mowed grassland soils were comparable, although there were significant differences in soil properties and vegetation [114], Continuous cultivation causes changes in soil properties, which in turn might affect the soil microbiome communities. As per the reports of Allison and Martiny [115], there are three potential impacts caused by land disturbance such as the microbial

structure might be affected, it might be changed but quickly return to the original composition (resilient), or might remain unchanged.

Climatic variables

Climate is an important driver of plant and soil microbiome composition. The role of climate in influencing plant microbiome community composition has to date been largely unheeded or found to be of little importance [116]. A recent study, however, across various ecosystems in Britain showed that rainfall and temperature gradients are two major climatic factors in shaping the bacterial community composition in plants [117]. Researchers de Vries et al. [118] reported that precipitation is an important driver of soil microbial community composition. The biomass of fungi and bacteria has been reported to increase with increasing mean annual precipitation (MAP), and the effect was more prominent for fungi, resulting in comparatively higher fungal abundance (increased F/B ratio) under higher precipitation levels. The above trends could be linked to higher soil organic matter contents in higher rainfall areas. In particular, in uplands where harsh climatic conditions prevail, a higher organic matter build-up is noticeable, which leads to fungi-dominated microbiome communities [119].

Conclusions and future perspective

The factors that influence microbiome assemblages and dynamics in plant and soil are now better understood, and research in this aspect is increasing. However, our knowledge on the underlying mechanism(s) of microbiome assemblages and how they influence the host plants is still lacking. Connecting the microbiome composition and diversity to their function is a great challenge for future research. For instance, to what extent could we use and manipulate the plant microbiome to boost sustainable agricultural production and environmental protection? We now know that that host genetic factor has a significant influence on microbiome diversity and structure, indicating that breeding and trait selection provide opportunities to select for desired microbiomes [45]. To have a more profound and broader knowledge on plant microbiome, there is a need to integrate novel molecular approaches (e.g., meta-omics), ecological models (e.g., food web theory, assembly of communities, or coexistence theory), and recent bioinformatics and statistical advances with a view to correlating community assemblages with ecological functions.

In the future, more emphasis should be placed on identifying the underlying mechanisms that drive microbiome community composition and assembly. We need to know the contributions of (1) the microbe-microbe interactions, (2) soil and other environmental variable and (3) various host traits in shaping community structure. Future research will direct toward solving some pertinent questions. For example, how stable are the drivers of microbiome community? To what extent do agricultural practices affect the microbiome of plant species? How predictable are these divers? With high throughput technologies, such as next-generation sequencing and metagenomics, we can begin to study endophyte microbiomes across hosts, environmental conditions, and at different time points and focus on the mechanisms of the plant-endophyte association.

Declaration of Competing Interest

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

16.1.5.5: Pollution and Bioremediation

Pollution and Bioremediation

Achieving sustainable life, for humans, animals, and the environment, requires a plan of action to mitigate anthropogenically-induced damage and develop future practices to maintain planetary homeostasis. One of the biggest threats to ourselves and the environment is the buildup of human waste and pollution (e.g. plastics, oil, synthetic products, etc.) that take a tremendously long time to naturally breakdown. With the human population predicted to continually climb, continuing the same destructive practices will only result in more waste generation in a fraction of the time that it takes for decomposition. One alternative means to solve the pollution problem is to use specialized microbiomes for bioremediation. That is, a specially designed microbial consortia could clean up (i.e. breakdown and assimilate) various toxic molecules much more quickly. However, this will take time to understand how and which type of microbes could perform these tasks and if there are any associated (negative) effects.

Alternative Strategies for Microbial Remediation of Pollutants via Synthetic Biology

Article by Jaiswal and Shukla, 2020 licensed under the terms of the Creative Commons Attribution License (CC BY).

Continuous contamination of the environment with xenobiotics and related recalcitrant compounds has emerged as a serious pollution threat. Bioremediation is the key to eliminating persistent contaminants from the environment. Traditional bioremediation processes show limitations, therefore it is necessary to discover new bioremediation technologies for better results. In this review we provide an outlook of alternative strategies for bioremediation via synthetic biology, including exploring the prerequisites for analysis of research data for developing synthetic biological models of microbial bioremediation. Moreover, cell coordination in synthetic microbial community, cell signaling, and quorum sensing as engineered for enhanced bioremediation strategies are described, along with promising gene editing tools for obtaining the host with target gene sequences responsible for the degradation of recalcitrant compounds. The synthetic genetic circuit and two-component regulatory system (TCRS)-based microbial biosensors for detection and bioremediation are also briefly explained. These developments are expected to increase the efficiency of bioremediation strategies for best results.

Introduction

The remediation processes aided by microorganisms present at the various contaminated scenarios constitute bioremediation (Basu et al., 2018; Kumar et al., 2019). Microbial remediation uses multiple metabolic pathways responsible for enzyme production (Sharma B. et al., 2018; Dangi et al., 2019). These enzymes mainly take part in the degradation pathways of xenobiotics (Junghare et al., 2019). There are different customary methods for bioremediation, primarily based on the site of bioremediation, *in* and *ex situ* (Tomei and Daugulis, 2013). *In situ* is applied to the site to minimize soil disturbance. This method is mostly adopted due to less expenditure from avoiding excavation and transport of contaminated soil (Khan et al., 2004). According to Khan et al., 2004 less disruption in *in situ* bioremediation causes less dust dispersion and hence better degradation (Joshi et al., 2016) of contaminant. Bioaugmentation, bioventing, biosparging, and engineered *in situ* bioremediation are main *in situ* bioremediation methods (Azubuike et al., 2016). *Ex situ* bioremediation methods are solid phase system (composting, landfarming, and biopiling) and slurry phase system (bioreactors) (Kumar et al., 2011). Transportation of soil to accelerate microbial degradation are done by solid and slurry phase systems, whereby treatments of domestic, industrial, and organic waste are done by *ex situ* bioremediation (Juwarkar et al., 2010). These traditional bioremediation methods take time and consume much cost expenditure, giving less result output. Traditional bioremediation (Duarte et al., 2017) processes showed the above limitations of extra time taking, less removal or dissimilation of pollutants, (Bharagava et al., 2019) disturbance to nature delicacy such as more land coverage for a long time, and a foul smell in the environment (Dangi et al., 2019; Kumar, 2019). Therefore, researchers are eager to discover new bioremediation technologies for best results. Dvoøák et al. (2017) described bioremediation via synthetic biology for boosting bioremediation strategies. This approach can catch the catabolic (Jacquiod et al., 2014) and metabolic complexities for reviewing the potential of the microbial population synthetically. The preliminary information for developing synthetic microbial models for bioremediation can be obtained by mining genes from the databases (Fajardo et al., 2019). The computer logics involvement can determine the microbial cell interactions with recalcitrant compounds (Kim et al., 2015). These strategies can together grasp the natural metabolic potential of microorganisms to transform into novel biological entities of interest (Dangi et al.,

2019). Furthermore, the regulation of metabolic pathways (Alves et al., 2018) in a controlled manner can also be achieved for bioremediation processes (Rochfort, 2005). This transition via synthetic biology application (Figure 1) for remediation purposes would improve the bioremediation processes via the involvement of potent (Zhu et al., 2017) dissimilating particular contaminants (Trigo et al., 2008). Synthetic biological systems mediate cellular modulations for efficient functioning and working of existing processes. They permit the modification of cellular processes *viz.* metabolic pathway acting for a particular chemical compound. The advancement of synthetic biology for bioremediation of various contaminants is attaining the focus of scientists and researchers. For instance, a sustainable synthetic microbial community's establishment for bioremediation is being investigated. Microbial interactions and quorum sensing within communities are vastly studied for application in the area of bioremediation with synthetic biology applications. Achievement of the synthetic genetic circuit of *Pseudomonas putida* proved to be the golden gadget for degradation studies. Besides this, genome editing by CRISPR-Cas, TALEN, and ZFNs adds knowledge for reviewing the progression in bioremediation studies. Synthetic microbial biosensors and metabolic engineering of cellular processes for utilization and detection of contaminant residues will remediate the environment from persistent recalcitrant pollutants. This review is focused on the above mentioned strategies and their elements (Figure 2) applicable for bioremediation purposes and research.

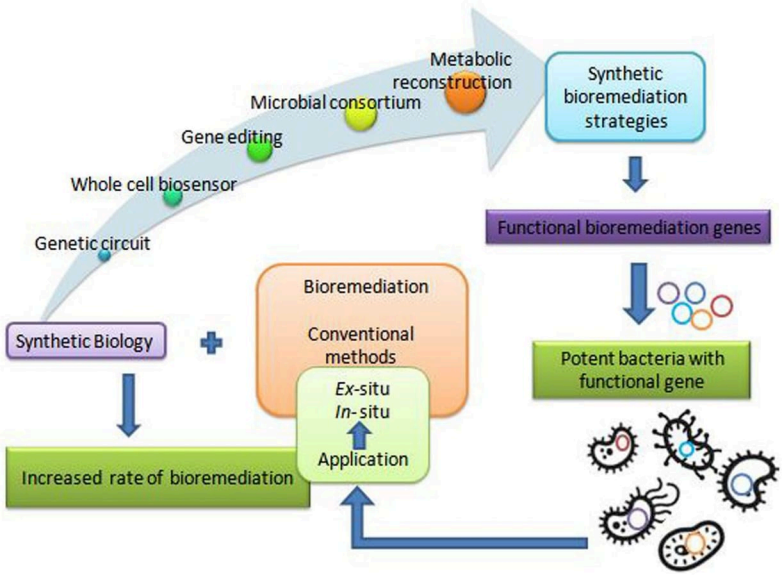

Figure 1. The strategies of synthetic biology applicable for bioremediation.

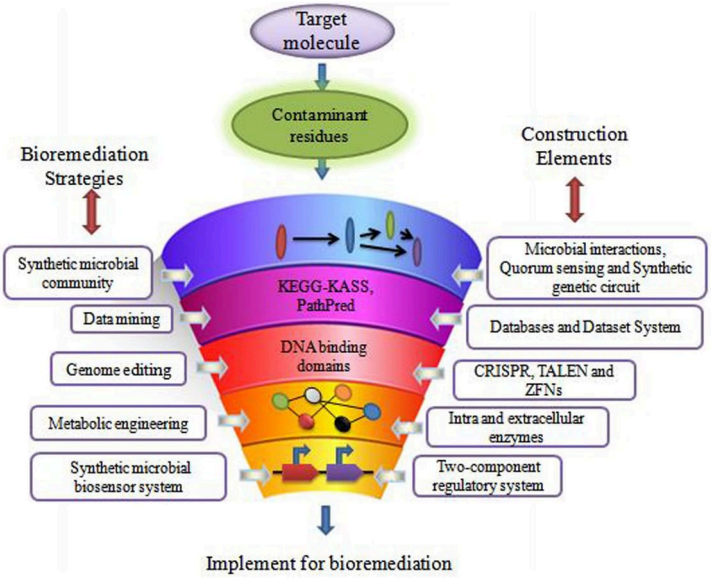

Figure 2. The components and their construction elements of synthetic biology for bioremediation studies.

Metabolic Reconstruction for Designing Synthetic Models

A computational platform is utilized for the reconstruction of cellular metabolism (Agapakis et al., 2012) via metabolic pathway analysis (MPA) (Banerjee et al., 2016). MPA mathematically represents the reactions of metabolism. This method is based on stoichiometric balance reactions so as to propose steady-state metabolic flux during cellular growth. The stoichiometry matrix imposes constraints of flux, making the consumption and production of the compound at a steady state (Bordbar et al., 2014). The maximum and minimum flux of a reaction can also be determined by providing the topper and least bound. This helps to define the extent of permissible flux supply (Richelle et al., 2016; Rawls et al., 2019). The next step is defining the objective according to the biological problem to be studied. This objective mathematically represents the reactions responsible for the phenotype appearance. The mathematical reactions and phenotype are combined with linear equations and solved by computational algorithms such as COBRA Toolbox11 and Matlab toolbox (Orth et al., 2010; Bordel, 2014). FBA is fundamentally simple, having immense applications in studying gaps, physiology, and genomes via systems biology approach (Kim et al., 2015; Hellweger et al., 2016). These gaps are missing metabolic reactions, making the genome partially known. FBA uses computational algorithms that can predict missing reactions *viz.* OptKnock and OptCom, which can knock out the genes responsible for producing the desired compound (Biggs et al., 2015). These approaches are beneficial for constructing microbial communities for bioremediation of particular contaminants (Khandelwal et al., 2013). However, MPA is the most challenging method when metabolic information is incomplete, making it difficult to obtain a real model (Covert et al., 2001). But this method shows cellular functions in the dynamic community, and thus is very useful for the prediction and exchange of metabolic flux in communities of microorganisms (Khandelwal et al., 2013). Recently, a metabolic model has been constructed by using two *Geobacter* species with parameterized electron transfer and metabolic exchange to characterize syntrophic growth dynamics. Such a system may have useful applications in the field of bioremediation and degradation of particular contaminants (Butler et al., 2010). A computational platform is also needed for better prediction of engineered genetic pathways for community dynamics. A graph-based tool Metabolic Tinker was developed by McClymont and Soyer to identify thermodynamically feasible biochemical routes for compounds deterioration (Johns et al., 2016). This may be applied to identify the routes for degradation of recalcitrant compounds by microbial consortia. These computational tools are utilized along with omics (Kim et al., 2014; El Amrani et al., 2015) and biological data for desired output (Berger et al., 2013) and toxicity prediction (i.e., META-CASETOX System) (Peijnenburg and Damborský, 2012). These are also applied for functional gene identification and their profile analysis, PCR analysis and drug discovery, etc (Dangi et al., 2019). Computer-aided drug discovery and development (CADDD) is used effectively with chemical and biological aspects, i.e., chemical structures accounting the biological role and its activity via ligand-based drug design, structure-based drug design, quantitative structure-property relationships, and quantitative structure-activity (Kapetanovic, 2008). Furthermore, Table 1 depicts similar methodologies applicable to bioremediation studies. De Jong (2002) analyzed the multicellular feedback control strategy in a bacterial consortium (Bruneel et al., 2011) to define the robustness conceivable under desired conditions.

Table 1. The methodologies applied for bioremediation research.

They utilized an ordinary differential equations (ODE)-based model and agent-based simulation on a consortium (Hawley et al., 2014; Atashgahi et al., 2018) of interacting species population for increasing the efficacy of the proposed feedback control strategy. The application of bioinformatics (Arora and Bae, 2014) resources is a prerequisite dimension for obtaining the data to begin the microbial bioremediation studies of recalcitrant compounds (Gong et al., 2012; Ofaim et al., 2019). This involves the information related to the degradation of xenobiotics by microbes and their pathways for dissimilation (Dao et al., 2019; Salam and Ishaq, 2019; Thelusmond et al., 2019; Wei et al., 2019). The data related to end products and intermediate metabolites released throughout degradation pathways can also be retrieved (Dvoøák et al., 2017). An extended information source linked to degradation is MetaRouter, allowing data (Singh and Gothalwal, 2018) for life sciences laboratories to explore degradation possibilities of recalcitrant compounds (Mohanta et al., 2015). The information on oxygenic degradation of xenobiotics can be retrieved from OxDBase, a biodegradative oxygenase database (Chakraborty et al., 2014; Shah et al., 2018). Oxygenase is a class of enzyme which transfers the oxygen molecule for oxidizing the chemical compound. They play a role in the degradation of organic compounds by aromatic ring cleavage (Jadeja et al., 2014). OxDBase is very particular in providing knowledge of oxygenases-catalyzed reactions, and is a powerful tool applicable to bioremediation studies (Singh,

2018). Bioconversion and biodegradation of persistent and toxic xenobiotics (Desai et al., 2010; Bao et al., 2017) compounds catalyzed by oxygenases decrease the compound sustainability and toxicity in the environment (Kües, 2015; Kondo, 2017). Therefore, OxDBase is very helpful in acknowledging the degradation processes involved in bioremediation (Shah et al., 2012). The transcriptional characterization of genes responsible for the biodegradation and biodissimilation of a particular compound has great significance in proposing molecular methodologies. This can be done by the Bionemo (Biodegradation Network Molecular Biology) database (Libis et al., 2016a). Bionemo contains the entries for sequences of genes coding for biodegradation (Carbajosa and Cases, 2010). It also links the gene transcription and its regulation (Libis et al., 2016b). The data retrieved from Bionemo can be used for designing cloning experiments and primers (Arora and Shi, 2010). Garg et al. (2014) used eMolecules and the EAWAG-BBD PPS database for the prediction of pathways involved in the biodegradation of 1-naphthyl-N-methyl carbamate. These above findings empower the researchers to analyze and establish what prerequisites must be fulfilled for developing synthetic bioremediation models.

Designing the Synthetic Microbial Communities

Recent advancements in the field of synthetic biology for environmental issues have shown a great impact. The use of GMOs in environmental biotechnology for remediation (Malla et al., 2018) of toxic compounds, xenobiotics, and pesticidal compounds are being done. To design a synthetic community, it is important to understand natural microbial communities (Schloss and Handelsman, 2008). In a natural community, it is difficult to find out which species are actually taking part in bioremediation (Großkopf and Soyer, 2014). Thus, a synthetic microbial community is a promising method for constructing an artificial microbial community with function-specific species for bioremediation purposes. These communities may act as a model system for the study of functional, ecological, and structural characteristics in a controlled manner. Großkopf and Soyer (2014), defined synthetic community by the culturing of two microbial species under well-defined conditions on the basis of interaction and function (Bruggeman and Westerhoff, 2007). These factors determine the dynamics and structure of the community. It is based upon the identification of processes and patterns engaged in by bacterial species. These microbial interaction patterns are metabolism-driven and responsible for community interaction (Wintermute and Silver, 2010). Social-based microbial interactions (i.e., mutualism, cooperation, and competition, etc.) and the total outcome of these interactions between two microbial populations can be +/+ and –/+ or +/–, respectively (Foster and Bell, 2012). It is said that community structure and function majorly depends on cooperation. The effect of cooperation on community dynamics is determined by engineered cooperation resulting in the synthetic community. Engineered cooperation between two microbial strains (Singh et al., 2016) can be done by manipulation of environmental conditions, i.e., knocking the genes out and in Zuroff et al. (2013). Beyond this, other interaction patterns have been analyzed with engineered microbial species in the synthetic community. Such an application of engineered interaction is highly recognizable in bioremediation strategies (Sharma, 2012). Synthetic biology provides greater potential for the sustainable existence of microorganisms (Dellagnezze et al., 2014) acting together in a large population. Thus, synthetic microbial communities are proved as a key strategy for the bioremediation of contaminants, i.e., pesticides, petroleum (Kachienga et al., 2018), oil spill, acid drainage (Serrano and Leiva, 2017), etc. For building the synthetic microbial communities, the engineered interspecies and intraspecies interactions can make cellular functions robust and enhance the capabilities of microbial consortia in various contaminated scenarios. Quorum sensing is a bacterial signaling mechanism, which is a density-dependent phenomenon via cell-cell communication and population level behavior. The signaling is done by the release and reception of chemical compounds by microbial candidates in a population. This leads to multicellular behavior (Obst, 2007), offering engineerable tasks to design function specific synthetic communities. These synthetic models can also be exploited to obtain a rational design that can lose the function when subjected to competition with other species in the natural environment. With the evolution of genomic constituents and gene transfer, the possibility of the gradual extinction of genetic circuits is present. Thus, strategies are required to maintain the robustness of the synthetic community, achieved via the synthetic models by the development of synergistic and cooperative properties that reduce instability and loss of function (Johns et al., 2016). A recent study by Coyte et al. (2015) suggests that competition among species is significant in determining the stability of communities, acting as a limiting factor in the stability of the synthetic community. Thus, these dynamics must be accelerated in order to design particular function specific synthetic communities for bioremediation purposes (Coyte et al., 2015).

Genetic and Metabolic Engineering

Enríquez (2016) said that genome editing is an umbrella term that refers to “scientific technological advances that enable rational genetic engineering at a local (gene) or global (genome) level to facilitate precise insertion, removal, or substitution of fragments of Deoxyribonucleic acid (“DNA”) molecules, comprising one or more nucleotides into the cell(s) of an organism’s genome.” Transcription-activators like effector nucleases (TALEN), clustered regularly interspaced short palindromic repeats (CRISPR-Cas), and zinc finger nucleases (ZFNs) are major gene editing tools used (Table 2). The most efficient and simple technique of gene editing has been described as CRISPR-Cas (Kanchiswamy et al., 2016). These tools can boost the process of bioremediation.

TALEN has a DNA-binding modular which is sequence-specific for the host genome (Utturkar et al., 2013). TALEN binding to DNA creates a double stranded break (DSB) in the target sequence and leaves sticky ends for stability. Similarly, ZFNs is also a DNA-binding domain composed of 30 amino acids. It introduces DSB at the target site of the host genome by the Fok1 cleavage domain. A new sense of using hybrid nucleases containing TALENs and ZFNs nucleases came to act for solving the molecular complications. The CRISPR-Cas system, on the other hand, has unique action properties of high sequence specificity and multiplex gene editing. This unique property is derived from bacteria *Streptococcus pyogenes* as immunity against the virus. The CRISPR-Cas system consists of crisper derived RNA (crRNA) and trans acting antisense RNA (trcRNA) joined by guide RNA (gRNA). gRNA directs the Cas9 enzyme to introduce DSB in the target DNA sequence by recognizing it. These gene editing tools create the knock-in and knock-out and are under processing for implementation in bioremediation studies (Kumar V. et al., 2018). Recent reports indicate though that the CRISPR-Cas system is mostly adopted and performed by researchers in model organisms i.e., *Pseudomonas* (Karimi et al., 2015; Nogales et al., 2020) or *Escherichia coli* (Chen et al., 2018; Marshall et al., 2018; Pontrelli et al., 2018). Nowadays, the new insights toward CRISPR tool kits and designing gRNA for expression of function-specific genes related to remediation in non-model organisms (i.e., *Rhodococcus rube*r TH, *Comamonas testosteroni* and *Achromobacter* sp. HZ01) are also suggested in the field of bioremediation (Mougiakos et al., 2016; Jusiak et al., 2016; Hong et al., 2017; Stein et al., 2018; Tang et al., 2018; Liang et al., 2020). For gene editing and metabolic engineering, the contaminant-inhabited bacteria are the most suitable candidates because they are used to survive and harbor in stress conditions of various toxic, recalcitrant and non-degradable xenobiotics, as discussed above. Moreover, understanding metabolic pathways seems to be important in studying the microbial bioremediation (Plewniak et al., 2018), i.e., bioremediation of toxic pollutants by the haloalkane dehalogenases production pathway and decontamination of pyrethroid from the soil via the biodegradation pathway of fenpropathrin studied in *Bacillus* sp. DG-02 (Chen et al., 2014). Metabolic engineering leads to modification of the existing pathway for the betterment of the bioremediation process (Michel et al., 2007). This approach majorly covers the study of microbial enzymes, i.e., oxidases, esterases, monooxygenases, oxidoreductases, phenoloxidases involved at various degradation steps (Figure 3A; Mónica and Jaime, 2019; Mujawar et al., 2019). Enzyme-based bioremediation has many advantages because it is an eco-friendly process. The genetic approach increases the perspective of getting recombinant enzymes. There are research reports of extracellular enzymes having a role in enzymatic bioremediation. For instance, arsenic bioremediation (Andres and Bertin, 2016; Choe and Sheppard, 2016; Akhter et al., 2017; Biswas et al., 2019) (bioaccumulation and biotransformation) is achieved *via* arsenite oxidase coded by *aioA* gene of *Klebsiella pneumonia* (Mujawar et al., 2019); enzymes released by white rot fungi degrade PAHs (polycyclic aromatic hydrocarbon) (Zhao and Poh, 2008; Košnár et al., 2019), dyes, TNT (2,4,6- Trinitrotoluene) and PCBs (polychlorinated biphenyls) (Gupte et al., 2016; Kutateladze et al., 2018; Sadańoski et al., 2018). Esterase D enzyme acts on β-endosulfan (organochlorine pesticide), producing simpler compounds (Mehr et al., 2017; Chandra et al., 2019). *LiP*s encoding hemoproteins from *Phanerochaete chrysosporium* degrade PAHs. However, incomplete or partial degradation of contaminants lead to simpler non-toxic degradable compounds which can be consumed by microbes (Kumavath and Satyanarayana, 2014) as intermediates in biological pathways or substrate, i.e., *LiP* (lignin peroxidase) dissimilate benzopyrene to three compounds of quinine, namely 1,6- quinone, 6,12- quinine and 3,6- quinine (Gupta and Pathak, 2020). Furthermore, *MnP* (Manganese peroxidase) oxidizes organic compounds in the presence of Mn(II) (Xu et al., 2018; Singh et al., 2019). Laccase, MFO (mixed function oxidases), glutathione S transferase, cytochrome P_{450} also acts in biodegradation of recalcitrant compounds (Singh, 2019; Boudh et al., 2019). Catechol 1,2-dioxygenase (intracellular enzyme) from *Pseudomonas* NP-6 dissimilate catechol to muconate compounds (Guzik et al., 2011). Also, enzyme immobilization (Cavalca et al., 2013; Sharma B. et al., 2018) increases the half-life, stability, and enzyme activity at a notable level. The enzymatic bioremediation is an elementary, expeditious, and environmental friendly method for microbial removal and degradation of persistent xenobiotics compounds (Sharma B. et al., 2018). Isolation and characterization of microorganisms with enzymatic capabilities have been done with the limitation of less productivity (Rayu et al., 2012). Organophosphates (OP) and organochlorines (OC), major constituents of insecticides, accumulate in the agricultural soil (Panelli et al., 2017) and reach the water bodies via agricultural run-off. Effective bioremediation of γ-hexachlorocyclohexane (OC) and methyl parathion (OP) has been reported by genetically engineered microorganisms (Gong et al., 2016). Moreover, bioremediation of organophosphates and pyrethroids has been experimented with using genetically modified *P. putida* KT2440 (Zuo et al., 2015). With the advent of metabolic engineering, the catabolism and degradation of various persistent compounds has been reported. The degradation pathways of methyl parathion and γ-hexachlorocyclohexane in *Sphingobium japonicum* and *Pseudomonas* sp. WBC-3 witnessed the bioremediation strategy (Liu et al., 2005; Miyazaki et al., 2006). Furthermore, 1, 2, 3-trichloropropane, a persistent constituent of fumigant, is dissimilated into the environment (Techtmann and Hazen, 2016) via heterologous catabolism by the assembly of three enzymes from two different microorganisms in *E. coli* (Dvorak et al., 2014). A metabolic pathway (Bertin et al., 2011) degrading organophosphorus and paraoxon is engineered by inserting the organophosphorus hydrolase gene (opd) and pnp operon encoding enzymes that convert p-nitrophenol into β-ketoadipate in *P. putida* (de la Pena Mattozzi et al., 2006). A study showed *pobA* and *chcpca* gene clusters of *Rhodococcus opacus* R7 take part in the bioremediation of naphthenic acid; more specifically, expression *aliA1* gene codes for fatty acid CoA ligase for degrading long chains of linear as well as alicyclic naphthenic acid (Zampolli et al., 2020). To minimize the accumulation, the above-mentioned strategy is attained using microbes for partial or complete mineralization of persistent compounds (Miyazaki et al., 2006).

Synthetic Genetic Circuit and Microbial Biosensor

The synthetic genetic circuit requires chassis for implantation. The *P. putida* is a HVB (Host Vector Biosafety) strain recognized as safe by the Recombinant DNA Advisory Committee. It is also referred to as GRAS (Generally Recognized as Safe) to release in the environment. It is ideal for the next generation of synthetic biology chassis panel because it can withstand high intolerant changing conditions including temperature, pH, solvents, toxins, osmotic, and oxidative stress. Also, *P. putida* has versatile metabolism and low nutrient requirements (Pabo and Nekludova, 2000). These qualities make this organism the best bacterial model for environmental bioremediation applications (Tanveer et al., 2018). Recently, the *P. putida* synthetic genetic circuit has been established for the designing of promoter genes and expression of the gene responsible for the degradation of persistent compounds (Adams, 2016). An extension of synthetic biology is the integration of genome with reporter system, and synthetic promoters of *P. putida* may be developed for synthetic bioremediation pathways. Elmore et al. use serine integrases for synthetic genetic circuit development. Microbial cells have the advantage of a cellular system, which controls cell growth and response to external factors like temperature, light, pH, and oxygen (Tropel and Van Der Meer, 2004). The external environment of microbes inhabiting the contaminated site will respond to concentrations of various persistent compounds present (Ray et al., 2018; Antonacci and Scognamiglio, 2019). Whole cell biosensors for checking the presence, detection and biodegradation potential of xenobiotics compounds (pharmaceutical residues, pesticides, paraffin, PAHs and PCBs, etc.) present (Adhikari, 2019) in environmental samples are attaining attention (Wynn et al., 2017; Heng et al., 2018; Patel et al., 2019). The reporter proteins acting microbe makes a color signal at the detection of particular contaminants *via* transducer (Zhang and Liu, 2016). A biosensor aiming for detection and bioremediation purposes must have enhanced contact between microbe and contaminant (Dhar et al., 2019). This helps the bacterium to adjust their cellular pathways in response to external environmental conditions and encodes the genes for utilizing the recalcitrant compounds as substrate (Bilal and Iqbal, 2019; Skinder et al., 2020). Synthetic biology strategies are feasible for removing a particular toxic compound because the genetic circuits can be developed against the exogenous environmental toxin (Checa et al., 2012; Tay et al., 2017). The synthetic genetic circuits are assembled via a two-component regulatory system (TCRS) in bacteria (Futagami et al., 2014; Uluşeker et al., 2017). This system acts upon environmental change, and thereby, cells respond to these changes. A prokaryotic TCRS has histidine kinase (HK) and response

regulator (RR). The HK is a sensor domain with an extracellular loop present as an integral membrane protein. HK also has a transmitter domain in the last cytoplasmic transmembrane, which is a highly conserved domain. Histidine phosphotransfer (DHp) and catalytic ATP-binding domain (CA) acts for molecular recognition of RR and ATP hydrolysis. The transmitter domain transmits the signal from periplasm to cytoplasm via PAS (Periodic circadian proteins, Aryl hydrocarbon nuclear translocator proteins, and single minded proteins), HAMP (HKs, Adenyltatecyclases, Methyltransferases, and Phosphodiesterases) and GAF (cGMP-specific phosphodiesterases, adenylyl cyclases, and formate hydrogenases) (Casino et al., 2010). Thus, HK senses the external environmental change and adds phosphate to conserved histidine. The HK also regulates RR by phosphorylating the aspartate residues. This promotes the promoter (Figure 3B) binding to activate the gene expression or vice-versa (Ravikumar et al., 2017). Therefore, TCRS-based synthetic biology application for biosensor development for cell-mediated detection and bioremediation can prove to be a new advancement.

Ecological Safety and Risk Assessment

The scientists and researchers are performing the experimental setup to study the bioremediation (Yergeau et al., 2012) potential against various pollutants like oil spill, plastics, synthetic dyes, organic hydrocarbons (Yadav et al., 2015), pesticides (Jaiswal et al., 2019a), heavy metals (Hemmat-Jou et al., 2018; Lebrazi and Fikri-Benbrahim, 2018), and other xenobiotics, etc (Rucká et al., 2017; Paniagua-Michel and Fathepure, 2018; Wu et al., 2020). Considering that bioremediation is performed in an open environment rather than in a closed fermentation tank, the ecological safety of bioremediation performing bacteria must be considered. Economic safety is justified by the metabolic aptness (Gillan et al., 2015) of microorganisms as compared to other traditional physical and chemical bioremediation methods. Besides, regulation for using genetically and metabolically modified bacteria is released to evaluate the possible risks (Khudur et al., 2019). The risk assessment is mainly done by regulatory agencies, i.e., Organization for Economic Cooperation and Development (OECD) at the application level for environmental safety (Russo et al., 2019; Alam and Murad, 2020; Pastor-Jáuregui et al., 2020). The possible risks are gene contamination in the native member of microbial consortium, leading to mislaying of the natural trait (Mills et al., 2019; Pineda et al., 2019; Rycroft et al., 2019). The competitiveness between natural and genetically modified species can give rise to selection pressure on non-target microflora (Kumar N. M. et al., 2018; Mohapatra et al., 2019). Moreover, environment and ecosystem risk assessments infer unpredictable and adverse effects, as discussed above (Cervelli et al., 2016; van Dorst et al., 2020). Particularly, the ecological risk assessment behind addition of GEMs (Genetically Engineered Microorganisms) (Benjamin et al., 2019; Ahankoub et al., 2020) to the native environment rather than a laboratory (Fernandez et al., 2019) is done mainly because of unnecessary delivery of antibiotic resistance marker along with recombinant genome of interest (Davison, 2002; Nora et al., 2019), and unintentional uptake or transfer of induced genes to other microorganisms (French et al., 2019; Janssen and Stucki, 2020). This phenomenon is definitely disturbing the microbial native genome entity (Gangar et al., 2019; Petsas and Vagi, 2019). Another aspect to consider is the change in microbial metabolism (Okino-Delgado et al., 2019), which may release uncertain toxic compounds into the environment, indirectly affecting (negatively) microbial candidates in this context (Myhr and Traavik, 2002). Under the TSCA (Toxic Substances Control Act) (Gardner and Gunsch, 2020), the Office of Pollution Prevention and Toxics (OPPT) programs (Pietro-Souza et al., 2020) of the United States Environmental Protection Agency (Leong and Chang, 2020; Saxena et al., 2020) monitors the environmental and health risks and releases premanufacture legal notice for the accreditation of field research outlines and prototypes (McPartland and McKernan, 2017; Khan et al., 2020). A magnificent example is given by University of Tennessee. In 1995, they gave application and suggested the risk evaluation of microbial bioremediation agents (mainly *Pseudomonas fluorescens* HK44) on the environment and health (Sayler et al., 1999; Khan et al., 2016; Sharma J. K. et al., 2018; El Zanfaly, 2019). Remarkably, the literature survey points toward a biowar weapon for humanity (Gómez-Tatay and Hernández-Andreu, 2019; Wang and Zhang, 2019), stating that gene editing tools left in bad hands could mislead ethical and moral duties (Khan, 2019; Thakur et al., 2019; Sharma et al., 2020).

Conclusion and Future Perspectives

The microbial bioremediation process for removal and detoxification of contaminants from the environment has now emerged as the best option. Synthetic biology is addressing the decontamination and remediation strategies for xenobiotics and related compounds from the environment. It has been observed that the requisite for understanding existing metabolic pathways is a must for developing synthetic models of bioremediation. Moreover, genomics reconstruction methods (Luo et al., 2014; Marco and Abram, 2019) and technologies made a solid platform for bioremediation studies. Satisfactory progress has been witnessed in the field of bioremediation among various contaminants with the role of specific genes and enzymes applicable via synthetic biology methodologies. Therefore, it is concluded that microbial synthetic biology remediation strategies not only increase the efficiency of microbial bioremediation processes for a particular contaminant, but also provide the best methodologies for researchers.

Author Contributions

SJ contributed to this article under the guidance of PS. SJ acknowledges the support and guidance of PS in pursuing a doctorate under his guidance.

Funding

The author SJ acknowledges Maharshi Dayanand University, Rohtak, India, for providing University Research Scholarship (URS). PS acknowledges the infrastructural support from Department of Science and Technology, New Delhi, Government of India, through FIST grant (Grant No. 1196 SR/FST/LS-I/2017/4).

Conflict of Interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

Forensic Microbiomes

Characterizing human and environmental microbiomes is not only important to maintain host and ecological health, but can have other far-reaching applications such as forensic science. Determination of unexplained situations and phenomenon can be quite challenging, and with advances in microbiomics, there is a possibility to generate sufficient data and evidence to provide viable answers and solutions.

Forensic Applications of Microbiomics: A Review

Article by Robinson et al., 2021 licensed under the terms of the Creative Commons Attribution License (CC BY).

The rise of microbiomics and metagenomics has been driven by advances in genomic sequencing technology, improved microbial sampling methods, and fast-evolving approaches in bioinformatics. Humans are a host to diverse microbial communities in and on their bodies, which continuously interact with and alter the surrounding environments. Since information relating to these interactions can be extracted by analyzing human and environmental microbial profiles, they have the potential to be relevant to forensics. In this review, we analyzed over 100 papers describing forensic microbiome applications with emphasis on geolocation, personal identification, trace evidence, manner and cause of death, and inference of the postmortem interval (PMI). We found that although the field is in its infancy, utilizing microbiome and metagenome signatures has the potential to enhance the forensic toolkit. However, many of the studies suffer from limited sample sizes and model accuracies, and unrealistic environmental settings, leaving the full potential of microbiomics to forensics unexplored. It is unlikely that the information that can currently be elucidated from microbiomics can be used by law enforcement. Nonetheless, the research to overcome these challenges is ongoing, and it is foreseeable that microbiome-based evidence could contribute to forensic investigations in the future.

Introduction

For over 100 years, microbiology has played a relatively diminutive role in forensic science (MacCallum and Hastings, 1899). In the early 1990s, the sequencing of amplified viral DNA was used to support a case alleging the transmission of Human Immunodeficiency Virus from a dentist to several patients in Florida, United States (Smith and Waterman, 1992). The emergence of PCR-mediated genotyping of bacteria was considered to be a valuable forthcoming tool in forensics—e.g., van Belkum (1994) suggested that forensic science would soon be a major area for the application of PCR-mediated genotyping due to the rapidity of technological advances at the time (van Belkum, 1994). In the mid-1990s, fungal and pollen spore analyses were also developed, allowing investigators to differentiate between soil types, which in turn allowed linking substrate items to particular sites (Bruce and Dettmann, 1996; Bryant and Mildenhall, 1998). However, it was not until the early 2000s and the rise of bioterrorism that *microbial forensics*—the "scientific discipline dedicated to analyzing evidence from a bioterrorism act, biocrime, or inadvertent microorganism/toxin release for attribution purposes"—emerged in response to the new threat (Budowle et al., 2003; Carter et al., 2017).

Many forensic applications have been limited to individual taxa analyses, and *microbial forensics* has, historically, been constrained by a lack of available and cost-effective sequencing technologies (Berglund et al., 2011; Kuiper, 2016). This approach has changed dramatically in the last decade as advances in genomic sequencing technology, and new methods for processing complex community datasets (and often low biomass samples) have led to the advent of a new field of microbiomics. The science and study of the microbiome (Statnikov et al., 2013; Capasso et al., 2019) combined with metagenomics (all genomes from a sample) have enhanced the development of the microbial forensic toolkit (Clarke et al., 2017; Hampton-Marcell et al., 2017).

As of March 2019, the conviction rate for homicides in England and Wales (United Kingdom) was only 79% (Office for National Statistics, 2019), slightly higher than in the US (~70%) (Bureau for Justice Statistics., 2019). Across the globe, there is also a high prevalence of wrongful convictions and often insufficient evidence to convict a perpetrator of a crime (Sangero and Halpert, 2007; Ingemann-Hansen et al., 2008; LaPorte, 2017; Walsh et al., 2017). According to the Innocence Project, a national litigation and public policy organization dedicated to exonerating wrongfully convicted individuals, to date, 375 people in the United States have been exonerated by DNA testing, including 21 who served time on death row (Innocent Project, 2020). There is thereby a

strong interest from the public, lawmakers, and the law enforcement system to augment and expand the forensic toolkit, including molecular methods. Microorganisms are abundant in and on the human body (microbial cells can outnumber or equal the total number of human somatic cells) (Noel et al., 2014; Sender et al., 2016; Vázquez-Baeza et al., 2018), in surrounding environments, and on objects associated with a crime (Desmond et al., 2018; Oliveira and Amorim, 2018). A growing body of evidence suggests that forensically relevant microbial profiles could be used as evidence or, at the very least, complement traditional investigative methods (Metcalf et al., 2017; Schmedes et al., 2017; Richardson et al., 2019; Phan et al., 2020). This use of microbial profiles as evidence is done using computational tools that are being developed alongside new approaches in bioinformatics, processing tools, and refined protocols. However, since the field is still in its infancy (Goudarzi et al., 2016; Komaroff, 2018) and historically underfunded (Morgan and Levin, 2019), there is much uncertainty as to the true potential of microbiomic tools in forensics.

In this review, we provide an overview of past, current, and future potential applications of microbiomics in forensics. Specifically, we will discuss the six most comprehensively researched themes (Figure 1): including geolocation (e.g., substrate analysis and different spatial dimensions and the power of machine learning), personal identification, biological sex determination, trace evidence, manner and cause of death (e.g., death by drowning), PMI, and other applications (e.g., localization through animal microbiomes).

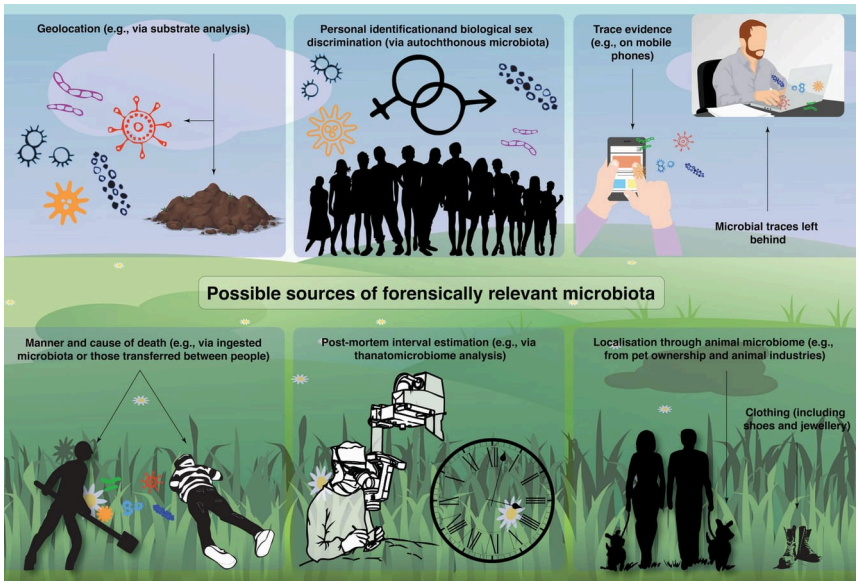

Figure 1. A summary of possible sources of forensically relevant microbiota identified by the literature review.

Major Themes in the Forensic Microbiology Literature

Geolocation

In the past few years, intensive work has been carried out to characterize environmental microbiome, particularly in urban environments and transit systems. These studies have demonstrated that unique community profiles may exist in certain areas of a city (Afshinnekoo et al., 2015; Rosenfeld et al., 2016), as well as “molecular echoes” of environmental events, and even a forensic capacity for geospatial microbiomic data (MetaSUB International Consortium, 2016; Danko et al., 2019a). In the following, we focus on two leading aspects of geolocalization.

Substrate Analysis

The potential of analyzing microbial profiles from the soil is increasingly being recognized in forensic microbiological research. Both the rhizosphere and bulk soil microbiomes exhibit a high level of heterogeneity between different sites. As such, with methodological refinement, soil microbiome samples could provide valuable biogeographic data to localize the origin of the soil sample. Another potential application is the acquisition of information to help determine the provenance of an item(s) associated with a crime.

Habtom et al. (2019) demonstrated distance-decay relationships between microbial samples from the soil at a local scale (25–1,000 m) (n = 5 sites, n = 2–4 soil types, and five replications). The results showed that the greater the distance between

the samples, the more they differed, suggesting that both soil type and geographic location are important factors in determining microbial community composition. Indeed, patch discrimination using the soil microbiome has previously been demonstrated (Macdonald et al., 2011), and Jesmok et al. (2016) correctly classified 95.4% of soil bacterial profiles to their location of origin using various methods including abundance charts, non-metric multidimensional scaling, analysis of similarity, and *k*-nearest neighbor. However, this was a feasibility study with a modest sample size (n = 19). Further studies with larger sample sizes and replications are needed to explore the full potential of this approach.

Evaluating the microbial communities in an assemblage of soil samples (e.g., soils from a crime scene or alibi site and other intermediary sites) could be useful in forensics. Samples originating from a mixture of different soil substrates have been correctly differentiated by using a combination of Ribosomal Intergenic Spacer Analysis and 16S rRNA gene sequencing (Demanèche et al., 2017). Recent evidence suggests that 18S rRNA gene sequencing can also provide greater discriminatory power over traditional Mid-Infrared spectroscopy at fine scales for eukaryotic species (Young et al., 2015). Furthermore, Sanachai et al. (2016) demonstrated that the site origin of soil, obtained from the sole of a shoe, could be elucidated by comparing the similarity of soil bacterial 16S rDNA profiles acquired by the denaturing gradient gel electrophoresis technique.

Despite the potential in this field, further limitations need to be identified and addressed. For example, Pasternak et al. (2019) identified several potentially limiting factors to consider when interpreting the results of microbiomic analyses. For instance, soil samples are incredibly complex and highly heterogeneous even at short spatial scales, which presents a major issue to using these in a forensic context, and microbiomes exhibit a high level of physical, chemical, and biological diversity in both space and time. Pasternak et al. (2013) showed that actinobacterial fingerprints significantly differed between two seasons (summer and winter) at the same sites—implying that temporally-associated issues could arise. Keet et al. (2019) have also pointed out that soil microbiome composition can change as a result of abiotic soil conditions and plant community patterns—which poses a considerable challenge to the accuracy of results.

Metagenomic analysis of gravesoil and the soil around human and non-human animal cadavers has been undertaken for forensic purposes. Carter et al. (2015) investigated microbial community succession in soils associated with swine cadavers across two seasons (summer and winter). They demonstrated that postmortem microbial communities changed in specific and reproducible ways, but decomposition effects on soil microbial communities differed significantly between seasons. The authors suggest that the ecological succession of microbial communities will be useful for forensic investigations, but future research should aim to gain a greater understanding of seasonality on decomposition. The sample size for this study was not explicitly stated, but according to the ordination plots, it appears to be modest ($n \leq 10$ per treatment). Therefore, results should be interpreted with caution.

Adserias-Garriga et al. (2017) investigated daily thanatomicrobiome changes in the soil as an approach to estimate PMI. They collected soil samples from around human cadavers (n = 1 male and n = 2 females) and demonstrated successional changes on a daily basis. Rapid growth of *Firmicutes* was observed from the bloat stage to advance decay (<5% relative abundance at day 1 to 75% relative abundance day 12), and the authors proposed a *Firmicutes* growth curve to estimate PMI. However, the authors state that the growth curve results may only apply under Tennessee summer conditions and that confirmatory research is needed using a larger number of cadavers and under different environmental conditions. The results do, however, corroborate those of Finley et al. (2016), who evaluated microbial communities associated with gravesoil human cadavers (n = 18). The researchers allowed the cadavers to decompose over a range of decomposition time periods (3–303 days) and showed increases in the relative abundance of *Firmicutes* in surface bodies over the decomposition period (from ~10% at 0–3 months to ~40% at 7–9 months).

Singh et al. (2018) investigated the spatial (0, 1, and 5 m) dynamics of human cadaver decomposition on soil bacterial community structure. They collected soil samples from each spatial buffer (n = 14 for the 0 m, n = 17 for both 1 and 5 m) and observed evidence of a predictable response to cadaver decomposition that varied over space. Bacterial community composition (beta diversity) at 0 m was significantly different from the 1 and 5 m communities, whereas there were no significant differences between the 1 and 5 m communities. The researchers also found that bacterial alpha diversity was significantly lower in the 0 m samples, suggesting that the additional nutrient input from the cadavers may reduce bacterial alpha diversity. This study provides additional spatial-compositional insights to complement the growing body of knowledge in this area of forensic microbiome applications.

Soil microbiome analysis has the potential to be used in forensics; however, additional research is required to validate the sensitivity and reproducibility of results (Young et al., 2017). Overall, to gain a greater understanding of both spatial and temporal dynamics associated with the microbiome and to develop techniques to mitigate similar pitfalls, further microbiome surveys are essential.

Different Spatial Dimensions and the Power of Machine Learning

The growing interest in sampling and predicting environmental microbiome profiles at different spatial scales and orientations (e.g., between households, cities, states, and altitudes) to provide information on the location and provenance of people and objects resulted in the development of a multitude of approaches. Chase et al. (2016) identified the three cities where nine offices were located with 85% accuracy based on analyzing office microbiome samples using sampling plates, and although this study suffers from a small sample size (n = 3 per office), it demonstrates potential with further refinement. Lax et al. (2014) analyzed samples from household occupants (n = 1625 from 18 participants in 10 houses) and their built environments. The authors matched feet microbiome samples to the house with 82.9% accuracy—a relatively low degree of accuracy from an evidentiary perspective but demonstrating the potential of such methods for fine-scale biolocalization. Walker and Datta (2019) analyzed whole-genome sequenced microbiota sampled from 12 cities in seven different countries as part of the 2018 CAMDA MetaSUB Forensic Challenge. The CAMDA dataset (n = 30) included three mystery samples. The authors applied machine learning techniques to identify the geographical provenance of the microbiome samples. Up to 90% of the samples were correctly classified, demonstrating the potential of machine learning applications to biogeography, although further evidence is necessary to employ these applications in an evidentiary context. In a related study, Ryan (2019) applied a random forest classifier built on a dataset of 311 city microbiome samples. Their method correctly classified 83.3% of the mystery samples. Grantham et al. (2019) presented a different algorithm for predicting the geolocation of fungal samples from dust (n = 1300) in the United States using deep neural network classifiers. Applied to a global dataset of samples from 28 countries, the authors state that their algorithms make "good point predictions" with >50% of the geolocation errors under 100 km for US-wide analysis and nearly 90% classification accuracy of a sample's country of origin for the global analysis. This particular field, combining microbiomics and machine learning, is in its infancy, and future studies would benefit from larger sample sizes and improved classification accuracy before such approaches can be used with confidence in a forensic context.

Another important spatial factor to consider is that microbiome compositions do not only differ in horizontal space. Skin microbiomes have also been shown to differ between humans living in high and low altitudes. For example, Zeng et al. (2017) collected skin microbiome samples from humans (n = 99) and pigs (n = 82) in Tibet. They found enrichments of several bacterial taxa (e.g., *Arthrobacter* sp., *Paenibacillus* sp., and *Carnobacterium* sp.) in samples collected from higher altitudes. Alpha diversity was also significantly lower in skin samples collected from individuals living at higher altitudes. This suggests a potential future route to determine geolocation based on altitudinal parameters via the analysis of skin microbiome samples in the future—although here too, methodological refinement will be essential. Furthermore, understanding how skin microbiomes may fluctuate throughout the life course will also be an essential factor to consider.

Overall, all the models prioritize classification over prediction abilities. To enable real-time prediction of geographical coordinates from sampling data, increasing the sample sizes geographically and temporally, and developing more rigorous methods is essential.

Personal Identification

A growing body of evidence suggests that human individuals may be uniquely identified based on stable autochthonous (i.e., native to a given environment) microbial profiles. This could have a substantial impact on forensic science—for example, in situations where the investigator cannot retrieve sufficient amounts of human DNA (i.e., from human somatic and germ cells). Yet it is unknown whether the variation in microbial communities between people is sufficient to identify individuals within large populations uniquely or stable enough to place them over time.

To answer some of these questions, Franzosa et al. (2015) tested different body site-specific microbial profiles and attempted to match them with 25–105 microbiome profiles during the person's first and second visits to the sampling site. The authors reported that these profiles were useful in distinguishing individuals at the initial sampling time point and that 30% of the individuals were still uniquely identified several months later. In this study, gut microbiome samples were used to pinpoint 80% of individuals (n = 120) up to a year later. These results are encouraging—particularly in shorter timescales—however, they still suffer from relatively high variability. As such, greater improvements, e.g., in methods and sampling effort, will be needed before such approaches can be useful in a forensic setting.

High resolution melting analysis that targeted the 16S rRNA gene from oral swab samples have also been used to demonstrate its potential in distinguishing between individuals (Wang et al., 2019), albeit with a very small sample size in this study (n = 5). Schmedes et al. (2018) demonstrated accurate identification of individuals (n = 12) based on skin swab samples from different body sites (n = 14). They achieved 97% accuracy by sampling shirts and 96% accuracy using palm samples based on 1-nearest neighbor classification on nucleotide diversity of the bacterial genome. In another recent study, the researchers utilized a similar approach to identify individuals (n = 51). They analyzed microbiome samples collected from three different body sites—the

manubrium (i.e., the upper-most segment of the sternum), the palmar surface of the hand, and the ball of the foot (Woerner et al., 2019). The researchers achieved 100% classification accuracy when conditioned on a maximum nearest neighbor distance for diversity, suggesting strong potential should these results be replicable in studies with much larger sample sizes.

Watanabe et al. (2018) suggested that minor taxa are one of the key factors for distinguishing between individuals. Their study analyzed microbiome samples (n = 66) from individuals (n = 11) over 2 years and achieved 85% accuracy in distinguishing individuals. They also used the same analytical methods to classify publicly available skin microbiome samples from individuals (n = 89) with a 78% identification accuracy. However, this level of accuracy is unlikely to be sufficient for forensic applications. The authors suggested that although personal identification is possible, the estimation of the accuracy decreases for larger cohorts due to increments of similar microbiome patterns. Overall, the use of microbiomics as a forensic tool to determine personal identification shows potential and technological viability and might be useful in situations where the investigator is unable to retrieve sufficient amounts of human DNA. Nonetheless, the findings fall short of the burden of proof. Improvements in the model's sensitivity and specificity are required, and a methodology to address potential contamination issues. Furthermore, a better understanding of the microbial dynamics across time and space is essential for the findings to have a forensics value.

Biological Sex Determination

Recent evidence supports another contribution of microbiomics toward personal identification –the discrimination of biological sex, which could be useful where sufficient quantities of human DNA are unable to be retrieved. For example, airborne bacteria communities have previously been characterized in indoor environments (Chan et al., 2009). Luongo et al. (2017) investigated airborne bacterial and fungal diversity (i.e., constituents of the "aerobiome") from different University dormitory rooms (n = 91). They used machine learning techniques and were able to predict the biological sex of room occupants with 79% accuracy based on relative abundances of the microbiota. Curiously, rooms occupied by males exhibited higher relative abundances of the microbiota. The authors suggested that it could be because males may shed more biological particles or use fewer cosmetic barriers such as skin lotions.

Biological sex-related differences in the human thanatomicrobiome—the microbial communities colonizing organs following death (*thanatos*, Greek for death) (Zhou and Bian, 2018)—have also been demonstrated by Bell et al. (2018). The authors compared amplicon signatures (using the 16S rRNA gene V1-2 and V4 regions) in the corpse heart tissue of 10 individuals and discovered key differences between males (n = 6) and females (n = 4). For example, *Streptococcus* sp. was found exclusively in male heart tissues, whereas females had a significantly higher prevalence of *Pseudomonas* sp. With refinement, such an approach could help to determine the biological sex of a corpse and the provenance of body parts.

In a study by Tridico et al. (2014), the authors "readily distinguished" male (n = 3) and female (n = 4) subjects based on the analysis of their pubic hair microbiomes. They identified *Lactobacillus* spp. that were unique to female participants. They also suggested that pubic hair is relatively insulated from the environment and colonized with niche-specific microbiota, which could be useful in forensic investigations. Unfortunately, the modest sample size of this study limits the conclusions that can be drawn from it. Nonetheless, the findings were supported by another small study by Williams and Gibson (2017), who identified individuals (n = 9) and their biological sex from pubic hair microbiota with an error ratio of 0.027 ± 0.058 and 0.017 ± 0.052, respectively. However, the sample sizes for all these studies are modest, and as such, further validation studies with larger sample sizes are needed before reliable conclusions can be drawn.

Interestingly, Phan et al. (2020) analyzed skin microbiome samples from both genders (n = 45) and found that the absence of the bacterial genus *Alloiococcus* could be useful in predicting female biological sex. The study showed a correlation between certain bacterial species and personal characteristics (e.g., biological sex). They specifically explored the presence/absence of microbiota from fingermarks left behind on surfaces and achieved a relatively modest 67% sex prediction accuracy using leave-one-out cross-validation analysis. Improvements in sample sizes and machine learning accuracy are necessary to explore the potential of this approach further. Additional research into whether certain bacteria (and other microorganisms) are distinct to females or simply related to external factors (such as cosmetic products on hands) would also be necessary.

Trace Evidence

There is an increasing interest in studying forensically relevant microbial profiles left behind on objects and surfaces. For instance, several studies showed that there is often a high level of bacterial presence on personal objects such as mobile phones (Koroglu et al., 2015; Kõljalg et al., 2017; Koscova et al., 2018; Kurli et al., 2018). Furthermore, human-associated items such as shoes and mobile phones have been shown to support distinct microbiomes (Lax et al., 2015; Coil et al., 2019).

Meadow et al. (2014) investigated the potential utility of mobile phones as "personal microbiome sensors." They selected 17

individuals and collected three samples (the cell phone's touch surface, their index finger, and their thumb). They demonstrated that bacterial communities sampled from mobile phones were more similar to their owners than other people. They found that about 22% of the taxa on participants' fingers were also found on their phones, whereas only 17% were shared with other people's phones. An individual's index finger shared approximately 5% more OTUs with their mobile phone than with everyone else's mobile phone in the study. Furthermore, 82% of the OTUs were shared between a person's index finger and their phone. Although promising, here again, the sample size and accuracy of results need to be increased in future studies.

Kodama et al. (2019) found that postmortem skin microbiomes could be associated with personal objects with a high degree of accuracy. Several of the objects in the study were associated with 100% accuracy (i.e., medical devices, eyeglasses, bottles, and steering wheels), whereas objects like computer devices, remote controls, and cell phones were associated with over 67% accuracy, suggesting that with refinement, skin microbiome samples could be reliably linked to objects at the scene. Furthermore, studies have found that the postmortem skin microbiomes were stable and similar to antemortem skin microbiomes for up to 60 h postmortem (Kodama et al., 2019).

Salzmann et al. (2019) investigated the microbial profiles of different bodily fluids (n = 22). They identified source-specific microbial signatures from various bodily fluids. For example, the phyla *Proteobacteria* was associated with skin and semen sources, whereas *Firmicute*s showed a higher prevalence in saliva and vaginal secretions. Dobay et al. (2019) suggest that even when body fluid is exposed to indoor conditions for 30 days, samples continue to harbor body-site-specific microbial signatures. Hanssen et al. (2017) also demonstrated promising results, albeit with a small sample size (n = 6), for the microbially-mediated classification of body fluids. They performed pattern recognition by fitting a linear discriminant analysis model using Principal Component scores and were able to classify saliva samples in 94% of the cases.

Neckovic et al. (2020) recently investigated the potential transfer of skin microbiomes between individuals and substrates (i.e., allochthonous microbiota). They found that skin microbiota has been reliably transferred through direct contact, that is, between individuals shaking hands. Microbiota also transmits through indirect contact, as demonstrated by individuals rubbing a substrate and then swapping substrates with another person. The authors suggested that such analysis could be useful to corroborate sexual assault cases or other contact-related crimes. They also suggested that further research should consider the relative surface area of contact, pressure, friction, and the duration of the contact.

Manner and Cause of Death

The 'manner of death' is a determination made by an expert following an investigation (e.g., a coroner, the police, or a medical examiner). Five manners of death are generally considered: natural, accidental, suicide, homicide, and undetermined (Advenier et al., 2016). Lutz et al. (2019) recently collected microbiome samples from 265 corpses from Finland, Italy, and the United States. The inspected cadavers differed in the manners of death: accidental death (n = 88), natural death (n = 106), homicide (n = 23), and suicide (n = 45). Their results suggested that *Lactobacillus, Enterobacteriaceae, Sediminibacterium, and Rhizobiale*s were associated with different manners of death. With further research, these associations could be developed into predictive markers that help to determine the manner of death. However, as noted by the authors, *Sediminibacterium* and *Rhizobiale*s bacteria may also represent environmental contamination, which needs to be controlled, and further validation through controlled experiments is needed to improve the reliability of their approach to determine the manner of death.

The potential of this microbiomics approach to determining the manner of death was corroborated in a recent study by Zhang et al. (2019) who, by obtaining samples during routine death investigations at the Wayne County Medical Examiner's Office (Detroit, Michigan, United States), found different biomarkers associated with the manner of death. In this study, *Xanthomonadaceae* was more prevalent in cases related to hospital deaths, whereas *Actinomyce*s sp. tended to be more prevalent in suicide cases. Increasing the numbers of samples generally increased the accuracy of the models. The authors cautioned that the prediction accuracy depends on the machine learning methods used and the number of anatomical sites analyzed. The authors suggest this study provides baseline information, and it could be possible to use machine learning to develop reference databases that allow microbially-mediated manner of death predictions in the future.

Kaszubinski et al. (2020) modeled beta-dispersion to test for manner and cause of death association using a microbiome data set of n = 188 postmortem cases (five body sites per case). The researchers demonstrated that beta-dispersion and demographic data could distinguish among manner and cause of death. In particular, they found that cardiovascular disease and drug-related deaths were correctly classified in 79% of cases. They found that binary logistic regression models were most effective at improving model success. This was an improvement over multinomial logistic regression models, which confirmed the manner and cause of death assessment only 62% of the time. The results of this study show promise for using postmortem microbiomes to indicate the manner of death. However, as the researchers' highlight, sample sizes need to be greater. Moreover, the development of large databases will likely be required to train models with high success rates prior to being used in practical

forensic contexts.

In terms of cause of death (i.e., the disease or injury that produces physiological disruption in the body leading to death), researchers such as Christoffersen (2015) have investigated the importance of microbiological testing. Studying autopsy results (n = 42), the author reported that the cause of death could be determined in 42% of the cases via microbiological analysis. The study highlighted factors indicative of a microbiologically related cause of death, such as a raised CRP measurements. Raised CRPs have also been implicated in SIDS as a cause of death (Rambaud et al., 1999; Szydlowski et al., 2013) and even for astronauts returning from space (Garrett-Bakelman et al., 2019). Deadly bacterial infections, such as infection or sepsis, may also occur following neonatal circumcision (Elhaik, 2016, 2019).

A specific forensic microbiome application for determining the cause of death is the diagnosis of 'death by drowning,' which is one of the leading causes of unnatural deaths worldwide (Domínguez et al., 2018; Cenderadewi et al., 2019). Analyzing the presence of diatoms (single-celled algae) has been the 'gold standard' for well over a decade; however, its reliability has been questioned (Kakizaki et al., 2009; Huys et al., 2012). Several studies have provided support for death by drowning diagnoses by designing real-time PCR assays with primers to detect bacterial species associated with aquatic environments, such as *Aeromonas* spp. (Aoyagi et al., 2009; Uchiyama et al., 2012; Rutty et al., 2015; Voloshynovych et al., 2019). These studies provided support for this cause of death diagnosis based on relatively high detection rates of microbiota, for example, 84% (n = 32), 75% (n = 20), and 84% (n = 43)—although to strengthen the cause of death diagnoses, the accuracy levels, and sample sizes could again be much improved. It has also been suggested that bioluminescent bacteria may be biomarkers for death by drowning in seawater. For example, Kakizaki et al. (2009) developed a simple assay targeting the 16S rRNA gene to identify bioluminescent colonies such as *Vibrio fischeri* and *Vibrio harveyi*. More recently, Lee et al. (2017) analyzed microbiome composition and pulmonary surfactant protein (SP-A) expression to develop a marker for diagnosis of death by drowning. They analyzed microbiota and histological appearance of both drowned and postmortem groups of experimental rats, comparing freshwater vs. marine water treatments. The authors found that 5513 and 5480 OTUs were unique to marine and freshwater, respectively. They also found that expression levels of SP-A were higher in the lungs of drowning victims compared to postmortem submersion. These findings could have important forensic value (e.g., determining both the type of environment and the timing of death) and demonstrate good potential for future applications. Marella et al. (2019) point out that other studies have focused on the presence of fecal bacteria, coliforms, and streptococcal bacteria to help determine the cause of death by drowning. These bacteria are sampled from the femoral artery and vein and the right and left ventricles. Fecal bacteria are considered to be always present in subjects who drowned compared with those with other cause of death diagnoses (Lucci et al., 2008; Marella et al., 2019). For example, Lucci and Cirnelli (2007) found fecal streptococcal presence in 100% of the freshwater drowning cases they studied (n = 22) and coliforms present in 90.91%. In this study, the control subjects (n = 30) uniformly showed an absence of fecal bacteria. In a later study, Lucci et al. (2008) assessed if the presence of these bacteria in the drowning medium could be detected in victims submerged after death. The researchers collected samples from drowned victims (n = 5 freshwater and n = 5 in seawater) and victims who were submerged after death (n = 3). Coliforms and streptococci were detected in all drowned victims but not in those submerged after death. These findings suggest that fecal coliforms and streptococci could be used as markers of drowning. However, the minuscule sample sizes must be interpreted with caution and increased considerably in future studies.

Postmortem Interval

The Thanatomicrobiome

Determining the PMI (the time elapsed since a person has died) is often an essential part of a criminal investigation. To improve PMI prediction accuracy, researchers have begun examining the thanatomicrobiome (Javan et al., 2016; Burcham et al., 2019). Postmortem, these communities overwhelm the immune system allowing for subsequent colonization (Javan et al., 2019). Preliminary studies suggest that these microbial communities may undergo important successional changes in organs that could aid in determining the PMI (Adserias-Garriga et al., 2017).

Early studies on model animals suggest that this is feasible. For over a 48-day period of decomposition, Metcalf et al. (2013) aimed to uncover a "microbial clock" to provide an estimate of PMI by sequencing the 16S rRNA gene for bacterial and archaeal communities and the 18S rRNA gene for microeukaryotes. Their model provided reliable PMI estimates (±3 days) (n = 223). However, the study was conducted in controlled conditions using experimental mouse models—thereby necessitating a degree of caution when extrapolating the data to 'real-life' situations. Another study investigated the decomposition of pig cadavers. Their model predicted the PMI within 2–3 h of the time of death with 94.4% accuracy (Pechal et al., 2014), demonstrating promise with further methodological refinement. Pechal et al. (2018) carried out a large-scale study of body microbiome samples (n = 188) that found postmortem microbiomes were stable, reflecting antemortem microbiomes 24–48 h after death. The researchers also found that specific bacterial taxa were important in predicting health status. For example, *Haemophilus* and *Fusobacterium*

were twice as abundant in healthy individuals, whereas *Rothia* was 0.09 times more abundant in heart disease cases. With further development, this could be used to indicate the state of human health during clinical investigations into a range of deaths, from chronic and natural to sudden and violent (Pechal et al., 2018). It is important to note that, although appropriate at the time, the bioinformatics approach used to process OTUs and to make functional predictions (e.g., QIIME 1.8 and PICRUSt 1) is now considered to be outdated. Furthermore, Amplicon Sequence Variants (ASV) may provide a richer taxonomic picture (Callahan et al., 2017).

Studying human subjects, Johnson et al. (2016) sampled the skin microbiome of decomposing human cadavers and developed an algorithm to estimate PMI. The authors achieved low error rates for skins samples and a PMI estimation accuracy of ±2 days (n = 144 from 21 cadavers), a substantial improvement compared to prior efforts (e.g., via entomological analysis). Belk et al. (2018) used 16S rRNA amplicon sequencing and found that creating models with the class or phylum taxonomic levels provided the most accurate predictions of PMI. This finding corroborated the study by Johnson et al. (2016) and illustrated its potential usefulness for forensics.

Another study using 454 pyrosequencing to determine abundances and diversity of the postmortem microbiome in several key organs such as the brain, heart, liver, and spleen found varying PMIs ranging from 29.5 to 240 h (Can et al., 2014). This study revealed that the most abundant taxa in postmortem microbial communities were the anaerobic, spore-forming Firmicute bacteria, *Clostridium* sp. Javan et al. (2017) confirmed that *Clostridium* sp. dominated at long PMIs, adding evidence to support the use of microbiomics in PMI determination in the future.

Localization Through Animal Microbiomes

Several studies have shown that animals from different taxonomic groups and environments possess unique microbial profiles. For example, Tibetan chickens *Gallus gallus*, Chinese Rhesus macaques *Macaca mulatta*, and plateau sheep *Ovis* spp. have unique gut microbiomes (Zhou et al., 2016; Huang et al., 2017; Zhao et al., 2018) shaped by genetic, geographical, and altitudinal factors. It has been demonstrated that the skin microbiomes of Estrildid finches, amphibians, bats, cetaceans, and dogs *Canis lupus familiaris* are unique (McKenzie et al., 2012; Avena et al., 2016; Erwin et al., 2017; Torres et al., 2017; Engel et al., 2018; Russo et al., 2018). Interestingly, Song et al. (2013) found that humans share microbial communities with their dogs.

With further investigations and methodological refinement, such capabilities point to the potential feasibility of linking a person with a site based on shared microorganisms with animals. Although further studies are needed, there is potential for forensic pathways to associate trace microbial profiles obtained from other species (unique to the given species) to a given environment and/or occupation (e.g., animal industries) or to pet ownership. For example, non-human animal-specific microbiota could potentially be detected on the body or clothing of a suspect or victim, which may be useful in the absence of sufficient animal DNA (i.e., from somatic and germ cells) evidence. This profile could then conceivably be traced to the point of contact with an animal or animal-based environments such as equine stables, pet shops, or zoos, thus complementing other traditional forensic evidence. However, this approach is mostly theoretical at the moment, and future research will be needed to test its feasibility.

Discussion

As of today, microbiome-based forensics are almost absent from criminal investigations and courts. To explain why this is so, we may divide the different possible applications of microbial forensics into two groups: first, reconstruction issues such as the cause of death and PMI, which ask “what happened?” and help elucidate the circumstances of the crime; and second, comparison issues such as geolocation and personal identification, which ask “how similar are these two DNA profiles?” and may (dis)connect a suspect from an object or a place (e.g., murder weapon or crime scene). Reconstruction applications for forensic use are easier to develop since competing propositions are usually well-defined and limited in number; if sufficient research is invested in ascertaining the microbial characteristics associated with each combination of possible environmental, spatial and temporal conditions, then reconstruction becomes straight-forward. For example, if a cadaver is found buried at a depth of 1 m in a desert in summertime, and the temporal succession of the gut microbial community for these environmental conditions has previously been established, then PMI can be inferred with a high degree of accuracy and certainty. Thus, reconstruction microbiomics can readily pass the *Daubert* standard set by the US supreme court (Daubert v. Merrell Dow Pharmaceuticals Inc, 1993) to be recognized as admissible evidence bearing sufficient scientific foundation, including general acceptance in the scientific community, known and acceptable rate of error, and so on.

Comparison microbiomic tools, on the other hand, may provide greater benefit to the criminal investigation but are harder to develop to a level that would satisfy the *Daubert* standard. The most beneficial way to employ such tools would be in a “one-to-many” configuration, similar to forensic human DNA analysis: a DNA profile from trace evidence is compared to all the profiles

(from known persons and locations) in a database, and if it exists in the database, its frequency in the relevant population (e.g., of soils) is calculated to enumerate the probability of encountering this profile by chance (i.e., originating from a location or person unrelated to the crime). At this time, however, there are hardly any relevant forensic databases of microbiomes that can be compared to trace evidence. In their absence, the only way to proceed in a forensic context is in a "one-to-one" configuration. For each criminal case, questioned samples (e.g., from a suspect's shoe) are compared to context samples from the crime scene, alibi area, and other relevant sites. This approach provides less benefit to the investigation because it can only give conclusions of exclusion, that two samples do not share the same origin, or relative conclusions, such as "sample A is more similar to sample B than it is to sample C." Inclusionary conclusions such as "sample A is very similar to sample B; the probability of a different sample, from another place, person or time, being this similar to sample B at random is 1 in X Million" is impossible without either an extensive database (which is costly to build and maintain) or thorough theoretical knowledge (which we do not have yet) regarding the factors that shape microbiomes. However, even for "one-to-one" analyses, we can provide a statistical evaluation of the evidence (Habtom et al., 2019) based on the Likelihood Ratio framework as recommended by the European Network of Forensic Science Institutes (Willis et al., 2015).

There are three more major hurdles to forensic tools of comparative microbiomics. The first one involves samples of mixed origins, containing substrates or DNA from different locations or persons. DNA analysis of mixtures is difficult even with simple human DNA profiles, and certainly more so with microbiomic DNA profiles which are far more complex. It is often impossible to tell with certainty which, or even how many, disparate microbiomes are present in the mixture, let alone accurately infer the DNA profile of each one. The famed 2016 report of the US President's Council of Advisors on Science and Technology [President's Council of Advisors on Science and Technology (US), 2016] found that the prevalent subjective analysis of complex human DNA mixtures by forensic experts is not a reliable methodology. Consequently, several computer programs were developed to interpret complex human DNA mixtures in an objective manner, and these are slowly being validated and accepted for routine forensic use. Software for objective analysis of microbiomic DNA mixtures may be built on this basis, but these are still years in the future. The second major hurdle is temporal variation. Contrary to human DNA, which can remain unchanged for years, microbial communities (both on the body and deposited as trace evidence) can fluctuate over time, often in correlation with changes in environmental parameters like moisture and pH (e.g., Pasternak et al., 2013). In cases where two samples for comparison are obtained at different times when markedly different environmental conditions prevail, mitigating the temporal changes in community structure is needed before analysis can ensue. So far, only a few studies have addressed this topic experimentally, mainly by applying various carbon sources to force the different microbial communities to "converge" (Pasternak et al., 2019), but so far with limited success. The third, and perhaps most challenging hurdle, is the problem of DNA transfer. In the past decade, human DNA evidence gained widespread credibility and acceptance in the courts so that the identification of a DNA profile from trace evidence as originating from a specific person is rarely disputed nowadays. Instead, it is becoming more and more common for the defense to challenge the method of deposition of the DNA, suggesting that it reached the crime scene by a legitimate activity (before or after the crime occurred) or by DNA transfer (e.g., when the innocent suspect shook the hand of the real perpetrator). This hurdle can sometimes be overcome by using the likelihood-ratio approach with activity-level propositions (Mayuoni-Kirshenbaum et al., 2020); however, similar to the former hurdles, this one is also very much still an open question, and it will take more time, effort, and research before microbiomics is ready to be employed and accepted within the legal system.

Conclusion

Over the last decade, advances in genomic sequencing and bioinformatics have given rise to microbiomics, which fructified in a growing compendium of tools seeking to explore the panoply of microorganisms present in our bodies and environment. The evidence examined in this review indicates that microbiomics could be a forensically relevant and promising discipline with a multitude of applications—from determining substrate provenance and acquiring trace evidence to identifying individuals and estimating PMI. These advances may allow various microbiomic data, like those obtained from thanatomicrobiome analysis, to be used by forensic scientists to address questions related to criminal investigations, or at least be used alongside other forensic methods.

Throughout their life-course, humans and their microbiomes undergo complex interactions and co-adaptation processes involving nutrient intake and resulting in the production of decomposition products such as metabolites. Following a person's death, these interactions change dramatically, and the microbiome composition and dynamics fluctuate accordingly. Understanding these colonizations and fluctuations represent major conceptual, methodological, and computational challenges—as do antemortem microbial dynamics. Related microbiome-based research in a forensics context and greater exploration of fungal and viral communities may also lead to an important enhancement in the forensic toolkit in the future.

Many challenges remain to overcome, such as contamination issues, modest study sample sizes, model over-specification and misspecification, prediction accuracies of machine learning techniques, understanding complex spatial and temporal variations in environmental microbiome dynamics, as well as risks and ethical concerns (Shamarina et al., 2017). Notably, even human DNA-

based evidence, which is far better understood, is not error-proof, as indicated by the Phantom of Heilbronn case (Daniel and van Oorschot, 2011). Moreover, the vast majority of published work used 16S or targeted sequencing approaches, which have known limitation for taxonomic resolution and could likely benefit from metagenomics methods (Ogilvie and Jones, 2015; McIntyre et al., 2017) and/or methods that utilize longer reads (Danko et al., 2019b; Foox et al., 2020). Also, more field-based testing and deployment of these sequencing methods could benefit from rigorous, titrated standards for ensuring accuracy (McIntyre et al., 2019). Given this, many of the applications reported in the literature should be considered proof of concepts rather than full-fledged forensic applications. Nonetheless, as Ogilvie and Jones (2015, p. 1) have summarized: "*it is clear that we remain in a period of discovery and revelation, as new methods and technologies begin to provide [a] deeper understanding of the inherent ecological characteristics of this [microbial] ecosystem.*"

Author Contributions

EE initiated the study. JR carried out the review. EE, JR, ZP, and CM wrote the manuscript. All authors approved the manuscript.

Funding

Payment for open access publication was made by Lund University. JR was undertaking a Ph.D. through the White Rose Doctoral Training Partnership (WRDTP), funded by the Economic and Social Research Council (ESRC). Grant code: ES/J500215/1.

Conflict of Interest

EE consults the DNA Diagnostics Center. CM is a co-founder of Biotia, Inc.

The remaining authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

Acknowledgments

We would like to thank the Starr Cancer Consortium (I13-0052), the Vallee Foundation, the WorldQuant Foundation, The Pershing Square Sohn Cancer Research Alliance, and the National Institutes of Health (R01AI151059), the NSF (1840275), and the Alfred P. Sloan Foundation (G-2015-13964).

16.1.8.1: Case Study #1 - Human Health

Case study #1 – The Farmer's Flu

Disclaimer: This is a fictitious scenario created for the purposes of microbiome, health, disease, and environmental education. Any names, characters, places and incidents either are products of the author's imagination or are used fictitiously. Any resemblance to actual events or locales or persons, living or dead, is entirely coincidental.

Part I – Background and Problem

During one week at the end of January of 2019, a high number of flu-like cases have appeared in the small city of Bogart, Iowa which has a population of approximately 50,000 people. 157 individuals were hospitalized over a two-week period, and large proportion included children under the age of 5 years old. Many common symptoms were initially observed in the majority of the patients, however, other less common symptoms manifested in some ill patients after about a week and earlier in those who were immunocompromised and with co-morbidities.

Common symptoms included:

- fever
- headache
- muscle pain or body aches
- shortness of breath
- vomiting
- diarrhea
- cough
- congestion or runny nose
- fatigue

Less common symptoms included:

- stiff neck
- lethargy
- chest pain
- swelling of the throat
- severe joint pain
- green, yellow, or bloody mucus production
- facial redness and swelling

Article 1: Respiratory Viral Infection-Induced Microbiome Alterations and Secondary Bacterial Pneumonia

Article 2: Allergic inflammation alters the lung microbiome and hinders synergistic co-infection with H1N1 influenza virus and Streptococcus pneumoniae in C57BL/6 mice

Initial epidemiological data showed that diseased individuals all were at or were in contact with someone who visited the farmer's

market the previous weekend. The market was established more than 20 years ago, and each weekend merchants open their stalls selling everything from pottery, jewelry, and linens to produce, homemade jams, and even livestock. The market is considered to be the staple of town commerce and entertainment, giving Bogart its cozy home-town feel, and even many consumers and merchants come in from the smaller surrounding towns to benefit from the commerce.

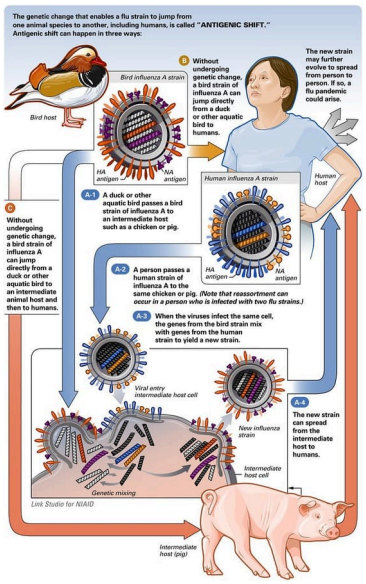

Figure 1. Antigenic shift of the Flu Virus. The genetic change that enables a flu strain to jump from one animal species to another, including humans, known as "antigenic shift." This process can happen in 3 ways: (A) strain is passed to an intermediate host from both human and animal where genetic recombination occurs, creating new strain that can spread to other animals. (B) without undergoing genetic change, the flu jumps directly from animal to human. (C) Without undergoing genetic change, the flu jumps to an intermediate host, then to humans.

Questions

1. What specific pathogens could be responsible for the observed symptoms and why would there be differences in the observed effects in different individuals?
2. Which microbiomes may be implicated in this disease and why?
3. Do you think this situation is a major public concern? Why or why not?

Case study #1 – The Farmer's Flu

Disclaimer: This is a fictitious scenario created for the purposes of microbiome, health, disease, and environmental education. Any names, characters, places and incidents either are products of the author's imagination or are used fictitiously. Any resemblance to actual events or locales or persons, living or dead, is entirely coincidental.

Part II – Approach, Implementation, Reasoning

Medical personnel took nasopharyngeal (NP) swabs of sick patients for testing. For children and older adults and those who were averse to NP swabs, nasal and throat swabs or aspirate specimens were collected (Flu specimen collection – CDC). Physicians prescribed various antiviral medication; either two doses per day of oral oseltamivir, four oral doses per day of umifenovir, or inhaled zanamivir for 5 days, and for patients in the hospital, one dose of intravenous peramivir or oral baloxavir for one day. They also prescribed prophylactic antimicrobials, including quinolones (moxifloxacin), cephalosporins (ceftriaxone and cefepime), or macrolides (azithromycin), or a glycopeptide (vancomycin). Other over the counter drugs were suggested to treat symptoms like fever and headache. Public health officials advised the community to get the flu vaccine as well.

Over the next few weeks, the number of cases increased and symptoms began to worsen for many. The initial assumption is a seasonal flu outbreak. Interestingly, more cases began to pop up in surrounding rural towns, and many patients were transported to the larger hospitals in the city to be put on ventilators. As mortality rates also began to rise, the CDC declared this situation a flu epidemic.

Article 1 – The respiratory microbiome and susceptibility to influenza virus infection

Article 2 – Secondary Bacterial Infections in Patients With Viral Pneumonia

Article 3 – Patterns in the longitudinal oropharyngeal microbiome evolution related to ventilator-associated pneumonia

---

Questions

1. What types of laboratory tests and analytical techniques do you think were being conducted? What problems could have arisen with the analysis of the patient's samples?
2. Why do you think both antibacterial and antiviral medication was prescribed? How would you explain the difference between treatments of a viral and a bacterial infection to a patient?
3. What reasons or factors could cause a high mortality rate in those infected with the influenza virus?

Any names, characters, places and incidents either are products of the author's imagination or are used fictitiously. Any resemblance to actual events or locales or persons, living or dead, is entirely coincidental.

Part III – Discussion

After several weeks of patient study and a rising number of mortality and cases, infections were confirmed to be from a mutated variant of influenza A (H1N1; i.e. swine flu). Medical officials believe the high mortality rate and other severe cases may be due to a secondary bacterial infection caused by a pathogen that is resistant to antimicrobials.

Further epidemiological analysis shows that the initial original cases were specifically in individuals who visited the livestock section of the farmer's market for an extended period of time.

Apologies, the video and audio are a bit glitchy.

Last line of defense antibiotics, polymixin (colistin) and carbapenems, were prescribed for patients not responding to the initial antibiotics. These patients were also put under quarantine in ICU wards as their symptoms began to worsen, which additionally included abdominal pain, bloody stool, and severe diarrhea that persisted in patients even after being discharged from the hospital.

Questions

1. How do you think antibiotic resistance of the secondary bacterial pathogen came about?
2. How could chemotherapy affect various microbiomes and potentially contribute to pathogenesis and other disease symptoms?
3. How would you inform the public about this situation, and what measures would you suggest to prevent transmission or

recurrence?

Case study #1 – The Farmer's Flu

Disclaimer: This is a fictitious scenario created for the purposes of microbiome, health, disease, and environmental education. Any names, characters, places and incidents either are products of the author's imagination or are used fictitiously. Any resemblance to actual events or locales or persons, living or dead, is entirely coincidental.

Part IV – Resolution

Research scientists, medical professionals, and epidemiologists finally pieced the 'Farmer's Flu' epidemic puzzle together using next generation sequencing technology and keeping detailed records of observational data.

Two farmers from a nearby rural town contracted the novel swine flu variant. They then brought the pigs to market in Bogart, where the flu spread. However, they not only spread the flu variant, but also a highly contagious antibiotic-resistant strain of *Haemophilus influenza* type B (Hib). One of the farmers was sick the week prior and therefore immunocompromised which allowed the development of this secondary infection. It is likely that this strain of *H. influenza* acquired antibiotic resistance via horizontal gene transfer from *Haemophilus parasuis,* which is commonly found in pigs.

As this respiratory disease was treated with multiple ineffective prophylactic antimicrobial drugs, patients' resident microbiomes became depleted and allowed for another infection by opportunistic pathogens. In the case of those who were hospitalized, many developed another secondary infection by *Clostridioides difficile*, resulting in gastrointestinal distress.

After a few months, with the use of both old and new treatment options, outreach to the public with information about the diseases, and proper community compliance, the epidemic came to an end. Bogart resumed as a quiet cozy town, and still holds its locally famed farmer's market.

Article 1 – Basic Characterization of Natural Transformation in a Highly Transformable Haemophilus parasuis Strain SC1401

Article 2 – The Gut-Lung Axis in Health and Respiratory Diseases: A Place for Inter-Organ and Inter-Kingdom Crosstalks

Article 3 – Translating Lung Microbiome Profiles into the Next-Generation Diagnostic Gold Standard for Pneumonia: a Clinical Investigator's Perspective

---

Questions

1. How is the gut microbiome linked with the oral and lung microbiomes? Explain how both of the secondary infections by *H. influenza* and *C. difficile* in this case could be related by their respective microbiomes.
2. What other diseases, conditions, or treatments have similar multi-microbiome effects?
3. What are some examples of novel microbiome diagnostic and treatments that could work to restore the affected microbiomes?

16.1.8.2: Case Study #2 - Environment

Case study #2 – The Land is Sick

Disclaimer: This is a fictitious scenario created for the purposes of microbiome, health, disease, and environmental education. Any names, characters, places and incidents either are products of the author's imagination or are used fictitiously. Any resemblance to actual events or locales or persons, living or dead, is entirely coincidental.

Part I – Background and Problem

Coffee production in South America has drastically decreased in the 2021-23 growing seasons. Specifically, the major farms in Columbia and Brazil which collectively contribute over half of each countries coffee (both specialty and commercial) production, have had severe crop failures. As a result, the price of a cup of coffee has noticeably increased, putting financial strain on suppliers and businesses.

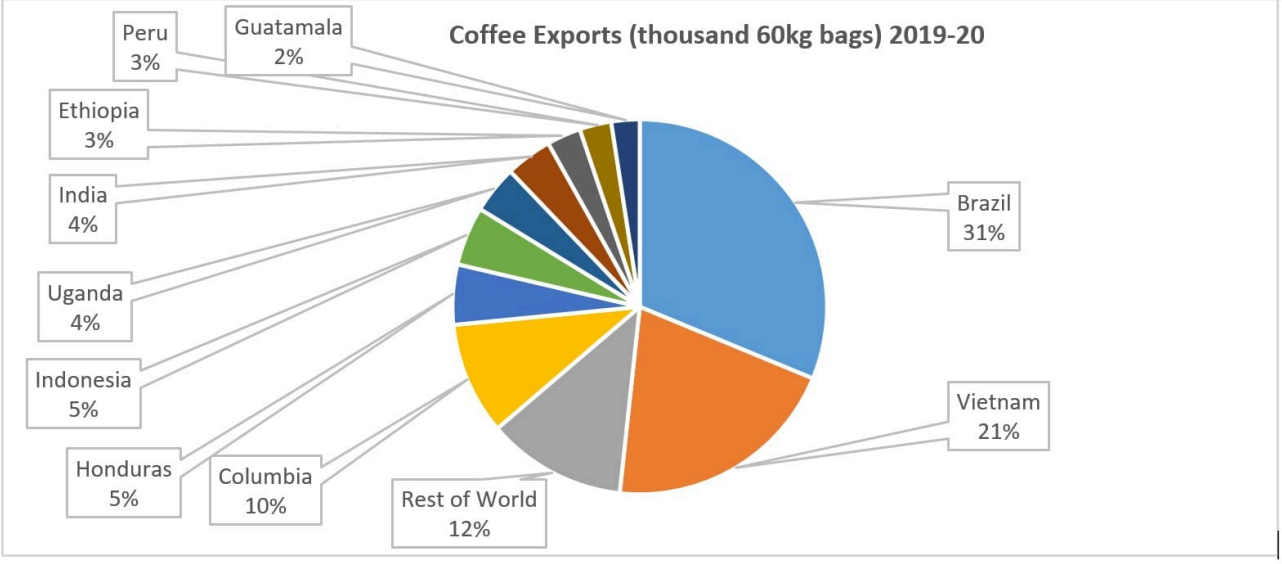

Figure 1. Coffee exports by country 2019-20. Source: International Coffee Organization

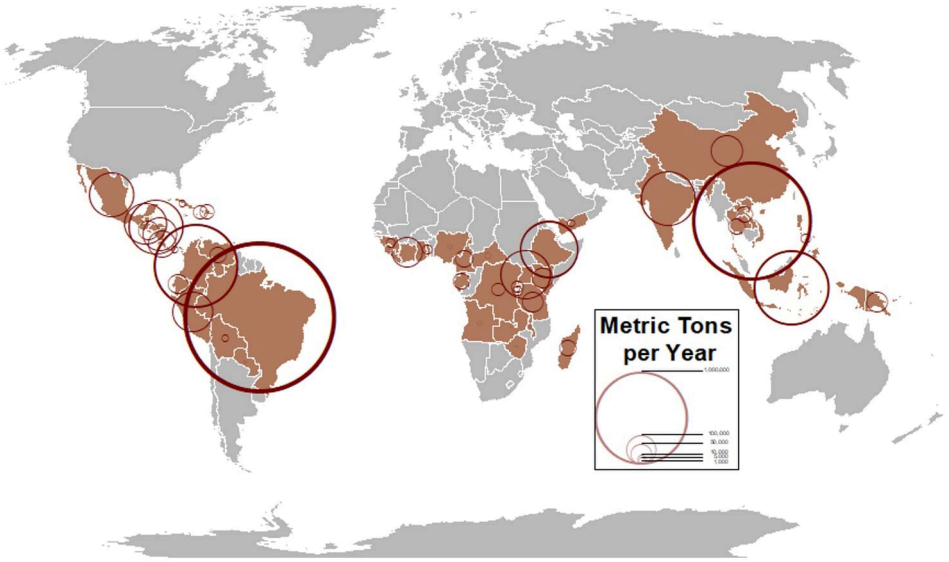

Figure 2. A world map of countries by coffee production, 2019.

Interestingly, the few years prior to this decline, coffee production was at an all-time high, with more coffee in the market than demanded. This dropped the price of coffee, and in many cases original farmers were not fairly compensated.

The International Coffee Organization (ICO) has tasked a team of researchers to identify potential problems to South American coffee plant failure and provide quick and efficient resolution.

Questions

1. As a scientific researcher, what are some factors you would take into consideration when addressing this problem?
2. What type of environmental microbiomes could be implicated in coffee plant crop failure and why?
3. Should other coffee farms in countries besides those in South America be worried about similar failure in their crops? Why or why not?

Case study #2 – The Land is Sick

Disclaimer: This is a fictitious scenario created for the purposes of microbiome, health, disease, and environmental education. Any names, characters, places and incidents either are products of the author's imagination or are used fictitiously. Any resemblance to actual events or locales or persons, living or dead, is entirely coincidental.

Part II – Approach, Implementation, Reasoning

Upon initial inspection, the unhealthy coffee plants exhibited yellowing of leaves, appearance of red-brown lesions, abnormal shape, damaged coffee berries, and little new growth or production. Researchers decided to take samples of healthy and unhealthy leaves and berries, as well as soil and root samples.

Article 2 – A metagenomics approach in the evaluation of the soil microbiome in coffee plantations under organic and conventional production in tropical agroecosystems

Video 1 – #2 Producer Crossover 2019

Video 2 – How countries farm and make coffee differently

Over the next year, other plantations in Columbia and Central American begin to experience similar declines in coffee plant health. Farmers were questioned about any changes in practices, and while there have been some adjustments do to the fluctuating coffee prices, traditional farming techniques have remained the same for the most part in smaller plantations. Larger plantations with intensive farming made more changes due to trader suggestions on improving yields including application of different fertilizers and hiring less experienced workers.

Questions

1. What type of analytical techniques do you think were or should be performed on the samples taken?
2. How could the observed symptoms of the unhealthy plants be connected to an associated microbiome?
3. How could human intervention exacerbate or ameliorate this situation?

Case study #2 – The Land is Sick

Disclaimer: This is a fictitious scenario created for the purposes of microbiome, health, disease, and environmental education. Any names, characters, places and incidents either are products of the author's imagination or are used fictitiously. Any resemblance to actual events or locales or persons, living or dead, is entirely coincidental.

Part III – Discussion

Analysis of the negatively affected plantations' soil showed a decline in plant growth promoting bacteria and mycorrhizae and an increase in bacterial and fungal pathogens like *Pseudomonas syringae* and *Cercospora coffeicola*.

Over the next few years (2022-24) coffee plants still struggle to grow in Central and South America. Other parts of the world, such as Vietnam and other Asian countries, are seeing a decline in crop health also, further contributing to global coffee market troubles. Many of these farms switched from shade-grown to intense sun-grown coffee to try to meet needs for demand. Larger corporations and roasters have purchased many of the smaller family farms to try to recoup losses and implement 'new and improved' growing strategies for increased production. This included switching to primarily sun-grown coffee, and application of large amounts of synthetic nitrogen fertilizer.

---

Questions

1. What factors could cause these changes in the soil microbiomes?
2. Why do you think coffee plantations across the globe are beginning to fail as well?
3. How does natural biodiversity benefit ecosystem health on both a micro and macro scale?

Case study #2 – The Land is Sick

Disclaimer: This is a fictitious scenario created for the purposes of microbiome, health, disease, and environmental education. Any names, characters, places and incidents either are products of the author's imagination or are used fictitiously. Any resemblance to actual events or locales or persons, living or dead, is entirely coincidental.

Part IV – Resolution

In 2030, most varieties of coffee are extinct, and only small amounts of coffee are produced on shade grown farms further from the equator. It appears that coffee plantations were severely impacted by increasing global temperatures, which altered ecosystem dynamics and promoted pathogen and pest invasion. Fungi, bacteria, and arthropods devastated already struggling coffee farms and with a major switch to sun-grown coffee, soil microbiomes were depleted and disease spread rapidly through monoculture crops. This switchover was prompted by an energy drink corporation, KAPOW!, which wanted to corner the caffeine market and boost production, though their expertise in growing coffee was lacking and the excessive use of synthetic fertilizers on already sun baked land which requires much more watering further doomed plantations. At least they now produce a cheap "coffee" flavored energy drink. It tastes terrible.

16.1.8.3: Case Study #3 - Synthesis (Create Your Own)

Develop your own case study related to microbiomes!

Group members (4-5) will develop and write an original case study involving a microbiome and health or environmental condition. Topics must be approved by the instructor beforehand. The case study should consist of 3 parts: (i) background and problem/issue, (ii) approach to solve, implementation, and reasoning, (iii) discussion of progression of the case study. The final part, (iv) resolution and conclusion will be completed by another group and presented over. The case study should have an interesting title, include references, images, figures, etc. from relevant resources (be sure to use in-text citations and include references at the end), and 3 critical thinking questions concluding each part (9 total).

The Integrative Human Microbiome Project

The Integrative HMP (iHMP) Research Network Consortium

Abstract

The NIH Human Microbiome Project (HMP) has been carried out over ten years and two phases to provide resources, methods, and discoveries that link interactions between humans and their microbiomes to health-related outcomes. The recently completed second phase, the Integrative Human Microbiome Project, comprised studies of dynamic changes in the microbiome and host under three conditions: pregnancy and preterm birth; inflammatory bowel diseases; and stressors that affect individuals with prediabetes. The associated research begins to elucidate mechanisms of host–microbiome interactions under these conditions, provides unique data resources (at the HMP Data Coordination Center), and represents a paradigm for future multi-omic studies of the human microbiome.

Main

Although the 'omics era has accelerated all aspects of biological research, its effects have been particularly apparent in studies of microbial communities and the human microbiome. In the 18 years since the publication of the first human genome, studies of the microbiome have grown from culture-based surveys of the oral cavity and gut to molecular profiles of microbial biochemistry in all ecological niches of the human body[1,2,3]. Epidemiology and model systems have been used to identify associations between changes in the microbiome and conditions ranging from autism[4] to cancer[5,6,7], and microbial and immunological mechanisms have been identified that affect, for example, the efficacy of drugs used to treat cardiac conditions[8] or survival during graft-versus-host disease[9].

Contemporary studies of the human microbiome have also been a source of basic biological and translational surprises, exposing a compelling range of novel findings and open questions. Every human being appears to carry their own, largely individual, suite of microbial strains[10,11], which are acquired early in life[12,13,14], differ between environments and populations[15,16], and can persist for years[17] or undergo relatively rapid transitions[18]. Microbial diversity manifests differently in different ecological niches of the body; for example, greater diversity is generally expected in the gut, but can be associated with dysbiotic states and risk of adverse events in the female reproductive tract. The microbiome can be perturbed by conditions such as inflammatory bowel disease and diabetes, but a variety of microbiome-linked health states, and the underpinnings of these links, remain unexplored. How dynamic is the microbiome during processes such as pregnancy or viral infection? Which changes in the microbiome represent causes rather than effects of changes in health? Which molecular elements of a personalized microbiome might be responsible for health outcomes, and how do they integrate with and maintain physiological processes such as the immune system and metabolism? And what ecological elements dictate the success of a microbiota transplant, and why are they successful in treating some individuals and conditions, but not others?

The National Institutes of Health Human Microbiome Project was one of the first large-scale initiatives to address a subset of these questions[19] (Fig. 1). Launched in 2007[20], the first phase of the program sought to determine whether there were common elements to 'healthy' microbiomes, in the absence of overt disease. Studies of both a baseline adult population[21,22,23] and 'demonstration' populations with specific disease states established typical ranges (for some populations) of microbial membership and enzymatic repertoires across the body, combinations of metabolic functions that were either prevalent or strain-specific, and some of the host factors (such as race or ethnicity) that determine this variation. Studies of targeted populations identified ecological states of niches such as the vagina[24,25], skin[26,27,28], and gut[29,30,31,32,33], among many others (https://www.hmpdacc.org/health/projectdemos.php). This first phase of the HMP (HMP1) thus yielded a wealth of community

resources: nucleotide sequences of microorganisms and communities from a large number of isolates, individuals, and populations (http://hmpdacc.org)[34,35,36,37]; protocols to support reproducible body-wide microbiome sampling and data generation[38,39,40]; and computational methods for microbiome analysis and epidemiology[41,42,43,44,45,46,47].

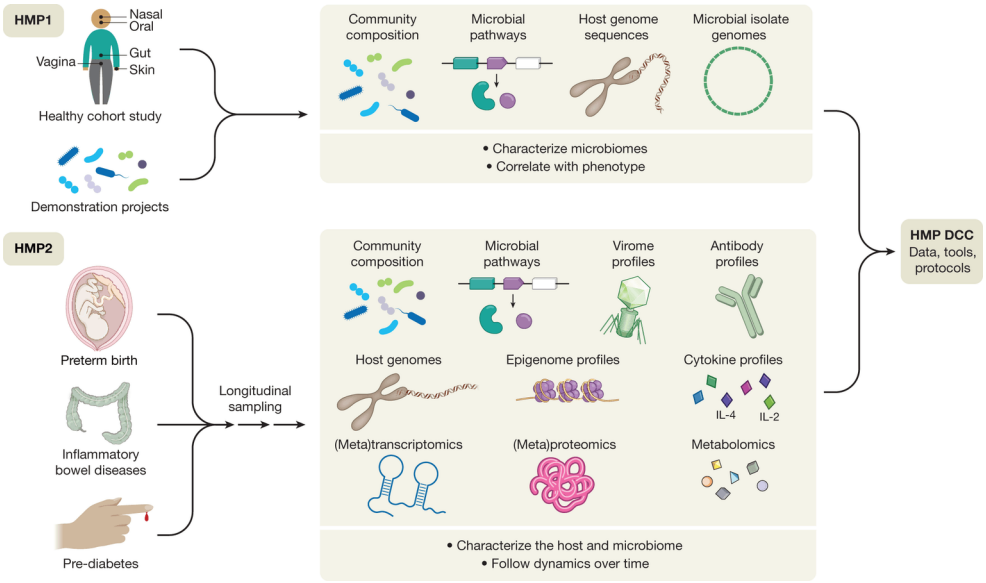

Fig. 1 The first and second phases of the Human Microbiome Project. The ten-year NIH Human Microbiome Project (HMP) program, organized into two phases (HMP1 and HMP2), developed reference sequences, multi-omic data sets, computational and statistical tools, and analytical and clinical protocols as resources for the broader research community. The HMP1 focused on the characterization of microbial communities from numerous body sites (oral, nasal, vaginal, gut, and skin) in a baseline study of healthy adult subjects, and included a set of demonstration projects that focused on specific diseases or disorders. The HMP2 expanded the repertoire of biological properties analysed for both host and microbiome in three longitudinal cohort studies of representative microbiome-associated conditions: pregnancy and preterm birth (vaginal microbiomes of pregnant women), inflammatory bowel diseases (gut microbiome) and prediabetes (gut and nasal microbiomes). These studies followed the dynamics of these conditions through multi-omic analyses of multiple measurement types over time, including changes in microbial community composition, viromics, metabolomic profiles, gene expression and protein profiles from both host and microbiome, and host-specific properties such as genetic, epigenomic, antibody, and cytokine profiles, along with other study-specific features. All sequences and multi-omic data, clinical information, and tools from both HMP1 and HMP2 are housed in the HMP Data Coordination Center (DCC) or referenced public or controlled-access repositories to serve as a central resource for the research community.

One of the main findings of the HMP1 was that the taxonomic composition of the microbiome alone was often not a good correlate with host phenotype—this tended to be better predicted by prevalent microbial molecular function or personalized strain-specific makeup[21]. This finding served as the foundation for the development of the second phase of the HMP, the Integrative HMP (iHMP or HMP2)[48], which was designed to explore host–microbiome interplay, including immunity, metabolism, and dynamic molecular activity, to gain a more holistic view of host–microbe interactions over time. This multi-omic program sought to expand the resource base available to the microbiome research community, to begin to address the relationship between host and microbiome mechanistically, and to address the questions introduced above. Disease-targeted projects within the HMP2 were therefore encouraged to use multiple complementary approaches in order to assess the mechanisms of human and microbial activity longitudinally and to provide protocols, data, and biospecimens for future work. These projects included three studies that followed the dynamics of human health and disease during conditions with known microbiome interactions, thus addressing important health outcomes directly while also serving as models of 'typical' microbiome-associated conditions of broad interest to the research community. These comprised pregnancy and preterm birth (PTB); inflammatory bowel diseases (IBD); and stressors that affect individuals with prediabetes. These studies, which have now reached the first stage of completion[49,50,51], together provide a wealth of information and insights about not only microbial dynamics, but also associated human host responses and microbial inter-relationships. A collection of more than 20 manuscripts to date describe some of these results at https://www.nature.com/collections/fiabfcjbfj, and together they provide a rich multi-omic data resource to be mined by future work (http://www.ihmpdcc.org).

The vaginal microbiome, pregnancy and preterm birth

Preterm birth can have devastating consequences for newborn babies, including death and long-term disability. In the United

States, approximately 10% of births are premature[52], and the incidence is even greater in lower-resource countries. Environmental factors, including the microbiome of the female reproductive tract, are important contributors to prematurity. Notably, these factors have a greater effect in women of African ancestry, who also bear the highest burden of PTB[53]. Infant mortality has been reduced in recent decades, but the incidence of PTB has not decreased[54], and progress in predicting individual risk of PTB has stalled. During pregnancy, the maternal immune system maintains a delicate balance of pro- and anti-inflammatory effectors[55], and contributors to PTB include breakdown in maternal–fetal tolerance, vascular disorders, stress, cervical insufficiency, premature rupture of the fetal membranes, and intra-amniotic infection[56]. Microbial ascension into the uterus is thought to precipitate PTB by disrupting the maternal immune balance, leading to spontaneous preterm labour, and/or by the release of microbial products (for example, collagenases, proteases or toxins) that compromise the integrity of fetal membranes and lead to premature rupture of the membranes[57].

The Multi-Omic Microbiome Study: Pregnancy Initiative (MOMS-PI) research group, as part of HMP2, characterized the microbiomes of pregnant women to gauge their effects on risk of PTB (Fig. 2). The project followed 1,527 women longitudinally through pregnancy and involved the collection of 2006,437 specimens, including maternal vaginal, buccal, rectal, skin and nares swabs, blood, urine, and birth products, as well as infant cord and cord blood, meconium and first stool, buccal, skin and rectal swabs. Subsets of these specimens underwent 16S rRNA gene taxonomic analysis, metagenomic and metatranscriptomic sequencing, cytokine profiling, lipidomics analysis, and bacterial genome analysis. The MOMS-PI team analysed 12,0039 samples from 597 pregnancies to investigate the dynamics of the microbiome and its interactions with the host during pregnancy leading to PTB[50].

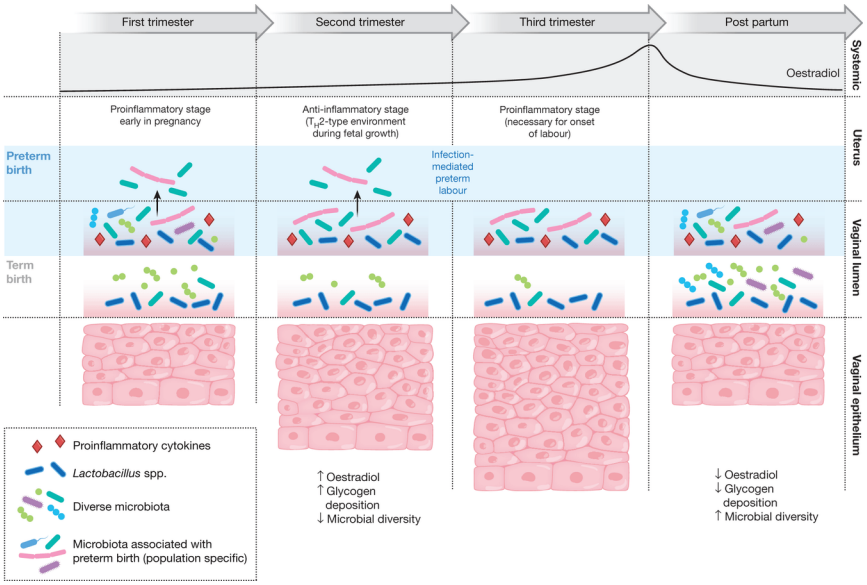

Fig. 2. The vaginal microbiome and its relationships with host factors in pregnancy and preterm birth. The MOMS-PI project followed 1,527 pregnancies longitudinally and involved the collection of 2006,437 biospecimens for analysis of host and microbial factors (16S amplicon, metagenomic, and metatranscriptomic sequencing; cytokine profiling; metabolomics; proteomics; genomics; and microbial isolate culture). Around 600 pregnancies were analysed in depth to assess features that lead to preterm birth; this analysis identified both host (for example, cytokine) and microbial (for example, ecological and specific strain) factors. As pregnancy progresses, with predictable changes in systemic oestradiol levels, the uterine and vaginal environments undergo various changes. The uterus switches from an early pro-inflammatory condition to an anti-inflammatory condition in the second trimester, and then back to a pro-inflammatory condition before the onset of labour. Meanwhile, specific changes in the microbiome of the vaginal lumen can be associated with preterm birth, possibly through mechanisms involving microorganisms travelling from the vagina to the uterus. The figure depicts an overview of longitudinal changes in the vaginal mucosal ecosystem and uterus during pregnancy.

These multi-omic investigations identified temporal changes in the vaginal microbiome associated with full-term pregnancies. Women who often began pregnancy with a vaginal microbiome of greater ecological complexity generally converged towards a more homogeneous *Lactobacillus*-dominated microbiome by the second trimester[58]. Interestingly, this trend was most pronounced in women of African ancestry with lower socioeconomic profiles. Although the overall MOMS-PI cohort was demographically diverse, most women who experienced spontaneous PTB at less than 37 weeks of gestation were of African ancestry. The MOMS-PI team (http://vmc.vcu.edu/momspi) also identified signatures of higher risk for PTB in women who experienced spontaneous preterm birth at less than 37 weeks of gestation[50]. Women who went on to experience spontaneous

PTB were less likely to exhibit a vaginal microbiota dominated by *Lactobacillus crispatus*, as previously reported in other populations[59,60,61,62], and were more likely to exhibit an increased proportional abundance of several taxa including *Sneathia amnii*, *Prevotella*-related clades, a Lachnospiraceae taxon known as BVAB1, and a *Saccharibacteria* bacterium known as TM7-H1. Notably, these taxa were also associated with low levels of vitamin D[63], suggesting that the vaginal microbiome might mediate a link between PTB risk and vitamin D deficiency[64]. The signatures of PTB were also reflected in metagenomic and metatranscriptomic measurements, and vaginal pro-inflammatory cytokines (including IL-1β, IL-6, MIP-1β and eotaxin-1) were positively correlated with PTB-associated taxa. Conveniently for future possible interventions, the vaginal microbiomes of mothers who experienced PTB were most distinct from those of control mothers early in pregnancy, and a preliminary model to predict risk of PTB was most sensitive and specific using vaginal microbiome profiles from samples collected before 24 weeks of gestation.

The MOMS-PI research group identified intriguing associations between the vaginal microbiota, host response, and pregnancy outcomes that are consistent with the involvement of microorganisms ascending from the vagina in at least some cases of spontaneous PTB. As an essential next step, the contribution of racial and demographic background to the vaginal microbiome in pregnancy with relation to pregnancy outcomes must be fully explored through harmonized, large-scale studies[50]. It is clear that PTB has a complex aetiology[56]. The relative contributions of fetal and maternal genetics and epigenetics, particularly as related to genetic variation of the innate immune system, should be explored. Harmonized large-scale studies would permit the development of population-specific risk assessment algorithms using vaginal microbiome profiles, features from genetic and prenatal (fetal) genetic screens, biomarkers such as cytokines and metabolites, and key clinical features from classic markers of risk including maternal age, body mass index, pregnancy history (including history of PTB), cervical length, and measures of stress and other environmental exposures. With the addition of new data from the microbiome, other environmental factors, and multi-omic inputs, new algorithms promise to improve our ability to predict risk of PTB early in pregnancy, to facilitate clinical trials by identifying high-risk patients, and ultimately to stratify patient populations into treatment groups.

The gut microbiome and inflammatory bowel disease

Studies of the gut microbiome in gastrointestinal disease have a particularly long and detailed history, especially in complex chronic conditions such as the inflammatory bowel diseases (IBD). IBD, including Crohn's disease and ulcerative colitis, affects millions of individuals worldwide, with increasing incidence over the past 50 years or more coinciding with multiple factors such as westernization, urbanization, shifts in dietary patterns, antimicrobial exposure, and many more that could influence host–microbiome homeostasis[65]. The microbiome has long been implicated in IBD, potentially as a causative or risk factor[66,67], as an explanation for heterogeneity in treatment response (that is, some individuals respond well to relatively benign aminosalicylates or corticosteroids whereas others still experience severe inflammation even after surgical intervention)[68], or as a novel point of therapeutic intervention (for example, by transplantation of faecal microbiota[69,70]). Although meta-omic techniques have been used to identify functionally consistent microbial responses that help to explain the gut microbiome's role as part of a pro-inflammatory feedback loop in the gut during disease[71], and a few strains of microorganisms have been shown to be IBD-specific[72], no comprehensive model of specific microbial, molecular, and immune interactions yet exists to explain the disease's onset and dynamic progression.

Therefore, to better characterize mechanisms of host–microbiome dysregulation during disease, the Inflammatory Bowel Disease Multi'omics Database (IBDMDB) project followed 132 individuals from five clinical centres over the course of one year each as part of HMP2 (Fig. 3). Integrated longitudinal molecular profiles of microbial and host activity were generated by analysing 1,785 stool samples (self-collected and sent by mail every two weeks), 651 intestinal biopsies (collected colonoscopically at baseline), and 529 quarterly blood samples. To the extent possible, multiple molecular profiles were generated from the same sets of samples, including stool metagenomes, metatranscriptomes[73], metaproteomes, viromes, metabolomes[74,75], host exomes, epigenomes, transcriptomes, and serological profiles, among others, allowing concurrent changes to be observed in multiple types of host and microbial molecular and clinical activity over time. Protocols and results from the study, further information about its infrastructure, and both raw and processed[76,77] data products are available through the IBDMDB data portal (http://ibdmdb.org), from the HMP2 Data Coordination Center (DCC; http://ihmpdcc.org), and in the accompanying manuscript[49].

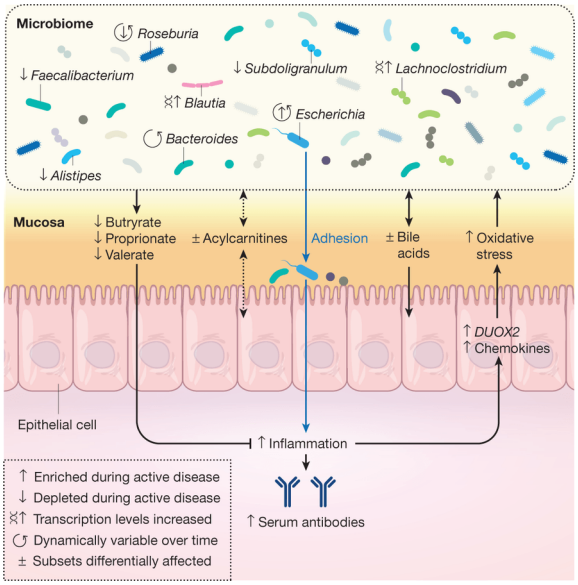

Fig. 3. Host-microbiome dynamics in IBD. The IBDMDB followed more than 100 participants with IBD (Crohn's disease or ulcerative colitis), as well control individuals without IBD, for one year each to assess host and microbial molecular activity during changes in disease activity and gastrointestinal inflammation. Nearly all measured host–microbiome properties showed changes in either activity or stability during disease, including those shown here—not only microbial taxa and microbial transcription, but also host- and microbiota-derived small molecules in the gut, epithelial transcriptional responses at multiple points along the colon, and circulating antibody levels in peripheral blood serology.

This unique study design allowed the IBDMDB to identify a variety of differences in the microbiome and host immune response over time during the course of the disease. Indeed, these dynamic changes were of much greater magnitude than were cross-sectional differences among clinical phenotypes, which have been emphasized by previous studies[67,71,78,79]. This was due in part to the prospective nature of the cohort, which recruited patients with Crohn's disease or ulcerative colitis during both active and quiescent periods of disease, showing that microbial compositions in patients with IBD often revert to more control-like, 'baseline' configurations when the disease is not active. By identifying the gut microbial configurations that were most different from baseline—regardless of specific disease state—the study defined a dysbiosis score that called out highly divergent microbial compositions, which share many features common to an overall inflammatory response (for example, tolerance to oxidative stress). This dysbiosis was not unique to the microbial response to inflammation, however, and was associated with other host and biochemical alterations, pointing to new potential directions for management of systemic dysregulation in IBD. These included large shifts in acylcarnitine pools and bile acids, increased serum antibody levels, and alterations in transcription for several microbial species. Concurrent transcriptomics and 16S amplicon mucosal community profiling from biopsies also identified potential host factors that might be able to shape the microbial community, in particular several chemokines, highlighting these as being involved in a potentially dysregulated interaction during periods of disease activity[49].

The study's longitudinal multi-omic profiles further allowed researchers to characterize the stability and dynamics of host–microbiome interactions during disease, in particular highlighting ways in which community state and immune responses are distinctly less stable in participants with IBD than in control, healthy individuals. In numerous cases, the microbiome of a participant with IBD changed completely over the course of only weeks (measured as maximal Bray–Curtis dissimilarity to earlier samples from the same subject), whereas such shifts were rare in individuals without IBD. The main microbial contributors to these large-scale shifts from one time point to the next largely mirrored the differences observed in dysbiosis, and the shifts frequently marked the entrance into or exit from periods of dysbiosis. Finally, the study's long-term, complementary molecular measurements enabled the construction of a network of more than 2,900 significant host and microbial cellular and molecular interactors during IBD, ranging from specific microbial taxa to human transcripts and small molecule metabolites. This network of mechanistic associations identified several key components that are central to the alterations seen in IBD, highlighting octanoyl carnitine, several lipids and short-chain fatty acids, the taxa *Faecalibacterium*, *Subdoligranulum*, *Roseburia*, *Alistipes*, and *Escherichia*, some at both the metagenomic and metatranscriptomic levels, and host regulators of interleukins[49]. Networks of mechanistic associations such as this may provide the key to disentangling the complex system of interactions that results in chronic inflammation in IBD and in other systemic microbiome-linked immune diseases.

Multi-omics profiling in prediabetes

Type 2 diabetes mellitus (T2D) affects more than 10% of the adult US population, and another 30% show early signs of the

disease (referred to as prediabetes)[80]; 70% of the latter will develop diabetes in their lifetime. T2D is characterized by complex host–microbiome interactions[81,82], but little is known about systemic alterations during prediabetes, their effects on biological processes, or the critical transition to full-blown T2D. Prediabetes and T2D are often associated with insulin resistance, and thus studies of individuals with prediabetes or insulin resistance offer unique opportunities to investigate the earliest stages of diabetes. It is essential to create a global and simultaneous profile of both host and microbial molecules in individuals with prediabetes over time, in order to fully understand the molecular pathways that are affected in people with prediabetes and/or insulin resistance and how these conditions affect both biological responses to environmental challenges (for example, viral infections[83,84]) and the onset of T2D.

To better understand T2D at its earliest stages, as part of iHMP, the Integrated Personal 'Omics Project (IPOP)[85] followed 106 healthy and prediabetic individuals during quarterly periods of health, respiratory viral infection (RVI) and other perturbations over about four years[51] (Fig. 4). In one such perturbation, a subset of 23 individuals underwent a directed weight gain followed by weight loss[86]. In total, 1,092 collections across all participants were profiled. For each visit, blood was assayed for host molecular 'omics profiling and two types of samples, nasal swabs and faeces, were collected for microbial profiling. Each participant's exome was sequenced once; otherwise, for each visit, 13,379 transcripts were profiled from peripheral blood mononuclear cells, 722 metabolites and 302 proteins from plasma, and 62 cytokines and growth factors from serum. In addition, thousands of gut and nasal microbial taxa and computationally predicted genes were profiled using 16S rRNA amplicons. All visits were also intensively characterized by 51 clinical laboratory tests. In addition, because of the focus on T2D, a number of glucose dysregulation tests were performed, including measurements of fasting glucose and haemoglobin A1C levels, oral glucose tolerance tests, and tests of insulin resistance.

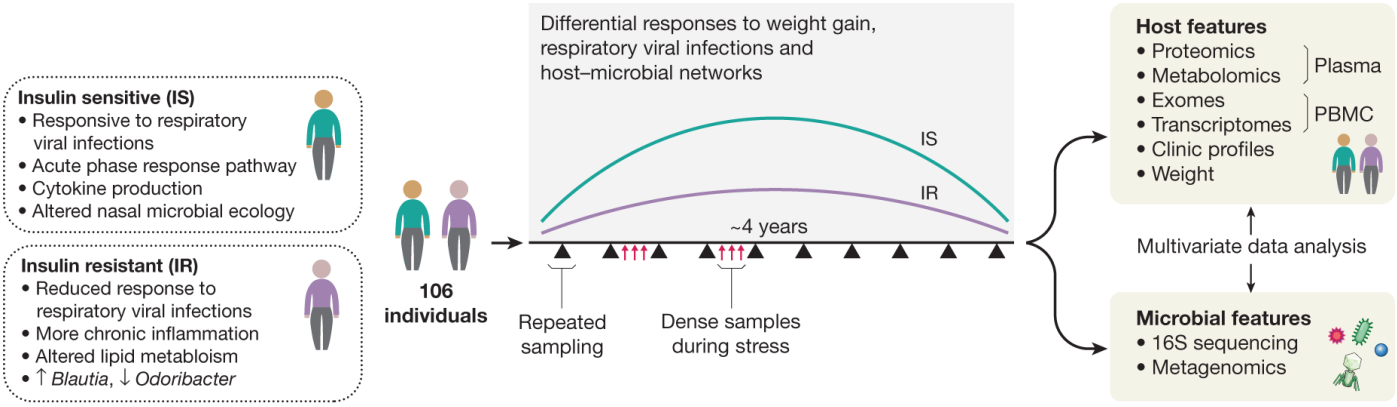

Fig. 4. Differential host and microbial responses to dietary perturbations and infectious disease in individuals with prediabetes. For integrated personal 'omics profiling of the microbiome during prediabetes, 106 participants were followed for up to four years, with samples (primarily blood and stool) collected quarterly and additional samples collected during periods of RVI and other stresses. The genomes of the participants were sequenced and measurements of transcriptomes, proteomes, metabolomes, and microbiomes taken at each visit, in addition to clinical details. Insulin-resistant individuals showed differences from insulin-sensitive participants in various measurements, both at baseline and in response to the stresses such as weight loss and RVI.

Baseline measurements were generally stable within individuals, even for long periods of time, with only some analytes changing significantly over time[51]. However, many analytes, such as clinical laboratory measurements, cytokine profiles, and gut microbial taxa (mostly those of low abundance) were highly variable between individuals. Participants who were ultimately insulin-resistant had distinguishable molecular and microbial patterns at baseline from those who were ultimately insulin-sensitive, and an analyte test was devised as part of the study in order to differentiate them. Notably, individuals undergoing RVI or changes in weight showed thousands of specific molecular and microbial changes during these perturbations, and insulin-resistant and insulin-sensitive individuals responded very differently to perturbations. For example, during RVI, insulin-resistant participants showed substantially decreased and delayed inflammatory responses (for example, the acute phase response and IL-1 signalling) and altered gut microbial changes when compared with insulin-sensitive participants (for example, in Lachnospiraceae and Rikenellaceae but not bacilli). Accordingly, there were fewer changes in nasal microbiota in insulin-resistant participants, and both the richness and the diversity of nasal microorganisms decreased during RVI in insulin-sensitive but not insulin-resistant participants. Furthermore, global co-association analyses among the thousands of profiled molecules revealed specific associations in insulin-resistant individuals that differ from those seen in insulin-sensitive participants and vice versa, indicating different patterns of host–microbiome interactions in the two groups[51].

Another important goal of the study was to assess how host–microbiome multi-omics and related emerging technologies can

be used to better manage patients' health. We found that taking millions of measurements per individual over time enabled the early detection of potential disease states[51,87]. These included early detection of T2D, which developed differently among participants and was better detectable with varied assays; for example, some individuals first exhibited measurements in the diabetic range on tests of fasting glucose, whereas others did so on tests of haemoglobin A1c, oral glucose tolerance tests, or even continuous glucose monitoring. These results, together with detailed characterization of glucose dysregulation over time, illustrate the heterogeneity of T2D development. Overall, the data led to microbially linked, clinically actionable health discoveries in a number of diseases in addition to T2D, including metabolic disease, cardiovascular disease, haematological or oncological conditions, and other areas; these signs were often present before symptom onset, demonstrating the power of using big data, including the microbiome, to better manage human health.

Resources from the HMP2

Together, the HMP1 and HMP2 phases have produced a total of 42 terabytes of multi-omic data, which are archived and curated by the DCC at at http://ihmpdcc.org and in public and/or controlled-access repositories such as the Sequence Read Archive (SRA; https://www.ncbi.nlm.nih.gov/sra), the Database of Genotypes and Phenotypes (dbGaP; https://www.ncbi.nlm.nih.gov/gap/), Metabolomics Workbench (https://www.metabolomicsworkbench.org/), and others (Fig. 5). All data on the DCC is available for unrestricted use, with a subset of project metadata also being shared when permitted by institutional review boards (IRBs), and other restricted data (for example, human genome sequences and protected metadata) available through controlled access at dbGaP (projects PRJNA398089, PRJNA430481, PRJNA430482, PRJNA326441, phs001719, phs000256, phs001626, phs001523, and others). The formal data models and associated entity relationship schemas produced by all phases of the HMP are freely available at https://github.com/ihmpdcc/osdf-schemas. The DCC website allows users to find, query, search, visualize, and download data from thousands of samples with associated metadata. Once a user has identified a set of files, conditions, subjects, or phenotypes of interest, he or she can add this set to a shopping cart for further operations. Files can then be directly downloaded for use at the user's local site or in the cloud. The HMP DCC efforts are thus by design consistent with the NIH's stated goals to make all data generated from NIH funding findable, accessible, interoperable, and reusable[88]. The success of these efforts is evidenced by a consistently high rate of user access to the web resources, with 9,000–12,000 user sessions each month, and a greater throughput anticipated after the publication of these resources here.

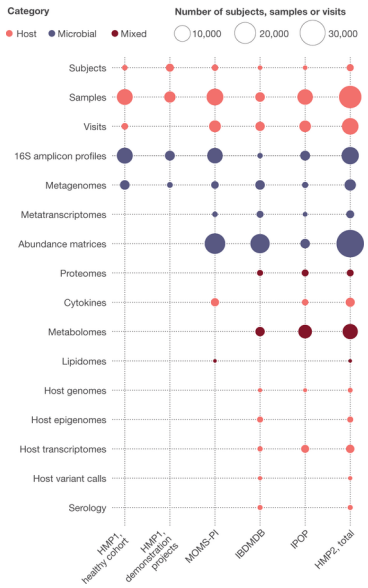

Fig. 5. Resources from HMP1 and HMP2 available at the DCC. The HMP DCC (http://ihmpdcc.org) hosts raw and processed data from both phases of the Human Microbiome Project, comprising in total more than 42 Tb of multi-omic data. From the HMP1, these include 16S rRNA gene amplicons and metagenomes from the healthy human subjects (HHS) baseline cohort, as well as resources from demonstration projects (https://www.hmpdacc.org/health/projectdemos.php) and genomes of associated microbial isolates. From the HMP2, these include data that IRBs gave permission to be made publicly available from the pregnancy and preterm birth (MOMS-PI), inflammatory bowel disease (IBDMDB), and prediabetes (IPOP) projects, with links to raw data in other repositories. Additional data deposited elsewhere including microbial reference genomes, HMP1 human genomes, and controlled access data for all HMP2 projects is also linked from the DCC. Categories of data are colour coded, and the number of items in each dataset is indicated by the size of the circles.

Complementary host–microbiome interactions

Although each of the three HMP2 studies revealed new biology within their respective areas of health and disease, a surprising range of host–microbiome immune and ecological features were common among them. The combination of shotgun metagenomics, untargeted metabolomics, and immunoprofiling was particularly effective, as in all projects this subset of molecular measurements tended to efficiently capture interpretable host and microbial properties that are linked to disease. Conversely, genetic variants were generally difficult to link to the microbiome in such small populations, which were necessary in order to deeply profile multi-omics over time, and we anticipate host sequencing to be more useful when integrated into larger cross-sectional surveys. Another notable property was that, as in most microbiome studies, changes that occurred within individuals, populations, or phenotypes were often much smaller than baseline variation between individuals. This is particularly true at microbiome-relevant time scales, for which repeated measures as rapid as days to weeks were necessary to capture the most specific host–microbiome interactions. Health-associated microbiome interactions can thus manifest in extremely diverse ways among individuals, making a combination of large-scale population surveys with within-subject longitudinal profiles essential for understanding the mechanisms of microbiome-linked disease.

As a result, other aspects of host–microbiome interactions were highly localized and subject-specific within each of the three studies. In all three conditions, microbial changes and associated host responses were strongest when captured at the time the changes occurred, and often within the tissue of origin. It is thus clear from these and other studies that host–microbiome interactions have both localized and systemic effects. Strong local perturbations initiated from either the host or microbial side can induce subsequent spatiotemporal responses that can continue over time and/or in other tissues, presumably with signals carried spatially by circulating small molecules and/or temporally by gene regulation or microbial growth, and involving regulatory circuits with both host and inter-microbial components. Continued coordinated efforts to measure the diverse host and microbial properties involved in each condition will thus be important for developing targeted and, when necessary, personalized therapies for microbiome-associated conditions, as well as for uncovering general principles that govern host–microbiome interactions. Other dynamic interactions that were not measured in all studies, such as an individual's first microbial exposures near birth and subsequent immune development, may also represent key contributors to baseline microbiome personalization and help to explain disease-linked dynamics based on events that took place years or even decades earlier.

Next steps in microbiome multi-omics

The collective results of the NIH HMP projects, alongside many other studies, show that the microbiome is an integral component of human biology, with a major role in health and well-being. Inter-individual variability and highly diverse host–microbiome responses over time have driven the development of new methods for population microbiome studies using multiple, complementary longitudinal measurements, as well as highlighting the need to follow such studies up with mechanistic models in order to validate causative associations. The successful close of the HMP program itself has left an enduring legacy of multiple scientific generations of trained human microbiome investigators; provided the resulting community with a wealth of data, analytical, and biospecimen resources; and positioned the NIH and other funding agencies to continue work in a broad range of microbiome-linked conditions[89]. Funding for microbiome science, human and otherwise, is now being coordinated among NIH Centers and Institutes (https://www.niaid.nih.gov/research/trans-nih-microbiome-working-group); other US government agencies including the National Science Foundation, Environmental Protection Agency, Department of Energy, National Institute of Standards and Technology, Department of Agriculture, National Oceanographic and Atmospheric Administration, National Aeronautics and Space Administration, and Department of Defense (https://commonfund.nih.gov/hmp/programhighlights); philanthropic organizations including the Bill and Melinda Gates Foundation, the March of Dimes, the Burroughs Wellcome Fund, the Sloan Foundation, the Keck Foundation, the Juvenile Diabetes Research Foundation, the Crohn's and Colitis Foundation, and others; and industry and public–private partnerships. Moreover, as complex global projects are launched to tackle aspects of personalized medicine, it is now obvious that it is informative to include components focused on the effect of the human microbiome.

As with any large study, the HMP2 has raised more new questions than it has answered. The aetiologies of baseline inter-individual differences in the microbiome, and of its dynamic changes over time, were not apparent even from the wide range of measurement types incorporated into these three studies and populations. Many immune and biochemical responses appear to be associated with specific strains that are unique to one or a few individual hosts, but it is not clear whether such strains are sufficient or necessary for their associated disease phenotypes. A few mechanisms were identified by which signals in the gut can be transmitted to systemic conditions such as diabetes, but not the specific small molecules or immune cell subsets by which they are likely to be transmitted—particularly in other health conditions that have not yet been studied in such detail. Finally, each HMP2 study was necessarily carried out within a geographically and genetically constrained population, and global differences in early life events, infectious disease exposure, or diet may change how microbiome dynamics contribute to human disease.

Human-associated microbiology now clearly extends beyond infectious and gastrointestinal diseases to areas barely imaginable a few decades ago, including metabolism, neoplasia, maternal and child health, and central nervous system function. As the NIH HMP comes to an end, it is clear that its results have revealed a multitude of new avenues of research and technologies for future investigation, and we look forward to new discoveries based on resources from the program and exciting findings yet to come.

16.2.1: Levels of Disease Prevention

Prevention includes a wide range of activities — known as “interventions” — aimed at reducing risks or threats to health. You may have heard researchers and health experts talk about three categories of prevention: primary, secondary and tertiary. What do they mean by these terms?

Primary prevention aims to prevent disease or injury before it ever occurs. This is done by preventing exposures to hazards that cause disease or injury, altering unhealthy or unsafe behaviours that can lead to disease or injury, and increasing resistance to disease or injury should exposure occur. Examples include:

- legislation and enforcement to ban or control the use of hazardous products (e.g. asbestos) or to mandate safe and healthy practices (e.g. use of seatbelts and bike helmets)
- education about healthy and safe habits (e.g. eating well, exercising regularly, not smoking)
- immunization against infectious diseases.

Secondary prevention aims to reduce the impact of a disease or injury that has already occurred. This is done by detecting and treating disease or injury as soon as possible to halt or slow its progress, encouraging personal strategies to prevent reinjury or recurrence, and implementing programs to return people to their original health and function to prevent long-term problems. Examples include:

- regular exams and screening tests to detect disease in its earliest stages (e.g. mammograms to detect breast cancer)
- daily, low-dose aspirins and/or diet and exercise programs to prevent further heart attacks or strokes
- suitably modified work so injured or ill workers can return safely to their jobs.

Tertiary prevention aims to soften the impact of an ongoing illness or injury that has lasting effects. This is done by helping people manage long-term, often-complex health problems and injuries (e.g. chronic diseases, permanent impairments) in order to improve as much as possible their ability to function, their quality of life and their life expectancy. Examples include:

- cardiac or stroke rehabilitation programs, chronic disease management programs (e.g. for diabetes, arthritis, depression, etc.)
- support groups that allow members to share strategies for living well
- vocational rehabilitation programs to retrain workers for new jobs when they have recovered as much as possible.

16.2.2: Sexually Transmitted Infections

What are some types of sexually transmitted diseases or sexually transmitted infections (STDs/STIs)?

Approximately 20 different infections are known to be transmitted through sexual contact. Here are descriptions of some of the most common and well known:

- Chlamydia
- Gonorrhea
- Genital Herpes
- HIV/AIDS
- Human Papillomavirus (HPV)
- Syphilis
- Bacterial Vaginosis
- Trichomoniasis
- Viral Hepatitis

Chlamydia

Figure 16.2.2.1. Cervicitis and mucopurulent endocervical discharge in female chlamydial infection.

Chlamydia is a common STD/STI caused by the bacterium *Chlamydia trachomatis*. Chlamydia can be transmitted during vaginal, oral, or anal sexual contact with an infected partner. While many individuals will not experience symptoms, chlamydia can cause fever, abdominal pain, and unusual discharge of the penis or vagina.

In women, whether or not they are having symptoms and know about their infection, chlamydia can cause pelvic inflammatory disease (PID). In PID, the untreated STD/STI progresses and involves other parts of the woman's reproductive system, including the uterus and fallopian tubes. This progression can lead to permanent damage to the woman's reproductive organs. This damage may lead to ectopic pregnancy (in which the fetus develops in abnormal places outside of the womb, a condition that can be life-threatening) and infertility.

Additionally, if the woman is pregnant, her developing fetus is at risk, because chlamydia can be passed on during her pregnancy or delivery and could lead to eye infections or pneumonia in the infant. If chlamydia is detected early, it can be treated easily with an antibiotic taken by mouth.

Gonorrhea

Gonorrhea is caused by the bacterium Neisseria gonorrhoeae, which can grow rapidly and multiply easily in the warm, moist areas of the reproductive tract. The most common symptoms of gonorrheal infection are a discharge from the vagina or penis and painful or difficult urination.

As with chlamydial infection, the most common and serious complications of gonorrhea occur in women and include pelvic inflammatory disease (PID), ectopic pregnancy, infertility, and the potential spread to the developing fetus if acquired during pregnancy. Gonorrhea also can infect the mouth, throat, eyes, and rectum and can spread to the blood and joints, where it can become a life-threatening illness.

In addition, people with gonorrhea can more easily contract HIV, the virus that causes AIDS. HIV-infected people with gonorrhea are also more likely to transmit the virus to someone else.

Syphilis

Syphilis infections, caused by the bacterium Treponema pallidum, are passed from person to person during vaginal, anal, or oral sex through direct contact with sores, called chancres. Between 2001 and 2009, the Centers for Disease Control and Prevention (CDC) data show that the syphilis rate increased each year. Those people at highest risk for syphilis include men having sex with both men and women and people residing in the south. The first sign of syphilis is a chancre, a painless genital sore that most often appears on the penis or in and around the vagina. Beyond being the first sign of a syphilis infection, chancres make a person two to five times more likely to contract an HIV infection. If the person is already infected with HIV, chancres also increase the

likelihood that the virus will be passed on to a sexual partner. These sores typically resolve on their own, even without treatment. However, the body does not clear the infection on its own, and, over time, syphilis may involve other organs, including the skin, heart, blood vessels, liver, bones, and joints in secondary syphilis. If the illness is still not treated, tertiary syphilis can develop over a period of years and involve the nerves, eyes, and brain and can potentially cause death.

Expectant mothers harboring the bacterium are at an increased risk of miscarriage and stillbirth, and they can pass the infection on to their fetuses during pregnancy and delivery. Infants that acquire congenital syphilis during pregnancy may suffer from skeletal deformity, difficulty with speech and motor development, seizure, anemia, liver disease, and neurologic problems.

STD/STI Data

CDC FACT SHEET

Reported STDs in the United States

2015 National Data for Chlamydia, Gonorrhea, and Syphilis

Many cases of chlamydia, gonorrhea, and syphilis continue to go undiagnosed and unreported, and data on several additional STDs — such as human papillomavirus, herpes simplex virus, and trichomoniasis — are not routinely reported to CDC. As a result, the annual surveillance report captures only a fraction of the true burden of STDs in America. However, it provides important insights into the scope, distribution, and trends in STD diagnoses in the country.

STDs are a substantial health challenge facing the United States. CDC estimates that nearly **20 million new sexually transmitted infections** occur every year in this country, half among young people aged 15–24, and account for almost $16 billion in health care costs. Each of these infections is a potential threat to an individual's immediate and long-term health and well-being. In addition to increasing a person's risk for acquiring and transmitting HIV infection, STDs can lead to chronic pain and severe reproductive health complications, such as infertility and ectopic pregnancy.

Figure 16.2.2.2. How STD's Affect Populations in the United States

Figure 16.2.2.3. Ages affected by chlamydia and gonorrhea infections

Genital Herpes

Genital herpes is a contagious infection caused by the herpes simplex virus (HSV). There are two different strains, or types, of HSV: herpes simplex virus type 1 (HSV-1) and type 2 (HSV-2). Both can cause genital herpes, although most cases of genital herpes are caused by HSV-2. When symptomatic, HSV-1 usually appears as fever blisters or cold sores on the lips, but it can also infect the genital region through oral-genital or genital-genital contact. Symptomatic HSV-2 typically causes painful, watery skin blisters on or around the genitals or anus. However, substantial numbers of people who carry these viruses have no or only minimal signs or symptoms.

Neither HSV-1 nor HSV-2 can be cured, and even during times when an infected person has no symptoms, the virus can be found in the body's nerve cells. Periodically, some people will experience outbreaks in which new blisters form on the skin in the genital area; at those times, the virus is more likely to be passed on to other people.

Pregnant women, especially those who acquire genital herpes for the first time during pregnancy, may pass the infection to their newborns, causing life-threatening neonatal HSV, an infection affecting the infant's skin, brain, and other organs.

HIV/AIDS

HIV, or the human immunodeficiency virus, is the virus that causes AIDS (acquired immunodeficiency syndrome). HIV destroys the body's immune system by killing the blood cells that fight infection. Once HIV destroys a substantial proportion of these cells (CD4 cells), the body's ability to fight off and recover from infections is compromised. This advanced stage of HIV infection is known as AIDS.

The CD4 count is like a snapshot of how well your immune system is functioning. CD4 cells (also known as CD4+ T cells) are white blood cells that fight infection. The more you have, the better. These are the cells that the HIV virus kills. As HIV infection progresses, the number of these cells declines. When the CD4 count drops below 200 due to advanced HIV disease, a person is diagnosed with AIDS. A normal range for CD4 cells is about 500-1,500. Usually, when a person with low CD4 cells starts HIV

medicines, the CD4 cell count increases as the HIV virus is controlled. Most, but not all, people will experience an increase in CD4 cells with effective HIV treatment.

People whose HIV has progressed to AIDS are very susceptible to opportunistic infections that do not normally make people sick and to certain forms of cancer.

AIDS can be prevented by early initiation of antiretroviral therapy in those with HIV infection. Transmission of the virus primarily occurs during unprotected sexual activity and by sharing needles used to inject intravenous drugs, although the virus also can spread from mother to infant during pregnancy, delivery, and breastfeeding.

In 2013, NIH-supported researchers reported that a 2-year-old child who was born with HIV and was treated starting in the first few days of life has had her HIV infection go into remission. This appears to be the first case of functional cure of HIV.

Human Papillomavirus (HPV)

HPV is the most common STD/STI. More than 40 HPV types exist, and all of them can infect both men and women. The types of HPVs vary in their ability to cause genital warts; infect other regions of the body, including the mouth and throat; and cause cancers of the cervix, vulva, penis, and mouth.

Although no cure exists for HPV infection once it occurs, regular screening with a Pap smear test can prevent or detect at an early stage most cases of HPV-caused cervical cancer. (A Pap smear test involves a health care provider taking samples of cells from the cervix during a standard gynecologic exam; these cells are examined under a microscope for signs of developing cancer).

A newly available vaccine protects against most (but not all) HPV types that cause cervical cancer. The American Academy of Pediatrics recommends this vaccine for school-aged boys and girls.

Bacterial Vaginosis

Bacterial vaginosis is a common, possibly sexually transmitted, vaginal infection in women of reproductive age. While it is healthy and normal for a vagina to have bacteria, just like the skin, mouth, or gastrointestinal (GI) tract, sometimes changes in the balance of different types of bacteria can cause problems.

Bacterial vaginosis occurs when problematic bacteria that are normally present only in small amounts increase in number, replace normal vaginal lactobacilli bacteria, and upset the usual balance. This situation becomes more likely if a woman douches frequently or has new or multiple sexual partners. The most common sign of a bacterial vaginosis infection is a thin, milky discharge that is often described as having a “fishy” odor. However, some women will have no symptoms at all.

Regardless of symptoms, having bacterial vaginosis increases the risk of getting other STDs/STIs and is also associated with pelvic inflammatory disease (PID), an infection of the female reproductive organs, including the uterus and the fallopian tubes (which carry eggs to the uterus), and postoperative infections. Preterm labor and birth are also possibly more common in women with bacterial vaginosis.

Trichomoniasis

Trichomoniasis infection is caused by the single-celled protozoan parasite Trichomonas vaginalis and is common in young, sexually active women. The parasite also infects men, though less frequently. The parasite can be transmitted between men and women as well as between women whenever physical contact occurs between the genital areas.

Although *Trichomonas* infections do not always cause symptoms, they can cause frequent, painful, or burning urination in men and women as well as vaginal discharge, genital soreness, redness, or itching in women. Because the infection can occur without symptoms, a person may be unaware that he or she is infected and continue to re-infect a sexual partner who is having recurrent signs of infection. As with bacterial STDs/STIs, all sexual partners should be treated at the same time to avoid re-infection.

NICHD-sponsored research has shown that during pregnancy, Trichomonas infection is associated with an increased risk of premature birth and infants with low birth weight. Moreover, infants born to mothers with Trichomonas infection are more than twice as likely as infants born to uninfected women to be stillborn or to die as newborns.

Viral Hepatitis

Viral hepatitis is a serious liver disease that can be caused by several different viruses, which can be transmitted through sexual

contact.

- Hepatitis A virus (HAV) causes a short-term or self-limited liver infection that can be quite serious, although it does not result in chronic infection. While there are other ways the virus can be transmitted, HAV can be spread from person to person during sexual activity through oral-rectal contact. Vaccination can prevent HAV infection.
- Hepatitis B virus (HBV) causes a serious liver disease that can result in both immediate illness and lifelong infection leading to permanent liver scarring (cirrhosis), cancer, liver failure, and death. HBV spreads through both heterosexual and homosexual contact as well as through contact with other bodily fluids, such as blood, through shared contaminated needles used for injecting intravenous (IV) drugs, tattooing, and piercing. Pregnant women with HBV can transmit the virus to their infants during delivery. HBV infection is preventable through vaccination.
- Hepatitis C virus (HCV) can cause an immediate illness affecting the liver, but it more commonly becomes a silent, chronic infection that leads to liver scarring (cirrhosis), cancer, liver failure, and death. HCV is most commonly transmitted through sharing needles or exposure to infected blood. However, it can spread through sexual contact or from mother to fetus during pregnancy and delivery. There is no vaccine for HCV, and treatments are not always effective.

16.2.3: STD/STI Treatments

Treatments for Specific Types of Sexually Transmitted Diseases and Sexually Transmitted Infections (STDs/STIs)

- Gonorrhea and Chlamydia
- Genital Herpes
- Human Papillomavirus (HPV)
- Syphilis
- Bacterial Vaginosis
- Trichomoniasis
- Viral Hepatitis
- HIV/AIDS
- During Pregnancy

Gonorrhea and Chlamydia

Gonorrhea and chlamydia are bacterial STDs/STIs that can be treated with antibiotics given either orally or by injection. Because the infections often occur together, people who have one infection are typically treated for both by their health care provider. Recent sexual partners should be treated at the same time.

Genital Herpes

Genital herpes outbreaks can be treated with antiviral drugs. Although this medication can limit the length and severity of outbreaks, it does not cure the infection. In addition, daily suppressive therapy (daily use of antiviral medication) for herpes can reduce the likelihood of transmission to partners. A pregnant woman known to have the infection must take additional care because she can pass the infection to her infant during delivery. Women who first acquire genital HSV during pregnancy are at highest risk of transmission to their infants. If a pregnant woman has an outbreak when she goes into labor, she may need to have a cesarean section (C-section) to prevent the infant from getting the virus during birth.

Human Papillomavirus (HPV)

A person who has an HPV infection cannot be cured. However, many HPV infections can be prevented with vaccination. Furthermore, a health care provider can treat genital warts caused by the virus as well as monitor and control a woman's risk of cervical cancer through frequent screening with Pap smear tests.

Syphilis

If recognized during the early stages, usually within the first year of infection, syphilis can be treated with a singular intramuscular injection of antibiotic. A person being treated for syphilis must avoid sexual contact until the chancre sores caused by the bacteria are completely healed to avoid infecting other people.

If a person does not recognize the infection early, or does not seek treatment immediately, longer treatment with antibiotics may be required. If left untreated, the infection can progress even further and potentially cause death. Although antibiotics can prevent the infection from getting worse, they cannot reverse damage that has already occurred.

Bacterial Vaginosis

Bacterial vaginosis can be treated with antibiotics, typically metronidazole or clindamycin. Generally, male sexual partners of women with bacterial vaginosis do not need to be treated because treatment of partners has not been shown to reduce the risk of recurrence. Treatment during pregnancy is recommended primarily for women at risk for preterm labor or having a low birthweight infant.

Trichomoniasis

Trichomoniasis can be treated with a single dose of an antibiotic, usually either metronidazole or tinidazole, taken by mouth. Often, *Trichomonas* infection recurs, so it is important to make sure that both you and your sexual partners are treated if you are diagnosed with this infection.

Viral Hepatitis

- Hepatitis A virus (HAV) infects the liver and may cause abdominal pain, nausea, and vomiting. Usually the infection gets better on its own without requiring treatment. In some cases, however, individuals may have lasting damage to their livers or may have such severe nausea and vomiting that they must be admitted to the hospital.
- Hepatitis B virus (HBV) can cause a lifelong infection but can be treated with antiviral medications. People with HBV infection will need to see a liver specialist with experience treating individuals with chronic liver disease. These individuals need to take special care not to pass on the virus to their sexual partners, and sexual partners should receive hepatitis B vaccine if not already immune.
- Hepatitis C virus can cause immediate illness affecting the liver or, more commonly, it can be a silent, chronic infection. As with hepatitis B, individuals with HCV may have a lifelong infection and will always be at risk of passing the virus on to their sexual partners. New treatments are available that can clear the infection in some individuals.

More information about hepatitis A, B, and C can be found on the Centers for Disease Control and Prevention website.

HIV/AIDS

There is no cure for HIV/AIDS. However, research into new treatments has improved outcomes for people living with the disease. A combination of antiretroviral drugs can be given in highly active antiretroviral therapy to control the virus, promote a healthy immune system, help people with the virus live longer lives, and reduce the risk of transmission.

During Pregnancy

Pregnant women who have certain types of STDs/STIs may pass them on to their infants during pregnancy or delivery. Therefore, it is important for women to be tested for such STDs/STIs as part of their early prenatal care to help ensure delivery of a healthy infant. The specific treatment will depend on which STD/STI is involved.

16.2.4: STD/STI Prevention- How to Prevet STI's

Every year, there are an estimated 20 million new sexually transmitted infections in the United States. Anyone who is sexually active can get an STI. Some groups are disproportionately affected by STI's:

- Adolescents and Young Adults
- Gay, Bisexual, & other Men who have Sex with Men
- Some Racial and Ethnic Minorities

The Good News: STI's ARE preventable. There are steps you can take to keep yourself and your partner(s) healthy. Here's How You Can Avoid (or reduce the risk of) giving or getting an STI:

Practice Abstinence

The surest way to avoid STI's is to not have sex. This means not having vaginal, oral, or anal sex.

Use Condoms

Using a condom correctly every time you have sex can help you avoid STI's. Condoms lessen the risk of infection for all STI's. **You still can get certain STI's, like herpes or HPV, from contact with your partner's skin even when using a condom.**

Most people say they used a condom the first time they ever had sex, but when asked about the last 4 weeks, less than a quarter said they used a condom every time.

Step by step male condom instructions

Have Fewer Partners

Agree to only have sex with one person who agrees to only have sex with you. Make sure you both get tested to know for sure that neither of you has an STI. This is one of the most reliable ways to avoid STI's.

Get Vaccinated

Figure 16.2.4.1. Get Vaccinated!

The most common STI can be prevented by a vaccine. The HPV vaccine is safe, effective, and can help you avoid HPV-related health problems like genital warts and some cancers.

Who should get the HPV vaccine?

- Routine vaccination for boys & girls ages 11 to 12

Catch-up vaccination for:

- Young women ages 13 to 26 and young men ages 13 to 21
- Gay, Bisexual, & other Men who have sex with Men up to age 26
- Men with compromised immune systems up to age 26

Talk With Your Partner

Talk with your sex partner(s) about STI's and staying safe before having sex. It might be uncomfortable to start the conversation, but protecting your health is your responsibility.

Get Tested

Many STI's don't have symptoms, but they can still cause health problems.

- Talk with your health care provider
- Search for CDC recommended tests
- Find a location to get tested for STDs

The only way to know for sure if you have an STI is to get tested.

If You Test Positive...

If either you or your partner is infected with an STI that can be cured (remember, some STI's cannot be cured), both of you need to start treatment immediately to avoid getting re-infected.

16.2.5: What are infectious diseases?

Infectious diseases are distinguished from other illnesses and disorders because they can be transmitted from someone who is ill either directly or indirectly to other individuals, who then develop the same infectious disease and are also able to pass it on. A familiar example is the 'common cold' which almost everyone has experienced at some time in their lives (Figure 16.2.5.1). Non-human animals and plants also suffer from infectious diseases, which cause massive losses to food crops and livestock, but our focus in this course is on infection in humans.

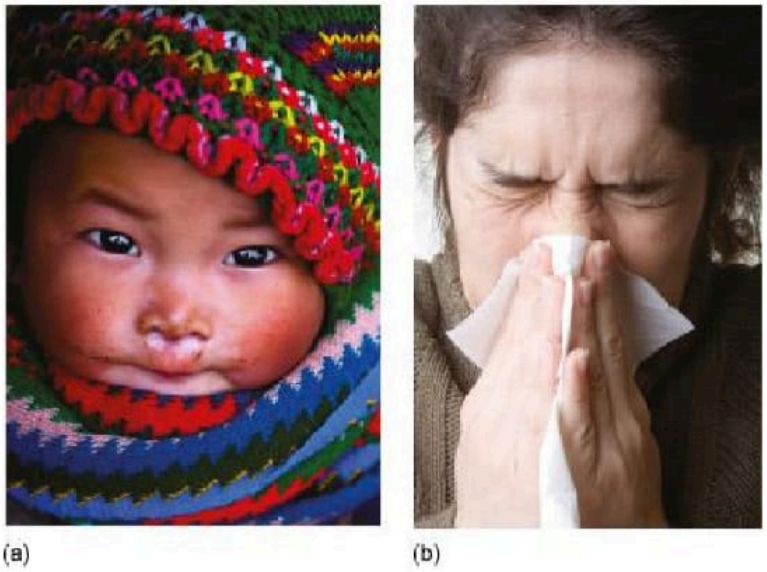

Figure 16.2.5.1. The common cold affects children and adults all over the world: (a) a child from Vietnam. (b) an adult in the United States

By contrast, health problems that cannot be transmitted between individuals, such as heart disease, diabetes, lung cancer, arthritis and depression, are known as non-communicable diseases (or NCDs). However, a few NCDs also have an infectious component, for example:

- in most cases of cervical cancer there is evidence of infection with a specific virus (the human papilloma virus, or HPV)
- hepatitis viruses cause liver disease and cancer of the liver
- a bacterium (Helicobacter pylori) causes stomach ulcers.

These examples illustrate the point that there is some overlap between some infectious and non-communicable diseases. For completeness, we should mention here that the third major category of diseases, disorders and disabilities is termed injuries, i.e. physical damage to the body caused by accidents or violence.

This page titled 16.2.5: What are infectious diseases? is shared under a CC BY-NC 4.0 license and was authored, remixed, and/or curated by Manomita Patra and Yeny Pena-Grafton.

16.2.6: Symptoms and signs of infection

Symptoms are sensations in the body that only the person who is unwell can experience; for example, a headache, pain in the abdomen, blurred vision and nausea are all symptoms, because no one but the sufferer can experience them. Lay people, including children, can usually describe their symptoms accurately or report them if asked the right questions, but symptoms are subjective experiences that others cannot observe or verify.

By contrast, the signs of a disease are indicators of illness that other people can observe (e.g. a runny nose and frequent sneezing). Considering the symptoms and signs together may give enough information for a trained health care worker to make a diagnosis, i.e. identify the underlying cause of the illness and give it a definite name.

This page titled 16.2.6: Symptoms and signs of infection is shared under a CC BY-NC 4.0 license and was authored, remixed, and/or curated by Manomita Patra and Yeny Pena-Grafton.

16.2.7: What causes infectious diseases?

Infectious diseases are transmitted between individuals by infectious agents, known as pathogens [path-oh-jens], from the Greek word *pathos* (to suffer) and *genès* (to produce). Pathogens produce a lot of human suffering and disability across the world, including in relatively wealthy nations like the United States. Most people have heard of at least some types of pathogen, for example bacteria or viruses.

The wider causes of infectious diseases range from insanitary living conditions in impoverished communities, to inadequate hygiene in the high-tech environments of modern hospitals (Figure 16.2.7.1). The impact of infectious diseases is therefore unequally distributed around the world, not only between countries, but also between individuals and groups within the same population.

Figure 16.2.7.1. Infectious diseases are a threat everywhere: (a) A shanty settlement without piped water or sanitation in Indonesia. (b) Testing for pathogens in a hospital laboratory in England.

Human biology is another factor to consider in explaining the cause of infectious diseases. Infancy and old age, inadequate nourishment, other illnesses and some types of medication can all create conditions in the body in which infection is more easily established. In addition, there are individual human behaviors, habits and traditional practices that contribute to the causes of infectious diseases by spreading pathogens from one person to another. These behaviors give some clues about the routes by which pathogens can be transmitted, as the next section describes.

This page titled 16.2.7: What causes infectious diseases? is shared under a CC BY-NC 4.0 license and was authored, remixed, and/or curated by Manomita Patra and Yeny Pena-Grafton.

16.2.8: Direct person-to-person transmission of pathogens

A new infection begins when pathogens leave the body of their host – the infected individual in which the pathogens are multiplying – and enter a new host. They may be repelled by defense mechanisms (i.e. skin) in the new host, or they may survive and reproduce in sufficient numbers to cause an infectious disease.

Transmission of pathogens can occur directly between people, or indirectly in the air, water or food, or via other animals to humans, or from sources in the environment. In this section we explore direct transmission.

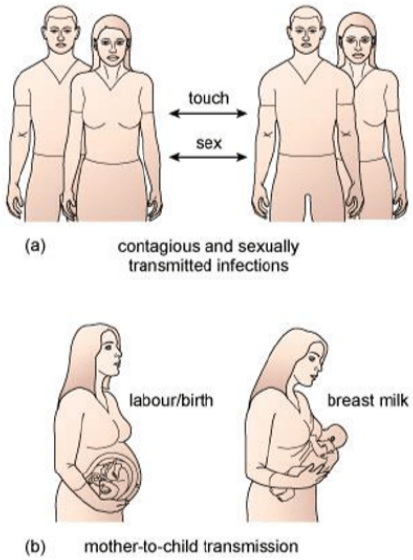

Figure 16.2.8.1. Direct person-to-person transmission of infection. (a) Contagion and sexual transmission. (b) Mother-to-child transmission.

Figure 16.2.8.1 represents the three ways in which pathogens can be transmitted by direct person-to-person contact. They are:

- Contagious infection, when touch, such as a handshake, transfers pathogens to a susceptible person; they may enter the new host through a cut or graze, or be transferred from hand to mouth.
- Sexually transmitted infection (or STI) involving infected semen, vaginal secretions, saliva or blood transmitting pathogens to the infected individual's partner during unprotected sex. This is the most common route for the worldwide spread of HIV (the human immunodeficiency virus), which causes AIDS (acquired immune deficiency syndrome). Sexual transmission is more likely if the partner's genitals, mouth or rectum are inflamed, for example, by another STI such as gonorrhea [gonn-or-ree-ah] or syphilis [siff-ill-iss].
- Mother-to-child transmission, when pathogens pass from mother to baby during labor and delivery, or via breast milk.

This page titled 16.2.8: Direct person-to-person transmission of pathogens is shared under a CC BY-NC 4.0 license and was authored, remixed, and/or curated by Manomita Patra and Yeny Pena-Grafton.

16.2.9: Indirect person-to-person transmission of pathogens

Indirect person-to-person transmission occurs when the original host sheds pathogens into the air, water, food or objects in the environment, which then infect someone else (Figure 16.2.9.1).

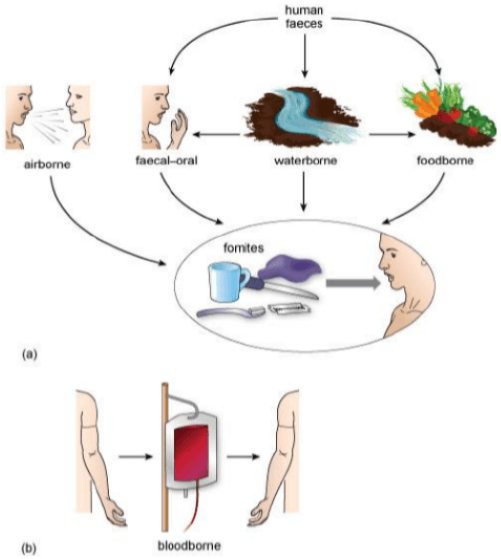

Figure 16.2.9.1. There are many routes for indirect person-to-person transmission of infection. Most airborne infections are transmitted when a cough or sneeze expels fine droplets of water (known as an aerosol) containing millions of bacteria or viruses. The aerosol droplets may be inhaled by a susceptible person, or settle on surfaces where the pathogens contaminate hands, utensils, clothing, water or food, which are then touched or consumed by someone else.

Figure 16.2.9.2. Coughs and sneezes spread diseases!

Waterborne infections are particularly common in parts of the world where large numbers of people don't have access to clean drinking water or safe disposal of sewage. Infected urine and feces from humans and animals can wash into lakes and streams, where the pathogens multiply and re-infect people when they drink or bathe in contaminated water. Some pathogens (including the bacteria that cause cholera, a serious diarrheal disease) live naturally in environmental water sources, so they will always pose a threat to health.

Fecal–oral infections (refer to solid waste, or excrement) occur when pathogens from feces enter the mouth and multiply in the

gut. Transmission occurs when unclean hands, dirty cooking utensils or food contaminated by feces enters the mouth. Flies can transfer pathogens from feces to food via their feet. Contact with feces is unavoidable when people are forced to defecate in the open because there is no sanitation. In these cases, people can get contaminated soil on their hands and the pathogens are easily transmitted from hand to mouth if there is no clean water or soap for hand washing.

Diarrheal diseases are often transmitted via the fecal–oral route, and some (e.g. cholera) are mainly waterborne. But they may also be due to foodborne infections caused by pathogens that originated in food components, for example, pathogenic bacteria in raw meat, eggs and on salad leaves.

Non-living objects in the environment, such as cups, spoons and door handles that people routinely touch, can also transmit infection and are known collectively as fomites [fohmytz]. Clothing can also act as a fomite, which is why hospital doctors rarely wear neckties that could drape across a patient during a medical examination and pick up infection that the next patient might acquire.

Medical procedures can also transmit bloodborne infections; for example, before the transmission of HIV was understood, thousands of infections occurred from HIVcontaminated blood transfusions. Bloodborne pathogens can also spread via shared needles and syringes among people who inject illegal drugs, such as heroin.

This page titled 16.2.9: Indirect person-to-person transmission of pathogens is shared under a CC BY-NC 4.0 license and was authored, remixed, and/or curated by Manomita Patra and Yeny Pena-Grafton.

16.2.10: Animal-to-human transmission of pathogens

Pathogens are often transmitted from animals to humans 'accidentally', for example via infected meat or water contaminated with animal feces. But there are two transmission routes in which the animal is an essential agent in the transfer of pathogens to humans. An example of zoonosis that may be familiar is influenza originating in pigs (swine flu) or poultry (bird flu). The influenza viruses that cause these diseases can sometimes be transmitted from animals to humans during the slaughter or handling of livestock. Some zoonotic influenza viruses pose a much greater health risk than the airborne seasonal influenza viruses that commonly circulate in human populations every winter.

Another route of transmission from animals to humans results in vector-borne infections. They differ from zoonoses in that they are transmitted by an invertebrate animal (without a backbone), mainly biting insects and ticks. The term 'vector' [vek-torr] comes from the Latin word for 'carrier', so in this context it means a carrier of an infectious disease. The pathogen must complete part of its life cycle in the vector, so transmission to humans may be prevented if the vectors can be killed. For example, Lyme disease is caused by a bacteria transmitted from birds or small mammals (such as deer) to humans by a type of tick.

There are many other vector-borne infections, including bubonic plague transmitted by rat fleas, typhus transmitted by ticks, and yellow fever transmitted by mosquitoes. In 2014, the World Health Organization– the branch of the United Nations responsible for coordinating and directing international policy and actions on health – devoted its annual 'World Health Day' to publicize the risk from vector-borne infections.

Emerging infectious diseases

Emerging infectious diseases (EIDs) is the collective term for a group of conditions that pose new threats to human health. EIDs can be distinguished into three types:

- New infectious diseases caused by previously unknown pathogens: Many of the diseases in this category are caused by zoonotic viruses, i.e. the viruses originated in other vertebrate animals, but at some point in the past they changed in ways that made them infectious to people. The best known 'new' infectious disease is AIDS but the virus that causes AIDS (HIV) may have originated in monkeys. Since HIV was identified in 1984, several other new infectious diseases caused by potentially fatal viruses have been identified. They include SARS (Severe Acute Respiratory Syndrome,), which may have originated in poultry, MERS (Middle East Respiratory Syndrome), which may have originated in camels, and zoonotic strains of influenza (swine flu and bird flu).
- Infectious diseases that have spread far outside their original range: One example is Ebola virus disease (EVD), a 'haemorrhagic' [hemm-orr-adj-ik] fever, which means it causes severe internal bleeding, among other symptoms. Cases have occurred from time to time in remote villages in West Africa, but the first urban cases were detected in the capital of Guinea in February 2014 and from there Ebola quickly spread to neighbouring Liberia and Sierra Leone. A few travellers or health workers caring for Ebola patients developed the disease in other countries, including Nigeria, Mali, Senegal and the USA. By October 2015, over 11 000 deaths had occurred from over 28 000 suspected, probable and confirmed cases (Centers for Disease Control and Prevention, 2015). Many of these cases have not been confirmed in a laboratory, so the 'case fatality rate' (the proportion of confirmed infected people who die) is unknown; however, it is likely to fall within the range of 30 to 60 per cent.

Previously declining infectious diseases that have resurged: Tuberculosis and some other infections caused by bacteria are a growing health concern because the causative pathogens are becoming increasingly resistant to antibiotics, which previously treated them successfully. So-called 'hospital super-bugs' are bacteria that have developed resistance to antibiotics in health care facilities, where antibiotics are heavily prescribed. An additional factor in countries where HIV/AIDS is common is that infection with HIV suppresses the body's immune defenses, so people with AIDS are more susceptible to other infections, including TB.

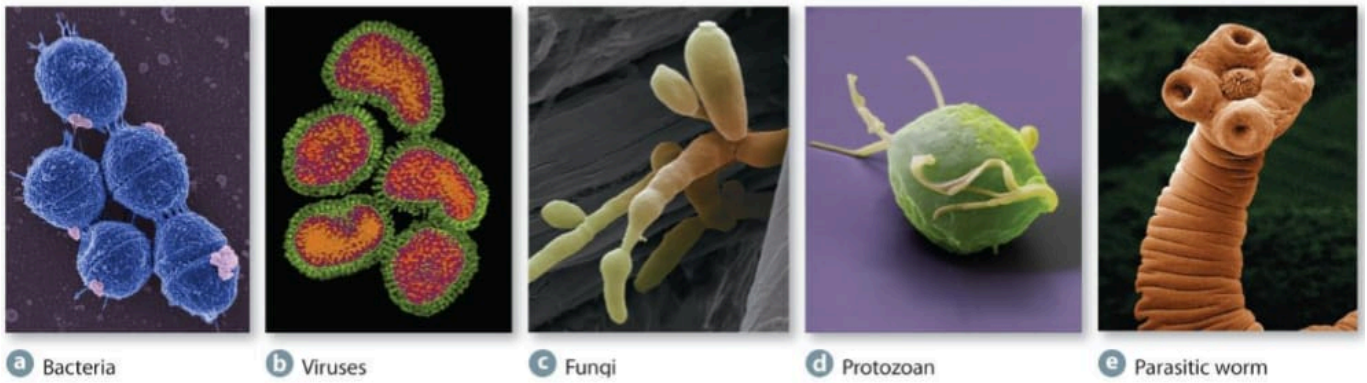

Figure 16.2.10.1. Examples of Five Major Types of Pathogens

This page titled 16.2.10: Animal-to-human transmission of pathogens is shared under a CC BY-NC 4.0 license and was authored, remixed, and/or curated by Manomita Patra and Yeny Pena-Grafton.

16.2.11: Immune Defenses Against Infectious Diseases

Natural barriers against pathogens

The physical and chemical barriers that prevent pathogens from getting into our body tissues in the first place are often overlooked. As Figure 6 shows, the most comprehensive barrier is the waterproof layer of skin that covers the body's surface. Human skin keeps most pathogens out as long as it remains intact. The speed with which a cut or graze can become infected is a reminder of the protection we normally get from our skin.

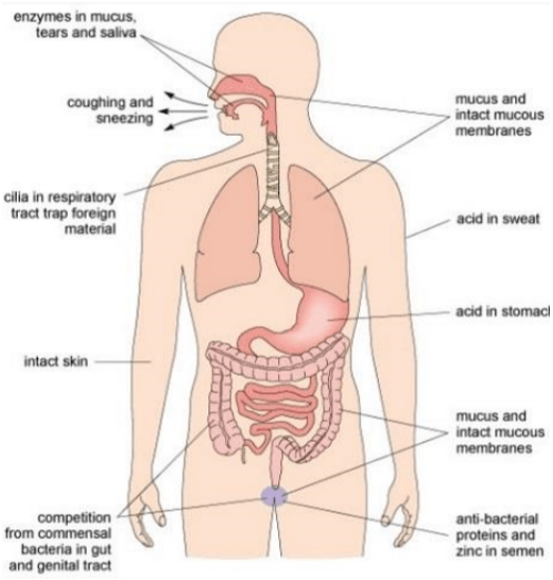

Figure 16.2.11.1. Physical and chemical barriers against infection

Vector-borne infections (e.g. malaria) are transmitted by biting invertebrates (e.g. mosquitoes) penetrating the skin when taking a blood meal. Humans are also vulnerable to invasion by pathogens in the air, food, water and soil, or during physical contact with infected people, some animals (e.g. pigs, dogs, poultry) or their feces. As Figure 16.2.11.1 illustrates, the inner surface of the respiratory system (nose, throat, airways and lungs), stomach, intestines, bladder and reproductive tract are lined with membranes that secrete jelly-like mucus, presenting a barrier against pathogens entering our tissues via these routes. Microscopic hairs called cilia [sill-ee-ah] line the respiratory system and 'beat' in unison to shunt mucus containing trapped pathogens towards the nose and mouth, where they can be expelled by coughing and sneezing, or swallowed into the stomach where acid destroys them.

Chemical barriers against infection include enzymes in tears, saliva and mucus that break down the surface of bacteria. The acid in sweat and in the stomach kills cellular pathogens and there are anti-bacterial proteins in semen (the fluid that contains male sperm). The more complex mechanisms of the immune system are only needed if pathogens breach these physical and chemical barriers.

The immune response to infection

The human immune system is an extremely complex network of interacting cells and biological molecules. The aim here is simply to give you an overview of how an immune response to infection develops, without going into too much detail. It occurs in three overlapping stages, the first of which is triggered when body cells are damaged. When tissues are injured, the damaged cells release chemicals that trigger the sequence of events described as inflammation. It occurs in response to any type of injury, such as a blow or a cut, an insect bite, or damage caused by pathogens multiplying in body tissues. Inflammation has four characteristic effects at the site of an injury, the first two of which are visible around the splinter shown in Figure 16.2.11.2:

- swelling

- redness
- heat
- pain

Figure 16.2.11.2. Inflammation of the tissues around a splinter

The inflamed area shows these signs because the local blood vessels dilate (get wider), increasing blood flow into the injury site, so it looks red as well as feeling warmer than the surrounding tissue. The walls of the blood vessels near the injury become leaky, allowing fluid, defensive proteins and immune system cells (described shortly) to flood into the area, which becomes swollen as a result. One of the proteins released during the inflammatory response also makes the area more sensitive to painful stimuli, so inflamed tissue is sore to touch.

Sites of tissue injury are vulnerable to invasion by pathogens so the benefits of inflammation generally outweigh the discomfort it causes. Flooding the area with fluid dilutes any pathogens that are already present, and the local concentration of immune system cells and defensive proteins enables an immune response to begin more quickly.

Leukocytes: the cells of the immune system

Once the barriers to infection have been breached and inflammation has begun, the active agents of the immune system, the *leukocytes* [loo-koh-sites], get to work. Leukocytes are often described as 'white blood cells' to distinguish them from the red blood cells that transport oxygen around the body; however, calling them 'blood' cells is misleading because leukocytes roam throughout the body tissues and only spend part of their lives in the bloodstream. In fact, they spend more time in the lymphatic system (Figure 16.2.11.3), the network of fine tubules that collect tissue fluid from all over the body and return it to the bloodstream.

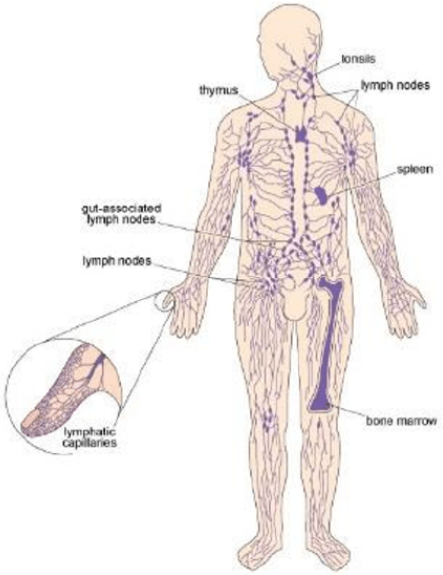

Figure 16.2.11.3. The human lymphatic system

The lymphatic system includes specialized organs and tissues where leukocytes develop. During an immune response to pathogens, we may become aware of swollen lymph nodes (popularly called 'glands') in the neck, armpits or groin, which enlarge

when the leukocytes they contain are multiplying near a site of infection.

Leukocytes can distinguish between 'self', the cells and proteins generated by the organism whose body they patrol, and 'non-self' (or 'foreign') material such as pathogens that originated outside the host's body. Leukocytes are *self-tolerant*, i.e. they do not normally attack the host's own cells or body proteins, but direct their actions only against non-self material that may pose a threat.

Although we have referred to 'the' immune response, as if it was just one thing, in fact, there are two types of immune response, distinguished as *innate* and *adaptive* immunity.

Innate immunity

All animals, even those with much simpler bodies than our own (e.g. parasitic worms) respond to tissue damage in ways that resemble inflammation in humans. They have cells similar to leukocytes and defensive proteins that flood into areas of tissue damage or infection. These leukocytes and proteins can defend the organism from pathogens because they recognize common patterns of molecules that occur in the structures of many different types of pathogens. These pathogen 'signature' molecules are known as PAMPs, or *pathogen-associated molecular patterns*.

The fact that PAMPs are commonly found in unrelated pathogens means that the leukocytes that recognize them cannot tell one type of pathogen from another. This *non-specific* immune response against pathogens is so widespread among animals that it is described as innate immunity ('innate' means 'inborn'). Some texts use the alternative term 'natural' immunity.

The leukocytes involved in innate immunity are of two general types, each with a different action against pathogens:

- Cytotoxic [sigh-toh-tox-ik] leukocytes, which simply means 'cell poisoning' (the prefix 'cyto' denotes a cell). These leukocytes have various methods of attaching to the outside of a pathogen and releasing destructive chemicals onto its surface. Worm larvae, bacteria and protists can all be killed this way.
- Phagocytic [fag-oh-sit-ik] leukocytes (the prefix 'phago' comes from a Greek word meaning 'to eat'), often abbreviated to phagocytes [fag-oh-sigh-tz]. These leukocytes engulf small pathogens such as bacteria, drawing them into the cytosol where destructive chemicals break them down. This action is termed phagocytosis [fag-ohsigh-toh-siss].

The anti-pathogen activities of certain specialized proteins are important contributors to the innate immune response. They include proteins that accelerate inflammation, target leukocytes onto pathogens or make host cells resistant to invasion by viruses. Their concentration increases rapidly in the bloodstream during an infection and this rise can be detected in blood tests as a diagnostic sign of infection.

In summary, all animals have innate immunity based on cells similar to human leukocytes and defensive proteins that defend the organism against pathogens 'in general' in a nonspecific way, i.e. these defenses cannot distinguish between one type of pathogen and another. Humans and other warm-blooded animals have an additional defensive capability called adaptive immunity, which differentiates specifically between pathogens, as the next section describes.

Adaptive Immunity

Adaptive immunity is due to the actions of two types of specialized leukocytes, known as T cells and B cells. (If you are interested, the letters denote 'thymus' and 'bone marrow', the tissues where each of these leukocytes mature.) We will describe their individual contributions to the adaptive immune response shortly, but first we focus on the most striking difference between innate and adaptive immunity. The clue lies in the word 'adaptive'.

T cells and B cells have recognition methods that distinguish between different pathogens (e.g. different species of bacteria), and they *adapt* during their first encounter with a particular pathogen. The second time they meet it in the body, the adaptive response begins earlier, lasts longer and is more effective than it was on the first occasion.

So, there is a much faster and increased response to a subsequent encounter with a pathogen and this demonstrates the adaptability of the immune system. This response is due to the production of long-lived memory cells that circulate in the body after the primary adaptive immune response subsides. These memory cells are specifically programmed to recognize the *same* pathogens that triggered the primary response if they ever get into the body again.

Antigens and the specific recognition of pathogens

Every type of pathogen has at least one (often many more) unique molecules known as antigens in their structure. In addition to

the PAMPs (pathogen-associated molecular patterns) shared by many different pathogens, each type of pathogen also has its own unique distinctive antigens. Each individual T cell and B cell (the leukocytes responsible for adaptive immunity) is programmed to recognize just one specific antigen, so it follows that each T or B cell can usually recognize only one type of pathogen, or at most two or three closely related pathogens that have very similar antigens. Recognition of an antigen by these adaptive leukocytes triggers an immune response against only those pathogens with that antigen in their structure. The political slogan 'One person, one vote' springs to mind as an analogy for 'One adaptive leukocyte, one target'!

Antibodies and B cells

Antibodies are very large proteins that contribute to adaptive immunity. A distinguishing feature of antibodies is that their structure includes at least two binding sites for antigens. B cells produce antibodies and also use them as their antigen receptors. The B cells carry antibodies embedded by the 'tail' in their outer cell membrane, with the binding sites facing outwards. This enables the B cell to bind to antigens that fit the binding sites in the antibodies it carries on its surface. This binding event is essential (but not sufficient on its own) to activate B cells into making a lot more antibody molecules that recognize the same antigen. These antibodies are released by the B cells and circulate in the bloodstream, tissue fluids and the lymphatic system. Antibodies are also abundant in the mucus membranes lining the respiratory system, the gut and the reproductive system, i.e. the sites in the body in contact with substances such as air, food, drinking water and sexual fluids that could contain pathogens.

Antibodies are often portrayed in the media as if they were 'magic bullets' that attack pathogens, but in fact they are more like 'waving flags' with a message that reads 'here is a pathogen – come and destroy it'. When antibodies bind to a pathogen, they simply label it for destruction by leukocytes with the innate ability to phagocytose (engulf) it, or cytotoxic (cell-killing) leukocytes and defensive proteins. You can think of them as recruiting the cells and defensive proteins of the innate immune system to join the attack. We conclude this tour of adaptive immunity by describing the T cells.

T cells in adaptive immunity

There are two types of T cells with different roles in adaptive immunity. The cytotoxic T cells release destructive chemicals onto their target's outer surface in much the same way as the cytotoxic leukocytes do in an innate immune response. But there is one crucial difference. Cytotoxic T cells are programmed to kill the body's *own* cells that have become infected by viruses or by the few types of bacteria and single-celled pathogens that can 'hide' inside the cells of their host (*Mycobacterium tuberculosis*, the bacteria that cause TB, can do this). Without the cytotoxic T cells, we woud be particularly susceptible to infectious diseases caused by these pathogens.

The other T cell type is called the **helper T cells**. They send activation signals to all the other leukocytes involved in inflammation, phagocytosis, cytotoxicity or production of antibodies by B cells. Recognition of a pathogen by binding to it is only the first step. The other leukocytes cannot take action against the pathogens they encounter without activation signals from the helper T cells.

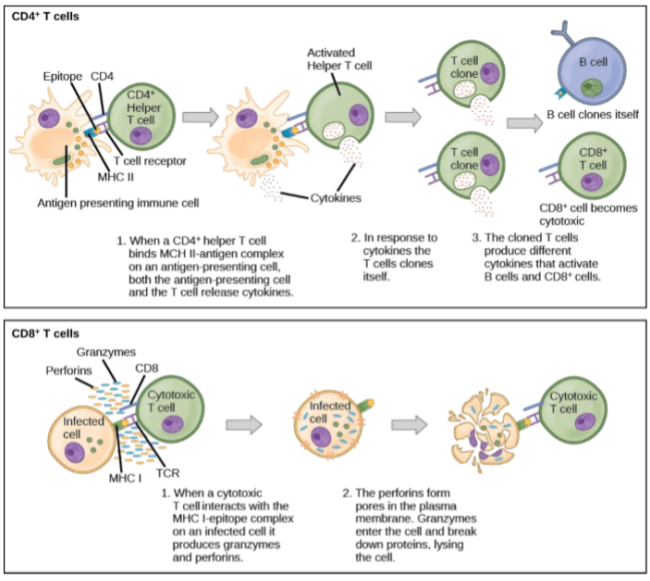

Figure 16.2.11.4. The Cell-Mediated Immune Response

Vaccination

Vaccination relies on the development of immunological memory for its protective effect. Vaccines contain killed pathogens, or extracts from pathogens, or modified strains of pathogens that are no longer harmful. For example, the MMR vaccine contains weakened (the technical term is 'attenuated') variants of the three viruses that cause measles, mumps and rubella (Figure 16.2.11.5).

Figure 16.2.11.5. The MMR vaccine contains live attenuated strains of measles, mumps and rubella viruses.

Note that each of the memory cells and the T cells and B cells generated in an adaptive immune response are specifically directed against just one type of pathogen or a very closely related strain. Vaccination with MMR vaccine is only protective against measles, mumps and rubella infection.

Despite decades of effort, medical science has so far been unable to produce effective vaccines against a number of important infectious diseases, including HIV/AIDS and other sexually transmitted infections (although trials of several candidate vaccines are underway). Vaccines against malaria have shown some potential, but they only protected about half the vaccinated children in large-scale African trials. There are no effective vaccines against infections caused by any other single-celled or multicellular parasites.

Some vaccines are effective only for a relatively short time, e.g. cholera vaccines give protection for only around six months. Others, such as the tetanus vaccine, need repeated booster doses. Annual influenza vaccinations are offered to vulnerable groups in the population because influenza viruses alter their antigens over time.

Opposition to vaccination

Another major challenge is parental opposition to vaccination because of concerns about vaccine safety. Some parents are understandably anxious about taking a healthy child to be given a vaccine derived from infectious agents. Most vaccines are injected, which can be a frightening and painful experience for a child. Of even greater concern is that some children experience a negative reaction to a vaccine, most often inflammation around the injection site and/or a mild fever lasting a day or two, but rare instances of more severe reactions such as convulsions sometimes occur.

Hesitancy about vaccinating a child is increased if parents have no experience of the disease the vaccine prevents, because it has become rare in communities with high vaccine coverage. Some parents conclude that vaccination is unnecessary and might expose their children to an avoidable risk.

Negative rumors about a vaccine are another deterrent. For example, the myth that vaccination is a Western plot to sterilize Muslim children has deterred parents in northern Nigeria, Pakistan and Afghanistan from allowing their children to be vaccinated against polio (Figure 16.2.11.6). Terrorist attacks have occurred against polio vaccination teams in all three countries – the only remaining locations where polio had not been eradicated by the WHO target of 2015.

Figure 16.2.11.6. Negative rumors about the oral polio vaccine did not deter this Nigerian child's parents from bringing her for vaccination.

An inevitable consequence of falling vaccination rates in a community is an increase in infections, sometimes with fatal outcomes. In 2014, the WHO warned that progress on eliminating measles had stalled and the number of deaths had begun to rise – from 122 000 in 2012 to 145 700 in 2013.

Countries urgently need to prioritize maintaining and improving immunization coverage. Failure to reverse this alarming trend could jeopardize the momentum generated by a decade of achievements in reducing measles mortality.

Even in countries where over 90% of children are fully vaccinated, uptake rates can plummet under pressure from negative rumors. For example, false claims in 1998 that the MMR vaccine caused autism led to a sustained fall in vaccinations in the United States and United Kingdom, followed by a significant rise in measles cases and, to a lesser extent, mumps. The largest outbreak of measles around Wales in 2012–13 caused more than 1200 cases and one death (Public Health Wales, 2013). Once parents saw the reality of measles infection and the misery and discomfort it causes, a rapid increase in uptake of the MMR vaccine followed the outbreak. The memory of infection fades in well-protected communities, until an outbreak reminds everyone of how devastating infectious diseases can be.

16.2.12: Risk Factors and Levels of Disease Prevention

What is a Risk Factor?

Part of learning how to take charge of your health requires understanding your risk factors for different diseases. Risk factors are things in your life that increase your chances of getting a certain disease. Some risk factors are beyond your control. You may be born with them or exposed to them through no fault of your own.

Some risk factors that you have little or no control over include your:

- Family history of a disease
- Sex/gender — male or female
- Ancestry

Some risk factors you can control include:

- What you eat
- How much physical activity you get
- Whether you use tobacco
- How much alcohol you drink
- Whether you misuse drugs

In fact, it has been estimated that almost 35 percent of all U.S. premature deaths in 2000 could have been avoided by changing just three behaviors:

- Stopping smoking
- Eating a healthy diet (eating more fruits and vegetables and less red meat)
- Getting more physical activity

You can have one risk factor for a disease or you can have many. The more risk factors you have, the more likely you are to get the disease. For example, if you eat healthy, exercise on a regular basis, and control your blood pressure, your chances of getting heart disease are less than if you are diabetic, a smoker, and inactive. To lower your risks, take small steps toward engaging in a healthy lifestyle, and you'll see big rewards.

People with a family health history of chronic disease may have the most to gain from making lifestyle changes. You can't change your genes, but you can change behaviors that affect your health, such as smoking, inactivity, and poor eating habits. In many cases, making these changes can reduce your risk of disease even if the disease runs in your family. Another change you can make is to have screening tests, such as mammograms and colorectal cancer screening. These screening tests help detect disease early. People who have a family health history of a chronic disease may benefit the most from screening tests that look for risk factors or early signs of disease. Finding disease early, before symptoms appear, can mean better health in the long run.

16.2.13: Immunity and Immunizations

In 2010, a pertussis (whooping cough) outbreak in California sickened 9,143 people and resulted in 10 infant deaths: the worst outbreak in 63 years (Centers for Disease Control 2011b). Researchers, suspecting that the primary cause of the outbreak was the waning strength of pertussis vaccines in older children, recommended a booster vaccination for 11–12-year-olds and also for pregnant women (Zacharyczuk 2011). Pertussis is most serious for babies; one in five needs to be hospitalized, and since they are too young for the vaccine themselves, it is crucial that people around them be immunized (Centers for Disease Control 2011b). Several states, including California, have been requiring the pertussis booster for older children in recent years with the hope of staving off another outbreak.

But what of people who do not want their children to have this vaccine, or any other? That question is at the heart of a debate that has been simmering for years. Vaccines are biological preparations that improve immunity against a certain disease. Vaccines have contributed to the eradication and weakening of numerous infectious diseases, including smallpox, polio, mumps, chicken pox, and meningitis.

However, many people express concern about potential negative side effects from vaccines. These concerns range from fears about overloading the child's immune system to controversial reports about devastating side effects of the vaccines. One misapprehension is that the vaccine itself might cause the disease it is supposed to be immunizing against.

Another commonly circulated concern is that vaccinations, specifically the MMR vaccine (MMR stands for measles, mumps, and rubella), are linked to autism. The autism connection has been particularly controversial. In 1998, a British physician named Andrew Wakefield published a study in Great Britain's Lancet magazine that linked the MMR vaccine to autism. The report received a lot of media attention, resulting in British immunization rates decreasing from 91 percent in 1997 to almost 80 percent by 2003, accompanied by a subsequent rise in measles cases (Devlin 2008). A prolonged investigation by the British Medical Journal proved that not only was the link in the study nonexistent, but that Dr. Wakefield had falsified data in order to support his claims (CNN 2011). Dr. Wakefield was discredited and stripped of his license, but the doubt still lingers in many parents' minds.

In the United States, many parents still believe in the now discredited MMR-autism link and refuse to vaccinate their children. Other parents choose not to vaccinate for various reasons like religious or health beliefs. In one instance, a boy whose parents opted not to vaccinate returned home to the U.S. after a trip abroad; no one yet knew he was infected with measles. The boy exposed 839 people to the disease and caused 11 additional cases of measles, all in other unvaccinated children, including one infant who had to be hospitalized. According to a study published in Pediatrics (2010), the outbreak cost the public sector $10,376 per diagnosed case. The study further showed that the intentional non-vaccination of those infected occurred in students from private schools, public charter schools, and public schools in upper-socioeconomic areas (Sugerman et al. 2010).

Consider these questions about immunization:

- Should parents be forced to immunize their children?
- How does this story of vaccines in a high-income region compare to that in a low-income region, like sub-Saharan Africa, where populations are often eagerly seeking vaccines rather than refusing them?
- Do you believe all children should receive vaccinations?

Immunity and Immunizations

Shots may hurt a little... but the diseases they can prevent can hurt a lot more! Immunization shots, or vaccinations, are essential. They protect against things like measles, mumps, rubella, hepatitis B, polio, diphtheria, tetanus and pertussis (whooping cough). Immunizations are important for adults as well as for children. Here's why.

Your immune system helps your body fight germs by producing substances to combat them. Once it does, the immune system "remembers" the germ and can fight it again. Vaccines contain germs that have been killed or weakened. When given to a healthy person, the vaccine triggers the immune system to respond and thus build immunity.

Before vaccines, people became immune only by actually getting a disease and surviving it. Immunizations are an easier and less risky way to become immune.

Optional Learning Activity

Take action to raise awareness of immunizations (e.g., Assist a school nurse to host an immunization education event for parents at a local school)

- Create and distribute an immunization reminder flyers to all the members of your organization, club or place of worship.

Vaccines

Vaccines are the best defense we have against serious, preventable, and sometimes deadly contagious diseases. Vaccines are some of the safest medical products available, but like any other medical product, there may be risks. Accurate information about the value of vaccines as well as their possible side-effects helps people to make informed decisions about vaccination.

Federal law requires that Vaccine Information Statements explaining vaccine benefits and risks be handed out whenever (before each dose) certain vaccinations are given. Vaccine Information Statements are available in Spanish and many different languages. In addition, more detailed information describing the benefits and risks of a particular vaccine is available in the Prescribing Information from the Food and Drug Administration.

The following sections answer common questions asked about vaccines and how vaccines are tested and monitored to ensure they are safe and effective. These sections are currently available in English only.
Vaccines are held to the highest standard of safety. The United States currently has the safest, most effective vaccine supply in history. Vaccines undergo a rigorous and extensive evaluation program to determine a product's safety and effectiveness. If a vaccine does receive approval, it is continuously monitored for safety and effectiveness.

Many partners work together to make sure vaccines are safe. Government health scientists work with manufacturers, health care providers, academia, and global health groups such as the World Health Organization to build a comprehensive vaccine safety system. At the Department of Health and Human Services, primarily three agencies work on vaccine safety:

- Centers for Disease Control and Prevention (CDC)
- National Institutes of Health (NIH)
- Food and Drug Administration (FDA)

Vaccines undergo rigorous and extensive testing to determine their safety and effectiveness prior to approval. Following approval, FDA carefully monitors the quality of vaccines—all manufactured lots must pass tests before they can be used. Vaccine manufacturers also must follow strict manufacturing standards, and FDA conducts routine inspections of manufacturing sites.

Scientists from FDA and CDC work closely to monitor reports of vaccine side effects (adverse events) after they are approved and used widely. FDA and CDC take all reports seriously, and work together to evaluate and address any potential problems.

Learning Activity

Watch this video titled Get The Picture: Childhood Immunizations:

This interactive element is not available in this format. Visit the link or scan the QR code to access it online.

View this YouTube Video online

After talking with parents across the country, CDC put together this short video to help answer the tough questions that real moms had about childhood immunizations.

Understanding the importance of vaccines is crucial for you to protect your children's health. Read the script

- Did watching this video help you decide on whether or not to get your child immunized?
- Interview some parents to find out what they think about this issue.

Potential Side Effects

Vaccines, like all medical products, may cause side effects in some people. Most of these side effects are minor, such as redness or swelling at the injection site. Read further to learn about possible side effects from vaccines.

Any vaccine can cause side effects. For the most part these are minor (for example, a sore arm or low-grade fever) and go away within a few days.

Remember, vaccines are continually monitored for safety, and like any medication, vaccines can cause side effects. However, a decision not to immunize a child also involves risk and could put the child and others who come into contact with him or her at risk of contracting a potentially deadly disease.

How Well Do Vaccines Work?

Vaccines work really well. No medicine is perfect, of course, but most childhood vaccines produce immunity about 90–100% of the time.

What about the argument made by some people that vaccines don't work that well . . . that diseases would be going away on their own because of better hygiene or sanitation, even if there were no vaccines?

That simply isn't true. Certainly better hygiene and sanitation can help prevent the spread of disease, but the germs that cause disease will still be around, and as long as they are they will continue to make people sick.

All vaccines must be licensed (approved) by the Food and Drug Administration (FDA) before being used in the United States, and a vaccine must go through extensive testing to show that it works and that it is safe before the FDA will approve it. Among these tests are clinical trials, which compare groups of people who get a vaccine with groups of people who get a control. A vaccine is approved only if FDA makes the determination that it is safe and effective for its intended use.

If you look at the history of any vaccine-preventable disease, you will virtually always see that the number of cases of disease starts to drop when a vaccine is licensed. Vaccines are the most effective tool we have to prevent infectious diseases.

Prevention

Vaccines help the body's immune system prepare for future attacks. Vaccines consist of killed or modified microbes, parts of microbes, or microbial DNA that trick the body into thinking an infection has occurred. A vaccinated person's immune system attacks the harmless vaccine and prepares for invasions against the kind of microbe the vaccine contained. In this way, the person becomes immunized against the microbe: if re-exposure to the infectious microbe occurs, the immune system will quickly recognize how to stop the infection.

This section explains more in detail about how your immune system works to prevent you from getting sick. Knowing how your immune system works may help you understand how vaccines work with your immune system to protect you.

What is the Immune System?

The immune system is a network of cells, tissues, and organs that work together to defend the body against attacks by "foreign" invaders. These are primarily microbes—tiny organisms such as bacteria, parasites, and fungi that can cause infections. Viruses also cause infections, but are too primitive to be classified as living organisms. The human body provides an ideal environment for many microbes. It is the immune system's job to keep them out or, failing that, to seek out and destroy them.

When the immune system hits the wrong target, however, it can unleash a torrent of disorders, including allergic diseases, arthritis, and a form of diabetes. If the immune system is crippled, other kinds of diseases result.

The immune system is amazingly complex. It can recognize and remember millions of different enemies, and it can produce secretions (release of fluids) and cells to match up with and wipe out nearly all of them.

The secret to its success is an elaborate and dynamic communications network. Millions and millions of cells, organized into sets and subsets, gather like clouds of bees swarming around a hive and pass information back and forth in response to an infection. Once immune cells receive the alarm, they become activated and begin to produce powerful chemicals. These substances allow the cells to regulate their own growth and behavior, enlist other immune cells, and direct the new recruits to trouble spots.

In addition, scientists are rapidly unraveling the genetic blueprints that direct the human immune response, as well as those that dictate the biology of bacteria, viruses, and parasites. The combination of new technology and expanded genetic information will no doubt reveal even more about how the body protects itself from disease.

Mounting an Immune Response

Infections are the most common cause of human disease. They range from the common cold to debilitating conditions like chronic hepatitis to life-threatening diseases such as AIDS. Disease-causing microbes (pathogens) attempting to get into the body must first move past the body's external armor, usually the skin or cells lining the body's internal passageways.

The skin provides an imposing barrier to invading microbes. It is generally penetrable only through cuts or tiny abrasions. The digestive and respiratory tracts—both portals of entry for a number of microbes—also have their own levels of protection. Microbes entering the nose often cause the nasal surfaces to secrete more protective mucus, and attempts to enter the nose or lungs can trigger a sneeze or cough reflex to force microbial invaders out of the respiratory passageways. The stomach contains a strong acid that destroys many pathogens that are swallowed with food.

If microbes survive the body's front-line defenses, they still have to find a way through the walls of the digestive, respiratory, or urogenital passageways to the underlying cells. These passageways are lined with tightly packed epithelial cells covered in a layer of mucus, effectively blocking the transport of many pathogens into deeper cell layers.

Mucosal surfaces also secrete a special class of antibody called IgA, which in many cases is the first type of antibody to encounter an invading microbe. Underneath the epithelial layer a variety of immune cells, including macrophages, B cells, and T cells, lie in wait for any microbe that might bypass the barriers at the surface.

Next, invaders must escape a series of general defenses of the innate immune system, which are ready to attack without regard for specific antigen markers. These include patrolling phagocytes, natural killer T cells, and complement.

Microbes cross the general barriers then confront specific weapons of the adaptive immune system tailored just for them. These specific weapons, which include both antibodies and T cells, are equipped with singular receptor structures that allow them to recognize and interact with their designated targets.

Immunity

Long ago, physicians realized that people who had recovered from the plague would never get it again—they had acquired immunity. This is because some of the activated T and B cells had become memory cells. Memory cells ensure that the next time a person meets up with the same antigen, the immune system is already set to demolish it.

Immunity can be strong or weak, short-lived or long-lasting, depending on the type of antigen it encounters, the amount of antigen, and the route by which the antigen enters the body. Immunity can also be influenced by inherited genes. When faced with the same antigen, some individuals will respond forcefully, others feebly, and some not at all.

An immune response can be sparked not only by infection but also by immunization with vaccines. Some vaccines contain microorganisms—or parts of microorganisms— that have been treated so they can provoke an immune response but not full-blown disease.

Immunity can also be transferred from one individual to another by injections of serum rich in antibodies against a particular microbe (antiserum). For example, antiserum is sometimes given to protect travelers to countries where hepatitis A is widespread. The antiserum induces passive immunity against the hepatitis A virus. Passive immunity typically lasts only a few weeks or months.

Vaccines

For many years, healthcare providers have used vaccination to help the body's immune system prepare for future attacks. Vaccines consist of killed or modified microbes, parts of microbes, or microbial DNA that trick the body into thinking an infection has occurred.

A vaccinated person's immune system attacks the harmless vaccine and prepares for invasions against the kind of microbe the vaccine contained. In this way, the person becomes immunized against the microbe. Vaccination remains one of the best ways to prevent infectious diseases, and vaccines have an excellent safety record. Previously devastating diseases such as smallpox, polio, and whooping cough (pertussis) have been greatly controlled or eliminated through worldwide vaccination programs.

Recommended Vaccines for Young Adults

The transition to adulthood is an exciting time in a young person's life. Starting a career, getting an apartment, entering college, or joining the armed forces all offer unique rewards and challenges.

Yet young adults may not know that some vaccines can make this transitional time a healthier one.

Vaccines recommended for young adults ages 19–24 include:

- Meningococcal conjugate vaccine, which helps prevent meningococcal disease
- Tdap vaccine, which protects against tetanus, diphtheria, and pertussis (also known as whooping cough)
- HPV vaccine, which protects against the viruses that cause most cervical cancers, anal cancer, and genital warts
- Seasonal flu vaccine

There may be other vaccines recommended for young adults because their health, job, or lifestyle may put them at higher risk for certain diseases. Young adults should talk to a doctor or nurse to find out if there are other vaccines that they may need.

Learning Activity

Take this quiz to find out to find out which vaccines **YOU** may need.

Antibiotic / Antimicrobial Resistance

Antibiotics and similar drugs, together called antimicrobial agents, have been used for the last 70 years to treat patients who have infectious diseases. Since the 1940s, these drugs have greatly reduced illness and death from infectious diseases. Antibiotic use has been beneficial and, when prescribed and taken correctly, their value in patient care is enormous.

However, these drugs have been used so widely and for so long that the infectious organisms the antibiotics are designed to kill have adapted to them, making the drugs less effective. People infected with antimicrobial-resistant organisms are more likely to have longer, more expensive hospital stays, and may be more likely to die as a result of the infection.

Sexually Transmitted Diseases and HIV

Sexually transmitted diseases (STDs) are infections that you can get from having sex with someone who has the infection. The causes of STDs are bacteria, viruses, and parasites. There are more than 20 types of STDs, including:

- Bacterial
  - Gonorrhea
- Viral
  - Genital herpes
  - HIV/AIDS
  - HPV
  - Syphilis
- Parasitic

- Trichomoniasis

Most STDs affect both men and women, but in many cases the health problems they cause can be more severe for women. If a pregnant woman has an STD, it can cause serious health problems for the baby.

If you have an STD caused by bacteria or parasites, your health care provider can treat it with antibiotics or other medicines. If you have an STD caused by a virus, there is no cure. Sometimes medicines can keep the disease under control. Correct usage of latex condoms greatly reduces, but does not completely eliminate, the risk of catching or spreading STDs.

Gonorrhea

Gonorrhea is a curable sexually transmitted disease. It is most common in young adults. The bacteria that cause gonorrhea can infect the genital tract, mouth or anus.

Gonorrhea does not always cause symptoms, especially in women. In men, gonorrhea can cause pain when urinating and discharge from the penis. If untreated, it can cause epididymitis, which affects the testicles and can lead to infertility. In women, gonorrhea can cause bleeding between periods, pain when urinating and increased discharge from the vagina. If untreated, it can lead to pelvic inflammatory disease, which causes problems with pregnancy and infertility. Gonorrhea can pass from mother to baby during pregnancy.

You can cure gonorrhea with antibiotics prescribed by your health care provider. Correct usage of latex condoms greatly reduces, but does not eliminate, the risk of catching or spreading gonorrhea.

Genital Herpes

Genital herpes is a sexually transmitted disease (STD) caused by a herpes simplex virus (HSV). It can cause sores on your genital or rectal area, buttocks, and thighs. You can get it from having sex, even oral sex. The virus can spread even when sores are not present. Mothers can also infect their babies during childbirth.

Symptoms of herpes are called outbreaks. You usually get sores near the area where the virus has entered the body. They turn into blisters, become itchy and painful, and then heal. Sometimes people do not know they have herpes because they have no symptoms or very mild symptoms. The virus can be more serious in newborn babies or in people with weak immune systems.

Most people have outbreaks several times a year. Over time, you get them less often and the symptoms become milder. The virus stays in your body for life.

Medicines do not cure genital herpes, but they can to help your body fight the virus. This can help lessen symptoms, decrease outbreaks, and lower the risk of passing the virus to others. Correct usage of latex condoms can reduce, but not eliminate, the risk of catching or spreading herpes.

Learning Activity

Watch this video about Molly's story and herpes.

HPV (or genital warts)

Human papillomaviruses (HPV) are common viruses that can cause warts. There are more than 100 types of HPV. Most are harmless, but about 30 types put you at risk for cancer. These types affect the genitals and you get them through sexual contact with an infected partner. They are classified as either low-risk or high-risk. Low-risk HPV can cause genital warts. High-risk HPV can lead to cancers of the cervix, vulva, vagina, and anus in women. In men, it can lead to cancers of the anus and penis.

Although some people develop genital warts from HPV infection, others have no symptoms. Your health care provider can treat or remove the warts. In women, Pap smears can detect changes in the cervix that might lead to cancer.

Correct usage of latex condoms greatly reduces, but does not eliminate, the risk of catching or spreading HPV. A vaccine can

protect against several types of HPV, including some that can cause cancer.

Trichomoniasis

Trichomoniasis is a sexually transmitted disease caused by a parasite. It affects both women and men, but symptoms are more common in women. Symptoms in women include a green or yellow discharge from the vagina, itching in or near the vagina and discomfort with urination. Most men with trichomoniasis don't have any symptoms, but it can cause irritation inside the penis.

You can cure trichomoniasis with antibiotics. In men, the infection usually goes away on its own without causing symptoms. But an infected man can continue to infect or reinfect a woman until he gets treated. So it's important that both partners get treated at the same time. Correct usage of latex condoms greatly reduces, but does not eliminate, the risk of catching or spreading trichomoniasis.

AIDS and HIV

AIDS was first reported in the United States in 1981 and has since become a major worldwide epidemic. AIDS is caused by the human immunodeficiency virus, or HIV. By killing or damaging cells of the body's immune system, HIV progressively destroys the body's ability to fight infections and certain cancers. People diagnosed with AIDS may get life-threatening diseases called opportunistic infections. These infections are caused by microbes such as viruses or bacteria that usually do not make healthy people sick.

Since 1981, more than 980,000 cases of AIDS have been reported in the United States to the Centers for Disease Control and Prevention (CDC). According to CDC, more than 1,000,000 Americans may be infected with HIV, one-quarter of whom are unaware of their infection. The epidemic is growing most rapidly among minority populations and is a leading killer of African-American males ages 25 to 44. According to CDC, AIDS affects nearly seven times more African Americans and three times more Hispanics than whites. In recent years, an increasing number of African-American women and children are being affected by HIV/AIDS.

- The U.S. HIV/AIDS epidemic began in 1981 and continues to disproportionately affect minorities, men who have sex with men of all races, women, and youth.
- More than 1 million people in the United States currently are living with HIV/AIDS.
- About 21 percent of those infected with HIV are unaware of their infection.
- Since the U.S. epidemic began, 617,025 people have died of AIDS.
- In 2008, there were approximately 42,439 new HIV infections, with the highest proportion among African Americans despite the fact that they make up only 12 percent of the U.S. population.

HIV

HIV stands for human immunodeficiency virus. It kills or damages the body's immune system cells. AIDS stands for acquired immunodeficiency syndrome. It is the most advanced stage of infection with HIV.
HIV most often spreads through unprotected sex with an infected person. It may also spread by sharing drug needles or through contact with the blood of an infected person. Women can give it to their babies during pregnancy or childbirth.

The first signs of HIV infection may be swollen glands and flu-like symptoms. These may come and go a month or two after infection. Severe symptoms may not appear until months or years later.

A blood test can tell if you have HIV infection. Your health care provider can perform the test.

There is no cure, but there are many medicines to fight both HIV infection and the infections and cancers that come with it. People can live with the disease for many years.

AIDS Prevention

Currently, there is no vaccine to prevent HIV infection nor is there a cure for HIV/AIDS. To reduce your risk of becoming infected with HIV or transmitting the virus to others

- Get tested regularly for HIV
- Practice abstinence
- Remain faithful to your spouse or partner
- Consistently use male latex or female polyurethane condoms
- Do not share needles

Detection and Treatment in HIV Prevention

Testing and treatment of sexually transmitted diseases (STDs) can be an effective tool in preventing the spread of HIV, the virus that causes AIDS. An understanding of the relationship between STDs and HIV infection can help in the development of effective HIV prevention programs for persons with high-risk sexual behaviors.

What is the link between STDs and HIV infection?

Individuals who are infected with STDs are at least two to five times more likely than uninfected individuals to acquire HIV infection if they are exposed to the virus through sexual contact. In addition, if an HIV-infected individual is also infected with another STD, that person is more likely to transmit HIV through sexual contact than other HIV-infected persons (Wasserheit, 1992).

There is substantial biological evidence demonstrating that the presence of other STDs increases the likelihood of both transmitting and acquiring HIV.

- **Increased susceptibility.** STDs appear to increase susceptibility to HIV infection by two mechanisms. Genital ulcers (e.g., syphilis, herpes, or chancroid) result in breaks in the genital tract lining or skin. These breaks create a portal of entry for HIV. Additionally, inflammation resulting from genital ulcers or non-ulcerative STDs (e.g., chlamydia, gonorrhea, and trichomoniasis) increase the concentration of cells in genital secretions that can serve as targets for HIV (e.g., CD4+ cells).
- **Increased infectiousness.** STDs also appear to increase the risk of an HIV-infected person transmitting the virus to his or her sex partners. Studies have shown that HIV-infected individuals who are also infected with other STDs are particularly likely to shed HIV in their genital secretions. For example, men who are infected with both gonorrhea and HIV are more than twice as likely to have HIV in their genital secretions than are those who are infected only with HIV. Moreover, the median concentration of HIV in semen is as much as 10 times higher in men who are infected with both gonorrhea and HIV than in men infected only with HIV. The higher the concentration of HIV in semen or genital fluids, the more likely it is that HIV will be transmitted to a sex partner.

How can STD treatment slow the spread of HIV infection?

Evidence from intervention studies indicates that detecting and treating STDs may reduce HIV transmission.

- **STD treatment reduces an individual's ability to transmit HIV**. Studies have shown that treating STDs in HIV-infected individuals decreases both the amount of HIV in genital secretions and how frequently HIV is found in those secretions (Fleming, Wasserheit, 1999).
- Herpes can make people more susceptible to HIV infection, and it can make HIV-infected individuals more infectious. It is critical that all individuals, **especially those with herpes**, know whether they are infected with HIV and, if uninfected with HIV, take measures to protect themselves from infection with HIV.
- Among individuals with both herpes and HIV, trials are underway studying if treatment of the genital herpes helps prevent HIV transmission to partners.

Learning Activity

Watch this video about AIDS from PBS.

Illness, Sickness, and Disease

Discussing the complexities of what constitutes a disease requires careful distinction among related, but distinct concepts.

In 1973, Susser, an epidemiologist, proposed some definitions that remain useful. He used “illness” to refer to the subjective sense of feeling unwell; illness does not define a specific pathology, but refers to a person’s subjective experience of it, such as discomfort, tiredness, or general malaise. The way a patient reports symptoms is influenced by his or her cultural background, and Susser applied the term “sickness” to refer to socially and culturally held conceptions of health conditions (e.g., the dread of cancer or the stigma of mental illness), which in turn influence how the patient reacts). The social perceptions of disease that Illich described modify the ways a patient perceives and presents his symptoms.

Cultural conventions likewise affect where the boundary between disease and non-disease is placed: menopause may be considered a health issue in North America, but symptoms are far less commonly reported in Japan. Disease implies a focus on pathological processes that may or may not produce symptoms and that result in a patient’s illness. For example, a patient complains of tiredness and malaise–his illness as he experiences it. He consults a doctor about it–because he believes that he might have a sickness. The doctor might attribute the patient’s symptoms to a thyroid condition–a disease.

This model focuses on pathological processes, and on understanding, diagnosing, and treating the physical and biological aspects of disease. The goal of treatment is to restore the patient’s physiological integrity and function. Diagnosis involves recognizing and applying a label to a pattern of signs and symptoms that is at least partly understood in terms of abnormal structure or function of cells, organs, and systems. This offers a rational basis for the investigation of effective treatments. For instance, a certain pattern of chest pain known as angina pectoris is understood biologically as a disorder of the coronary arteries that causes cardiac ischemia, and the treatments it are geared to the specific causes of restoring cardiac blood flow and reducing cardiac effort.

Early biomedical conceptions supposed that a disease is either present or absent: a bacterium has invaded the body or it has not. However, as medicine increasingly tackled conditions, such as hypertension, which represent deviations from normal values, which themselves have a range and can be debated, it became apparent that there may be no set threshold for defining disease. Thus, instead of being seen as a state that is qualitatively distinct from health, many diseases have to be approached as a quantitative threshold on a continuum of biological variability. Organizations such as the World Health Organization (WHO) and the National Institutes of Health have proposed different classifications of hypertension and have changed how they constitute hypertension over time. Hypertension can be mild, moderate or severe, or defined as pre-hypertension or hypertension stage 1 or stage 2.

Optional: Video Lectures about Epidemics

Epidemics in Western Society is a course taught Frank Snowden at Yale.

This course consists of video lectures with an international analysis of the impact of epidemic diseases on western society and culture from the bubonic plague to HIV/AIDS and the recent experience of SARS and swine flu.

Leading themes include:

- infectious disease and its impact on society
- the development of public health measures
- the role of medical ethics
- the genre of plague literature
- the social reactions of mass hysteria and violence
- the rise of the germ theory of disease
- the development of tropical medicine
- a comparison of the social, cultural, and historical impact of major infectious diseases
- the issue of emerging and re-emerging diseases

TABLE OF CONTENTS

Microbiomes: Health and the Environment was created to provide accessible insight into the novel and complex world of polymicrobial community interactions. As we push forward into the future of medicine and environmental health, it is imperative that we learn from each other, from history, and keep up to date with the latest advances in research and technology. This book not only provides content from the latest microbiome studies, but contains interactive tools, videos, and thought-provoking questions to help the reader hone and truly understand the respective topic. Though there is much overlap between themes due to the ubiquitous nature of microbes, the book is broken down into sections pertaining to both human health (e.g., gut health and disease, as well as other organ-specific niches) and aspects of the environment (e. g., nutrient cycling and climate change, marine health, soil and plant health, etc.) influenced by microbes. However, the content is designed to bridge ideas and aspects between these themes to support the One Health concept: that the health of people, animals, and the environment are all interconnected. This project will continue to grow with new findings, and adapt with the ever-changing world of microorganisms.

17.1: BONUS- ENVIRONMENTAL WELLNESS - A HEALTHY PLANET

Learning Outcomes

By the end of this chapter you will be able to:

- Explain the relationship of CO2 to climate change.
- Provide evidence of climate change.
- Explain the impact of climate change on public health.
- List strategies for increasing health of the planet.

How are you impacting the environment?

How is the environment impacting you?

Mahatma Gandhi is quoted as saying, “Earth provides enough to satisfy every man’s needs, but not every man’s greed.” What was Gandhi trying to convey with that statement? Maybe, that the Earth does not have limitless resources for human consumption and that we as humans impact the health of the planet by the choices we make. All humans live on one planet, planet Earth. Some call Earth “Mother Earth” because Earth nurtures life just like a mother. Human societies throughout history have symbols and depictions of Earth as a nurturer since every species on Earth depends on the resources of the planet for existence. The relationship between humans and the environment is studied through a branch of public health known as **Environmental Health**. Environmental health seeks to understand how the environment impacts human health and how humans impact the health of the planet.

17.1.1: Climate Literacy

Climate Science Literacy is an understanding of your influence on climate and climate's influence on you and society. It is important for each human living on earth to understand climate. Society needs citizens who understand the climate system and know how to apply that knowledge in their careers and in their engagement as active members of their communities.

A climate-literate person:

- Understands the essential principles of Earth's climate system.
  - Essential Principle 1: The Sun is the Primary Source of Energy for Earth's Climate System
  - Essential Principle 2: Climate is regulated by complex interactions among components of the Earth system.
  - Essential Principle 3: Life on Earth depends on, is shaped by, and affects climate.
  - Essential Principle 4: Climate varies over space and time through both natural and man-made processes.
  - Essential Principle 5: Our understanding of the climate system is improved through observations, theoretical studies, and modeling.
  - Essential Principle 6: Human activities are impacting the climate system.
  - Essential Principle 7: Climate change will have consequences for the Earth system and human lives
- Knows how to assess scientifically credible information about climate.
- Communicates about climate and climate change in a meaningful way.
- Is able to make informed and responsible decisions with regard to actions that may affect climate.

This chapter is intended to help build your climate literacy.

17.1.2: Climate Change and Global Warming

“Climate change” and “global warming” are often used interchangeably but have distinct meanings. Global warming is the long-term heating of Earth’s climate system observed since the pre-industrial period (between 1850 and 1900) due to human activities, primarily fossil fuel burning, which increases heat-trapping greenhouse gas levels in Earth’s atmosphere. Climate change is long-term changes in the average weather patterns that have come to define Earth’s local, regional and global climates.

Global Warming: The Greenhouse Effect

Imagine stepping into a greenhouse. The temperature inside and outside of a greenhouse can be very different. Outside of a greenhouse you can feel the heat from the sun’s rays, but the heat can escape to the atmosphere, however, inside the greenhouse, the sun’s rays are turned to heat and the heat is trapped by the greenhouse. The way a greenhouse traps heat making it warmer inside than outside, is similar to how the greenhouse gases in the Earths atmosphere, such as CO2, trap heat and increase the temperature of the planet.

Earth is surrounded by the earth’s atmosphere, which is an envelope of gases surrounding the earth. The sun provides solar radiation to our planet that passes through the earths atmosphere. When the Sun’s solar rays hit our planet the solar radiation turns to heat. Gases in the atmosphere, such as carbon dioxide, nitrous oxide, methane, and water vapor, block heat from escaping, thus trapping in heat inside our atmosphere.

The trapping of heat is called the Greenhouse effect. Global warming refers to the recent and ongoing global average increase in temperature near the Earth’s surface. Scientists attribute the global warming trend observed since the mid-20th century to the “greenhouse effect.”

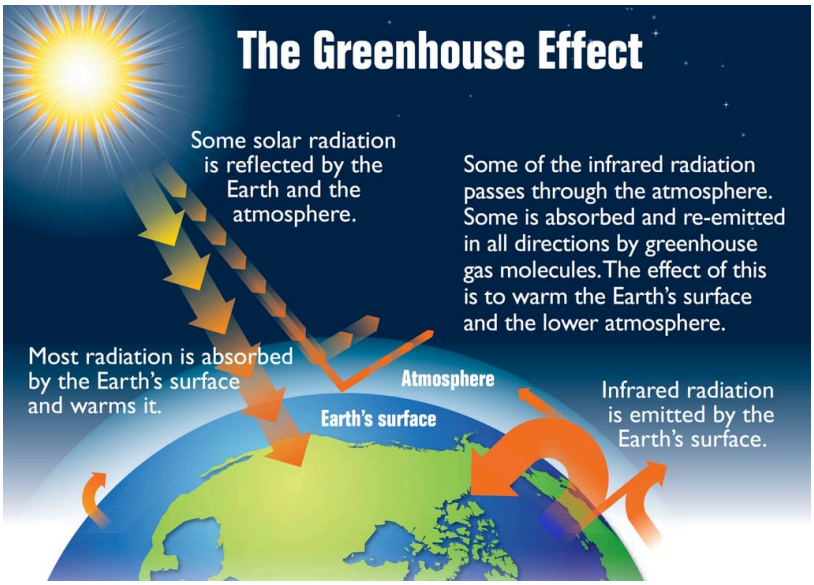

Figure 17.1.2.1**: The Greenhouse effect**

Evidence/Indicators of Climate Change

A picture is worth 1,000 words

Nasa has provided a library of "Images of Change" that show show a before and after comparison of land masses, glaciers, oceans, etc to depict how climate change is impacting the world around you. Some of the pictures show more recent changes, for example how the drought has changed Lake Powell, others show changes over time, such as the Muir Glacier Melt in Alaska.

Figure 17.1.2.2: Muir Glacier Melt, Alaska. 1941 compared to 2004

The Earth's climate is changing. Observations from around the world show the **widespread effects** of increasing greenhouse gas concentrations on Earth's climate. For example:

- High temperature extremes, droughts, and heavy precipitation events are becoming more frequent and intense.
- Glaciers and snow cover are shrinking, and sea ice is retreating.
- Seas are warming, rising, and becoming more acidic, and marine species are moving to new locations in colder waters.
- Flooding is becoming more frequent along the U.S. coastline.
- Growing seasons are lengthening, and areas burned by wildfire are growing.

The Environmental Protection Agency has compiled a key set of indicators[1] related to the causes and effects of climate change. The climate change indicators provide important information on how and why the climate is changing. These indicators include: greenhouse gases, weather and climate, oceans, snow and ice, health and society, and ecosystem

Greenhouse gases

Ice cores[2] are like frozen time capsules that allow scientists to reconstruct climate far into the past. Using ice cores, scientists have been able to measure greenhouse gas emissions from over 800,000 years ago. Ice cores provide a direct measurement of greenhouse gases thus are considered a gold standard. As greenhouse gas emissions from human activities increase, they build up in the atmosphere and warm the climate, leading to many other worldwide changes in the atmosphere, on land, and in the oceans. Greenhouse gases from human activities are the most significant driver of observed climate change since the mid-20th century.

Summary of key points:

- In the United States, greenhouse gas emissions caused by human activities increased by 2 percent from 1990 to 2019. Since 2005, however, total U.S. greenhouse gas emissions have decreased by 12 percent. Carbon dioxide accounts for most of the nation's emissions and most of the increase since 1990. Transportation is the largest source of greenhouse gas emissions in the United States, followed by electricity generation. Emissions per person have decreased slightly in the last few years.
- Worldwide, net emissions of greenhouse gases from human activities increased by 43 percent from 1990 to 2015. Emissions of carbon dioxide, which account for about three-fourths of total emissions, increased by 51 percent over this period. As with the United States, the majority of the world's emissions result from transportation, electricity generation, and other forms of energy production and use.
- Concentrations of carbon dioxide and other greenhouse gases in the atmosphere have increased since the beginning of the industrial era. Almost all of this increase is attributable to human activities. Historical measurements show that the current global atmospheric concentrations of carbon dioxide are unprecedented compared with the past 800,000 years, even after accounting for natural fluctuations.
- From 1990 to 2019, the total warming effect from greenhouse gases added by humans to the Earth's atmosphere increased by 45 percent. The warming effect associated with carbon dioxide alone increased by 36 percent.

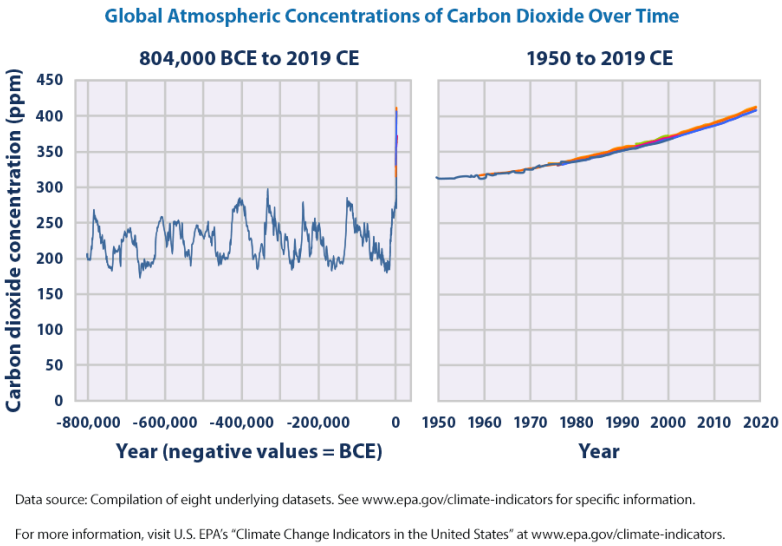

Figure 17.1.2.3: Global Atmospheric Concentrations of Greenhouse Gases

Weather and climate

Rising global average temperature is associated with widespread changes in weather patterns. Weather is what conditions of the atmosphere are over a short period of time, and climate is how the atmosphere "behaves" over relatively long periods of time.

Summary of Key Points

- Average temperatures have risen across the contiguous 48 states since 1901, with an increased rate of warming over the past 30 years.
- Eight of the top 10 warmest years on record have occurred since 1998. All of the top 10 warmest years on record worldwide have occurred since 2005.
- Since 1896, average winter temperatures across the contiguous 48 states have increased by nearly 3°F. Spring temperatures have increased by about 2°F, while summer and fall temperatures have increased by 1.4°F.
- Record-setting daily high temperatures have become more common than record lows. Since the 1970s, unusually hot summer days (highs) and unusually hot summer nights (lows) have become more common over the last few decades. Unusually cold winter temperatures have become less common—particularly very cold nights (lows).
- Heat waves are occurring three times more often than they did in the 1960s—about six per year compared with two per year. The average heat wave season is 47 days longer, and individual heat waves are lasting longer and becoming more intense.
- Since 1901, precipitation has increased at an average rate of 0.1 inches per decade over land areas worldwide. However, shifting weather patterns have caused certain areas, such as the Southwest, to experience less precipitation than usual.
- The prevalence of extreme single-day precipitation events remained fairly steady between 1910 and the 1980s but has risen substantially since then. Nationwide, nine of the top 10 years for extreme one-day precipitation events have occurred since 1996.
- Floods have generally become larger across parts of the Northeast and Midwest and smaller in the West, southern Appalachia, and northern Michigan. Large floods have become more frequent across the Northeast, Pacific Northwest, and parts of the northern Great Plains, and less frequent in the Southwest and the Rockies.
- Drought trends vary by region, as the West has generally experienced more drought while the Midwest and Northeast have become wetter.
- The southwestern United States is particularly sensitive to changes in temperature and thus vulnerable to drought, as even a small decrease in water availability in this already arid region can stress natural systems and further threaten water supplies. Several measures indicate persistent and more severe drought conditions in recent years.

Oceans

Covering about 70 percent of the Earth's surface, the world's oceans have a two-way relationship with weather and climate. The oceans influence the weather on local to global scales, while changes in climate can fundamentally alter many properties of the oceans.

Summary of Key Points

- The amount of heat stored in the ocean has increased substantially since the 1950s. Ocean heat content not only determines sea surface temperature, but also affects sea level and currents.
- Sea surface temperatures have been consistently higher during the past three decades than at any other time since reliable observations began in the late 1800s.
- When averaged over all of the world's oceans, sea level has risen at a rate of roughly six-tenths of an inch per decade since 1880. Changes in sea level relative to the land vary by region. Along the U.S. coastline, sea level has risen the most along the Mid-Atlantic coast and parts of the Gulf coast, where several stations registered increases of more than 8 inches between 1960 and 2020. Sea level has decreased relative to the land in parts of Alaska and the Pacific Northwest.
- As sea level rises, dry land and wetlands can turn into open water. Along many parts of the Atlantic coast, this problem is made worse by low elevations and land that is already sinking. Between 1996 and 2011, the coastline from Florida to New York lost more land than it gained.
- Flooding is becoming more frequent along the U.S. coastline as sea level rises. Every site measured has experienced an increase in coastal flooding since the 1950s. The rate is accelerating at most locations along the East and Gulf coasts. The East Coast suffers the most frequent coastal flooding and has generally experienced the largest increases in the number of flood days.
- The ocean has become more acidic over the past few decades because of increased levels of atmospheric carbon dioxide, which dissolves in the water. Higher acidity affects the balance of minerals in the water, which can make it more difficult for certain marine animals to build their protective skeletons or shells.

Snow and Ice

The Earth's surface contains many forms of snow and ice, including sea, lake, and river ice; snow cover; glaciers, ice caps, and ice sheets; and frozen ground. Climate change can dramatically alter the Earth's snow- and ice-covered areas because snow and ice can easily change between solid and liquid states in response to relatively minor changes in temperature.

Summary of Key Points

- The part of the Arctic Ocean covered by ice is typically smallest in September, after the summer melting season. Arctic sea ice has decreased over time, and in September 2020 it was the second smallest ever recorded. The length of the melt season for Arctic ice has grown, and the ice has also become thinner, which makes it more vulnerable to further melting.
- Antarctic sea ice has increased slightly overall since 1979, though it has decreased in the last few years. Slight increases in Antarctic sea ice are outweighed by the loss of sea ice in the Arctic during the same time period.
- Since 1992, the giant ice sheets that cover Greenland and Antarctica have each lost more than 100 billion metric tons of ice per year on average. The total amount of ice lost from 1992 to 2018 was enough to raise sea level worldwide by an average of roughly seven-tenths of an inch.
- Glaciers in the United States and around the world have generally shrunk since the 1960s, and the rate at which glaciers are melting has accelerated over the last decade.
- Lakes in the northern United States are freezing later and thawing earlier compared with the 1800s and early 1900s.
- Since the early 1970s, all five of the Great Lakes have experienced a long-term decrease in the maximum area that freezes each year, but the decrease is only statistically meaningful in one lake (Superior). The number of frozen days per year has also decreased for all five lakes since the early 1970s.
- Total snowfall has decreased in most parts of the country since widespread records began in 1930. One reason for this decline is that nearly 80 percent of the locations studied have seen more winter precipitation fall in the form of rain instead of snow.
- Between 1972 and 2020, the average portion of North America covered by snow decreased at a rate of about 1,870 square miles per year, based on weekly measurements taken throughout the year. The length of time when snow covers the ground has become shorter by nearly two weeks since 1972, on average.
- The amount of snow on the ground (snowpack) in early spring decreased at 86 percent of measurement sites in the western United States between 1955 and 2020 and snowpack at all sites declined by an average of 19 percent during this time period.
- About 80 percent of Alaska's land is underlain by permafrost, which refers to rock or soil with ice that stays frozen for two or more years. Between 1978 and 2020, permafrost temperatures increased at 14 out of 15 long-term monitoring sites in Alaska.
- The number of days per year with unfrozen ground has increased at an average rate of about four days per decade in both the contiguous 48 states and Alaska. Unfrozen days have generally increased across North America, with some variability by region.

Health and Society

Changes in the Earth's climate can affect public health, agriculture, water supplies, energy production and use, land use and development, and recreation.

Summary of Key Points

- Since 1979, more than 11,000 Americans were reported to have died as a direct result of heat-related illnesses such as heat stroke, and even more died where heat was a contributing factor.
- From 2001 to 2010, a total of about 28,000 heat-related hospitalizations were recorded across 20 states.
- Since 1979, more than 19,000 Americans were reported to have died from exposure to cold temperatures, and even more died where exposure to cold was a contributing factor.
- As the U.S. climate has warmed in recent years Americans in the North and West are using less energy for heating and more energy for air conditioning, while much of the Southeast has experienced the opposite results.

- Since 1973, the average amount of electricity used by Americans at home during the summer has nearly doubled, but it appears to have leveled somewhat in recent years. Conversely, the average American's winter use of natural gas (the most common home heating fuel) has decreased since 1974.
- Nationwide, the rate of reported cases of Lyme disease has nearly doubled since 1991. The number and distribution of reported cases of Lyme disease have increased in the Northeast and upper Midwest over time, where some states now report 50 to 110 more cases of Lyme disease per 100,000 people than they did in 1991.
- The length of the growing season for crops and other plants has increased in almost every state. States in the Southwest (e.g., Arizona and California) have seen the most dramatic increase. In contrast, the growing season has become slightly shorter in two states (Alabama and Georgia). The observed changes reflect earlier spring warming as well as later arrival of fall frosts. The length of the growing season has increased more rapidly in the West than in the East.
- Since the late 1940s, the annual number of growing degree days increased at 75 percent of the locations measured across the contiguous 48 states. The average change was a 9 percent increase. The largest increases occurred in the West and the Northeast.
- The length of ragweed pollen season has increased at 10 out of 11 locations studied in the central United States and Canada since 1995 allowing ragweed plants to produce pollen later into the year, potentially prolonging the allergy season for millions of people.

Ecosystems

Ecosystems provide humans with food, clean water, and a variety of other services that can be affected by climate change.

Summary of Key Points

- Since 1983, the United States has had on average 70,000 recorded wildfires per year. The top 10 years with the largest acreage burned since 1983, have all occurred since 2004 with many of the largest increases occurring in western states.
- Over the past 79 years, minimum, maximum, and average streamflows have changed in many parts of the country—some higher, some lower. Among rivers and streams strongly influenced by snowmelt, peak flow from winter-spring runoff is happening at least five days earlier than it did in the mid-20th century.
- From 1960 through 2014, water temperature increased at 79 percent of the stream sites measured in the Chesapeake Bay region.
- Between 1960 and 2020, water temperatures increased by 1.9°F in the Snake River at a site on tribal lands in eastern Washington. Several species of salmon use the Snake River to migrate and spawn, and these salmon play an important role in the diet, culture, religion, and economy of the region's Native Americans.
- Since 1985, summer surface water temperatures have increased in 32 of the 34 lakes with long-term records that this indicator tracks across North America.
- Water levels in most of the Great Lakes appear to have declined slightly over the last few decades.
- Long-term studies have found that bird species in North America have shifted their wintering grounds northward by an average of more than 40 miles since 1966, with several species shifting by hundreds of miles. Some birds shift their range or alter their migration habits to adapt to changes in temperature or other environmental conditions.
- Shifts in location have occurred among several economically important fish and shellfish species that have moved about 20 miles, and 21 feet deeper in the water, between 1982 and 2018. For example, American lobster, black sea bass, and red hake in the Northeast have moved northward by an average of 113 miles.
- Leaf growth and flower blooms are examples of natural events whose timing can be influenced by climate change. In general, leaf and bloom events are happening earlier throughout the North and West but later in much of the South. for example, Cherry Blossom Bloom Dates in Washington, D.C. Peak bloom dates of the iconic cherry trees in Washington, D.C., recorded since the 1920s, indicate that cherry trees are blooming slightly earlier than in the past. Bloom dates are key to planning the Cherry Blossom Festival, one of the region's most popular spring attractions.

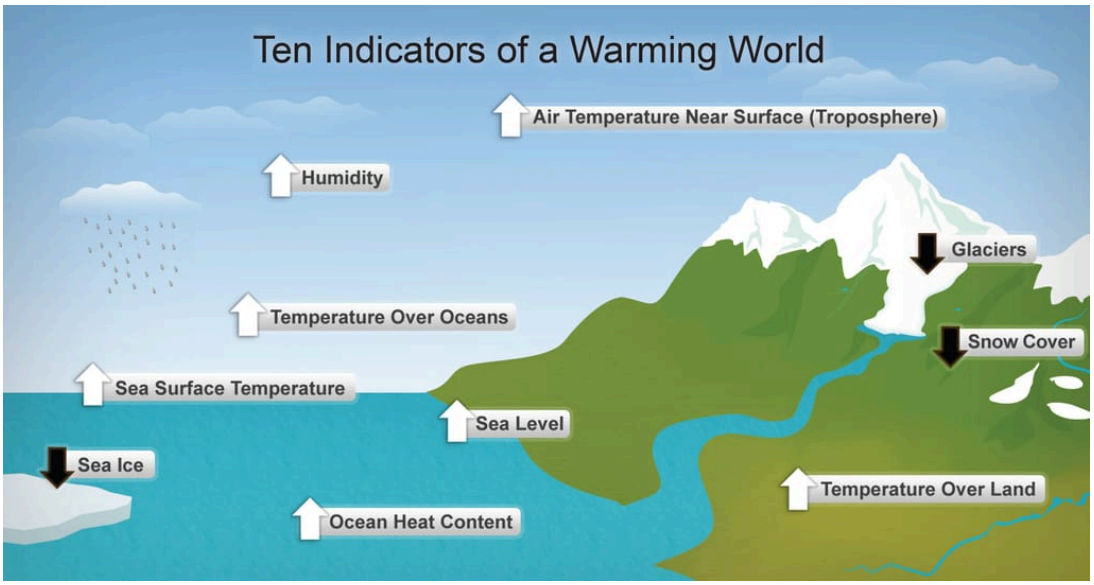

Figure 17.1.2.3: Ten Indicators of a Warming World

Exercises: Data, data, and more data

Are you curious how the U.S. compares to other countries in the various elements of climate change? Do you like looking at data and graphs? If so, check out "Our World in Data" to view extensive data and graphs on climate change for the U.S. and around the world.

Impacts of Climate Change on Human Health

Climate change is a significant threat to the health of the American people and every American is vulnerable to the health impacts associated with climate change. The U.S. Global Change Research Program's (USGCRP's) National Climate Assessment (NCA) process has published a scientific assessment on the impact of climate change on human health[3].

With climate change, the frequency, severity, duration, and location of weather and climate phenomena, like rising temperatures, heavy rains and droughts, and some other kinds of severe weather, are changing. This means that areas already experiencing health-threatening weather and climate phenomena are likely to experience worsening impacts, it also means that some locations will experience new climate-related health threats. Climate changes that impact human health include: wildfires, heat waves, drought, cold waves and winter storms, sea level changes, hurricanes, floods, extreme precipitation, and rising temperatures.

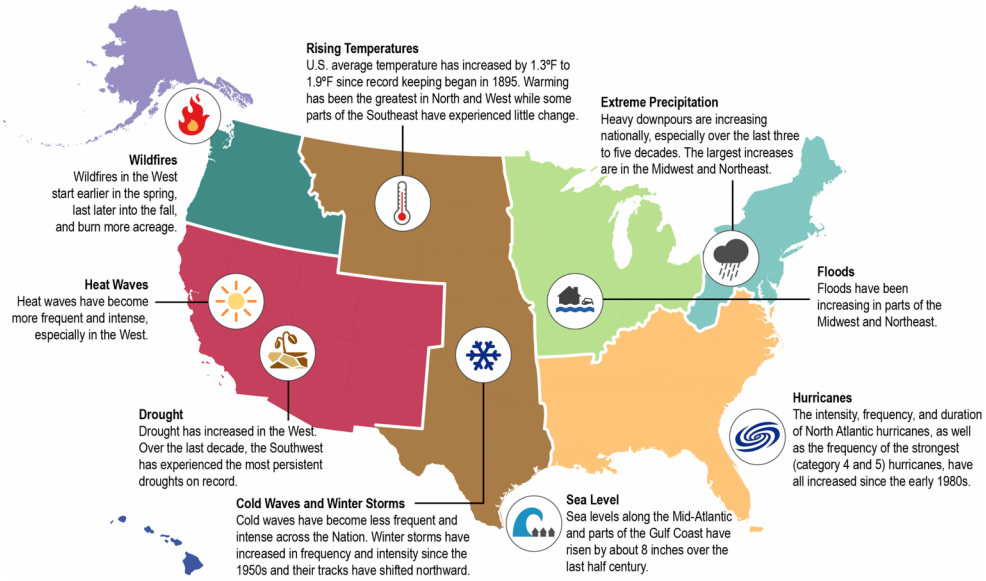

Figure 17.1.2.4: Major U.S. national and regional climate trends

Changes in the environment may have numerous impacts to existing health conditions and the development of new diseases.

Table 17.1.2.1: Health Risks Associated with Climate Change
Source: Adapted from Impacts of Global Climate Change on Health: Climate Change and Health

Health Conditions	Possible Influences of Climate Change
ALZHEIMER'S DISEASE	Persons with cognitive impairments are vulnerable to extreme weather events that require evacuation or other emergency responses.
ASTHMA	Asthma is exacerbated by changes in pollen season and allergenicity and in exposures to air pollutants affected by changes in temperature, humidity, and wind.
CHRONIC OBSTRUCTIVE PULMONARY DISEASE (COPD)	COPD patients are more sensitive than the general population to changes in ambient air quality associated with climate change.
DIABETES	Diabetes increases sensitivity to heat stress; medication and dietary needs may increase vulnerability during and after extreme weather events.
CARDIOVASCULAR DISEASE	Cardiovascular disease increases sensitivity to heat stress.
MENTAL ILLNESS	Mental illness may impair responses to extreme events ; certain medications increase sensitivity to heat stress.
OBESITY	Obesity increases sensitivity to high ambient temperatures.
DISABILITY	Persons with disabilities may find it hard to respond when evacuation is required and when there is no available means of transportation or easy exit from residences.

The following sections provide key findings from the "The Impacts of Climate Change on Human Health in the United States: A Scientific Assessment." In the official report, each key finding is notated with a level of confidence, from medium to high levels of confidence based on scientific analyses.

Temperature-Related Death and Illness

Key findings:

- By the end of the century, an increase of thousands to tens of thousands of premature heat-related deaths in the summer and a decrease of premature cold-related deaths in the winter are projected each year as a result of climate change.
- Days that are hotter than usual in the summer or colder than usual in the winter are both associated with increased illness and death.

- Some populations are more vulnerable to death or illness due to high temperatures such as children, older adults, people working outdoors, the socially isolated and economically disadvantaged, those with chronic illnesses, as well as some communities of color.

Air Quality Impacts

Key Findings

- Changes in the climate affect the air we breathe, both indoors and outdoors.
- Climate-driven increases in ozone will cause premature deaths, hospital visits, lost school days, and acute respiratory symptoms
- Changes in climate, specifically rising temperatures, altered precipitation patterns, and increasing concentrations of atmospheric carbon dioxide, are expected to contribute to increases in the levels of some airborne allergens and associated increases in asthma episodes and other allergic illnesses .
- Climate change is projected to increase the number and severity of naturally occurring wildfires in parts of the United States, increasing emissions of particulate matter and ozone precursors and resulting in additional adverse health outcomes.

Extreme Events

Key Findings

- Extreme weather events can cause death or injury during an event (for example, drowning during floods), however health impacts can also occur before or after an extreme event, as individuals may be involved in activities that put their health at risk, such as disaster preparation and post-event cleanup.
- Climate change will increase exposure risk in some regions of the United States due to projected increases in the frequency and/or intensity of drought, wildfires, and flooding related to extreme precipitation and hurricanes.
- Many types of extreme events related to climate change cause disruption of infrastructure, including power, water, transportation, and communication systems, that are essential to maintaining access to health care and emergency response services and safeguarding human health.
- Climate change will increase exposure risk to coastal flooding due to increases in extreme precipitation and in hurricane intensity and rainfall rates, as well as sea level rise and the resulting increases in storm surge

Vector-Borne Diseases

Key Findings

- Vector-borne diseases are illnesses that are transmitted by vectors, which include mosquitoes, ticks, and fleas.
- Climate change is expected to alter the geographic and seasonal distributions of existing vectors and vector-borne diseases.
- Ticks capable of carrying the bacteria that cause Lyme disease and other pathogens will show earlier seasonal activity and a generally northward expansion in response to increasing temperatures associated with climate change. Longer seasonal activity and expanding geographic range of these ticks will increase the risk of human exposure to ticks.
- Alterations in the distribution, abundance, and infection rate of mosquitoes will influence human exposure to bites from infected mosquitoes, which is expected to alter risk for human disease.
- Vector-borne pathogens are expected to emerge or reemerge due to the interactions of climate factors with many other drivers, such as changing land-use patterns.

Water-Related Illness

Key Findings

- Increases in water temperatures associated with climate change will alter the seasonal windows of growth and the geographic range of suitable habitat for freshwater toxin-producing harmful algae, certain naturally occurring Vibrio bacteria, and marine toxin-producing harmful algae. These changes will increase the risk of exposure to waterborne pathogens and algal toxins that can cause a variety of illnesses.
- Runoff from more frequent and intense extreme precipitation events will increasingly compromise recreational waters, shellfish harvesting waters, and sources of drinking water through increased introduction of pathogens and prevalence of toxic algal blooms. As a result, the risk of human exposure to agents of water-related illness will increase.
- Increases in some extreme weather events and storm surges will increase the risk that infrastructure for drinking water, wastewater, and stormwater, will fail due to either damage or exceedance of system capacity, especially in areas with aging infrastructure. As a result, the risk of exposure to water-related pathogens, chemicals, and algal toxins will increase in recreational and shellfish harvesting waters, and in drinking water where treatment barriers break down.

Food Safety, Nutrition, and Distribution

Key Findings

- Climate change, including rising temperatures and changes in weather extremes, is expected to increase the exposure of food to certain pathogens and toxins. This will increase the risk of negative health impacts
- Elevated sea surface temperatures will lead to greater accumulation of mercury in seafood, while increases in extreme weather events will introduce contaminants into the food chain. Rising carbon dioxide concentrations and climate change will alter incidence and distribution of pests, parasites, and microbes, leading to increases in the use of pesticides and veterinary drugs
- The nutritional value of agriculturally important food crops, such as wheat and rice, will decrease as rising levels of atmospheric carbon dioxide continue to reduce the concentrations of protein and essential minerals in most plant species.
- Increases in the frequency or intensity of some extreme weather events associated with climate change will increase disruptions of food distribution by damaging existing infrastructure or slowing food shipments. These impediments lead to increased risk for food damage, spoilage, or contamination, which will limit availability of and access to safe and nutritious food depending on the extent of disruption and the resilience of food distribution infrastructure.

Mental Health and Well-Being

Key Findings

- Many people exposed to climate-related or weather-related disasters experience stress and serious mental health consequences.
- Specific groups of people are at higher risk for distress and other adverse mental health consequences from exposure to climate-related or weather-related disasters. These groups include children, the elderly, women (especially pregnant and post-partum women), people with preexisting mental illness, the economically disadvantaged, the homeless, and first responders
- Many people will experience adverse mental health outcomes and social impacts from the threat of climate change, the perceived direct experience of climate change, and changes to one's local environment.
- Increases in extreme heat will increase the risk of disease and death for people with mental illness, including elderly populations and those taking prescription medications that impair the body's ability to regulate temperature.

Populations of Concern

Key Findings

- Across the United States, people and communities differ in their exposure, their inherent sensitivity, and their adaptive capacity to respond to and cope with climate change related health threats [Very High Confidence]. Vulnerability to climate change varies across time and location, across communities, and among individuals within communities.
- People experience different inherent sensitivities to the impacts of climate change at different ages and life stages. For example, the very young and the very old are particularly sensitive to climate-related health impacts.
- Climate change threatens the health of people and communities by affecting exposure, sensitivity, and adaptive capacity. Social determinants of health, such as those related to socioeconomic factors and health disparities, may amplify, moderate, or otherwise influence climate-related health effects, particularly when these factors occur simultaneously or close in time or space.
- The use of geographic data and tools allows for more sophisticated mapping of risk factors and social vulnerabilities to identify and protect specific locations and groups of people

17.1.3: Healthier Home, Community, Country, and World

Although climate change has enormous impacts on health, there are additional concerns and actions that you can take to increase your environmental health.

Overpopulation

Average life expectancy in 1900 was 48 years, and today that has increased to about 78 years. We have made incredible advances that have contributed to an increase our life expectancy. For example, infant mortality rates have decreased dramatically during the 20th century, from 165 deaths per 1,000 births in 1900 to 7 deaths per 1,000 births today, advances in fertility treatments have provided new opportunities for conceiving children, and people have lived safer healthier lives with advances like clean drinking water, car safety belts, and work hard hats. These advances have helped to increase our worldwide population. The world population reached 1 billion people in 1803 and in just over 100 years, that population doubled to 2 billion people in 1928. It then took only about 50 years to double the population again to 4 billion people by 1975. By 2023 the population is expected to double again to 8 billion people. With these trends in growth the population is likely to reach 8.5 billion in 2030 and 9.7 billion in 2050.

Many believe overpopulation is the root cause of environmental health issues we are facing today. It is unknown how many people the Earth can support, however scientist do believe there is a limit and that humans are negatively impact the health of the planet which in turn is causing health issues for people. Overpopulation may cause food shortages, increase rate of disease transmission due to living closer together, lack of clean water, fear of limited employment opportunities for the demand, and disappearance of nonrenewable energy, such as the estimation that natural gas will run out in the next 35 years. With current population growth trends it becomes even more important for humans to take care of the planet.

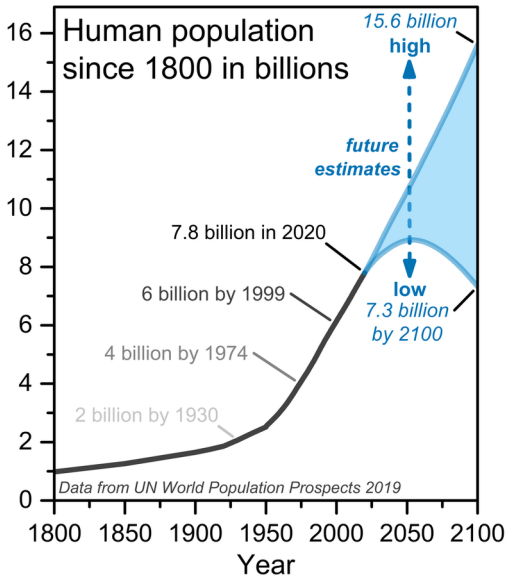

Figure 17.1.3.6: Human Population Growth since 1800

Energy Use: Fossil Fuels to Renewable Energy

All forms of electricity generation have an environmental impact on our air, water and land, but it varies. Of the total energy consumed in the United States, about 40% is used to generate electricity, making electricity use an important part of each person's environmental footprint. The total amount of greenhouse gases that are emitted into the atmosphere each year by a person, family, building, organization, or company are called the carbon footprint.

Producing and using electricity more efficiently reduces both the amount of fuel needed to generate electricity and the amount of greenhouse gases and other air pollution emitted as a result. Electricity from renewable resources such as solar, geothermal, hydropower, and wind generally do not contribute to climate change or local air pollution since no fuels are combusted.

Clean energy includes renewable energy, energy efficiency and efficient combined heat and power.

Measure and reduce your energy impact

How much energy are you using? What is your carbon footprint? How can you reduce your impact?

- Use EPA's household carbon footprint calculator to estimate your household's annual emissions and find ways you can cut emissions.
- Learn about the many ways to save in your home and track your progress with "My ENERGY STAR"
- Use Power Profiler to learn about the air emissions associated with your home or business's electricity use.
- Use AirNow to learn about local air quality.
- Use MyEnvironment to access local environmental quality information.

Waste

We all play a role in helping to prevent and remove trash in the environment. You can take action at home, school, and work to ensure a cleaner community and healthier waters.

Most of the trash that pollutes our rivers, lakes, estuaries, and oceans comes from sources on land. Plastic trash, in particular, threatens human health, aquatic ecosystems, and the economy. The most effective way to prevent trash from polluting our waterways is to reduce the amount of waste you create.

How much trash ends up in the ocean?

One of the most extreme and dramatic examples of the amount of trash that ends up in the ocean is known as the Great Pacific Garbage Patch, or "garbage island." It is is a collection of marine debris in the North Pacific Ocean between California and Hawaii[4]. The collection is estimated to be about double the size of the state of Texas.

The garbage patch was discovered in 1997 by Charles Moore. Moore had just finished a Los Angeles-to-Hawaii sail race known as the Transpac and he decided to take a short cut back to LA. He said, "on the way back to our home port in Long Beach, California, we decided to take a shortcut through the [North Pacific subtropical] gyre, which few seafarers ever cross. Fishermen shun it because its waters lack the nutrients to support an abundant catch. Sailors dodge it because it lacks the wind to propel their sailboats... as I gazed from the deck at the surface of what ought to have been a pristine ocean, I was confronted, as far as the eye could see, with the sight of plastic"[5].

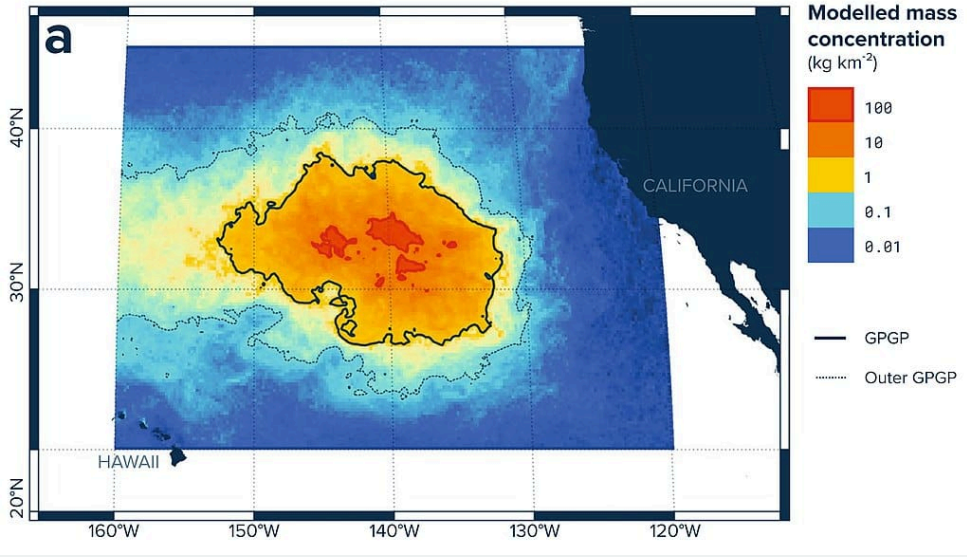

Figure 17.1.3.7: Map of the Great Pacific Garbage Patch

The 3 R's: Reduce, Reuse, and Recycle

The first goal should be to reduce your impact by reducing the energy you use, reducing the amount of waste you produce, reducing the amount of water you consume, etc.

The second goal should be to reuse as much as possible. Buy used items, repurpose items, share items with others, etc.

The last goal should be to recycle. Recycle plastics, aluminum, paper, etc to allow for them to be reused.

The following are tips to achieve the 3 R's.

- Think Green Before You Shop.
  - Do you really need it? Will you really use it?
  - How "green" is it? Is it built to last? Is it "energy star" rated? Is it made of recyclable material?
  - Can you borrow it or buy it used instead?
- Reduce your food waste by shopping smart.
  - Buy only what you need, compost food scraps, and donate unused food to food banks or shelters.
  - One-third of all food in the United States goes uneaten. The EPA estimates that in 2018, about 81 percent (about 20.3 tons) of households' wasted food ended up in landfills or combustion facilities.
  - Preventing food from going to waste is one of the easiest and most powerful actions you can take to save money and lower your climate change footprint by reducing greenhouse gas (GHG) emissions and conserving natural resources.
- Reuse or repurpose items such as old clothing, cloth grocery bags, and containers to prevent waste.
- Buy used items to reduce waste as well as the emissions created by producing new materials or disposing of them in landfills.
- Donate unused clothing, electronics and building materials to make sure others can reuse them too! One person's trash is another person's treasure. Instead of discarding unwanted appliances, tools or clothes, try selling or donating them
- Buy products made with recycled content. Check labels to see if a product or its packaging is made from recycled materials. You help close the recycling loop by buying new products made from recycled materials
- Know before you throw.
  - Know what items your local recycling program collects and encourage your household to recycle right and recycle more.
  - Unsure how to recycle? Visit Earth911-More ideas,Less waste for help
- Maintain and repair products, like clothing, tires and appliances, so that they won't have to be thrown out and replaced as frequently.
- Borrow, rent or share items that are used infrequently, like party decorations, tools or furniture.
- Learn about what you can do at home, at school, at work and in your community!

Sustainability

Sustainability is based on a simple principle: Everything that we need for our survival and well-being depends, either directly or indirectly, on our natural environment.

The National Environmental Policy Act of 1969 committed the United States to sustainability, declaring it a national policy “to create and maintain conditions under which humans and nature can exist in productive harmony, that permit fulfilling the social, economic and other requirements of present and future generations.”

Production, processing, packaging, and transportation of food is highly dependent on the use of fossil fuels and chemical fertilizers. These can greatly harm our health and the health of the environment. As a consumer, you have power to make a difference by considering the impact of your choices. Opting for local, healthy, environmentally responsible food helps promote both personal health and overall health of the community.

Choose foods that:

- Do not harm the environment.
- Support and preserve rural communities.
- Are healthy and nutritious.
- Respect farm animals.
- Provide farmers with fair wages.
- Are free of added toxins.
- Are grown locally.
- Do not harm the health of farm workers.

What can you do?

Find out what you can do to help make a difference in our environment every day. Whether you’re at home, on the go, in the office, or at school, there are many opportunities to go green by Reducing, Reusing, and Recycling.

Review the tips for home, school, work, communities, travel, and holiday/events. Identify strategies that you could implement to support a healthy planet:

Healthy Community Design

The way we design and build our communities affects our physical and mental health. How can communities come together to design healthier places to work, play, and live? The American Institute of Architects, American Planning Association, American Public Health Association, American Society of Civil Engineers, American Society of Landscape Architects, National Recreation and Park Association, U.S. Green Building Council, and Urban Land Institute have come together for a joint call to action to implement healthier places.

Examples of work to create healthier places include:

- Northwest Arkansas: Turning the wheels to build biking infrastructure and access
- Phoenix: Design strategies for burning health issues
- Los Angeles: Convening new partnerships, breaking out of silos
- Salinas, California: A neighborhood's plans for a vibrant transformation
- Denver: A stormwater problem becomes a health equity opportunity
- Colorado: Broadening the discussion about health and the built environment
- Washington, D.C.: A lesson plan for health and health equity
- South Bend, Indiana: Driving results for community safety and health
- Winchester, Kentucky: Reimagining parks, health and an entire small town
- Baltimore: An alley becomes a gateway to a healthier community

17.1.4: End-of-Chapter Material

Key takeaways for this Chapter

- Every citizen needs to be climate literate.
- The planet is warming due to the greenhouse effect, also known as global warming.
- The Earths climate is changing causing numerous problems with our weather, oceans, snow/ice, and ecosystems.
- Human health is being negatively impacted by climate change.
- Humans can take actions to increase the health of the planet

17.1.5.1: Introduction

Environmental health includes both the human impact on the earth, as well as the health effects of different environmental exposures (chemicals, gasses, radiation, etc.) on humans. According to the World Health Organization (WHO):

> Healthier environments could prevent almost one quarter of the global burden of disease....Clean air, stable climate, adequate water, sanitation and hygiene, safe use of chemicals, protection from radiation, healthy and safe workplaces, sound agricultural practices, health-supportive cities and built environments, and a preserved nature are all prerequisites for good health (WHO, 2020).

Why is environmental health such a large and active area of public health?

Environmental factors contribute to leading causes of morbidity and mortality around the world, causing nearly 1 in 4 human deaths globally in 2016 (WHO, n.d.). Recognizing that human health is interconnected to the health of animals as well as the entire ecosystem in which we live, the One Health framework has been developed to promote an interdisciplinary approach to environmental health. Taking this holistic approach can help to reduce zoonotic disease transmission, improve access to food and clean water, and mitigate and adapt to the effects of climate change (WHO, 2022). Environmental health draws on the sciences of biology, ecology, chemistry, engineering, and more to address hazards that threaten human (and animal) health.

In this chapter, we'll start with an overview of environmental health and how public health approaches environmental hazards. Then we will look at several specific environmental health concerns:

- Clean air
- Clean water
- Waste management
- Food and drug safety
- Climate change
- Occupational health

17.1.5.2: Learning Outcomes

At the completion of chapter, students will be able to

1. Discuss pollution as a major risk to human health at this time, in particular in the developing world.
2. Discuss risk assessment and the concept that "the dose makes the poison".
3. List sources and types of pollutants, including the six criteria pollutants, and explain the difference between primary and secondary pollutants.
4. Describe the role of the Environmental Protection Agency (EPA) in protecting the environment.
5. Outline the provisions of the Clean Air Act, and explain the purpose of air quality standards.
6. List the major types of indoor air pollutants and describe ways to reduce exposure to them.
7. Explain the difference between point source and nonpoint source pollution (and what difference it makes when you are trying to reduce pollution)
8. Give examples of biological and nonbiological pollutants that threaten our drinking water.
9. Define the term "waterborne disease outbreak" and give examples of agents that can cause such an outbreak.
10. Describe the measures communities take to ensure the quality of drinking water and to manage wastewater.
11. Explain the general purpose of the Clean Water Act and the Safe Drinking Water Act.
12. Define pest, pesticide, target organism and nontarget organism.
13. Explain some of the health and safety concerns with pesticide use.
14. Describe the composition of municipal solid waste (MSW) and outline acceptable MSW management strategies.
15. Discuss the importance of "reduce, reuse, recycle" as an approach to reducing waste.
16. Define hazardous waste and give some examples.
17. Identify approaches used by the FDA, the USDA, and local health departments use to ensure food safety.
18. Describe in general terms how the FDA ensures drug safety.
19. Discuss occupational health risks and protections in relationship to environmental health.
20. Discuss climate change as a risk to human health, including how it may affect rates of infectious disease, access to food and clean water, natural disasters, forest fires, air quality and heat exhaustion.
21. Explain mitigation and adaptation as strategies to cope with climate change.
22. Discuss how measures to address climate change may also contribute to improvements in overall health (for example, prevention of chronic disease) – the "co-benefits" of action on climate change.

17.1.5.3: What is environmental health

Here are a pair of definitions to get us started.

Environmental health – the study and management of environmental conditions that affect the health and well-being of humans

Environmental hazards – factors or conditions in the environment that increase the risk of human injury, disease, or death

Please watch this short video from the American Public Health Association for a quick overview of the environment's impact on health:

YouTube Video

This interactive element is not available in this format. Visit the link or scan the QR code to access it online.

View this YouTube Video online

Environmental health is a very broad and essential component of protecting the public's health. Environmental health can work to prevent injuries (such as poisoning and burns), infectious diseases (such as those spread by parasites in water or food) and chronic conditions (such as cancer and asthma).

Environmental health also focuses on occupational health and working conditions. By examining the conditions at work sites and the physical risks to health, environmental health measures can keep us safer on the job.

Environmental health works to improve big systems that we interact with every day - such as how clean water will be delivered, how food will be processed, and how waste of all kinds will be disposed of.

Fundamentally, environmental health works to make sure that our communities, our workplaces, our water supply, and our nation as a whole are as free of hazards as possible.

How big of an influence is the environment on health?

The Lancet, a major medical journal from the UK, has released a number of studies about the effect of pollution on health. One landmark one came out in 2016. While in many past analyses, environmental causes of disease and injury have been generally seen as significant yet not huge -- maybe causing 5-15% of deaths -- the report from *The Lancet* offered a new view. They say that pollution kills up to 9 million people a year -- making it one of the leading causes of death. **Check out this brief video from *The Lancet* (required) -- captions available:**

17.1.5.4: Environmental Health and the Emergence of the Modern Environmental Movement

If you think back to the story about John Snow breaking the handle off the Broad Street pump, to stop the spread of cholera in London in the 1850's, then you can see that public health has always been concerned about environmental health. Access to clean water and the question of how to dispose of sewage were among the first priorities of public health. Even today, in much of the world, these are the fundamental health problems that need to be addressed, to stop the spread of disease.

The modern environmental movement in the U.S. really kicked off in 1962 with the publication of *Silent Spring*, by Rachel Carson, a book that showed how pesticides were affecting the health of birds and were moving through our food supply and into our own bodies. Environmental health professionals joined with others - chemists, biologists, activists, farmers - to demand safety standards for pesticides and other chemicals in our environment.

Today, however, while there is regulation of SOME chemicals in our environment (usually through EPA, USDA or the FDA), thousands more chemicals are put into consumer products, agricultural products and industrial uses than could ever be tested for risks to human health. Often, a dangerous chemical does not start to be regulated until after it has caused some notable harm.

OPTIONAL: watch this five-minute clip about Rachel Carson's work and the growing awareness of pesticides in the 1960's.

NOTE to self: in Home > Older Versions > H54-W13-EnviroHealth-NoCC there are some "test your understanding" questions and an image from NYT probably not fair use.

17.1.5.5: Measuring Risk

If I had to write on a post-it how environmental health workers assess risk, I'd jot down two phrases: the dose makes the poison and risk-benefit analysis.

The golden rule of toxicology: The dose makes the poison

Let's talk about "**the dose makes the poison**" first. This relates to hazard mapping. Just as something in the workplace that is hazardous in large quantities might not be hazardous in small quantities (for example, a match is less hazardous than a pizza oven), the dose of any kind of chemical or toxin makes all the difference between whether it is dangerous (poisonous, even) - or not.

One of the key tasks in toxicology (the study of toxins) is to determine how much of any given chemical can harm us. We are not able to live in a world without chemicals - even if we didn't produce gobs of them (for example, the chemicals in personal care products), we would still be exposed to naturally-occurring chemicals in the environment. The Environmental Protection Agency (EPA) tests about 1,500 new chemicals every year - yet upwards of 80,000 chemicals are used in commercial production in the US alone.

Many, many chemicals we come in contact with have not been tested, or not tested enough.

Even so, toxicologists do important work to determine *what dose is safe* - or in the case of medicines, even therapeutic. Anything can be a poison in too high a dose - even water. You may have heard of cases of people chugging gallons of water and having to be hospitalized as a result. The opposite is not true, however - it is not true that everything is safe in a small-enough dose (as there are some chemicals that are not safe in any dose).

The dose makes the poison. How much of something enters the body makes all the difference in how the body will respond.

Whose body? When measuring the safety of a chemical, researchers have to take into account that there are populations that are especially vulnerable - babies, children, elders, people with suppressed immune systems, etc. A calculation is made, for example, that if 10 mg is the safe dose for healthy adult, then a child should be exposed to no more than 10% of that.

Chemicals that were already in use before the 1970's wave of environmental regulations often have not been tested or assessed for safety. Industry was allowed to continue using what it had been using in the past, unless some new evidence emerged of its danger.

Tylenol (acetaminophen) is an important example to consider. Tylenol is very effective and very safe at the prescribed dose. It often causes less stomach pain than aspirin or ibuprofen, and it can be used in babies and children (aspirin, on the other hand, is not safe for children). It is frequently recommended by doctors and physicians, for these reasons. Yet Tylenol is responsible for a surprisingly high number of deaths every year in the US - something like 400 a year. This is because it is poisonous at higher-than-recommended doses. For someone who has a weakened liver already (due to illness or alcohol consumption), or for a child, taking as little as one or two extra pills of Tylenol beyond the recommended dose, can be poisonous. In general, we prefer to see medications where there is a bigger distance between an effective dose (say, 400 mg) and a dangerous dose (600 or 800 mg). But because Tylenol has been in use for a long time - and it does a good job, at the right dose - it continues to be widely prescribed and sold over the counter. (For more about the risks of Tylenol, you might want to listen to this optional episode of This American Life.)

Risk-Benefit Analysis

It is impossible to remove all hazards, all risks. The key question is, what risks are acceptable to us? And why?

Risk-benefit analysis is something we all do, informally. For example, if I go in late to work, there is a risk I will get in trouble. However there is a benefit to me too - maybe 15 extra minutes of sleep, or a chance to take the later train that isn't crowded. If the risk associated with arriving late is very great - say, I might get fired - then it is likely to outweigh the benefit. If the risk is small - I might get a nasty look from the boss - then the benefit starts to seem more attractive. If the benefit is very great - say, I go in late because I'm interviewing for a better job - then that could outweigh even a steep risk (like getting fired).

Environmental health professionals define and quantify the risks and benefits associated with different human activities and with different technological solutions. In addition to understanding science and public health and engineering, environmental health professionals may benefit from some studying math and economics, too.

Risk-benefit analysis also is reflected in discussions of environmental justice. We have to ask, whose risk? whose benefit? Communities are often presented with a choice about an environmental hazard that is phrased as jobs versus environment. That is, the benefit of industry is that it offers jobs, and the risk is that it pollutes. In many cases, this can be a false choice, when there is a third option available (even if it is more expensive), such as safe clean jobs in an industry that has minimized pollution to an acceptable level.

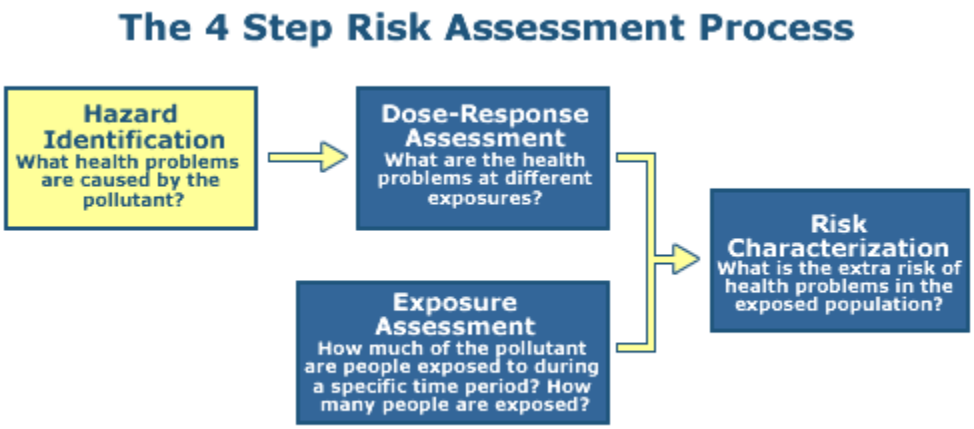

Figure 17.1.5.5.1: The 4 Step Risk Assessment Process. (Public Domain; EPA via https://www.epa.gov/risk/conducting-...isk-assessment)

Risk assessment typically involves four steps:

1. Hazard Identification: What health problems are caused by the pollutant in question?
2. Dose-Response Assessment: What are the health problems at different exposures? (at some doses, even a hazardous substance may be safe)
3. Exposure Assessment: How much of the pollutant are people exposed to during a specific time period? How many people are exposed?
4. Risk Characterization: What is the extra risk of health problems in the exposed population? (For example, while cancer may already be a risk, the exposure to asbestos increases the risk of cancer, so we want to quantify that "extra risk" associated with the asbestos exposure.)

Knowing how large the risk is, we can weigh it against the benefits that generating the pollution might bring. That decision is often a political decision, as there is no one scientific measure to determine if a certain benefit is worth the risk.

Test your understanding:

17.1.5.6: Laws to Protect the Environment and Human Health

Environmental regulation was developed in response to the growing awareness of environmental risks, many of them man-made, many of them the result of industrialized agriculture and manufacturing. In the 1970's, laws were passed that still shape the health of our environment today.

Some of the most important environmental laws included:

- **The Clean Air Act amendments of 1970**- which required monitoring and regulation of six common air pollutants known to be health hazards (substances that negatively affect health). These six pollutants (called the "criteria air pollutants") include
  - particulate matter such as smoke, soot and ash (which is especially dangerous to human health when the particulates are very small and can stick in the lungs)
  - sulfur dioxide and nitrogen oxides (two common causes of "acid rain" that are mostly produced by industry)
  - carbon monoxide (highly poisonous, and largely created by motor exhaust - improvements in the engineering of cars and trucks has greatly reduced this toxin in the atmosphere)
  - ozone (a form of oxygen (O_3) that is very protective for us when it is in the upper atmosphere but quite toxic when it is appears at ground level
  - lead (highly toxic to the nervous system, blood and kidneys, especially for children who get exposed to lead when their brains are still developing - common in paint, some plastics and until the mid-1970's in gasoline)
- **The Clean Water Act of 1972** (amended in 1977 and more times since then) - the set goals for ensuring that lakes and rivers should be "fishable" and "swimmable" and that pollutants should not be discharged or spilled into lakes, rivers or other parts of the water supply. It also set in place standards for treatment of waste water from sewage as well as industrial waste, and instituted measures to minimize pollution from rain and storm runoff (which can wash agricultural chemicals from fields and gasoline from streets into rivers).

- **The Safe Drinking Water Act of 1974** (rewritten in 1996) - which required the Environmental Protection Agency (EPA) to set standards for local water systems, which are enforced at the state level. Drinking water is treated usually through a process that includes sedimentation, coagulation, filtration and disinfection - to remove contaminants that could affect health. While many people now prefer bottled water (due to excellent marketing from the corporations that benefit from the sale of bottled water), in the U.S. tap water is of very high quality - in fact, it is often safer than bottled water (which is less tightly regulated).

> Recent Supreme Court decisions have limited the reach of the Clean Water Act and the Clean Air Act, for example, limited the scope of environmental reviews, removing some wetlands from the Clean Water Act protections, and limiting the EPA's ability to regulate carbon pollution and some other pollutants (ADD CITATION). These changes along with changes in the EPA and a political environment that questions the role of regulations on business may lead to changes in how these laws are implemented, in reality.

NOTE: there are some "test your understanding" questions from SoftChalk I could put in here

17.1.5.7: Clean Air

While air pollution is certainly a contributor to climate change via GHGs, it also harms human health in other ways. Air pollution is generated both by natural (biogenic) and human (anthropogenic) sources. Wildfires and volcanoes can spew particulate matter into the air, while vehicle emissions and industrial pollutants produce smog and other gasses. Some air pollutants also undergo chemical reactions when exposed to sunlight which create harmful ground level ozone. Wind currents and water vapor can carry pollutants miles away from their original source. The WHO asserts that both ambient (outdoor) and indoor air pollution contribute to over 7 million deaths around the world each year (WHO, 2019).

The Clean Air Act of 1970 regulates air pollution by empowering the Environmental Protection Agency (EPA) to set and enforce air quality standards. There are six pollutants for which the EPA sets National Ambient Air Quality Standards (NAAQS) for, which are called **criteria pollutants.** These include carbon monoxide, sulfur dioxide, nitrogen oxide, particulate matter, ozone, and lead. In 1990 the Clean Air Act was amended to include another category of **hazardous air pollutants**, such as volatile organic compounds (VOCs), pesticides, herbicides, and radionuclides (Frumkin, 2016). The Agency for Toxic Substances and Disease Registry (ATSDR), an agency of the U.S. Department of Health and Human Services, responds to potential toxic emergencies, assists local public health departments, conducts research, and maintains a registry with toxicological profiles of the health effects of natural and man-made hazardous substances that affect our soil, water, and air (ATSDR, 2024).

Primary air pollution is released straight from its source. For example, carbon monoxide is released from motor vehicle exhaust and the combustion of fossil fuels in power plants. It is also released in smoke from forest fires, and is present in environmental (or “second-hand”) tobacco smoke. When other compounds like nitrogen oxides and sulfur dioxide are exposed to sunlight, they can undergo chemical reactions that create ozone and particulate matter. These subsequent pollutants are called **secondary** air pollution. Thus, air quality is often worse on warm, sunny, summer days than on colder, winter days (Frumkin, 2016, Seabert et al., 2021).

Figure 11.4.2.1: Smoke cloud from the Mosquito Fire in California, September 2022. Cal Fire. (Public domain, via Wikimedia Commons)

Ozone is both beneficial and hazardous to human health depending on where it exists. In the stratosphere (upper layer of Earth’s atmosphere), ozone blocks harmful UV rays from the sun and protects humans, plants, and animals below - preventing things like skin cancer and cataracts. Compounds called chlorofluorocarbons (CFCs) were used extensively in the mid-20th century to make aerosol propellants, for refrigerators, and in building materials, but these and other pollutants were found to be depleting the ozone layer. Fortunately, in 1987, the Montreal Protocol was signed and countries began phasing out production of ozone depleting substances. Scientists predict that it will be completely repaired by the middle of the 21st century (EPA, 2023). Ground level ozone (in the troposphere) on the other hand, is quite harmful to humans, plants and animals. It can damage the heart and lungs and lead to a variety of chronic diseases (USGCRP, 2023a). Ozone can also be worse in the summer months as a layer of warm air called an inversion layer will trap pollution closer to ground level instead of letting it disperse upward into the stratosphere (Seabert et al., 2021).

Particulate matter is made up of very fine particles of dust, soot, and other solids or liquids of varying sizes. When breathing through the nose, larger particles are typically caught in the nose and upper respiratory system, trapped in mucus and expelled in coughs and sneezes. However, fine particulate matter, or PM2.5 (particulate matter smaller than 2.5 micrometers) can get inhaled much deeper into the lungs and cause damage to lung tissue, as well as increasing the risks of cardiovascular and neurological issues (USGCRP, 2023a). Particulate matter comes from dust, smoke, industrial pollution, vehicle emissions, pollen, and even sea-spray (Frumkin, 2016). We often see particulate matter in the air as smog or brownish haze, hovering over a city-scape on a sunny day.

Air pollution disparately affects minoritized communities including people of color and those of lower socioeconomic status, both in urban and rural areas. This can often be connected to policies and practices such as redlining, as well as industrial zoning. Exhaust from diesel trucks and industrial facilities can be much higher in urban areas, whereas rural areas may be more exposed to pollution from agricultural practices - such as dust and pesticides from crops, or emissions from concentrated animal feeding operations (aka “factory farms). Power plants also release air pollution as well as GHGs. Air quality is made worse by climate change, particularly during heat waves, which may create more secondary air pollution (USGCRP, 2023a).

While the EPA monitors and regulates ambient air pollution, it does not have the same oversight of indoor air pollution. Indoor air pollution can come from building materials, insulation, environmental tobacco smoke, and burning wood, coal, kerosene and even natural gas for cooking or warmth. Mold, mildew, pet dander and dust can also cause respiratory problems. Household cleaning products can release VOCs, which can be particularly harmful to the respiratory system if certain compounds are mixed and then inhaled. Improperly vented combustion for cooking or heating releases carbon monoxide, nitrogen oxides, and particulate matter into the household air. Radon is a radioactive gas that is released from uranium-rich rocks, and can seep into cracks in a home’s foundation and cause lung cancer. Switching to cleaner fuel sources for cooking (such as electricity), removing sources of pollution (such as environmental tobacco smoke), using appropriate ventilation when using cleaners or solvents, and using central ventilation and air conditioning (HVAC) filters or portable air filters are all ways to reduce indoor air pollutants. Additionally, any home improvement projects done on old houses should first be tested for asbestos and lead - as these were commonly used in building materials in the 20th century (EPA, 2014). According to the WHO, 2.3 billion people around the world still use solid fuel for cooking (such as wood, charcoal, and dung), exposing mostly women and children to high levels of air pollution and increasing the risk of respiratory and cardiovascular diseases, cancers, and some infectious diseases as well. In low and middle-income countries, efforts can be made to move toward cleaner fuel sources, such as natural gas and electricity, which would improve air quality, reduce GHGs, and improve health equity (WHO, 2023).

Figure 11.4.2.2: Woman feeding a cast iron wood stove. (Public Domain, CDC/ Dawn Arlotta, 2009.)

This home’s interior, though beautiful, houses a potential hazard on many levels, therefore, special care need be taken in order to safely operate this wood-burning stove, for not only does it generate a terrific amount of heat, it does so using flame, rather than electricity, which is much more difficult to control. This woman was about to place what appears to be a piece of treated lumber (which can also release harmful pollutants) into the stove as fuel.

NOTE: For more about ozone and how the world came together to start fixing the "ozone hole", please see the page on Additional Resources.

17.1.5.8: CLEAN WATER

Humans cannot survive without water. Nearly all cities and towns have been built around sources of freshwater for drinking and agricultural uses. While our “blue planet” may be covered in water, the majority of it is too salty to be used for these purposes. In fact, only about 1% of the water on earth is both freshwater and accessible to humans via the water cycle (aka hydrological cycle). Water from melting snowpack and rain flows through rivers and streams to lakes and oceans and sinks into underground aquifers. From lakes and oceans it is evaporated into the atmosphere as water vapor. Eventually once this water vapor condenses into clouds and gets heavy enough, it is returned to the ground via precipitation (rain, snow, etc.) Freshwater is accessible to humans from two sources. **Surface water** includes any water source open to the air: lakes, rivers, streams, ponds, etc. The other source is **groundwater** which comes from underground aquifers, wells, and springs. Groundwater has long been considered more ideal for human use since it has been filtered through soil and rock, and will thus require less treatment. Surface water is often full of dirt, microbes, and pollutants which requires an extensive filtration and disinfection process in order to be drinkable (Frumkin, 2016).

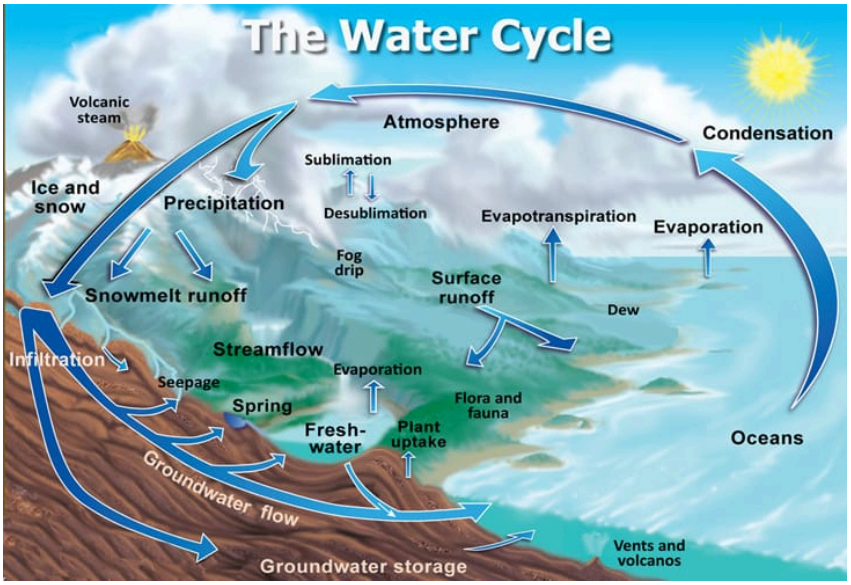

Figure 17.1.5.8.1: Water Cycle Summary.. (Copyright; John Evans and Howard Periman, USGS, Public domain, via Wikimedia Commons)

Drinking water can get contaminated by pollutants, chemicals, or biological contaminants from a variety of sources. **Point source** contamination occurs when there is a single source or multiple identifiable sources - such as a specific pipe dumping industrial chemicals into a stream, or several septic tanks leaching fecal matter into groundwater. **Nonpoint source** contamination occurs from an array of different sources - such as pesticides from agricultural runoff, or when rainwater picks up gasoline and oil on roadways. There are many different types of contaminants; they may be organic or inorganic chemicals, biological contaminants (such as bacteria, viruses, or protozoa), and even pharmaceuticals - which can lead to antibiotic resistance (see chapter on infectious diseases). Drinking water must therefore be properly filtered, disinfected, transported (via well-maintained pipes), and regularly tested in order to prevent toxic exposures or waterborne illnesses in humans and animals (Frumkin, 2016).

Particularly in developing countries around the world, many infectious diseases and toxic exposures can be prevented with improved access to water, sanitation, and hygiene practices. Combined, these are called **WASH.** The WHO estimates that despite major progress in the last 30 years, diseases caused by unsafe WASH still account for over 1.4 million deaths (in 2019), the majority of those related to diarrheal diseases - which affect hundreds of thousands of young children each year (WHO, 2023a). Sanitation and the proper treatment and disposal of wastewater also significantly impact exposure to pathogens. While wastewater can be an important source of water recycling (such as greywater from sinks and showers), many countries may lack sewage facilities, and open defecation is still practiced in many low-income countries, particularly in rural areas. Overall, inadequate sanitation accounted for the highest percentage of diarrheal disease deaths (38%). Yet sanitation is closely related to safe drinking water, which accounted for 35% of diarrheal disease deaths (WHO, 2023a). Open defecation or inadequate disposal of fecal matter can easily contaminate surface water, which may be collected downstream for drinking and agricultural uses. Proper handwashing behaviors (i.e. using soap, washing after potential fecal contact or before preparing food), are also extremely effective at reducing pathogen transmission. Both the resources - soap and water - and the education (knowing why it is important) are necessary to change behaviors. Yet even in high income countries these behaviors are not universally practiced

(WHO, 2023a).

Although improving WASH is of particular importance in low and middle income countries, there are many potential sources of contamination in high income countries as well. In the U.S. there are two laws that primarily govern safe water sources: the Clean Water Act (CWA, 1972), and the Safe Drinking Water Act (SDWA, 1974, amended in 1986 and 1996). The CWA empowers the EPA to regulate surface water for fishing and recreation, as well as wastewater management - requiring industries and municipalities to pre-treat any wastewater before it enters into waterways. This law also prevents oil spills that could affect inland water and tasks the EPA with responding to those that do happen. The SDWA governs the treatment and delivery of drinking water to municipalities; protecting surface and groundwater sources of drinking water, as well as enforcing health standards for all public drinking water systems (Frumkin, 2016, and EPA, 2013). Even with these protections in place, water contamination still occurs, and tends to most often impact historically marginalized communities.

17.1.5.8.1: Flint Water Crisis

Figure 17.1.5.8.1.1: Water tower at the water treatment plant in Flint, Michigan. (Unknown, United States Environmental Protection Agency, Public domain, via Wikimedia Commons. April 11th, 2016.)

The story of the Flint Michigan water crisis is one of a human-made public health catastrophe that could have been avoided at several junctions. Flint, Michigan is a majority Black city. In 2014, 40% of the residents there lived in poverty (Murembya, & Guthrie, 2016). Flint was having a financial crisis, and an emergency manager was appointed by Michigan's governor. One of the ways proposed to save money was to switch Flint's water source: from the Detroit Water and Sewerage Department (DWSD) to the Karegnondi Water Authority (KWA), which was building pipeline from Lake Huron - where Flint, Detroit and other towns already sourced their drinking water. Upon hearing of this plan, the DWSD terminated its contract with Flint effective 2014, but the KWA pipeline wouldn't be ready until 2016 (Dixon, n.d., Kennedy, 2016). Until the pipeline was completed however, they needed an alternative water source for the city of Flint. For this, they turned to the Flint River, which had been the city's water source up until the 1960's (Kennedy, 2016).

Instead of treating the water or testing to ensure that the water would not corrode the city's aging pipe system, city officials took a "wait and see" approach. Barely a month after the switch, residents in Flint began to complain about their tap water's color and odor. Some people developed rashes or hair loss by showering or bathing in it (Runwal, 2024). By August, officials had detected E. coli bacteria, which prompted them to increase the chlorine levels and issue boil advisories to residents. Meanwhile, an outbreak of Legionnaire's disease, caused by the bacteria *Legionella pneumophila, was* correlated to the water source switch and improper chlorination (Zahran et al., 2018), causing the deaths of at least 12 people (Runwal, 2024). By January of 2015, other compounds (by products of disinfection which are carcinogenic) had also been found in the water - this violated the SDWA and forced the city to take some action (Kennedy, 2016).

In February, high levels of lead were found in the water of a resident's home. While the EPA issued an internal memo expressing concerns about lead contamination, the city officials in the Michigan's Department of Environmental Quality (MDEQ) downplayed the reports and insisted that Flint's water was safe. Meanwhile, researchers from Virginia Tech University were finding dangerously high lead levels in the water supply and blood levels in children (Kennedy, 2016). Lead is a neurotoxin which is especially harmful for children: it can cause learning disabilities, behavioral problems, as well as affecting growth and potentially causing anemia or in some kids - seizures. If ingested by pregnant women it can harm the growth of the fetus and lead to premature birth. And in adults, exposure to lead is associated with cardiovascular, kidney, and reproductive problems (EPA, 2016). In September of 2015, the city finally issued a lead warning to the city, and in October a state of emergency was declared and Flint switched back to the Detroit water supply (Kennedy, 2016). But the hazards were not over.

The pipes that brought water to the city were old, and made of lead and galvanized iron. Since the Flint river already had higher levels of chloride, this began to corrode the pipes, and the chlorine added to reduce the *E. coli* bacteria corroded the pipes even more. By the time the water was switched back to the Lake Huron source, it was too late - in April of 2016 the water was declared still unsafe to drink by Virginia Tech researchers (Kennedy, 2016). Many Flint residents have continued to drink bottled water as the pipes are slowly replaced throughout the city - even though the free bottled water program ended in 2018 (Runwal, 2024). Many of the city and public health officials were criminally indicted for not following proper procedures and covering up reports of

contamination, and even Governor Rick Snyder had charges related to his apparent inaction for 17 months during the water crisis. Yet many of these cases were thrown out on technicalities by the Michigan State Supreme Court, leaving Flint's residents doubting anyone will be held accountable (White, 2022). The state of Michigan was ordered to pay out $600 million in a settlement to Flint's residents - a portion of which will also cover legal fees (White, 2021).

In late 2019, PBS's investigatory news show Frontline broadcast this documentary on the Flint water crisis, why it happened, and what it means for the rest of the country. If you would like to understand more about the Flint Water Crisis, you can view it here (optional).

17.1.5.8.2: Case Study- The Jackson Water Crisis

Figure 17.1.5.8.2.1: A Mississippi National Guard soldier takes water to a person's car at the Mississippi State Fairgrounds in Jackson, Mississippi, Sept. 1, 2022. Nearly 600 Mississippi National Guardsmen were set up across seven sites through Jackson for people to collect bottled water and non-potable water from water buffalo trucks during the water crisis. (Copyright; Staff Sgt. Connie Jones, U.S. Army National Guard, CC BY 2.0, via Wikimedia Commons.)

The residents of Jackson, Mississippi are no strangers to boil-water advisories. The city has dealt with infrastructure problems for years; massive leaks, *E. coli* and lead concerns, and a lack of funding and staffing to maintain its aging water and sanitation facilities (Pettus, 2022). A cold snap in 2021, and heavy winter storms in 2022 caused pipes to burst and shut off water supplies to thousands (Adams, 2023). When heavy rains caused the nearby river to overflow in the summer of 2022, one of the city's two water treatment facilities was compromised (Breslow, 2022). Since low water pressure allows bacteria and other contaminants to seep in through cracks in the aging pipes, residents were under yet another boil-water advisory, and bottled water was distributed (Pettus, 2022).

Jackson's chronic water crisis demonstrates the complex interplay of social determinants of health, environmental health, public health policies, and politics. To begin with, 80% of the 150,000 residents in Jackson, Mississippi are Black, and a quarter of them (25%) are at or below the poverty threshold (Pettus, 2022). Mississippi has a long history of racism and white supremacy, with Jackson at the center of the Freedom Riders protest, when civil rights activists were arrested for riding segregated public transportation from DC (Contributors to Wikimedia projects, 2024). Jim Crow laws, housing discrimination and underinvestment in communities of color have disproportionately exposed Black populations to environmental hazards (USGCRP, 2023c). After the integration of schools in the 1960s, white families moved out of Jackson *en masse* over the next several decades - so called "white flight" to the surrounding suburbs (Wiggins & Morrow, 2022). For these and other reasons, tax income to the city has declined, and Jackson has long had problems with finding money to fix its infrastructure (Pettus, 2022), some of which is over 100 years old (SPLC, 2023). Jackson's history of discrimination and underinvestment are compounded by emerging environmental factors. Climate change is contributing to more rainfall and severe storms - including hurricanes and more severe flooding in the southeast U.S. region (USGCRP, 2023c). While an EPA investigation into the recent water crisis concluded that state agencies did not racially discriminate against Jackson's residents in distributing federal funds for infrastructure updates (Muhammad & Judin, 2024), it is clear that a combination of systemic and historic racism, poverty, policies, and climate change are contributing to the struggles Jackson is facing in providing clean water to its residents.

17.1.5.9: WASTE MANAGEMENT

Modern humans create much more waste than our animal counterparts and even our human predecessors. According to the EPA, the average American produces nearly 5lbs of trash per day, the majority of which is paper and food waste. Compare that with 1960 - when the average was only 2.68lbs of trash per person, per day (EPA, 2023a). Obviously the amount of garbage the U.S. is producing has increased substantially over the last 70 years. This waste is usually categorized as one of the following: municipal solid waste, special waste, or hazardous waste, with certain considerations for the disposal of each (Frumkin, 2016). But once it is removed from household or industrial trash bins, it doesn't just disappear. What do we do with it? Do we store it somewhere? Recover it and use it to make other products? Pay another country to take it? And what is the effect of all of this refuse on the environment and the planet as a whole?

Figure 17.1.5.9.1: Trash Day - Arlington, Massachusetts, USA. Left to right: recycling, compost, trash, yard waste. (Copyright; Daderot, CC0, via Wikimedia Commons, June 2023.)

San Francisco has set the goal of becoming a "zero waste city" -- with nothing or almost nothing going to landfills. While we haven't reached this goal yet, San Francisco recycles and composts more waste than any other city in the US! See this short news story from CBS to learn more about San Francisco's waste management program. As you learn more about waste management in the following pages, you can refer back to this example from San Francisco.

17.1.5.9.1: Types of Trash/Municipal Waste

Garbage is categorized as municipal solid waste (MSW), special waste, or hazardous waste according to specific characteristics. MSW includes nearly all household trash: paper, plastic, glass, aluminum, food scraps, textiles (old clothing etc.), yard trimmings, and wood (Frumkin, 2016). But this trash generated by homes, businesses and schools actually accounts for only about 2-5% of the total amount of waste products produced in the U.S. (Seabert et al., 2021). Special waste accounts for almost anything that isn't the typical household waste but also doesn't fall into the hazardous waste category. This includes:

- Medical waste: medical devices, syringes, sharps, blood-soaked bandages, gloves, gowns - anything that comes in contact with blood or bodily fluids. This must be disposed of separately to general MSW in order to protect workers from contracting infectious diseases. Typically this waste is incinerated before being disposed of along with MSW (Frumkin, 2016).
- Construction debris: any building materials (other than asbestos), such as drywall, wood, metal, tile, cement etc. are typically disposed of at special construction waste sites or along with MSW. Asbestos has to be carefully removed and disposed of in order to prevent inhalation which can cause cancers and other lung diseases such as mesothelioma (EPA, 2013a).
- Mining waste: which can be liquids or fine, ground up rocks called "tailings", which can contain heavy metals and byproducts from mining such as sulfuric acid or cyanide. If mining waste storage dams break they can wreak havoc and cause damage to the local environment, or release toxic substances into rivers and lakes (*Tailings*, 2017).
- Agricultural waste: solid animal waste or runoff from farms may include pesticides, pathogens, or antibiotics (which may encourage antibiotic resistant microbes) (Frumkin, 2016). Growing and processing grains, legumes, fruit and vegetable products also generates plant waste, which could be useful for biofuels or compost (Sadh et al., 2018).
- Radioactive waste: may include the nuclear fuel and waste products or clothing and protective gear that has come in contact with it. While the U.S. struggles to find a permanent solution for disposing of nuclear waste (high-level radioactive waste), the less dangerous, low-level reactive waste is typically disposed of in special landfills (Frumkin, 2016).
- Sewage sludge: is typically separated from wastewater as part of the treatment process, and chemically treated to remove pathogens. These solids are either put in landfills or used in agriculture as fertilizer (Frumkin, 2016).
- eWaste (electronic waste): includes computers, phones, printers, televisions, gaming devices, or anything with electronic components that are non working or obsolete. These may still contain valuable materials that can be extracted and recycled, but if disposed of improperly can leach heavy metals into the environment (Seabert et al., 2021).

The best solution for waste is simply not to make it in the first place. For example, offices can convert to modern technology and use electronic communications and documents (such as email and electronic signatures) to reduce paper waste production. Food production companies can utilize less plastic packaging. Companies that ship products can combine shipments and reduce unnecessary paper and cardboard use. Reducing the production of waste would be the best option, followed by recycling or recovering "waste" to be reused for other purposes. For example, old tires can be broken down into crumb rubber and used to make playground equipment, truck bed liners, and other products that benefit from the elasticity of the rubber (Frumkin, 2016). Some waste can be used to generate energy through combustion, or the conversion of food waste into compost or animal feed. If nothing more can be used from the waste or if it is too hazardous to keep around, then treatment and proper disposal are the only other options (EPA, 2018). See Fig. \({17{.}1{.}5{.}9{.}1{.}\eatSpaces{1} \endSpaces}\ below for a diagram of the waste management hierarchy.

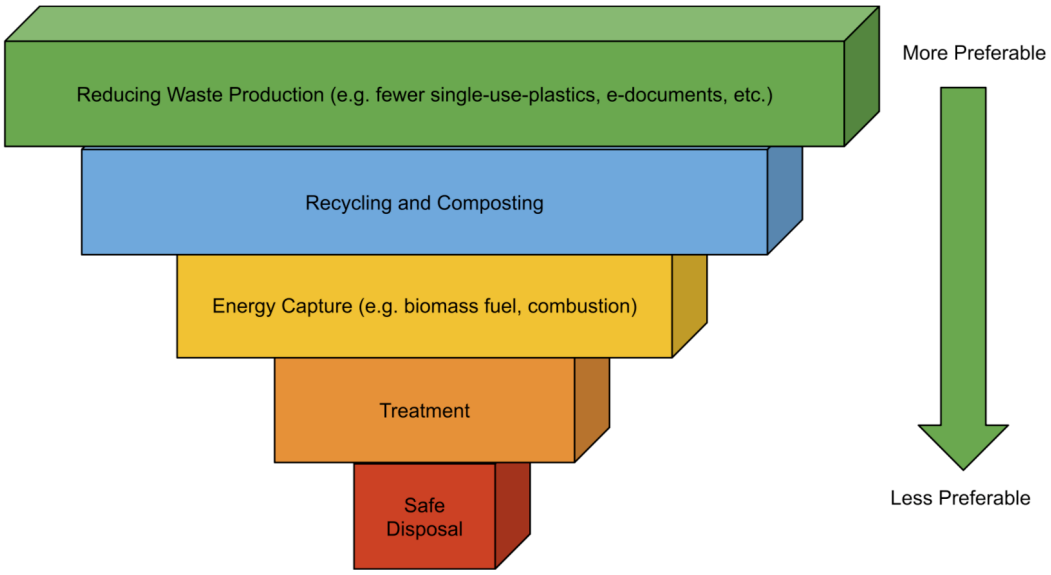

Figure 17.1.5.9.1.1: Waste Management Hierarchy. Adapted from https://www.epa.gov/trinationalanalysis/waste-management.

17.1.5.9.2: Recycling and Composting

In 2018, the United States generated 292.4 million tons of MSW, and recycled or composted 94 million tons of it - amounting to about 32.1% of the total. While some other methods were also used to recover energy or create animal feed, over ½ of all waste still ended up in a landfill. While this may not seem like progress, the amount of MSW discarded in landfills has remained relatively constant since 1990 - in spite of population growth - while other methods like recycling and composting have grown (EPA, 2023a). While metals (like steel and aluminum), glass and paper products (including cardboard), are relatively easy to recycle, plastics are much less commonly recycled. Approximately 9% of the world's plastic containers, bottles, bags and other materials are recycled; 50% end up in landfills, another 20% are mismanaged (burned or dumped, potentially ending up in lakes and rivers), and 0.5% end up in the ocean (Ritchie et al., 2023). See Fig. 17.1.5.9.2.1 below.

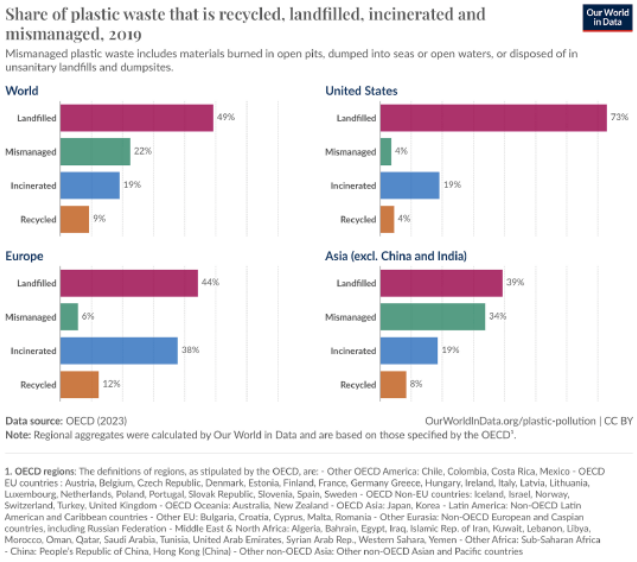

Figure1 17.1.5.9.2.1: Plastic Pollution.. (Copyright; CC-BY OurWorldInData.org/plastic-pollution)

Plastic pollution is particularly hazardous because of the characteristics of plastic that make it so desirable. Plastic is durable, and doesn't break down easily. It may take a plastic water bottle floating in the ocean nearly 450 years to decompose (Harris, 2023), broken down by UV rays into smaller and smaller pieces called microplastics. The **Great Pacific Garbage Patch** is really a misnomer because it's not an island or "patch" of trash floating in the Pacific Ocean: much of the plastic pollution is microplastics, swirling around the ocean currents like a plastic soup (Evers, 2024). These microplastics can get into our food and water sources, be ingested by birds and fish, and make their way up the food chain into human tissues. Microplastics have been found in the human gastrointestinal tract and in placental tissue (Ragusa et al., 2021). We may even be breathing in microplastics in the air, which can get into lungs and eventually the bloodstream. Exposure to microplastics and the chemicals that make them could have profound effects on human health, particularly in the immune system response to plastic toxins, chronic inflammation, and a myriad of other subsequent health problems (Prata et al., 2020). The best way to manage plastic waste is not to rely on recycling, but to produce less of it in the first place.

Composting is another way to manage biodegradable waste such as food waste. In the U.S., it is estimated that 30-40% of the food supply ends up as waste - much of that at the retail or consumer level (USDA, n.d.). Food waste may include inedible food scraps such as eggshells or fruit rinds, but it also includes food that could have been consumed but perhaps was spoiled or uneaten. Not only does the food wasted cost energy to grow and transport, it also produces methane gas while decomposing in a landfill - contributing to GHG production and climate change. Food waste can be reduced at the retail and consumer levels by only producing and purchasing what is needed, donating leftover food and preventing spoilage. Composting is also a much better use of food waste, as it produces usable fertilizer for agricultural and landscaping purposes (EPA, 2015). While backyard composting can support a home garden, industrial or large-scale composting has much greater potential for managing food waste, yard waste, sludge and other agricultural or industrial wastes. Bacteria and fungi feed off of the waste products, creating heat which destroys undesirable microbes and weed seeds, and turns the solids into excellent fertilizer for plants. When those raw materials are chipped up into smaller pieces, combined in appropriate ratios, and well-aerated, the composting process can be completed more quickly and produce high-quality soil amendment (Sherman, 2020). As of 2022, California requires that organics

be disposed of separately to recyclables and MSW in order to be composted or used to generate biofuel (CalRecycle, 2024).

17.1.5.9.3: Sanitary Landfills and Combustion

Much of the trash we produce ends up in landfills, which are essentially encapsulated and buried under layers of dirt. In order to protect groundwater and surface water from potentially toxic **leachate** -liquids that accrue from the decomposition of waste - the sanitary landfill needs to be lined with plastic and have adequate drainage. The leachate may be collected and treated before it too is stored. Additionally, decomposition of waste produces gasses and heat - which can cause emissions or even catch fire if not properly vented. Sometimes the methane produced by a landfill can be collected, treated, and used for energy. After waste is dumped into the landfill, it needs to be covered with soil in order to prevent pests (rodents, birds, or insects) from getting into it or the wind from blowing it out of the landfill (Frumkin, 2016). It may seem obvious that landfills are limited by capacity and location: no one wants to live near a landfill, and what should be done once the landfill is full?

Combustion of waste is another option. Although open incineration of trash was often practiced in backyards up until the mid 20th century, this practice creates high levels of pollution - particulate matter and GHGs - that pose a risk to the community and planet. The Clean Air Act of 1970 essentially put an end to this practice in the U.S., although it is still common in other developing countries. Incinerators in the U.S. can be used to produce energy and get rid of waste, but they must have expensive technology to reduce air pollution. The resulting ash can also become problematic to dispose of (Frumkin, 2016, Seabert et al., 2021).

17.1.5.9.4: Hazardous Waste, RCRA and CERCLA

Hazardous waste is typically industrially-produced waste that is ignitable, corrosive, reactive, or toxic; meeting specific criteria established by the EPA. Two key federal laws regulate hazardous waste: the Resource Conservation and Recovery Act (RCRA, 1976) and the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA, 1980), also known as the "Superfund". The first, RCRA, gave the EPA authority for regulating both hazardous and solid waste management, including setting standards for sanitary landfills. It requires tracking of hazardous materials from "cradle to grave", or from production, to transportation, use, and eventually disposal and treatment (Frumkin, 2016). The most common method for disposing of hazardous waste is underground injection, where hazardous waste is deposited into deep wells in the ground. Care must be taken, however, that groundwater aquifers are protected (Seabert et al., 2021). The second law, CERCLA, set up a fund to address already existing hazardous waste sites that had been abandoned, and created the ATSDR (see Clean Air, above). To create this fund, taxes are levied on the industries most commonly responsible which produce petroleum and other toxic chemicals. If the polluter can be found, they are held responsible for paying for the cleanup, but if not, then the superfund does. The EPA has identified over 300,000 waste sites, but only about 2,000 of them were deemed hazardous enough to go on the National Priority List (NPL) and be targeted for cleanup (Frumkin, 2016, Seabert et al., 2021). As of June, 2024, the current list has 1340 sites, 457 deleted sites (where cleanup and remediation has been completed), and 39 proposed sites to be added to the NPL (EPA, 2024).

17.1.5.10: Food and Drug Safety

Long before the CWA and SDWA, the U.S. government recognized the need to regulate food and drug safety. The United States Department of Agriculture (USDA) was established by President Abraham Lincoln in 1862. In 1906 the Pure Food and Drugs Act was passed, requiring accurate labeling of food, drug, cosmetic and liquor products. The same year, the Federal Meat Inspection Act required that meat was processed in sanitary facilities - tasking the USDA with inspecting and enforcing these requirements. In 1938, congress passed the Federal Food, Drug and Cosmetic Act, which gave the newly rebranded Food and Drug Administration (FDA) the responsibility of establishing food safety standards (USDA, 2018). Today, the USDA is responsible for meat and dairy products, the EPA governs pesticides and fertilizers, and the FDA takes care of the remaining food products, drugs, and cosmetics.

Food borne disease outbreaks are defined as 2 or more cases of a similar illness that results from eating a particular food. Foodborne illnesses are typically caused by pathogens like bacteria, viruses, or other parasites that have gotten into the food source - often due to water or equipment contamination, unsafe cooking or serving practices (like failing to cook food thoroughly or leaving at room temperature for too long), or behaviors (such as failure of staff to wash hands). Pasteurization of dairy products is highly protective against bacterial outbreaks in dairy, and the sale of “raw” milk is illegal for this reason (Seabert et al., 2021). Although rare, there is also the possibility for intentional poisoning or bioterrorism, as happened in 1984 when a religious cult in Oregon intentionally contaminated a local city’s salad bars and water supply with *Salmonella* bacteria (Oh, 2017). Local and state public health agencies are typically responsible for investigating foodborne illness outbreaks, but they work closely with the USDA and FDA inspectors (Seabert et al., 2021). While Hollywood has perpetuated an image of the ill-tempered health inspector threatening to close down a beloved restaurant, these public servants actually protect the public from a plethora of potentially deadly disease outbreaks.

Pesticides are any materials used to kill, repel, or change the behavior of a pest that could potentially harm humans. This includes herbicides (which kill unwanted plants, or weeds), insecticides (which kill insects), fungicides (which kill fungi), rodenticides (which kill rodents), and even antimicrobials (which kill bacteria and viruses) (Frumkin, 2016). Technically, a pest is any animal, insect, or plant that poses a threat to humans - everything from the mosquitos that transmit malaria, to cockroaches in a kitchen, to rats in subway stations, or dandelion weeds in a front lawn. Pesticides must often be used with other tactics (like barriers for example) in order to prevent resistance developing in the target pest.

Pesticides can be either synthetic (man-made), or naturally-derived. Some synthetic pesticides have been found to have acute and chronic neurotoxic effects, and tend to linger in the environment (like DDT, which was banned in 1972) (EPA, 1972). Just because a pesticide is naturally-derived does not make it safe - arsenic and nicotine sulfate are naturally derived but are very toxic. In agricultural practice, the USDA regulates pesticides which can be used for conventional and organic agriculture. While conventional growers can use synthetic or natural pesticides, organic producers must only use products from a list published by the Organic Materials Review Institute (OMRI), which are mostly natural in origin, with a few exceptions (Andrews & Rose, 2018).

Most exposure to pesticides falls into two categories: residential and occupational. Residential exposure occurs when pesticides are used to prevent insects, rodents, or weeds around the home or yard. These can cause accidental poisoning (particularly in children), and are sometimes used in intentional poisoning (suicide/homicide) attempts. Occupational risk is highest for agricultural workers who administer the pesticide, and thus have more concentrated exposure. They may also expose family members if the pesticide lingers on clothing or materials brought home (Frumkin, 2016). As with any substance, the dose makes the poison, so amount and duration of exposure are important variables in identifying the toxicity of a substance. The EPA has categories of pesticides based on their toxicity levels with the following labels:

- Caution = relatively low toxicity.
- Warning = moderate toxicity.
- Danger = high toxicity (Frumkin, 2016, Andrews & Rose, 2018).

17.1.5.11: Climate Change and Environmental Health

The changes to climate due to carbon pollution (CO_2, methane and other so-called "greenhouse gasses") create a number of hazards to human health. This is a pressing concern within the field of environmental health.

Here is a short video explanation of climate change, from National Geographic:

In the following pages, you will read about climate's connection to health:

- What is climate change
- Climate's effects on health
- Prevention climate change and adapting to climate change
- Co-benefits of action on climate change
- Climate policies

Research about climate change:

Over the years, there have been a number of reliable scientific reports about climate change, ranging from individual research studies in journals, to comprehensive assessments of risk conducted by the US government, to international reports under the auspices of the UN. You might find it beneficial to browse through these resources.

USA, 2024: The Fifth National Climate Assessment.

Under the United Nations: The Intergovernmental Panel on Climate Change (which has issued a number of reports).

American Public Health Association: Hub for climate, health, and equity.

These resources offer a glimpse of the variety of effects of climate change on health, including

- Heat-related illness
- Spread of vectors (mosquitoes, ticks, etc.) and infectious diseases
- Air pollution and particulate matter
- Water-borne diseases
- Changes in the food supply
- Extreme weather and disasters (floods, fires, storms, etc.)
- Mental health effects

17.1.5.12: Climate Change

One of the most pressing concerns in environmental health is the effects of climate change on the planet, and human and animal populations. **Climate change** refers to the shifts in climate over time in various regions across the globe. Many of these shifts are due to **global warming**, or the observable increase in average temperature of the earth. The term “global warming” sometimes causes confusion because people think it means all temperatures will be higher throughout the year. Instead, it’s better to think of global warming as the driver of climate change, because the increasing average global temperature is causing shifts to different regional climates across the globe - including more severe storms, droughts, and permanent changes to ecosystems.

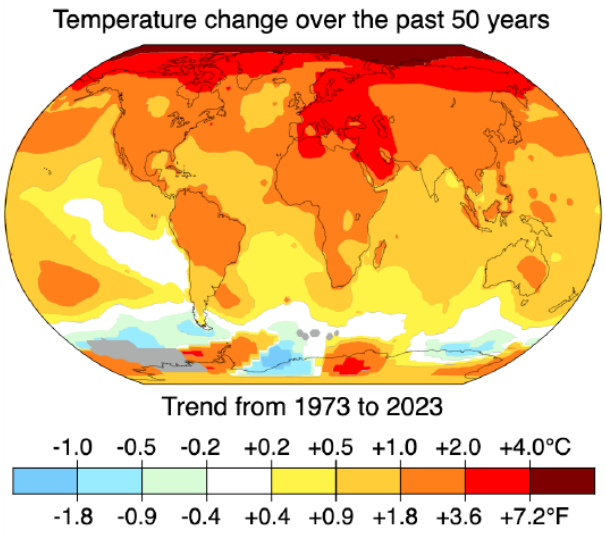

Figure 17.1.5.12.1: Change in Average Temperature With Fahrenheit. (Copyright; CC0, NASA’s Scientific Visualization Studio, Key and Title by uploader

How do we know that the earth is warming? Evidence from ice cores collected from Greenland and Antarctica, plus ambient temperature data collected since 1958 demonstrate that although the earth has gone through cycles of warming and ice ages, human activity since the industrial revolution has caused much more warming in the last 150 years than occurred in the ~800,000 years prior. Images from space show ice sheets and glaciers melting and shrinking, dumping fresh water into the ocean. And since the middle of the last century, scientists have tracked a 2 °F increase in the average temperature of the planet, with the most significant increase happening in the last 4 decades (NASA, 2024).

Figure 17.1.5.12.2: Melting Canadian glacier. (Katherine

Lean, CDC/ CDC Connects, 2017.)

This glacier located along the Icefields Parkway, near Banff National Park, Canada, is melting, showcasing the effect global climate change is having on the environment. The glaciers in this area have been studied since the 1950s, making them some of the longest scientifically observed glaciers in the world. Photo Credit:

This most recent and rapid global warming is considered to be **anthropogenic** (caused by human activity), not something that would typically happen from natural sources alone. Anthropogenic factors include the release of **Greenhouse Gasses (GHG)**. These GHGs include carbon dioxide (CO_2), methane (CH_4), and nitrous oxide (N_2O),and are released into the atmosphere from the burning of fossil fuels for energy, as well as from modern agricultural practices. Trees actually remove CO_2 from the atmosphere and store it in their trunks - so forests become “carbon sinks”. Deforestation therefore also contributes to global warming by cutting into carbon sinks - thus decreasing the amount of CO_2 collected (Burke & Weill, 2023). These GHGs left floating in the atmosphere trap heat from the sun and reflect it back down to the earth, causing an increase in the average temperature - much like a greenhouse uses glass walls to trap heat from the sun and keep the interior warmer for plants. Since the 1970s, the release of GHGs has increased much faster than in years prior, with the largest spike happening after the turn of the 21st century (Frumkin, 2016). Part of this is due to global population growth, which certainly contributes to the demand for energy production and thus the burning of fossil fuels to make it. However, the largest contributors to GHG tend to be the wealthiest countries, and per-capita GHG emissions are higher for more economically developed countries than for less economically developed countries. So it’s not just that more people require more energy, it’s also the behaviors and demands of wealthy societies that are driving GHG emissions. Still, as a few countries like Germany and the Netherlands have demonstrated, quality of life can be maintained while reducing GHG emissions through the use of technology and renewable energy sources (Ritchie & Roser, 2020). See figures 17.1.5.12.3 and 17.1.5.12.4 below.

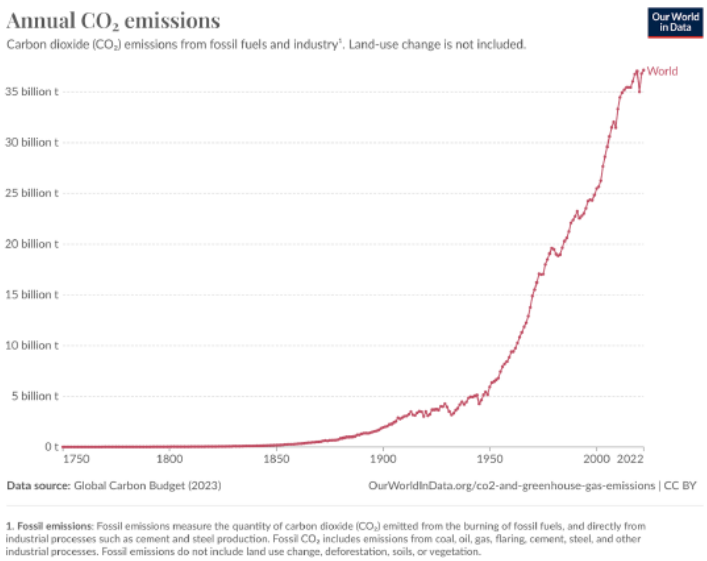

Figure 17.1.5.12.3: Annual CO_2 emissions from fossil fuels and

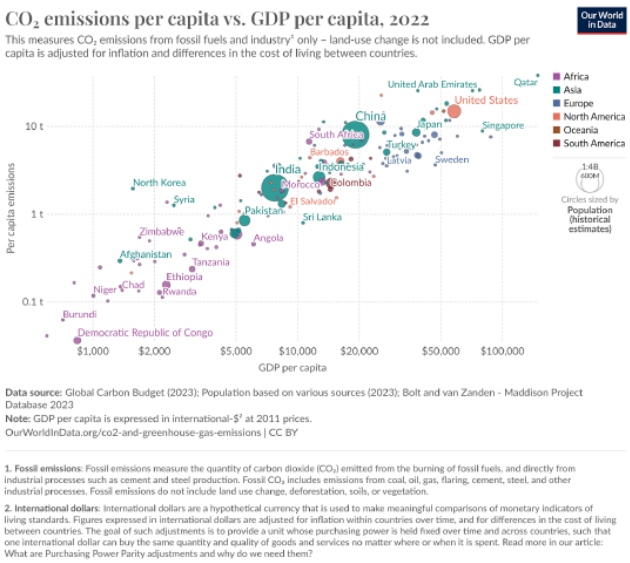

Figure 17.1.5.12.4: CO_2 emissions per capita vs. gross domestic product (GDP) per capita. (Copyright; CC-BY Our World in Data)

industry. (Copyright; CC-BY Our World in Data)

Increasing the Earth's average surface temperature has several consequences. When the ocean warms even just a little, it expands. As ice sheets and glaciers on land melt, they also contribute to rising sea levels. (Melting icebergs don't contribute to increased sea levels, as their volume is already accounted for - like ice cubes in a glass of water). Increases in ocean temperature can cause the "bleaching" of coral reefs, essentially killing them and the marine life that rely on them for food and shelter (NOAA, 2023). On land, the higher temperatures cause more evaporation of water from plants and soil, leading to droughts. Warming air can also hold onto more water vapor, which can also cause more extreme weather - like severe rainstorms, hurricanes, and flooding (Frumkin, 2016). As warm air travels toward the poles, it shifts the cold air from the polar vortex (low pressure air at the north and south poles) which can cause severe winter storms - like the unexpected snowstorms experienced in Texas in 2021 which caused massive failures in the power grid (Burke & Weill, 2023). While some rain is needed for vegetation growth, very wet springs followed by dry summers cause all that vegetation to dry out. In 2021 during the summer, dry timber and windy conditions led to mega wildfires in the Sierra Nevada mountains (Sierra Nevada Conservancy, 2022). Droughts can not only dry out plants, but also make the soil less permeable, causing flooding when substantial rains do fall, and allowing precious rainwater to wash away into the ocean instead of sinking into groundwater aquifers (Fry & Reyes-Velarde, 2019). And if heavy rains follow a wildfire, they can cause mudslides that change terrain and threaten homes and roads (Burke & Weill, 2023). .

Climate change might include changes in temperature, rain or snowfall, drought, or wind that influence the overall climate for that region. **Climate** is a term used to describe *average* weather patterns. Southern California for example has a mostly mediterranean (arid or semi-arid) climate around the coastal cities and Los Angeles, gradually shifting to a desert climate in the Mojave desert and inland regions. Los Angeles has pretty mild temperature changes over the seasons, with some rainfall in the winter, and dry, sunny summers. The desert areas get much less rain of course, and have more temperature extremes, getting hotter in the summer and colder in the winter. **Weather** is made up of the temperature, atmospheric pressure, precipitation, wind, and humidity at any given time and can change rapidly. Certain weather patterns may be predictable for a particular climate, but the two are not the same by definition. Over time, if the climate changes in a specific area, there may be more extreme weather patterns, and there will be changes in the overall ecology of that region - which may positively or negatively influence its ability to support life of the plants and animals who live there (Burke & Weill, 2023).

In our California example, the average temperature in the Los Angeles (LA) region has already increased since the middle of the 20th century, and is expected to be 4-5 °F warmer by the middle of the century. This increase in temperature is causing more of the snowpack to melt from the nearby mountains, and more of the water sources across the state to evaporate. The combination of warm, dry summers and substantial rainstorms in the winter will cause more vegetation to grow in the spring and become dry, wildfire fuel in the summer. Subsequent rains will increase the risk of mudslides and soil erosion. Along the coast, higher sea levels will threaten coastal communities, which, along with mudslides can cause severe danger to lives and homes (California Climate Adaptation Strategy, 2024). Central California has a mediterranean climate similar to LA, which is conducive to growing fruit and nut orchards and crops that require rain in the winter and warm sun in the summer. If the entire climate in central CA becomes more desert-like, it will severely impact the state's large agricultural economy. For example, almond orchards in CA produce 80% of the world's almonds - but these trees require many years to mature and need water year round (Chea, 2021).

The distinction between **climate** and **weather** is an important one. Climate is the average of weather conditions (temperature,

rainfall, etc.) over a 30-year period. Weather is what we call the atmospheric conditions at any given moment -- sun, rain, heat, snow, etc. The focus on climate over weather in studying what's happening on earth is akin to public health's focus on population health over individual health. For example, a 5% increase in the number of days an individual misses work or school due to illness might not be a big deal -- but a 5% increase across a population is a very big deal. Similarly, while any given day in San Francisco the temperature goes up or down 2 degrees Celcius (about 5 degrees Fahrenheit) and no one thinks twice, when the climate heats up by 2 degrees Celsius, it is a very big deal indeed.

17.1.5.13: The Health Effects of Climate Change

As global warming causes a cascade of climate changes and weather pattern disruptions, these too cause changes to the ecological systems in which we live, which in turn affect human health. Besides the dangers of extreme weather events, which can be deadly on their own, climate change will affect both physical and human health in many ways. According to the most recent (5th) National Climate Assessment from the U.S. Global Change Research Program:

Health risks from a changing climate include higher rates of heat-related morbidity and mortality; increases in the geographic range of some infectious diseases; greater exposure to poor air quality; increases in some adverse pregnancy outcomes; higher rates of pulmonary, neurological, and cardiovascular diseases; and worsening mental health (USGCRP, 2023b)

And these risks to health are not equal across America or across the globe. Social determinants of health also influence which populations will be at higher risk for experiencing the health effects of climate change, with the most severe impacts being felt by communities and countries with less wealth, fewer resources, less education, and those historically marginalized by the rest of society. Even within relatively wealthy countries, the populations most at risk include the elderly, unhoused, children, pregnant people, and those with chronic conditions and disabilities (USGCRP, 2023b).

While warmer temperatures in some areas actually increase the capacity to grow food, they can harm crops and farmers in other regions, and disrupt the food supply chain. The northern regions in Siberia (Russia) and Canada are now warm enough to grow crops that would not have survived before (like soy and wheat), but South Asia, South America, and Africa will experience significant losses to dietary staples (wheat, corn, etc.). Warmer weather also encourages the growth of pests, fungi, and other plant diseases, causing more crop losses (Frumkin, 2016). Warmer ocean temperatures threaten fish and shellfish, which are important sources of protein for many Indigenous communities (USGCRP, 2023b). And although CO_2 can be removed from the air by certain trees and plants, it can also change the nutrient content in some food sources like rice and soybeans. Meanwhile, weeds, allergy-producing plants (like ragweed), and poisonous plants (like poison ivy) thrive in the heat and higher CO_2 (Frumkin, 2016). Food insecurity is already high in many of the same places experiencing negative agricultural effects of climate change.

Foodborne, waterborne, and vector borne pathogens are likely to increase with climate change via several pathways. Many bacteria and fungi thrive in warm, humid climates, and many vectors (like mosquitos) breed in standing water. Water sources can be contaminated with runoff from heavy rains and flooding, and can contribute to food contamination via irrigation and washing of plants. Water shortages may also prompt people to turn to other sources of water like nearby lakes and streams, which are more likely to be contaminated with runoff and/or pathogens. And higher temperatures also promote harmful algal blooms (colonies of algae), both in freshwater (lakes) and saltwater (oceans), which can be harmful to humans and other marine organisms. Vectors like mosquitoes and ticks have spread further as other regions warm, bringing with them diseases like malaria, West Nile virus, dengue fever, and chikungunya. Even fungal diseases like Valley Fever are expected to spread north with drought conditions (Frumkin, 2016, USGCRP, 2023).

Many regions are experiencing higher-than average temperatures, and more frequent heat waves, or extreme heat events (EHE). In the summer of 2023, Phoenix experienced a record 31-day streak of temperatures over 110 °F (The Associated Press, 2023). While the American Southwest is not stranger to hot summers, other regions also experienced severe heat waves for which they have little history or preparation. In 2021, the Northwestern states and Canada (typically a cooler, “oceanic” climate) experienced a “heat dome” which caused high temperatures over the summer (Zhang et al., 2023). Similar heatwaves have hit Australia, China, Japan, and Europe (Zachariah et al., 2023), and can be particularly dangerous in regions that aren’t typically prepared for hot summers with air conditioning in buildings and public transportation. EHEs can cause acute heat-related illnesses (HRIs) such as heat exhaustion, dehydration, and heat stroke, and they also increase risks for cardiovascular events and kidney problems in those with chronic diseases like diabetes, as well as health complications for infants and pregnant people.

People most at risk for HRIs are older folks, young children, and pregnant people, as well as those who take certain medications, those who lack housing or air conditioning, and those who work outside. Social determinants of health also impact disparities in HRIs. If folks lack the money to pay for high electric bills, they may not run their air conditioning during the summer months. And poorer, urban communities may actually experience hotter conditions than wealthier suburban neighborhoods. A lack of tree cover/greenspace and more cement can create “urban heat islands” up to 4°F hotter, and less likely to cool down at night. But plants that provide shade and absorb CO_2 need irrigation, which is why wealthier neighborhoods tend to have more of them (Dialesandro et al., 2021, USGCRP, 2023b). See Figure 11.3 below for region-specific climate change effects in the U.S.

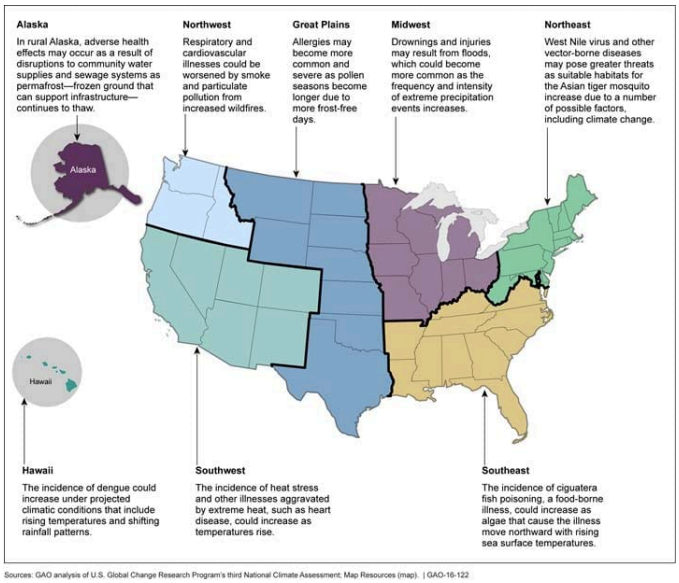

Figure 17.1.5.13.1: Examples of Potential Health Impacts from Climate Change in the United States, by Region. U.S. Government Accountability Office from Washington, DC, United States. (Public domain, via Wikimedia Commons. November 10, 2015)

Figure 11.3 Examples of Potential Health Impacts from Climate Change in the United States, by Region. U.S. Government Accountability Office from Washington, DC, United States, Public domain, via Wikimedia Commons. November 10, 2015.

Climate change affects mental health in several ways. People may lose everything in a natural disaster like a hurricane, wildfire, or flood. They may lose friends and family members, pets, photographs, homes and vehicles, and entire communities. They might lose their jobs and livelihoods to a natural disaster, or a change in climate - particularly in agricultural economies. Experiencing environmental trauma can have a severe and long-lasting impact on mental health, often causing post-traumatic stress disorder (PTSD) and heightened anxiety for many years (USGCRP, 2023). Historically minoritized communities and those who have fewer resources to begin with are often those the most harmed. For example in 2005, Hurricane Katrina devastated parts of New Orleans. The areas hardest hit were home to majority Black residents due to historical redlining practices which had segregated homeownership to certain parts of the city. These neighborhoods were below sea level, and so experienced the worst flooding (Burke & Weill, 2023). And the recovery has been just as difficult - nearly 175,000 Black New Orleans residents were displaced, and 75,000 have still not returned almost 2 decades later. Housing costs increased, flood insurance became expensive, and the federal program designed to fund rebuilding efforts ended up being sued for shortchanging poorer recipients and trying to collect overpayments (SPLC, 2023).

What happened after Hurricane Katrina is perhaps a microcosm of the displacement of communities due to climate change. Severe weather and natural disasters may destroy neighborhoods, towns, and even cities, forcing inhabitants to move elsewhere. Likewise, heatwaves and droughts may make agriculture unsustainable in certain regions, forcing people to migrate. Indigenous peoples already experience disparate impacts which threaten traditional ways of life, as well as the destruction of culturally and spiritually significant landscapes (USGCRP, 2023b). These and other socioeconomic impacts threaten civil and international conflict, and will likely disrupt global economies - all of which will have cascading effects on human health. See Fig. 17.1.5.13.2 below for a diagram outlining these health effects of climate change.

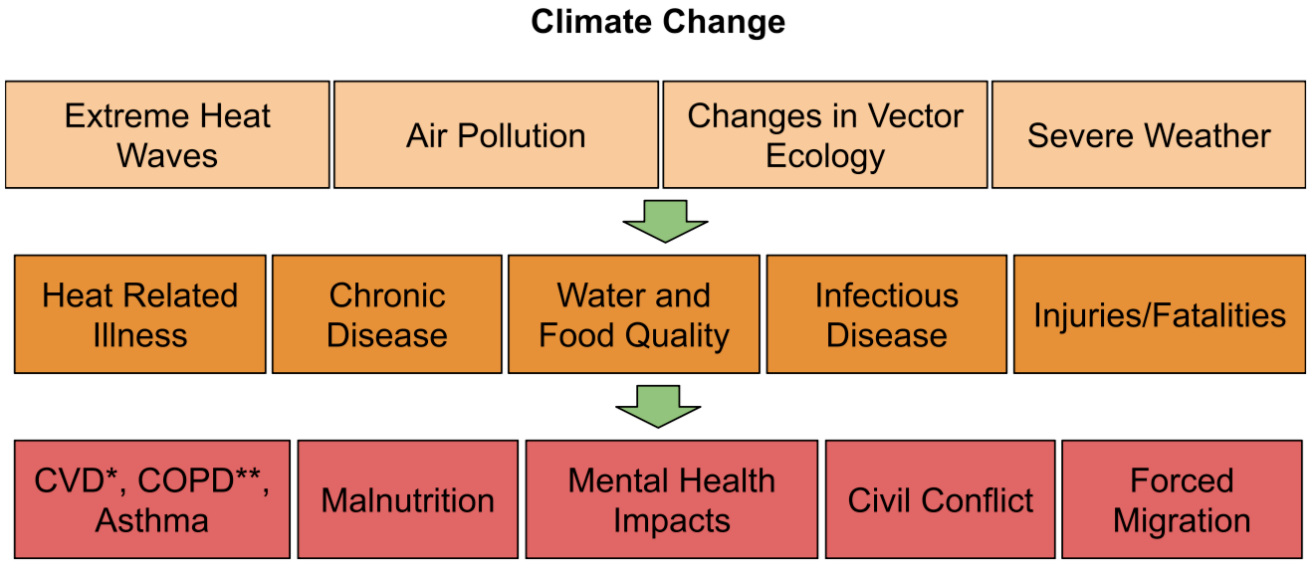

Figure 17.1.5.13.2: Health Effects of Climate Change. *Cardiovascular Disease (CVD). **Chronic Obstructive Pulmonary Disease (COPD).

17.1.5.14: Preventing Climate Change and Adapting to Climate Change

There are (at least) two major approaches to addressing the vast health risks of climate change. Public health professionals play a role in both of these approaches, alongside other scientists, activists and others. Public health voices have been particularly prominent in finding ways to adapt to climate change here in California, for example.

One approach is to try to PREVENT the planet from warming, or from warming as much or as quickly.

- This would include putting less carbon into the air (through alternative energy or reduced use of petroleum products).
- It could include planting trees and gardens, or other ways of capturing carbon from the environment and storing it, to slow the warming of the climate.

Another approach is to ADAPT to the reality of climate change and try to ameliorate or reduce the health effects of this warming.

- This approach is fundamentally different -- although not contradictory (one can support both approaches).
- This approach says, how do we save lives, given that mosquitoes and other vectors are moving into new regions, natural disasters are becoming more common, crops are failing in many parts of the world, and all the other specific ways that the increased variability in the climate are ALREADY impacting health.

As you can imagine, there are MANY things we can do to help our communities be more resilient in the face of one of the greatest creeping threats to human health.

Can you think of more ways we can use ideas, tools, policies or programs that we've seen throughout the semester to help adapt to a changing climate here in California? You might think of things we saw in the Environmental Health chapter, or way back at controlling infectious and noninfectious diseases, or community organizing techniques, or adding the specific health needs of elders -- or any other topic we've touched on this semester. They all can play a part in responding to climate change.

17.1.5.15: Co-Benefits of Taking Steps to Address Climate Change

The "good news" of taking action to reduce (mitigate) climate change and to adapt to a changing climate is that some steps to reduce carbon pollution can improve health in two ways. Obviously, by reducing climate change effects, that is good for human health. But some steps also have co-benefits for health -- side effects that improve health in other ways.

For example, walking or riding a bike avoids the carbon exhaust of driving -- and it is good for circulatory health (heart and arteries), and good for mood.

Eating more vegetables and less meat is good for the planet -- and good for digestion and reducing obesity.

Burning less coal slows climate change -- and also reduces asthma and heart disease associated with soot.

Please watch this short video from the World Health Organization on health action to respond to or prevent climate change, and its co-benefits.

17.1.5.16: CLIMATE CHANGE POLICY

In December of 2015, 196 countries signed the Paris Agreement - a legally binding international treaty to address climate change. This treaty mandates that signatory countries set their own goals to reduce their impact on climate change, while recognizing that low-income countries may need extra funding and support in order to join in climate mitigation efforts to reduce their GHG emissions, as well to adapt to the adverse effects of climate change they are already experiencing. The long-term target of the Paris Agreement is to keep the increase in Earth's average temperature (compared to pre-industrial levels) well below 2 ℃, while pursuing the target of at or below 1.5 ℃ - since warming below 2℃ will still cause substantial climate change impacts like droughts, floods, and extreme storms. The agreement includes nationally determined contributions (NDCs) by each country; commitments to take economy-wide steps to lower GHG emissions (UNFCCC, 2015). As of the early 2020's warming is already at 1.2 ℃, yet if all of the long-term targets for GHG emissions the Paris Agreement were implemented in full and on time, it is possible that warming could be kept at or below that dire 2 ℃ mark by 2100 - but unlikely that warming could be kept under 1.5 ℃. To reach this more aggressive goal, signatory countries would have to move up their net zero emissions targets, cut CO_2 emissions by 45% and other GHG emissions substantially by the year 2030, and support other countries in doing so as well (especially low-income countries) (Meinshausen et al., 2022). Unfortunately, the United States is behind on its NDC of lowering GHG emissions by 50-52% below 2005 levels by 2030, despite positive projections assumed from implementing the Inflation Reduction Act (IRA) and Infrastructure Investment and Jobs Act (IIJA) signed into law by President Joseph Biden. In order to close the gap, the Environmental Protection Agency (EPA) could use the Clean Air Act (see below) to set more aggressive standards for lowering pollution across industries, and the federal government could expand funding for forestry and agricultural incentives to promote mitigation and sequestration (removal of GHGs) (Clean Air Task Force, 2023).

Climate Policy in Recent US Policy

In August 2022, Congress passed the Inflation Reduction Act, which was biggest piece of legislation on climate in decades. It invested more money for addressing climate change and reducing carbon emissions than ever before. Here is a 5-minute video explanation from PBS NewsHourfrom when the law was new. The goal set the US on track for a 40% reduction in emissions.

However, with elections come many changes to policy. The current Trump Administration has been emphasizing investments and incentives for the gas and oil industries, and rollbacks to many of the climate measures in the Inflation Reduction Act (like incentives to buy electric cars). It is too early to measure the impact of these changes, but it seems likely that the 40% reduction in emissions that was forecase in 2022 will not be reached this decade.

17.1.5.16.1: The Paris Agreement

In December of 2015, 196 countries signed the Paris Agreement - a legally binding international treaty to address climate change. This treaty mandates that signatory countries set their own goals to reduce their impact on climate change, while recognizing that low-income countries may need extra funding and support in order to join in climate mitigation efforts to reduce their GHG emissions, as well to adapt to the adverse effects of climate change they are already experiencing. The long-term target of the Paris Agreement is to keep the increase in Earth's average temperature (compared to pre-industrial levels) well below 2 ℃, while pursuing the target of at or below 1.5 ℃ - since warming below 2℃ will still cause substantial climate change impacts like droughts, floods, and extreme storms. The agreement includes nationally determined contributions (NDCs) by each country; commitments to take economy-wide steps to lower GHG emissions (UNFCCC, 2015). As of the early 2020's warming is already at 1.2 ℃, yet if all of the long-term targets for GHG emissions the Paris Agreement were implemented in full and on time, it is possible that warming could be kept at or below that dire 2 ℃ mark by 2100 - but unlikely that warming could be kept under 1.5 ℃. To reach this more aggressive goal, signatory countries would have to move up their net zero emissions targets, cut CO_2 emissions by 45% and other GHG emissions substantially by the year 2030, and support other countries in doing so as well (especially low-income countries) (Meinshausen et al., 2022). Unfortunately, the United States is behind on its NDC of lowering GHG emissions by 50-52% below 2005 levels by 2030, despite positive projections assumed from implementing the Inflation Reduction Act (IRA) and Infrastructure Investment and Jobs Act (IIJA) signed into law by President Joseph Biden. In order to close the gap, the Environmental Protection Agency (EPA) could use the Clean Air Act (see below) to set more aggressive standards for lowering pollution across industries, and the federal government could expand funding for forestry and agricultural incentives to promote mitigation and sequestration (removal of GHGs) (Clean Air Task Force, 2023).

The United States has been in and out of the Paris Agreement. It was signed during the Obama Administration, then the first Trump Administration withdrew the US from the agreement, then the Biden Administration rejoined, then the second Trump Administration withdrew. This inconsistency may weaken US influence in future climate-related negotiations. US nonparticipation in the Paris Agreement is projected to slow the world's progress toward the goal of no more than a 2° C. rise in temperature of the overall climate, compared with pre-industrial levels, by taking off the table more than a third of the projected reduction in emissions under the Paris Agreement (Larch & Wanner, 2024).

17.1.5.16.2: Climate Change Policy in California

In the state of California (CA), “The 100 Percent Clean Energy Act of 2018,” Senate Bill 100 (SB 100, De León) requires all electricity generation to be produced by zero-carbon sources by 2045, and at least 60% of the state’s electricity should be generated via renewable resources by 2030. Renewable energy resources include solar, wind, geothermal, bioenergy, fuel cells, and existing hydroelectric and nuclear power plants (no new nuclear power plants are to be built). According to the initial multi-agency assessment report, CA will need to triple its current electricity capacity to meet demands, and triple its solar and wind build rate. Battery storage build rates need to increase by nearly 8 times the current rate. These and other considerations to maintain a “flexible” grid will cost nearly $4.6 billion dollars by 2045. Yet, the report is positive that the goal of 100% renewable energy for electricity customers and state agencies is doable by the target year (Gill, Gutierrez, & Weeks, 2021). At the same time, the Clean Air Resources Board also enacted a rule to require all new cars and light trucks sold in CA must be fully electric or plug-in hybrids by 2035. Projections estimate that this will cut GHG emissions from motor vehicles in half by 2040, and substantially reduce cardiopulmonary deaths, emergency room visits, and asthma attacks related to smog for CA residents (CARB, 2022).

17.1.5.16.3: Emergency preparedness (whether emergency is climate related or not)

Public health plays a key role in emergency preparedness for all kinds of disasters -- whether they are climate related or not. The need for a public health role in assessing risks, ensuring the availability of adequate medical resources, and carrying out prevention and intervention strategies seems to get highlighted in each major disaster (natural or human-caused) that occurs.

- The health dangers to the rescue and cleanup crews at the site of the World Trade Center after the September 11, 2001 attacks plus the mysterious anthrax attack through the mail that killed several people and threatened more in Washington, DC pointed to the need for public health expertise in responding to these disasters and planning for future bioterrorism attacks.
- The huge health inequities related to Hurricane Katrina in New Orleans in 2005 revealed the need to attend to vulnerable populations when managing emergencies and, on the prevention end, to involve communities in developing emergency plans that will actually work for them.
- The relative public health success in managing the pandemic of H1N1 flu in 2009-2010 showed that advance planning works -- the death count from this relatively mild but highly contagious flu strain was kept low through rapid public health action (around 284,000 deaths worldwide, according to the World Health Organization, cited by the Mayo Clinic).
- Obviously, the covid-19 pandemic that began in late 2019 and by 2020 was causing major disruptions and deaths worldwide pointed to both the value of emergency planning where it worked to prevent worse outcomes and the shortfalls of existing plans, given that this coronavirus has caused more than 7 million deaths worldwide to date.

Some of the roles that public health organizations can play in emergency preparedness include

- Surveillance. The public health practice of routine monitoring of disease outbreaks can assist in identifying a potential emergency in its earliest stages -- whether the pathogen is naturally occurring or spread through bioterrorism. With climate change, we expact vector-borne diseases (like malaria and dengue) to spread into new regions as mosquitoes, ticks and other disease-carrying animals migrate to newly-warm areas. Surveillance will be key to detecting these outbreaks early.
- Epidemiological and laboratory investigation of pathogens. Epidemiological investigation and analysis can determine the identity, source, and mode of transmission for disease agents (pathogens). Understanding how a disease spreads is essential to developing effective interventions to stop the spread. Laboratory capacity to test rare or unusual agents is not found everywhere -- different laboratories have different specializations -- yet the network of public health laboratories together need to be ready for any emerging threat.
- Risk communications. In an emergency, communication is more vital than ever. Public health communications to the public should be clear, concise, and accurate. When information changes -- as it undoubtedly will -- the change in message to the community must be explained adequately. (Otherwise, the public may be confused or distrust the messages.) Public health can also assist with interagency communication and coordination during an emergency.
- Planning. Involving key stakeholders, including vulnerable communities, in making emergency preparedness plans is a strength of public health planning efforts. Planning can help ensure that emergency medical services and hospital capacity can respond to a health emergency, including providing for the safety of medical personnel. Public health emergency preparedness can include running possible scenarios, establishing action protocols, training personnel, maintaining relationships among partnering agencies, and analyzing the vulnerability of specific communities. Where possible, planning efforts can help vulnerable communities reduce their exposure, for example, reducing the risk of wildfire, preparing cooling stations in advance of heatwaves so vulnerable people have a place to go to cool off, or reducing construction in flood zones.
- Community-wide response. Public health agencies can play a role in coordinating community-wide responses to an emergency, where many different entities are involved.
- Stockpiling supplies. In preparation for pandemic flu, the US, for example, stockpiled antiviral medications effective against the flu. These were not effective against covid, yet may still be a welcome forethought should the avian flu H1N5 evolve to be easily transmitted among humans, a public health nightmare. Stockpiles of masks, respirators, and other supplies is also warranted.

More about ozone

Every semester, I've noticed some students get confused about **ozone**! Ozone is a three-atom modecule of oxygen (O_3). We can't use it to breathe (we breathe ithe two-atom version, O_2). Ozone is produced through a variety of industrial processes and also naturally. Having *some* ozone around isn't a threat (remember, "the dose makes the poison.") Having high concentrations of **surface-level ozone** -- meaning, ozone in the air we walk around in at the surface of the earth -- is problematic, though. It increases the risk of many lung diseases and can actually injure our lungs. That's why ozone is a criteria pollutant that the EPA closely monitors -- one of six criteria pollutants that are common and especially important to human health.

But what about the ozone layer? Ozone in the upper atmosphere is very important to protecting humans from harmful radiation from the sun. Ozone in the upper atmosphere is like sunscreen for the planet -- it protects us all from cancer. The upper atmosphere is far from where we walk around breathing, so ozone up there is no threat to human health -- in fact, quite the opposite.

What's the hole in the ozone layer, and what's happening with it? Due to the use of certain chemicals (CFCs) in lots of manufactured products (from hair spray to refrigerators), CFC pollution has caused a breakdown of ozone in the upper atmosphere, especially over Antartica, where a hole in the ozone layer was discovered in the 1980's. **In a rare example of international cooperation on environmental dangers**, every country in the world signed the Montreal Protocol, agreeing to stop using CFCs. The hole in the ozone layer is recovering and is expected to close sometime in the middle of the 2100's. Success is in progress!

You can see more about this through this 2-minute NASA video, or this 8-minute Vox explainer video. Both are OPTIONAL.

Is the hole in the ozone layer connected to climate change? Not much! They are two different problems, with different causes. There are a *few* connections between the two, though, which you can read about at this NASA blog post if you are curious.

History of Environmental Health:

This 2011 video offers a historical view of environmental health. Some of the early successes of this branch of public health are ones we take for granted now, yet had a huge impact in their day. This video lacks closed captions -- it is an optional, supplementary resource.

18.1: PREVENTING INJURIES AND VIOLENCE

Learning Outcomes

By the end of this chapter you will be able to:

- Recognize the common types of unintentional and intentional injuries
- Identify ways to reduce chances of unintentional and intentional injuries
- Explain how risk from injury changes throughout life stages.

What steps can you take to reduce the chances of accidental injuries?

How can you reduce chances of injuries from violence?

There are many choices you make in life that impact your health and well-being and some of those choices, like smoking cigarettes, have a direct connection to a negative health implication, like lung cancer. Although the choices you make may or may not directly impact the possibility of suffering intentional and unintentional injuries, understanding the most common reasons for injury can help you increase your safety.

18.1.1: Introduction to Intentional and Unintentional Injuries

Throughout the world, injuries, both unintentional and violence-related, take the lives of 4.4 million people each year (nearly 8% of all deaths). For people ages 5-29, three of the top five causes of death are injury-related. In the United States, unintentional injuries are the leading cause of death in children, adolescents, and adults younger than 45 years. In 2018, unintentional injuries were the cause of 24.8 million people to visit their doctor and 97.9 million to visit the emergency room with an additional 1.2 million visited the emergency room due to an assault. Unintentional injuries ranked as the 4th overall leading cause of death in 1980, increased to the 3rd leading cause of death by 2018, and moved back to 4th in 2020 when COVID took the 3rd ranking. Some good news is that data from 1950-2018 show a reduction in deaths due to unintentional injuries from 78 per 100,000 to 48 per 100,000, however homicide has remained relatively the same from 5.1 to 5.9 per 100,000 people [1].

Injuries and violence cost billions of dollars each year in health care costs, lost productivity and law enforcement. There are also numerous costs to personal well-being including:

- Premature death
- Years of potential life lost
- Disability and disability-adjusted life years lost
- Poor mental health
- Increased risk of suicide
- High medical costs
- Lost productivity
- Chronic diseases like heart disease, diabetes and cancer
- Social problems such as poverty, crime and violence

Both intentional and unintentional injuries are public health concerns that are addressed worldwide and in the U.S. The National Center for Injury Prevention and Control (NCIPC) was launched in 1992 to focus specifically on injuries as an important topic for public health. The NCIPC, along with the CDC and NIH, provide research-based evidence and resources to meet goals to reduce injuries.

Table 18.1.1.1 *: Year 2020 Intentional and Unintentional Death Rates*[2]

Cause of Death	Number of Deaths	Deaths per 100,000 people
Unintentional fall deaths	42,112	12.8
Motor Vehicle traffic deaths	40,698	12.4
Unintentional Poisoning deaths	87,404	26.5
All poisoning deaths	97,034	29.5
Firearm homicides	19,384	5.9
All firearm deaths	45,222	13.7
All homicide deaths	24,576	7.5
Firearm suicides	24,292	7.4
Suffocation suicides	12,495	3.8
Poisoning suicides	5,528	1.7
All suicides	45,979	14.0
All injury deaths	278,345	84.5
All unintentional deaths	200,995	61

18.1.2: Unintentional Injuries

Unintentional injuries are often referred to as “accidents,” meaning something that was not intended. These include falls, drowning, motor vehicle crashes, fires, and poisoning.

Falls

For adults over 65 years, falls are the leading cause of death due to injury. In 2019 older adult falls caused 34,000 deaths, 3 million visits to the emergency room, and over 800,000 hospitalizations attributing to over $50 billion in medical costs annually. It is estimated that more than one out of four older people fall each year with one out of five falls causing serious injury. Traumatic brain injuries (TBI) and hip fractures are the most common serious injuries. The injuries associated with falls impact a persons quality of life making it hard for a person to get around, do everyday activities, or live on their own. Many people who fall, even if they’re not injured, become afraid of falling. This fear may impact their quality of life by causing a person to cut down on their everyday activities. When a person is less active, they become weaker and this increases their chances of falling.

Fall risk and prevention tips include:

- Lower body weakness, difficulties with walking and balance, or foot pain or poor footwear
  - Do exercises that make your legs stronger and improve your balance. Tai Chi is a good example of this kind of exercise.
  - Ask your doctor or healthcare provider to evaluate your risk for falling and talk with them about specific things you can do.
- Vitamin D deficiency (that is, not enough vitamin D in your system)
  - Ask your doctor or healthcare provider about taking vitamin D supplements.
- Use of medicines, such as tranquilizers, sedatives, or antidepressants. Even some over-the-counter medicines can affect balance and how steady you are on your feet.
  - Ask your doctor or pharmacist to review your medicines to see if any might make you dizzy or sleepy. This should include prescription medicines and over-the counter medicines.
- Vision problems
  - Have your eyes checked by an eye doctor at least once a year, and be sure to update your eyeglasses if needed.
  - If you have bifocal or progressive lenses, you may want to get a pair of glasses with only your distance prescription for outdoor activities, such as walking. Sometimes these types of lenses can make things seem closer or farther away than they really are.
- Home hazards or dangers such as broken or uneven steps, and throw rugs or clutter that can be tripped over.
  - Get rid of things you could trip over.
  - Add grab bars inside and outside your tub or shower and next to the toilet.
  - Put railings on both sides of stairs.
  - Make sure your home has lots of light by adding more or brighter light bulbs.
  - Keep items you use often in cabinets you can reach easily without using a step stool.
  - Use non-slip mats in the bathtub and on shower floors.

Drowning

Drowning is the process of experiencing respiratory impairment from submersion or immersion in liquid. Drowning can happen in seconds and is often silent. It can happen to anyone, any time there is access to water. Not all drownings are fatal, drowning injuries can cause brain damage and other serious outcomes, including long-term disability. Drowning kills nearly 4,000 people each year in the United States and is the leading cause of injury death for children 1 to 4 years of age. For every child who dies from drowning, another eight receive emergency department care for non-fatal drowning. Not all drownings are fatal, drowning injuries can cause brain damage and other serious outcomes, including long-term disability.

Drowning risk and prevention tips include:

- Not being able to swim
  - Adults and children should participate in formal swim lessons.
- Missing or ineffective fences around water

    - A four-sided isolation fence which separates the pool area from the house and yard reduces a child's risk of drowning by 83% compared to three-sided property-line fencing (which encloses the entire yard, but does not separate the pool from the house).
- Lack of close supervision
    - Drowning can happen quickly and quietly anywhere there is water, especially to unsupervised children. It happens in lakes and oceans, pools, bathtubs, and even buckets of water. Drowning can occur when lifeguards are present.
    - Use the buddy system! Always swim with another person.
- Location
    - The highest risk locations for drowning vary by age. Among infants under 1 year old, two thirds of all drownings occur in bathtubs. Most drownings happen in home swimming pools among children ages 1-4. More than half of fatal and nonfatal drownings among people 15 years and older occur in natural waters like lakes, rivers, or oceans.
    - It is important to know the risks or natural water, such as ocean rip currents.
- Not wearing life jackets
    - Life jackets can prevent drowning during water activities, especially boating and swimming.The U.S. Coast Guard reported 613 boating-related deaths in 2019, 79% of these deaths were drowning related, and of those who died from drowning 86% were not wearing life jackets.
- Drinking alcohol or using drugs
    - Among adolescents and adults, alcohol use is involved in:
        - up to 70% of deaths associated with water recreation,
        - nearly 1 in 4 emergency department visits for drowning, and
        - about 1 in 5 reported boating deaths.

Motor Vehicle Crashes

In 2021, more than 43,000 people died in motor vehicle crashes in the United States, that is more than 117 people killed in crashes every day. There were over 2.1 million emergency department visits for injuries from motor vehicle crashes in 2020. Deaths from crashes in 2021 resulted in over $430 billion in total costs—including medical costs and cost estimates for lost quality of life and lives lost. Motor vehicle injuries are often associated with distracted, impaired, or inexperienced drivers.

Distracted Drivers

- Distracted driving is doing another activity that takes the driver's attention away from driving that can increase the chance of a motor vehicle crash. There are three main types of distracted driving: visual (taking your eyes off the road), manual (taking your hands off the wheel), and cognitive (taking your mind off driving).
- In 2021, 3,100 people were killed and about 424,000 were injured in crashes involving a distracted driver. Not all persons killed by distracted drivers were in cars, about 1 in 5 were walking, riding their bikes, or otherwise outside a vehicle.
- Prevention: Do not multitask while driving. Whether it's adjusting your mirrors, selecting music, eating, making a phone call, or reading a text or email—do it before or after your trip, not during.

At 55 mph, sending or receiving a text is like driving the length of a football field with your eyes closed.

Child Passenger Safety

- Motor vehicle injuries are a leading cause of death among children in the United States. But many of these deaths can be prevented. Always buckling children in age- and size-appropriate car seats, booster seats, and seat belts reduces serious and fatal injuries by up to 80%.

Seatbelts

- Although most drivers follow these safety measures on every trip, there are still millions who don't. In fact, it is estimated that 2,549 lives (of people 5 years and older) could have been saved in 2017 alone if all motor vehicle occupants were restrained on every trip.

Teen Drivers

- In 2019, almost 2,400 teens in the United States aged 13–19 were killed and about 258,000 were treated in emergency departments for injuries suffered in motor vehicle crashes. That means that every day, about seven teens died due to motor vehicle crashes, and hundreds more were injured. In addition, motor vehicle crash deaths among teens 15–19 years of age

resulted in about $4.8 billion in medical and work loss costs for crashes that occurred in 2018.
- Teens who are at especially high risk for motor vehicle crashes are: Males, teens driving with teen or young adult passengers, and newly licensed teens.
- Risk factors include: Inexperience, nighttime and weekend driving, not using a seat belt, distracted driving, speeding, alcohol/drug use

Older drivers

- In 2019, about 8,000 older adults (aged 65+) were killed in traffic crashes, and more than 250,000 were treated in emergency departments for crash injuries. This means that each day, more than 20 older adults are killed and almost 700 are injured in crashes. Drivers aged 70+ have higher crash death rates per mile driven than middle-aged drivers (aged 35-54). Higher crash death rates among this age group are primarily due to increased vulnerability to injury in a crash. Across all age groups, males have substantially higher death rates than females.
- Age-related declines in vision and cognitive functioning (ability to reason and remember), as well as physical changes, might affect some older adults' driving abilities.

Impaired driving

- Every day, 29 people in the United States die in motor vehicle crashes that involve an alcohol-impaired driver, this is one death every 50 minutes. The annual cost of alcohol-related crashes totals more than $44 billion.
- Drugs other than alcohol (legal and illegal) are involved in about 16% of motor vehicle crashes. In 2018, 12.6 million people reported driving under the influence of marijuana or other illicit drugs.
- Drugs other than alcohol (legal and illegal) are involved in about 16% of motor vehicle crashes.

Pedestrian Safety

- More than 7,000 pedestrians were killed on our nation's roads in crashes involving a motor vehicle in 2020. That's about one death every 75 minutes.
- Alcohol, speeding, and location are major risk factors for pedestrian deaths caused by motor vehicles.
- Adults aged 65 years and older accounted for 20% of all pedestrian deaths in 2020, yet were only about 17% of the U.S. population.
- Pedestrian injuries can be reduced by: increasing your visibility, using cross walks, using designated sidewalks/paths, avoiding distractions while walking like headphones, and avoid walking when impaired.

Motorcycle Safety

- More than 5,500 motorcyclists died on our nation's roads in 2020, and more than 180,000 were treated in emergency departments for crash injuries.
- Motorcycle helmets are important to save lives. In 2017, helmets saved an estimated 1,872 lives and an additional 749 more lives could have been saved if all motorcyclists had worn helmets. Motorcycle helmets are 37 percent (for riders) and 41 percent (for passengers) effective in preventing deaths. Helmets reduce the risk of head injury by 69%.

Bicycle Safety

- Bicycle trips make up only 1% of all trips in the United States. However, bicyclists account for over 2% of people who die in a crash involving a motor vehicle on our nation's roads. Nearly 1,000 bicyclists die and over 130,000 are injured in crashes that occur on roads in the United States every year.
- Adults ages 55-69 have the highest bicycle death rates and adolescents, teens, and young adults have the highest rates of bicycle-related injuries treated in emergency departments (EDs).
- Male bicyclists have death rates 6 times higher and injury rates 5 times higher than females.

Fires

Fire is fast, in less than 30 seconds a small flame can turn into a major fire. In 2019, there were 1,291,500 fires which caused 3,704 deaths, 16,600 injuries, and accounts for $14.8 billion.

Home fire safety:

- Smoke alarms

    - Put smoke alarms on every level of your home and inside/outside of all sleeping areas.
    - Test them often to make sure they work and replace them after 10 years.
- In the kitchen
    - Do not leave the room when cooking, if you leave the kitchen turn off the burners.
    - Move flammable objects away from the cooking area.
    - Turn pot handles toward the back of the stove to avoid unintentionally knocking them.
- Home heating
    - Move flammable objects away from fireplaces, wood stoves, space heaters, or radiators.
    - Never use an extension cord with a space heater.
    - Ensure space heaters have an auto turn off if tipped over.
    - Have your chimney inspected.
- Smoking in the house
    - If you smoke in your home you have an increased risk of home fires.
    - Never smoke in bed or when drowsy
    - Ensure all cigarettes are completely put out- use water to ensure!
- Young children and older adults
    - Keep children away for anything that gets hot.
    - Keep matches and lighters out of reach of children.
    - Teach children how to escape the home if you cannot help them in the event of a home fire.
    - Older adults may need assistance to escape a home fire.

Poisoning

Poisoning is one of the top three causes of fatal unintentional injuries. In response to public health concerns regarding poisoning, in 1980 the National Capital Poison Center (NCPC) was founded, which is an independent, not-for-profit 501(c)(3) organization. There are 2 ways to get help from Poison Control: online at webPOISONCONTROL® or by phone at 1-800-222-1222.

As the primary organization providing help with poisoning, the NCPC data provides a picture of the commonality of injuries associated with poisoning. In 2020, the 55 U.S. poison control centers provided telephone guidance for over 2.1 million human poison exposures, which included:

- 6.4 poison exposures/1000 population,
- 37.9 poison exposures in children younger than 6 years/1000 children,
- 1 poison exposure reported to U.S. poison control centers every 15 seconds.
- In 2020, adults comprised almost half of all exposures (47%), followed by children younger than 6 (39%), then teens (8%).

Common types of poisoning include food poisoning, poisonous plants, and carbon monoxide poisoning.

Food poisoning symptoms can be anywhere from mild to very serious and may include: Upset stomach, stomach, cramps, nausea, vomiting, diarrhea, and fever. Some foods are more associated with foodborne illnesses and food poisoning than others, such as raw animal foods. While certain foods are more likely to make you sick, any food can get contaminated in the field, during processing, or during other stages in the food production chain, including through cross-contamination with raw meat in kitchens.

Many native and exotic plants are poisonous to humans when ingested or if there is skin contact with plant chemicals. However, the most common problems with poisonous plants arise from contact with the sap oil of several native plants that cause an allergic skin reaction—poison ivy, poison oak, and poison sumac.

Everyone is at risk for Carbon monoxide (CO) poisoning. CO, an odorless, colorless gas, that can cause sudden illness and death. CO is found in fumes produced any time you burn fuel in cars or trucks, small engines, stoves, lanterns, grills, fireplaces, gas ranges, or furnaces. CO can build up indoors and poison people and animals who breathe it. The most common symptoms of CO poisoning are headache, dizziness, weakness, upset stomach, vomiting, chest pain, and confusion. CO symptoms are often described as “flu-like.” If you breathe in a lot of CO it can make you pass out or kill you. People who are sleeping or drunk can die from CO poisoning before they have symptoms. It is important to use Carbon Monoxide detectors to know if CO is present.

- 14.1: Cell Division has no license indicated.

18.1.3: Intentional Injuries - Violence

There are many forms of intentional injury, or violence. The CDC approaches violence using the “Social-Ecological Model: a Framework for Prevention”. The framework encourages viewing violence and violence prevention as a multifaceted interconnected dynamic including the individual, their relationships, their community, and our society.

- The Individual
  - Individuals factors such as age, education, income, substance use, or history of abuse impact the risk of violence. A focus on attitudes, beliefs, behaviors, along with training on conflict resolution, safe dating, and healthy relationship may positively impact their risk of violence.
- Relationships
  - A person’s closest social circle-peers, partners and family members-influences their behavior and contribute to their experience. Parenting, mentors, effective communication, and problem solving may support effective relationships to prevent violence.
- Community
  - Where a person lives, works, or goes to school can impact their risk of violence. Creating safe physical and social environments may reduce violence in the community.
- Societal
  - A focus on society asks us to understand and look at how our society either encourages or inhibits violence, for example how social or cultural norms use violence to resolve conflicts or how wealth and health inequalities impact violence risk.

Community Violence

Community violence is interpersonal violence generally outside the home that is perpetrated by individuals who are not intimately related to the victim and who may or may not know each other. Examples include assaults, homicides, fights among groups, and shootings in public places, such as schools and on the streets. Acts of community violence include but are not limited to riots, sniper attacks, gang wars, drive-by shootings, bullying, workplace assaults, terrorist attacks, torture, bombings, war, ethnic cleansing, and widespread sexual, physical, and emotional abuse.

Young people are disproportionately impacted by violence in their communities, including firearm injuries and deaths. Violence is a leading cause of death and nonfatal injuries among adolescents and young adults; over half of US homicides in 2019 occurred among those ages 15 to 34. Unfortunately, data show significant increases in homicide rates in 2020 compared to 2019.

People’s health outcomes are influenced by the conditions in which they live, work, play, and learn. These conditions are called social determinants of health. Systemic racism, bias, and discrimination; economic instability; concentrated poverty; and limited housing, education, and healthcare access drive health inequities, such as violence. Communities of color often disproportionately experience these negative conditions, placing residents at greater risk for poor health outcomes. For example, Black or African American, American Indian, and Alaskan Native, and Hispanic or Latino persons have higher homicide rates than other racial and ethnic demographic groups. Research indicates that youth and young adults (ages 10-34), particularly those in communities of color, are disproportionately impacted.

Community violence can cause significant physical injuries and mental health conditions such as depression, anxiety, and post-traumatic stress disorder (PTSD). Living in a community experiencing violence is also associated with increases in risk of developing chronic diseases, as concerns about violence may prevent someone from engaging in healthy behaviors, such as walking, bicycling, using parks and recreational spaces, and accessing healthy food outlets. Violence scares people out of participating in neighborhood activities; limits business growth and prosperity; strains education, justice, and medical systems; and slows community progress.

The Division of Violence Prevention (DVP) at the Centers for Disease Control and Prevention (CDC) is focused on preventing community violence by identifying and implementing science-based programs, policies, and practices with partners and communities to disseminate, implement, and scale-up strategies based on the best available evidence to create safer communities, such as:

- Changing social norms through street outreach/violence interruption programs.
- Changing the physical environment through Crime Prevention Through Environmental Design (CPTED).

- Preventing future risk and lessening the harms of violence exposure through hospital-community partnerships, and treatment services such as Trauma-Focused Cognitive Behavior Therapy ®(TF-CBT) and Multisystemic Therapy® (MST).
- Strengthening economic supports through job training and summer jobs programs.
- Strengthening youth's skills through universal school-based programs to help youth develop skills to prevent violence and engage in healthy behaviors.
- Connecting youth to caring adults and activities such as mentoring and after-school programs.

Intimate and Partner Violence

Intimate partner violence (IPV) is abuse or aggression that occurs in a romantic relationship. "Intimate partner" refers to both current and former spouses and dating partners. **IPV is common.** It affects millions of people in the United States each year and often starts early and continues throughout life. When IPV occurs in adolescence, it is called teen dating violence (TDV). About 1 in 4 women and nearly 1 in 10 men have experienced contact sexual violence, physical violence, and/or stalking by an intimate partner during their lifetime and reported some form of IPV-related impact. About 11 million women and 5 million men who reported experiencing contact sexual violence, physical violence, or stalking by an intimate partner in their lifetime said that they first experienced these forms of violence before the age of 18. Youth from groups that have been marginalized, such as sexual and gender minority youth, are at greater risk of experiencing sexual and physical dating violence.

IPV can vary in how often it happens and how severe it is and might include:

- **Physical violence** is when a person hurts or tries to hurt a partner by hitting, kicking, or using another type of physical force.
- **Sexual violence** is forcing or attempting to force a partner to take part in a sex act, sexual touching, or a non-physical sexual event (e.g., sexting) when the partner does not or cannot consent.
- **Stalking** is a pattern of repeated, unwanted attention and contact by a partner that causes fear or concern for one's own safety or the safety of someone close to the victim.
- **Psychological aggression** is the use of verbal and non-verbal communication with the intent to harm another partner mentally or emotionally and/or to exert control over another partner.

IPV Prevention includes:

Teach safe and healthy relationship skills

- Social-emotional learning programs for youth
- Healthy relationship programs for couples

Engage influential adults and peers

- Men and boys as allies in prevention
- Bystander empowerment and education
- Family-based programs

Disrupt the developmental pathways toward partner violence

- Early childhood home visitation
- Preschool enrichment with family engagement
- Parenting skill and family relationship programs
- Treatment for at-risk children, youth and families

Create protective environments

- Improve school climate and safety
- Improve organizational policies and workplace climate
- Modify the physical and social environments of neighborhoods

Strengthen economic supports for families

- Strengthen household financial security
- Strengthen work-family supports

Support survivors to increase safety and lessen harms

- Victim-centered services
- Housing programs
- First responder and civil legal protections
- Patient-centered approaches
- Treatment and support for survivors of IPV, including TDV
- Workplace Injuries

Sexual Violence

Sexual violence is sexual activity when consent is not obtained or freely given. It is a serious public health problem in the United States that affects millions of people each year in the United States and profoundly impacts lifelong health, opportunity, and well-being. Researchers know the numbers underestimate this problem because many cases are unreported. Victims may be ashamed, embarrassed, or afraid to tell the police, friends, or family about the violence. Victims may also keep quiet because they have been threatened with further harm if they tell anyone or do not think anyone will help them.

Sexual violence impacts every community and affects people of all genders, sexual orientations, and ages. Anyone can experience or perpetrate sexual violence. The perpetrator of sexual violence is usually someone the victim knows, such as a friend, current or former intimate partner, coworker, neighbor, or family member. Sexual violence can occur in person, online, or through technology, such as posting or sharing sexual pictures of someone without their consent, or non-consensual sexting.

The data shows:

- **Sexual violence is common.** More than 1 in 3 women and 1 in 4 men have experienced sexual violence involving physical contact during their lifetimes. Nearly 1 in 5 women and 1 in 38 men have experienced completed or attempted rape, and 1 in 14 men was made to penetrate someone (completed or attempted) during his lifetime.
- **Sexual violence starts early.** One in 3 female rape victims experienced it for the first time between 11-17 years old and 1 in 8 reported that it occurred before age 10. Nearly 1 in 4 male rape victims experienced it for the first time between 11-17 years old and about 1 in 4 reported that it occurred before age 10.
- **Sexual violence is costly.** Recent estimates put the lifetime cost of rape at $122,461 per victim, including medical costs, lost productivity, criminal justice activities, and other costs.

Sexual Violence Prevention includes:

Promote Social Norms that Protect Against Violence

- Bystander approaches
- Mobilizing men and boys as allies

Teach Skills to Prevent Sexual Violence

- Social-emotional learning
- Teaching healthy, safe dating and intimate relationship skills to adolescents
- Promoting healthy sexuality
- Empowerment-based training

Provide Opportunities to Empower and Support Girls and Women

- Strengthening economic supports for women and families
- Strengthening leadership and opportunities for girls

Create Protective Environments

- Improving safety and monitoring in schools
- Establishing and consistently applying workplace policies
- Addressing community-level risks through environmental approaches

Support Victims/Survivors to Lessen Harms

- Victim-centered services
- Treatment for victims of SV
- Treatment for at-risk children and families to prevent problem behavior including sex offending

Firearm Violence

A firearm injury is a gunshot wound or penetrating injury from a weapon that uses a powder charge to fire a projectile. Weapons that use a power charge include handguns, rifles, and shotguns. Injuries from air- and gas-powered guns, BB guns, and pellet guns are not considered firearm injuries as these types of guns do not use a powder charge to fire a projectile.

Firearm violence is a serious public health problem that impacts the health and safety of Americans. Important gaps remain in our knowledge about the problem and ways to prevent it. Addressing these gaps is an important step toward keeping individuals, families, schools, and communities safe from firearm violence and its consequences.

Firearm injuries are a serious public health problem. In 2020, there were 45,222 firearm-related deaths in the United States, that's about 124 people dying from a firearm-related injury each day. More than half of firearm related deaths were suicides and more than 4 out of every 10 were firearm homicides.

More people suffer nonfatal firearm-related injuries than die. More than seven out of every 10 medically treated firearm injuries are from firearm-related assaults. Nearly 2 out of every 10 are from unintentional firearm injuries. There are few intentionally self-inflicted firearm-related injuries seen in hospital emergency departments. Most people who use a firearm in a suicide attempt, die from their injury.

Firearm injuries affect people in all stages of life. In 2020, firearm-related injuries were among the 5 leading causes of death for people ages 1-44 in the United States.

Some groups have higher rates of firearm injury than others. Men account for 86% of all victims of firearm death and 87% of nonfatal firearm injuries. Rates of firearm violence also vary by age and race/ethnicity. Firearm homicide rates are highest among teens and young adults 15-34 years of age and among Black or African American, American Indian or Alaska Native, and Hispanic or Latino populations. Firearm suicide rates are highest among adults 75 years of age and older and among American Indian or Alaska Native and non-Hispanic white populations.

There are many types of firearm injuries, which can be fatal or nonfatal:

- **Intentionally self-inflicted**
  - Includes firearm suicide or nonfatal self-harm injury from a firearm
- **Unintentional**
  - Includes fatal or nonfatal firearm injuries that happen while someone is cleaning or playing with a firearm or other incidents of an accidental firing without evidence of intentional harm
- **Interpersonal violence**
  - Includes firearm homicide or nonfatal assault injury from a firearm
- **Legal intervention**
  - Includes firearm injuries inflicted by the police or other law enforcement agents acting in the line of duty
    - For example, firearm injuries that occur while arresting or attempting to arrest someone, maintaining order, or ensuring safety
  - The term *legal intervention* is a commonly used external cause of injury classification. It does not indicate the legality of the circumstances surrounding the death.
- **Undetermined intent**
  - Includes firearm injuries where there is not enough information to determine whether the injury was intentionally self-inflicted, unintentional, the result of legal intervention, or from an act of interpersonal violence.

It is important to store all firearms safely when not in use. Putting a firearm out of sight or out of reach is **not safe storage and not enough** to prevent use by children or unauthorized adults.

Drug Overdose

Drug overdoses are now the leading cause of injury deaths in the United States, and most overdoses involve opioids. More than

932,000 people have died since 1999 from a drug overdose. In 2020, 91,799 drug overdose deaths occurred in the United States. The age-adjusted rate of overdose deaths increased by 31% from 2019 (21.6 per 100,000) to 2020 (28.3 per 100,000). Opioids, mainly synthetic opioids (other than methadone), are currently the main driver of drug overdose deaths. 82.3% of opioid-involved overdose deaths involved synthetic opioids. Research shows that people who have had at least one overdose are more likely to have another. In 2020, an **estimated 41.1 million Americans** needed substance use disorder treatment, but **only 2.6 million people** with a substance use disorder in the past year received treatment.

Prevention Startegies include:

- **Increase and maximize** use of prescription drug monitoring programs, which are state-run databases that track prescriptions for controlled substances and can help improve opioid prescribing, inform clinical practice, and protect those at risk.
- **Learn** about the risks of prescription opioids and about the help and resources that are available for someone who may be struggling with opioid use disorder.
- **Treat opioid use disorder** by increasing access to substance use disorder treatment services, including Medication-Assisted Treatment (MAT) and Medications for Opioid Use Disorder (MOUD).
- **Reverse overdose** by expanding access to naloxone, a drug used to reverse overdose, for community members (family members and neighbors) and service providers (i.e., first responders).

Child Abuse and Neglect

Child abuse and neglect are serious public health problems that can have long-term impact on health, opportunity, and wellbeing. At least 1 in 7 children have experienced child abuse or neglect in the past year in the United States. however this is likely an underestimate because many cases are unreported. In 2020, 1,750 children died of abuse and neglect in the United States. Experiencing poverty can place a lot of stress on families, which may increase the risk for child abuse and neglect. Rates of child abuse and neglect are 5 times higher for children in families with low socioeconomic status. In the United States, the total lifetime economic burden associated with child abuse and neglect was about $592 billion in 2018. This economic burden rivals the cost of other high-profile public health problems, such as heart disease and diabetes.

This issue includes all types of abuse and neglect of a child under the age of 18 by a parent, caregiver, or another person in a custodial role (such as a religious leader, a coach, a teacher) that results in harm, the potential for harm, or threat of harm to a child. There are four common types of abuse and neglect:

- **Physical abuse** is the intentional use of physical force that can result in physical injury. Examples include hitting, kicking, shaking, burning, or other shows of force against a child.
- **Sexual abuse** involves pressuring or forcing a child to engage in sexual acts. It includes behaviors such as fondling, penetration, and exposing a child to other sexual activities.
- **Emotional abuse** refers to behaviors that harm a child's self-worth or emotional well-being. Examples include name-calling, shaming, rejecting, withholding love, and threatening.
- **Neglect** is the failure to meet a child's basic physical and emotional needs. These needs include housing, food, clothing, education, access to medical care, and having feelings validated and appropriately responded to.

Risk Factors for Victimization include

Individual Risk Factors

- Children younger than 4 years of age
- Children with special needs that may increase caregiver burden (e.g., disabilities, mental health issues, and chronic physical illnesses)

Risk Factors for Perpetration

- Caregivers with drug or alcohol issues
- Caregivers with mental health issues, including depression
- Caregivers who don't understand children's needs or development
- Caregivers who were abused or neglected as children
- Caregivers who are young or single parents or parents with many children
- Caregivers with low education or income

- Caregivers experiencing high levels of parenting stress or economic stress
- Caregivers who use spanking and other forms of corporal punishment for discipline
- Caregivers in the home who are not a biological parent
- Caregivers with attitudes accepting of or justifying violence or aggression

Family Risk Factors

- Families that have household members in jail or prison
- Families that are isolated from and not connected to other people (extended family, friends, neighbors)
- Families experiencing other types of violence, including relationship violence
- Families with high conflict and negative communication styles

Community Risk Factors

- Communities with high rates of violence and crime
- Communities with high rates of poverty and limited educational and economic opportunities
- Communities with high unemployment rates
- Communities with easy access to drugs and alcohol
- Communities where neighbors don't know or look out for each other and there is low community involvement among res
- dents
- Communities with few community activities for young people
- Communities with unstable housing and where residents move frequently
- Communities where families frequently experience food insecurity

Prevention Strategies include:

Strengthen economic supports to families

- Strengthening household financial security
- Family-friendly work policies

Change social norms to support parents and positive parenting

- Public engagement and education campaigns
- Legislative approaches to reduce corporal punishment

Provide quality care and education early in life

- Preschool enrichment with family engagement
- Improved quality of child care through licensing and accreditation

Enhance parenting skills to promote healthy child development

- Early childhood home visitation
- Parenting skill and family relationship approaches

Intervene to lessen harms and prevent future risk

- Enhanced primary care
- Behavioral parent training programs
- Treatment to lessen harms of abuse and neglect exposure
- Treatment to prevent problem behavior and later involvement in violence

Suicide

Suicide is death caused by injuring oneself with the intent to die. A suicide attempt is when someone harms themselves with any intent to end their life, but they do not die as a result of their actions.

Suicide rates increased 30% between 2000–2018, and declined in 2019 and 2020. Even with the decline in 2020, Suicide was

still a leading cause of death in the United States, with nearly 46,000 deaths in 2020. This is about one death every 11 minutes. In 2020, suicide was among the top 9 leading causes of death for people ages 10-64 and was the second leading cause of death for people ages 10-14 and 25-34. The number of people who think about or attempt suicide is even higher. In 2020, an estimated 12.2 million American adults seriously thought about suicide, 3.2 million planned a suicide attempt, and 1.2 million attempted suicide.

Americans with higher than average rates of suicide are veterans, people who live in rural areas, and workers in certain industries and occupations like mining and construction. Young people who identify as lesbian, gay, or bisexual have higher rates of suicidal thoughts and behavior compared to their peers who identify as heterosexual. People who have experienced violence, including child abuse, bullying, or sexual violence have a higher suicide risk.

Suicide and suicide attempts cause serious emotional, physical, and economic impacts. People who attempt suicide and survive may experience serious injuries that can have long-term effects on their health. They may also experience depression and other mental health concerns. The good news is that more than 90% of people who attempt suicide and survive never go on to die by suicide.

Suicide and suicide attempts affect the health and well-being of friends, loved ones, co-workers, and the community. When people die by suicide, their surviving family and friends may experience shock, anger, guilt, symptoms of depression or anxiety, and may even experience thoughts of suicide themselves.

Being connected to family and community support and having easy access to health care can decrease suicidal thoughts and behaviors.

Suicide Prevention strategies include:

- Strengthen economic supports
  - Strengthen household financial security
  - Housing stabilization policies
- Strengthen access and delivery of suicide care
  - Coverage of mental health conditions in health insurance policies
  - Reduce provider shortages in underserved areas
  - Safer suicide care through systems change
- Create protective environments
  - Reduce access to lethal means among persons at risk of suicide
  - Organizational policies and culture
  - Community-based policies to reduce excessive alcohol use
- Promote connectedness
  - Peer norm programs
  - Community engagement activities
- Teach coping and problem-solving skills
  - Social-emotional learning programs
  - Parenting skill and family relationship programs
- Identify and support people at risk
  - Gatekeeper training
  - Crisis intervention
  - Treatment for people at risk of suicide
  - Treatment to prevent re-attempts
- Lessen harms and prevent future risk
  - Postvention
  - Safe reporting and messaging about suicide

- 11: Module 8- Cellular Respiration has no license indicated.

18.1.4: End-of-Chapter Material

Key takeaways for this Chapter

- Unintentional injuries have routinely been ranked 3rd-4th for overall causes death.
- For people ages 5-29, three of the top five causes of death are injury-related
- Common unintentional injuries result from falls, drowning, motor vehicle crashes, fires, and poisoning.
- Common intentional injuries results from community violence, intimate partner violence, sexual violence, firearm violence, drug overdoses, child abuse/neglect, and suicide.
- Understanding how injuries occur can help you to make safer choices for yourself and help others who may need assistance.

18.1.5: Preventing Violence and Injury- Optional Continued Learning

The videos below provide an opportunity to expand on your learning from the chapter. As you watch the video, make a list of what you notice and what you wonder. This is a great strategy to listen purposefully, engage with the content, and look for deeper opportunities for self growth, self-reflection, and learning.

What do you **notice**?

- How does this topic support, expand, or challenge the content in the chapter?
- How does this topic connect to health topics from other chapters?
- How does this topic connect with your prior learning, your experiences, your work, your family, or your life in general?
- How does this topic help you to more fully understand health and wellness?

What do you **wonder**?

- How has this topic sparked your curiosity?
- What would you like to know more about?
- What questions did you have as you reviewed the topic?
- What other popular and scholarly sources support or refute this topic?

Videos for continued learning and application

Note: These videos are intended to more fully reflect on health. You might agree or disagree with the videos and that is ok! Utilize these videos to critically think through the topics and identify other sources, both scholarly and popular, to convey your learning.

18.2: OCCUPATIONAL HEALTH CONCERNS

Occupational health "is an area of work in public health to promote and maintain highest degree of physical, mental and social well-being of workers in all occupations." (WHO. 2025). Occupational health workers aim to prevent physical and psychological illness on the job, as well as to prevent injuries. As you can see, this is quite a broad topic, and more than we can cover on one page. Here we will look at some connections between occupational health and environmental health. Later, in the chapter on injury prevention, we will take a closer look preventing injuries on the job.

Biological, chemical, and physical hazards on a job site can contribute to worker illness. Perhaps the most iconic example is black lung disease -- a disease common among coal miners who inhale coal dust and other minerals, greatly affecting their respiratory health and often shortening their lives.

The same principles of risk assessment for environmental health apply to risk assessment for occupational health -- it's just more focused on the workplace. Public health workers focused on occupational health would scan for dangers in the indoor air in the workplace, in the water (if relevant), and in exposures to hazardous waste or other dangerous substances.

The next two pages highlight some key occupational health policy to protect worker health -- improvements that were often won through the collective power of unions, as well as through public health action -- and a brief overview of common occupational illnesses and injuries.

18.2.1: Occupational Health Policy

18.2.2: Workplace Injuries and Illnesses

This page titled 18.2: Occupational Health Concerns is shared under a CC BY-NC 4.0 license and was authored, remixed, and/or curated by Manomita Patra and Yeny Pena-Grafton.

18.2.1: Occupational Health Policy

Occupational health hazards have been recognized since antiquity, but it wasn't until the industrial revolution that there was widespread awareness of the need to regulate workplaces. Initially these efforts were based on sanitation, cleanliness, and reducing worker injuries - which were common in many factories (Seabert et al., 2021). After decades of industrial tragedies including deaths nearly every other day in steel mills, a plethora of coal mine accidents, the Triangle Shirtwaist factory fire, the Hawk's Nest Tunnel disaster, and others, worker's unions and environmentalists worked together to lobby congress for worker's protections in the 1960's (Frumkin, 2016). The Occupational Safety and Health Act (OSH Act) has only been around for just over 50 years, as it was signed into law by President Richard Nixon in 1970. It began by setting standards for worker exposure to specific environmental hazards, such as asbestos, lead, and cotton dust. Since then more standards have been established to protect workers from injuries, bloodborne pathogens, and other environmental toxins (OSHA, n.d. -b). The OSH Act also established the Occupational Safety and Health Administration (OSHA) to set and enforce these standards, and the National Institute for Occupational Safety and Health (NIOSH) to conduct research and make recommendations for these health standards (Seabert et al., 2021). Because of these laws and oversight agencies, it is widely accepted that employers are responsible for providing "safe workplaces, free of recognized serious hazards" (Frumkin, 2016).

Figure 18.2.1.1: Hydraulic fracking operation at night. (CDC/ Theresa Roebuck, 2016)

"This 2016 image depicted the process of hydraulic fracturing, or fracking, a 24/7 activity, and showed how the need for occupational health and safety never stops. NIOSH researchers from the Western States Division, and the Division of Applied Research and Technology, were the first to systematically document hazardous exposures to workers at fracking sites, including exposures to respirable crystalline silica (RCS), diesel particulate matter, and volatile organic compounds. This sand mover operator was monitoring the sand level in the blender tub, framed in the bottom left handrail. His half-face cartridge respirator may not have been providing a high enough assigned protection factor to protect him from the elevated concentration of RCS, to which he was exposed. This photograph was taken in Encinal, Texas, during a test of a NIOSH-developed engineering control, known as the NIOSH mini-baghouse retrofit assembly, installed to reduce RCS emissions."

Prior to the industrial revolution, common law principles held the worker at fault for any injuries they received while on the job, and some employers went so far as to require "death contracts" as an acknowledgement of the employee of the potential dangers - and perhaps deadliness - of their work. In the late 19th century, Prussia was the first country to create worker's liability and insurance laws in an effort to maintain the loyalty of the working class while squashing Marxist and socialist political movements. Other European countries and the U.S. followed suit, although it took until 1948 for the last state to enact worker's compensation laws. While these laws did provide for monetary compensation in the form of employer-funded insurance policies, they also protected the companies from the threat of lawsuits (Guyton, 1999). Currently, each state in the U.S. has its own worker's compensation system, rules, and regulations, which may cover or exclude certain injuries or illnesses (Frumkin, 2016). Notably, in many states, agricultural employers are exempt from the requirements to provide workers' compensation, even though agricultural work is some of the most dangerous. Fourteen states (including California) do require workers' compensation for agricultural

businesses, and enforce penalties for non-compliance (Mikolajczyk, 2022).

18.2.2: Workplace Injuries and Illnesses

Workplace injuries include both relatively minor injuries like cuts or bruises, and major injuries like amputations, fractures, loss of an eye, or severe burns and acute poisoning. Non-fatal injuries are most commonly slips, trips, and falls, or contact with equipment (CDC/NIOSH, 2022). Motor vehicle accidents are the most common source of fatal workplace injuries, but deaths from violence and unintentional overdoses have also increased over the last several years (BLS, 2023). In 2022, workplace injuries and deaths in the U.S. had a price tag of 167 billion dollars; including the lost productivity, medical expenses, and administrative costs. Compared to the number of people in the workforce, that's just over $1000 per worker. There were also 108 million days of work lost to injuries that happened in 2022 or in years prior (National Safety Council, 2024a).

Workplace illnesses are often more difficult to connect to workplace exposures since symptoms can often take many years to develop. These include skin diseases, loss of hearing from industry noise, or cancers developed from exposure to environmental toxins used in industrial processes. Workplace-related respiratory conditions include (among others) silicosis - which is developed from inhaling silica dust commonly from grinding or sanding rocks or cement, coal worker's pneumoconiosis - aka black lung disease, and asbestosis - caused by inhaling asbestos fibers (Seabert et al., 2021). Those working outdoors such as farmers, construction workers, and firefighters are also at higher risk for heat-related illness such as heat stroke and heat exhaustion - particularly in the summer months (Riley et al., 2018).

In 2022, the BLS reported 5,486 fatal work injuries, an increase of 5.7% from 2021. The BLS also reported 2.8 million nonfatal work-related injuries and illnesses in private industry, up 7.5% from 2021. Including government jobs as well, the rate of nonfatal injury and illness was 3% of all workers for 2022 (BLS, 2023a). The highest rates of nonfatal work-related injuries and illnesses were found in transportation and warehousing, as well as agriculture, forestry, fishing and hunting. The highest total numbers of nonfatal injuries and illnesses were recorded for the healthcare and social assistance sector however, likely due to the high number of workers employed in those occupations. See Fig. 18.2.2.1 below.

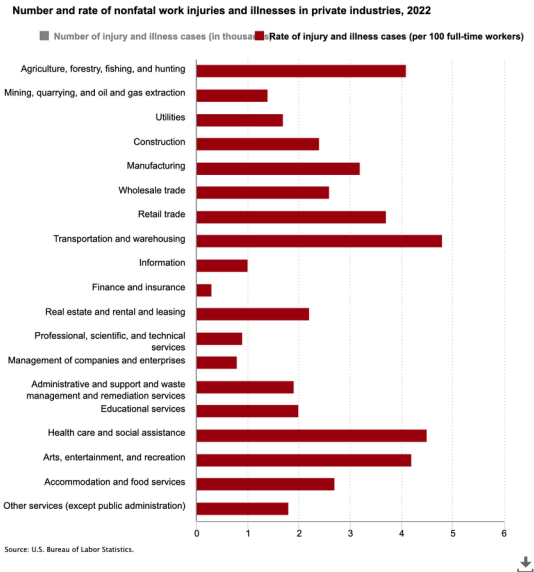

Figure 18.2.2.1: Rate of nonfatal injuries and illnesses (per 100 full-time workers), by private industries, 2022.(CC0, U.S. Bureau of Labor Statistics.)

According to the BLS, the fatal injury rate in 2022 was 3.7 per 100,000 full-time equivalent (FTE) workers. However, this rate was higher for African American or Black workers (4.2 per 100,000 FTE workers) and Hispanic or Latino workers (4.6 per 100,000 FTE workers). Those between the ages of 55-64 have the highest number of fatalities (BLS, 2023b). These demographic differences may indicate disparities in exposures to hazards, or perhaps a lack of protections in certain sectors of industry.

19: MAKING SMART HEALTH CHOICES

Learning Objectives

By the end of this chapter you will be able to:

- Deduce whether health information is valid and reliable.
- Utilize tools to critically analyze health websites.
- Compare complementary and western medicine.
- Explain common challenges associated with Aging.

What will you do to make sure you are not tricked by health fraud?

Have you considered being an organ donor?

How will you plan for retirement?

What will you do to stay healthy as you age?

Every year we get one year older chronologically, does this mean we also get one year older biologically? Our biological age is the age of our body and this is not dependent on our chronological age. You can be a 30 year old who is very healthy and has a biological age closer to 20 year old, or you can be a 30 year old who lives an unhealthy lifestyle and has a biological age closer to 40. Our biological age is highly influenced by the lifestyle choices we make.

In 1900, people lived on average just 47.3 years and by the year 2000, Americans lived an average of 76.8 years. Life expectancy nearly doubled in just 100 years. The leading causes of death in 1900 were highly related to infectious disease. Through numerous public health measures life expectancy has drastically increased and the leading causes of death have transitioned to be more related to a persons lifestyle choices.

The good news is that Americans are living longer lives, but the bad news is that the increase in our older population brings an increase in chronic diseases, such as hypertension, diabetes, arthritis, and dementia. It is estimated that 80% of older adults have a chronic health condition. With so many older adults having chronic health conditions we know there will continue to be an increased need for caregivers. This creates a potential problem because although our older population is growing, or birth rates are declining which may reduce the amount of people to serve as caretakers.

19.1: Health Literacy

Chapter one of this book provided a brief introduction to health literacy, this chapter expands on the importance of critically consuming health information throughout your life and as you age. The CDC defines personal health literacy as the degree to which individuals have the ability to find, understand, and use information and services to inform health-related decisions and actions for themselves and others.

Finding reliable health information

Millions of consumers get health information from magazines, TV or the Internet. Some of the information is reliable and up to date; some is not. How can you tell the good from the bad to make sure you are making your own health decisions based on the best information?

First, recognize that content on the Internet is unregulated; anyone can publish anything on the Internet. There is sound medical information on the Internet along with dangerous information. You need to be able to tell the difference.

Ask yourself the following:

- Why did the person create the page?
- What's in it for them?
- Are they trying to sell me something?

The following tips can help you to find current, unbiased information based on research[1].

- Consider the source–Use recognized authorities
  - Know who is responsible for the content.
  - Look for an "about us" page. Check to see who runs the site: is it a branch of the Federal Government, a non-profit institution, a professional organization, a health system, a commercial organization or an individual.
  - There is a big difference between a site that says, "I developed this site after my heart attack" and one that says, "This page on heart attack was developed by health professionals at the American Heart Association."
  - Web sites should have a way to contact the organization or webmaster. If the site provides no contact information, or if you can't easily find out who runs the site, use caution.
- Focus on quality–All Web sites are not created equal
  - Does the site have an editorial board? Is the information reviewed before it is posted?
  - This information is often on the "about us" page, or it may be under the organization's mission statement, or part of the annual report.
  - See if the board members are experts in the subject of the site. For example, a site on osteoporosis whose medical advisory board is composed of attorneys and accountants is not medically authoritative.
  - Look for a description of the process of selecting or approving information on the site. It is usually in the "about us" section and may be called "editorial policy" or "selection policy" or "review policy."
  - Sometimes the site will have information "about our writers" or "about our authors" instead of an editorial policy. Review this section to find out who has written the information.
- Be a cyber skeptic–Quackery abounds on the Web
  - Does the site make health claims that seem too good to be true? Does the information use deliberately obscure, "scientific" sounding language? Does it promise quick, dramatic, miraculous results? Is this the only site making these claims?
  - Beware of claims that one remedy will cure a variety of illnesses, that it is a "breakthrough," or that it relies on a "secret ingredient."
  - Use caution if the site uses a sensational writing style (lots of exclamation points, for example.)
  - A health Website for consumers should use simple language, not technical jargon.
  - Get a second opinion! Check more than one site.
- Look for the evidence–Rely on medical research, not opinion
  - Does the site identify the author? Does it rely on testimonials?
  - Look for the author of the information, either an individual or an organization. Good examples are "Written by Jane Smith, R.N.," or "Copyright 2013, American Cancer Society."

    - If there are case histories or testimonials on the Web site, look for contact information such as an email address or telephone number. If the testimonials are anonymous or hard to track down ("Jane from California"), use caution.
- Check for currency–Look for the latest information
    - Is the information current?
    - Look for dates on documents. A document on coping with the loss of a loved one doesn't need to be current, but a document on the latest treatment of AIDS needs to be current.
    - Click on a few links on the site. If there are a lot of broken links, the site may not be kept up-to-date.
- Beware of bias–What is the purpose? Who is providing the funding?
    - Who pays for the site?
    - Check to see if the site is supported by public funds, donations or by commercial advertising.
- Advertisements should be labeled. They should say "Advertisement" or "From our Sponsor."
    - Look at a page on the site, and see if it is clear when content is coming from a non-commercial source and when an advertiser provides it. For example, if a page about treatment of depression recommends one drug by name, see if you can tell if the company that manufactures the drug provides that information. If it does, you should consult other sources to see what they say about the same drug.
- Protect your privacy–Health information should be confidential
    - Does the site have a privacy policy and tell you what information they collect?
    - There should be a link saying "Privacy" or "Privacy Policy." Read the privacy policy to see if your privacy is really being protected. For example, if the site says "We share information with companies that can provide you with useful products," then your information isn't private.
    - If there is a registration form, notice what types of questions you must answer before you can view content. If you must provide personal information (such as name, address, date of birth, gender, mother's maiden name, credit card number) you should refer to their privacy policy to see what they can do with your information.
- Consult with your health professional–Patient/provider partnerships lead to the best medical decisions.

Health Fraud

When you see statements like "miracle cure," "revolutionary scientific breakthrough," or "alternative to drugs or surgery," what you should be thinking is, "bogus product," "Danger," or "Health fraud alert!"

Health fraud scams have been around for hundreds of years[2]. The snake oil salesmen of old have morphed into the deceptive, high-tech marketers of today. They prey on people's desires for easy solutions to difficult health problems, from losing weight to curing serious diseases like cancer. According to the Food and Drug Administration (FDA), a health product is fraudulent if it is deceptively promoted as being effective against a disease or health condition but has not been scientifically proven safe and effective for that purpose. Health fraud scams can do more than waste your money, they can cause serious injury or even death.

Scammers promote their products through newspapers, magazines, TV infomercials and cyberspace. You can find health fraud scams in retail stores and on countless websites, in popup ads and spam, and on social media sites like Facebook and Twitter. It is important to understand the signs of fraudulent health product.

The FDA provides the following list of 6 Tip-offs to Rip-offs:

1. One product does it all. Be suspicious of products that claim to cure a wide range of diseases. The agency continues to send warning letters and take enforcement action as appropriate against companies marketing fake cure-all products. These miracle cures don't exist – they're bogus – and the only thing these companies are selling is false hope.
2. Personal "success" testimonials. Success stories, such as, "It cured my diabetes" or "It immediately stopped my COVID-19 infection," are easy to make up and are not a substitute for scientific evidence. Reviews found on popular online marketplaces and social media can be fake.
3. Quick fixes. Few diseases or conditions can be treated quickly, even with legitimate products. Beware of language such as, "Lose 30 pounds in 30 days," "protects from viral infections," or "eliminates skin cancer in days."
4. "All natural" cure or treatment. Don't be fooled by descriptions like "all-natural cure." Such phrases are often used in health fraud as an attention-grabber to suggest that a product is safer than conventional treatments. These terms don't necessarily equate to safety. Some plants found in nature (such as poisonous mushrooms) can be harmful or even kill when consumed. Moreover, the FDA has found numerous products promoted as "all-natural" cures or treatments that contain hidden and dangerously high doses of prescription drug ingredients or other active pharmaceutical ingredients.
5. "Miracle cure." Alarms should go off when you see this claim or others like it such as, "new discovery," "guaranteed results," or "secret ingredient." If a real cure for a serious disease were FDA-approved, it would be widely reported through the media and prescribed by licensed health professionals—not plastered on advertisements in social media and messaging

apps, or buried in websites, print ads, and TV infomercials.
6. Conspiracy theories. Claims like “This is the cure our government or Big Pharma doesn’t want you to know about” are used to distract consumers from the obvious, common-sense questions about the so-called miracle cure.

19.2: Healthcare

Health Insurance in the U.S.

No one plans to get sick or hurt, but most people need medical care at some point. Health insurance covers essential health benefits critical to maintaining your health and treating illness and accidents, for example getting free preventive care, like vaccines, screenings, and some check-ups, even before you meet your deductible. Health insurance protects you from unexpected, high medical costs by paying less for covered in-network health care, even before you meet your deductible. People without health coverage are exposed to these costs, which can sometimes lead into extreme debt or even into bankruptcy.

The U.S. does not have universal health coverage, meaning the government does not provide health insurance for every person, rather the U.S. health system is a mix of public and private, for-profit and nonprofit insurers and health care providers[5]. The federal government provides Medicare, medicaid and the Children's Health Insurance Program (CHIP). Private insurance is provided primarily by employers and people can also purchase their own health insurance coverage. Although there are options for health insurance, there are still about 8.5% of Americans who are un-insured, which is a reduction from 16% in 2010 before the passing of the Patient Protection and Affordable Care Act.

Medicare is health insurance for:

- People 65 or older (eligible to sign up for Medicare 3 months before turning 65)
- Those with a disability, End-Stage Renal Disease (ESRD), or ALS (also called Lou Gehrig's disease) may be able to sign up before 65.

Medicaid is a joint federal and state program that:

- Helps with medical costs for some people with limited income and resources.
- Offers benefits not normally covered by Medicare, like nursing home care and personal care services.

The Children's Health Insurance Program (CHIP) is a joint federal and state program that:

- provides health coverage to eligible children, through both Medicaid and separate CHIP programs.

Managed Care Plans

- Managed care plans are a type of health insurance. They have contracts with health care providers and medical facilities to provide care for members at reduced costs. These providers make up the plan's network. How much of your care the plan will pay for depends on the network's rules.
    - With an Health Maintenance Organizations (HMO) you choose a primary care doctor who coordinates most of your care. HMO's usually only pay for care within their specified network of doctors/providers. HMO plans typically have lower monthly premiums. You can also expect to pay less out of pocket.
    - With a Preferred Provider Organizations (PPO) you tend to have higher monthly premiums in exchange for the flexibility to use providers both in and out of network without a referral. Out-of-pocket medical costs can also run higher with a PPO plan.
    - Point of Service (POS) plans let you choose between an HMO or a PPO each time you need care.

If you're unemployed, or your employer does not provide health insurance, you may be able to get an affordable health insurance plan through the Health Insurance Marketplace. The Health Insurance Marketplace was developed in response to the Patient Protection and Affordable Care Act passed in 2010. Its primary goal is to achieve universal health insurance coverage by facilitating cooperation among employers, citizens, and the government. Its other objectives are to make healthcare more affordable while simultaneously increasing healthcare quality and reducing unnecessary spending[6].

The Affordable Care Act (ACA) created a dramatically different marketplace for individual health insurance through three key reforms: prohibiting insurers from considering subscribers' health status or risk; providing substantial subsidies for millions of people to purchase individual coverage, many for the first time in their lives; and creating an "exchange" structure that facilitates comparison shopping. Due to the ACA the uninsured rate has dropped from 16 percent in 2010 to 8.5%.

Universal Healthcare

The World Health Organization states that:

- Half of the world's population do not have access to the health care they need.
- 100 million people are driven into poverty each year through out-of-pocket health spending.
- 75% of national health policies strategies and plans are aimed at moving towards universal health coverage.
- Over 930 million people spend at least 10% of their household income on health care.

In an effort to bring healthcare to all people across the world, The World Health Organization (WHO) is encouraging all countries of the world to adopt Universal Health Coverage (UHC). The WHO is providing support and technical expertise to advance universal health coverage in 115 countries, representing a population of at least 3 billion people. The goal is to bridge global commitments with country action to achieve universal health coverage.

The WHO defines universal healthcare as "ensuring that all people have access to needed health services (including prevention, promotion, treatment, rehabilitation and palliation) of sufficient quality to be effective while also ensuring that the use of these services does not expose the user the financial hardship. It includes the full range of essential health services, from health promotion to prevention, treatment, rehabilitation, and palliative care."

Many countries offer universal healthcare, these include:

- Australia (Healthcare System in Australia)
- Canada (Canadian Health Care System)
- France (French Healthcare System)
- Germany (German Healthcare System – GKV)
- Ireland (Healthcare System in Ireland)
- Italy (Healthcare System in Italy)
- Japan (Japanese Healthcare System)
- New Zealand (New Zealand's Healthcare System)
- Portugal (Healthcare System in Portugal)
- Spain (Healthcare System in Spain)
- Sweden (Sweden's Healthcare System)
- United Kingdom (Healthcare System in the UK)

19.3: Health Care Choices - The Affordable Health Care Act (ACA)

Health care choices in the United States can be broadly divided into two main categories: public health care (government-funded) and private health care (privately funded). The two main publicly funded health care programs are Medicare, which provides health services to people over 65 years old as well as people who meet other standards for disability, and Medicaid, which provides services to people with very low incomes who meet other eligibility requirements. Other government-funded programs include service agencies focused on Native Americans (the Indian Health Service), Veterans (the Veterans Health Administration), and children (the Children's Health Insurance Program).

Health care in the United States is a complex issue, and it will remain complex with the continued enactment of the Patient Protection and Affordable Care Act (PPACA). This Act, sometimes called "ObamaCare" for its most noted advocate, former President Barack Obama, represents large-scale federal reform of the United States' health care system. It expands eligibility to programs like Medicaid and CHIP, helps guarantee insurance coverage for people with pre-existing conditions, and establishes regulations to make sure that the premium funds collected by insurers and care providers go directly to medical care. It also includes an individual mandate, which requires everyone to have insurance coverage or pay a penalty. A series of provisions, including significant subsidies, are intended to address the discrepancies in income that are currently contributing to high rates of uninsurance and underinsurance.

How much do you know the Affordable Health Care Act?

You need to be fully informed about what the PPACA provides. Here is a list of key changes to the United States health care system as a result of the PPACA:

- Insurers are prohibited from denying coverage to individuals due to pre-existing conditions.
- Premiums must be the same for everyone of a given age, regardless of preexisting conditions.
- Dependents are permitted to remain on their parents' insurance plan until their 26th birthday.
- Individuals are required to buy health insurance or pay a penalty (known as the individual mandate). This applies to everyone not covered by an employer sponsored health plan, Medicaid, Medicare or other public insurance programs (such as Tricare). Also exempt were those facing a financial hardship or who were members in a recognized religious sect exempted by the Internal Revenue Service.
- Essential health benefits must be provided. The National Academy of Medicine defines the law's "essential health benefits" as "ambulatory patient services; emergency services; hospitalization; maternity and newborn care; mental health and substance use disorder services, including behavioral health treatment; prescription drugs; rehabilitative services and devices; laboratory services; preventive and wellness services and chronic disease management; and pediatric services, including oral and vision care" and others rated Level A or B by the U.S. Preventive Services Task Force. In determining what would qualify as an essential benefit, the law required that standard benefits should offer at least that of a "typical employer plan".
- Additional preventive care and screenings for women. This includes Well-woman visits, gestational diabetes screening for pregnant women, domestic and interpersonal violence screening and counseling, FDA-approved contraception methods, and contraceptive education and counseling, breastfeeding support, supplies, and counseling, HPV DNA testing, for women 30 or older, sexually transmitted infections counseling, and HIV screening and counseling for sexually active women. This mandate applies to all employers and educational institutions except for religious organizations. These regulations were included on the recommendations of the Institute of Medicine.
- Annual and lifetime coverage caps on essential benefits were banned.
- Prohibits insurers from dropping policyholders when they get sick.
- All health policies sold in the United States must provide an annual maximum out of pocket (MOOP) payment cap for an individual's or family's medical expenses (excluding premiums). After the MOOP payment cap is reached, the insurer must pay all remaining costs.
- Preventive care, vaccinations and medical screenings cannot be subject to co-payments, co-insurance or deductibles. Specific examples of covered services include: mammograms and colonoscopies, wellness visits, gestational diabetes screening, HPV testing, STI counseling, HIV screening and counseling, contraceptive methods, breastfeeding support/ supplies and domestic violence screening and counseling.
- The law established four tiers of coverage: bronze, silver, gold and platinum. All categories offer the essential health benefits.

The categories vary in their division of premiums and out-of-pocket costs: bronze plans have the lowest monthly premiums and highest out-of-pocket costs, while platinum plans are the reverse. The percentages of health care costs that plans are expected to cover through premiums (as opposed to out-of-pocket costs) are, on average: 60% (bronze), 70% (silver), 80% (gold), and 90% (platinum).

- Insurers are required to implement an appeals process for coverage determination and claims on all new plans.
- Employer mandate. Businesses that employ 50 or more people but do not offer health insurance to their full-time employees pay a tax penalty if the government has subsidized a full-time employee's healthcare through tax deductions or other means. This is commonly known as the employer mandate. This provision was included to encourage employers to continue providing insurance once the exchanges began operating. Approximately 44% of the population was covered directly or indirectly through an employer.
- Insurers must spend at least 80–85% of premium dollars on health costs; rebates must be issued to policyholders if this is violated.

Many Americans worry that governmental oversight of health care represents a federal overstepping of constitutional guarantees of individual freedom. Others welcome a program that they believe will make health care accessible and affordable to everyone.

Watch this tour of the HealthCare.gov website to find out more.

Covered California

In California, the health care marketplace is called Covered California. This is where Californians can shop and compare health insurance plans under the Patient Protection and Affordable Care Act. The Department of Health Care Services sponsors Covered California to help health insurance shoppers get the coverage and care that is right for them. Visit CoveredCA.com for more information.

This page titled 19.3: Health Care Choices - The Affordable Health Care Act (ACA) is shared under a CC BY-NC 4.0 license and was authored, remixed, and/or curated by Manomita Patra and Yeny Pena-Grafton.

- 11.7A: Antibody Proteins and Antigen Binding is licensed CC BY-SA 4.0.

19.4: Health Insurance - Key Terms

Part of health literacy is understanding key health insurance terms. This will allow for educated decisions when choosing a health insurance plan. Below are some basic key terms that are helpful to understand when researching health insurance plans:

In-Network Providers: health care providers who are contracted with your health insurance plan to provide services at a contracted or discounted rate.

Out-of-Network Providers: health care providers who are not contracted with your health insurance plan. Out-of-network coinsurance usually costs you more than in-network coinsurance because there is no contracted or discounted rate.

Exclusive Provider Organization (EPO): A managed care plan where services are covered only if you use doctors, specialists, or hospitals in the plan's network (except in an emergency).

Health Maintenance Organization (HMO): A type of health insurance plan that usually limits coverage to care from doctors who work for or contract with the HMO. It generally won't cover out-of-network care except in an emergency. An HMO may require you to live or work in its service area to be eligible for coverage. HMOs often provide integrated care and focus on prevention and wellness.

Point of Service (POS): A type of plan where you pay less if you use doctors, hospitals, and other health care providers that belong to the plan's network. POS plans require you to get a referral from your primary care doctor in order to see a specialist.

Preferred Provider Organization (PPO): A type of health plan where you pay less if you use providers in the plan's network. You can use doctors, hospitals, and providers outside of the network without a referral for an additional cost.

Premium: The amount paid for your health insurance every month. In addition to your premium, you usually have to pay other costs for your health care, including a deductible, copayments, and coinsurance.

Deductible: The amount you pay for covered health care services before your insurance plan starts to pay. With a $2,000 deductible, for example, you pay the first $2,000 of covered services yourself.

Many health insurance plans cover certain services such as check-ups, disease management, and preventive services before the deductible has been met. Family plans often have both an individual deductible, which applies to each person, and a family deductible, which applies to all family members.

Generally, plans with lower monthly premiums have higher deductibles. Plans with high monthly premiums usually have lower deductibles. Those who use their health insurance often would probably be wise to choose a plan with a slightly higher premium but a lower deductible, which may save money in the long-term.

After paying the deductible, you will usually pay only a copayment or coinsurance for covered services. Your insurance company pays the rest.

Copayment: A fixed amount ($20, for example) you pay for a covered health care service after you've paid your deductible. Let's say your health insurance plan's allowable cost for a doctor's office visit is $100. Your copayment for a doctor visit is $20. If you've paid your deductible: You pay $20, usually at the time of the visit. If you haven't met your deductible: You pay $100, the full allowable amount for the visit.

Copayments (sometimes called "copays") can vary for different services within the same plan, like drugs, lab tests, and visits to specialists.

Coinsurance: The percentage of costs of a covered health care service you pay (20%, for example) after you've paid your deductible. Let's say your health insurance plan's allowed amount for an office visit is $100 and your coinsurance is 20%. If you've paid your deductible: You pay 20% of $100, or $20. The insurance company pays the rest. If you haven't met your deductible: You pay the full allowed amount, $100.

Out-of-pocket maximum: The most you have to pay for covered services in a plan year. After you spend this amount on deductibles, copayments, and coinsurance, your health plan pays 100% of the costs of covered benefits.

Although this is not an all-encompassing list of key terms for health insurance, these are some of the terms you are likely to encounter when shopping for health insurance.

More in-depth information can be found at Healthcare.gov/glossary.

This page titled 19.4: Health Insurance - Key Terms is shared under a CC BY-NC 4.0 license and was authored, remixed, and/or curated by Manomita Patra and Yeny Pena-Grafton.

- 11.7B: Antibody Genes and Diversity is licensed CC BY-SA 4.0.

19.5: Choices in Medical Care

Choosing the right medical professional can be difficult and will vary depending on your day-to-day health status. Below is a brief list of medical professionals you can visit for a variety of health issues:

Primary Care Practitioner (PCP) is a medical professional whom you can go to for routine ailments, preventive care, general medical advice, and appropriate referrals. The primary care provider for most people is a medically trained family practitioner, an internist, or a pediatrician.

Conventional or Allopathic medicine, or traditional Western medical practice, is based on scientifically validated methods and procedures and involves the application of the scientific method; cause and effect.

Complementary medicine and alternative medicine; unconventional practices used alongside or instead of conventional medicine. Examples include chiropractic's, massage therapy, acupuncture, acupressure, and herbal remedies.

Other PCP include

Osteopath: general practitioner who receives medical training similar to MD , but is more involved in musculoskeletal focus than internal focus.

Nurse practitioners are professional nurses with advanced training obtained through either a master's degree program or specialized nurse practitioner program. They have the authority and training to conduct diagnostic tests and prescribe medications (in some states). Nurses may also earn the clinical doctor of nursing degree (ND), a doctorate of nursing science (DNS or DNSc), or a research-based doctorate (PhD) in nursing.

Physician assistants must work under the supervision of a physician and are legally permitted to prescribe drugs in all states.

Other practitioners:

Nurses are highly trained and strictly regulated practitioners who provide a wide range of services including patient education, counseling, community health and disease prevention information, and administration of medications.

Licensed registered nurses (RN) have completed either a 4-year program leading to a Bachelor of Science degree (BSN) or a 2-year associate degree program.

Licensed practical or vocational nurses (LPN or LVN) have completed a one- to two-year training program.

Ophthalmologist holds a medical degree and can perform surgery. An optometrist evaluates visual problems but is not a trained physician.

Podiatrist: specialize in care of the foot; extensive training similar to MD; can prescribe and perform surgery.

Dentists are specialists who diagnose and treat diseases of the teeth, gums, and oral cavity. Orthodontists are specialists in the alignment of teeth. Oral surgeons perform surgical procedures to correct problems of the mouth, face, and jaw.

Questions are the Answer

Whichever health care professional you choose to visit, your health depends on good communication. Asking questions and providing information to your doctor and other care providers can improve your care. Quality health care is a team effort. You play an important role. One of the best ways to communicate with your doctor and health care team is by asking questions. Because time is limited during medical appointments, you will feel less rushed if you prepare your questions before your appointment.

- Your doctor wants your questions.
- Doctors know a lot about a lot of things, but they don't always know everything about you or what is best for you.

- Your questions give your doctor and health care team important information about you, such as your most important health care concerns.
- That is why they need you to speak up.

Health Facilities

Health facilities are places that provide health care. They include hospitals, clinics, outpatient care centers and specialized care centers, such as birthing centers and psychiatric care centers. When you choose a health facility, you might want to consider

- How close it is
- Whether your health insurance will pay for services there
- Whether your health care provider can treat you there
- The quality of the facility

Quality is important. Some facilities do a better job than others. One way to learn about the quality of a facility is to look at report cards developed by state and consumer groups.

Look for a hospital that:

- Is accredited by the Joint Commission on Accreditation of Healthcare Organizations (JCAHO).
- Is rated highly by the State and by consumer groups or other organizations.
- Has a lot of experience and success in treating your condition.
- Monitors quality of care and works to improve quality.

In choosing a nursing home or other long-term care facility, look for one that:

- Has been found by State agencies and other groups to provide quality care.
- Provides a level of care, including staff and services, that will meet your needs.

Choosing the right medications: Brand Name vs. Generic

You may need to take medicines every day, or only once in a while. Either way, you want to make sure that the medicines are safe and will help you get better. In the United States, the Food and Drug Administration is in charge of assuring the safety and effectiveness of both prescription and over-the-counter medicines.

Even safe drugs can cause unwanted side effects or interactions with food or other medicines you may be taking. They may not be safe during pregnancy. To reduce the risk of reactions and make sure that you get better, it is important for you to take your medicines correctly.

Understanding Generic Drugs

Generic drugs are important options that allow greater access to health care for all Americans. They are copies of brand-name drugs and are the same as those brand name drugs in dosage form, safety, strength, route of administration, quality, performance characteristics and intended use.

Health care professionals and consumers can be assured that FDA approved generic drug products have met the same rigid standards as the innovator drug. All generic drugs approved by FDA have the same high quality, strength, purity and stability as brand-name drugs. And, the generic manufacturing, packaging, and testing sites must pass the same quality standards as those of brand name drugs.

Generic Drugs: Questions and Answers

What are generic drugs?

A generic drug is identical -- or bioequivalent -- to a brand name drug in dosage form, safety, strength, route of administration, quality, performance characteristics and intended use. Although generic drugs are chemically identical to their branded counterparts, they are typically sold at substantial discounts from the branded price. According to the Congressional Budget Office, generic drugs save consumers an estimated $8 to $10 billion a year at retail pharmacies. Even more billions are saved

when hospitals use generics.

Are generic drugs as effective as brand-name drugs?

Yes. A generic drug is the same as a brand-name drug in dosage, safety, strength, quality, the way it works, the way it is taken and the way it should be used.

FDA requires generic drugs have the same high quality, strength, purity and stability as brand-name drugs.

Not every brand-name drug has a generic drug. When new drugs are first made they have drug patents. Most drug patents are protected for 20 years. The patent, which protects the company that made the drug first, doesn't allow anyone else to make and sell the drug. When the patent expires, other drug companies can start selling a generic version of the drug. But, first, they must test the drug and the FDA must approve it.

Creating a drug costs lots of money. Since generic drug makers do not develop a drug from scratch, the costs to bring the drug to market are less; therefore, generic drugs are usually less expensive than brand-name drugs. But, generic drug makers must show that their product performs in the same way as the brand-name drug.

How are generic drugs approved?

Drug companies must submit an abbreviated new drug application (ANDA) for approval to market a generic product. The Drug Price Competition and Patent Term Restoration Act of 1984, more commonly known as the Hatch-Waxman Act, made ANDAs possible by creating a compromise in the drug industry. Generic drug companies gained greater access to the market for prescription drugs, and innovator companies gained restoration of patent life of their products lost during FDA's approval process.

New drugs, like other new products, are developed under patent protection. The patent protects the investment in the drug's development by giving the company the sole right to sell the drug while the patent is in effect. When patents or other periods of exclusivity expire, manufacturers can apply to the FDA to sell generic versions.

The ANDA process does not require the drug sponsor to repeat costly animal and clinical research on ingredients or dosage forms already approved for safety and effectiveness. This applies to drugs first marketed after 1962.

What standards do generic drugs have to meet?

Health professionals and consumers can be assured that FDA approved generic drugs have met the same rigid standards as the innovator drug. To gain FDA approval, a generic drug must:

- contain the same active ingredients as the innovator drug (inactive ingredients may vary)
- be identical in strength, dosage form, and route of administration
- have the same use indications
- be bioequivalent
- meet the same batch requirements for identity, strength, purity, and quality
- be manufactured under the same strict standards of FDA's good manufacturing practice regulations required for innovator products

19.6: Health Disparity

Despite prevention efforts, some groups of people are affected by HIV/AIDS, viral hepatitis, STI's, and TB, more than other groups of people. The occurrence of these diseases at greater levels among certain population groups more than among others is often referred to as a health disparity. Differences may occur by gender, race or ethnicity, education, income, disability, geographic location and sexual orientation among others. Social determinants of health like poverty, unequal access to health care, lack of education, stigma, and racism are linked to health disparities.

Health in the United States is a complex and often contradictory issue. One the one hand, as one of the wealthiest nations, the United States fares well in health comparisons with the rest of the world. However, the United States also lags behind almost every industrialized country in terms of providing care to all its citizens. The following sections look at different aspects of health in America.

Health by Race and Ethnicity

When looking at the social epidemiology of the United States, it is hard to miss the disparities among races. The discrepancy between African Americans and white Americans shows the gap clearly; in 2008, the average life expectancy for white males was approximately five years longer than for African American males: 75.9 compared to 70.9. An even stronger disparity was found in 2007: the infant mortality rate for African Americans was nearly twice that of white Americans at 13.2 compared to 5.6 per 1,000 live births (U.S. Census Bureau 2011). According to a report from the Henry J. Kaiser Foundation (2007), African Americans also have higher incidence of several other diseases and causes of mortality, from cancer to heart disease to diabetes. In a similar vein, it is important to note that ethnic minorities, including Mexican Americans and Native Americans, also have higher rates of these diseases and causes of mortality than whites. Lisa Berkman (2009) notes that this gap started to narrow during the Civil Rights movement in the 1960s, but it began widening again in the early 1980s.

What accounts for these perpetual disparities in health among different ethnic groups?

Much of the answer lies in the level of health care that these groups receive. The National Healthcare Disparities Report (2010) shows that even after adjusting for insurance differences, racial and ethnic minority groups receive poorer quality of care and less access to care than dominant groups. The Report identified these racial inequalities in care: Black Americans, American Indians, and Alaskan Natives received inferior care than Caucasian Americans for about 40 percent of measures Asian ethnicities received inferior care for about 20 percent of measures Among whites, Hispanic whites received 60 percent inferior care of measures compared to non-Hispanic whites (Agency for Health Research and Quality 2010). When considering access to care, the figures were comparable.

Health by Socioeconomic Status

Discussions of health by race and ethnicity often overlap with discussions of health by socioeconomic status, since the two concepts are intertwined in the United States. As the Agency for Health Research and Quality (2010) notes, "racial and ethnic minorities are more likely than non-Hispanic whites to be poor or near poor," so many of the data pertaining to subordinate groups is also likely to be pertinent to low socioeconomic groups. Marilyn Winkleby and her research associates (1992) state that "one of the strongest and most consistent predictors of a person's morbidity and mortality experience is that person's socioeconomic status (SES). This finding persists across all diseases with few exceptions, continues throughout the entire lifespan, and extends across numerous risk factors for disease."It is important to remember that economics are only part of the SES picture; research suggests that education also plays an important role. Phelan and Link (2003) note that many behavior-influenced diseases like lung cancer (from smoking), coronary artery disease (from poor eating and exercise habits), and AIDS initially were widespread across SES groups. However, once information linking habits to disease was disseminated, these diseases decreased in high SES groups and increased in low SES groups. This illustrates the important role of education initiatives regarding a given disease, as well as possible inequalities in how those initiatives effectively reach different SES groups.

Health by Gender

Women are affected adversely both by unequal access to and institutionalized sexism in the health care industry. According a recent report from the Kaiser Family Foundation, women experienced a decline in their ability to see needed specialists between 2001 and 2008. In 2008, one quarter of females questioned the quality of her health care (Ranji and Salganico 2011). In this report, we also see the explanatory value of intersection theory. Feminist sociologist Patricia Hill Collins developed this theory, which suggests we cannot separate the effects of race, class, gender, sexual orientation, and other attributes. Further examination of the lack of confidence in the health care system by women, as identified in the Kaiser study, found, for example, women categorized as low income were more likely (32 percent compared to 23 percent) to express concerns about health care quality, illustrating the multiple layers of disadvantage caused by race and sex.

We can see an example of institutionalized sexism in the way that women are more likely than men to be diagnosed with certain kinds of mental disorders. Psychologist Dana Becker notes that 75 percent of all diagnoses of Borderline Personality Disorder (BPD) are for women according to the Diagnostic Statistical Manual of Mental Disorders. This diagnosis is characterized by instability of identity, of mood, and of behavior, and Becker argues that it has been used as a catch-all diagnosis for too many women. She further decries the pejorative connotation of the diagnosis, saying that it predisposes many people, both within and outside of the profession of psychotherapy, against women who have been so diagnosed (Becker).

Many critics also point to the medicalization of women's issues as an example of institutionalized sexism. Medicalization refers to the process by which previously normal aspects of life are redefined as deviant and needing medical attention to remedy. Historically and contemporaneously, many aspects of women's lives have been medicalized, including menstruation, pre-menstrual syndrome, pregnancy, childbirth, and menopause.

The medicalization of pregnancy and childbirth has been particularly contentious in recent decades, with many women opting against the medical process and choosing a more natural childbirth. Fox and Worts (1999) find that all women experience pain and anxiety during the birth process, but that social support relieves both as effectively as medical support. In other words, medical interventions are no more effective than social ones at helping with the difficulties of pain and childbirth. Fox and Worts further found that women with supportive partners ended up with less medical intervention and fewer cases of postpartum depression. Of course, access to quality birth care outside of the standard medical models may not be readily available to women of all social classes.

Summary

Despite generally good health in the U.S. compared with less-developed countries, America is still facing challenging issues such as a prevalence of obesity and diabetes. Moreover, Americans of historically disadvantaged racial groups, ethnicities, socioeconomic status, and gender experience lower levels of health care. Mental health and disability are health issues that are significantly impacted by social norms.

19.7: Aging

More than 10,000 people turn 65 every day in the United States, and people are living longer, healthier lives. Healthy lifestyles, planning for retirement, and knowing your options for health care and long-term care are more important than ever before.

Across the world, the number and proportion of people aged 60 years and older in the population is increasing. In 2019, the number of people aged 60 years and older was 1 billion. This number will increase to 1.4 billion by 2030 and 2.1 billion by 2050. This increase is occurring at an unprecedented pace and will accelerate in coming decades, particularly in developing countries. This historically significant change in the global population requires adaptations to the way societies are structured across all sectors. For example, health and social care, transportation, housing and urban planning. Working to make the world more age-friendly is an essential and urgent part of our changing demographics.

- Between 2015 and 2050, the proportion of the world's population over 60 years will nearly double from 12% to 22%.
- By 2020, the number of people aged 60 years and older will outnumber children younger than 5 years.
- In 2050, 80% of older people will be living in low- and middle-income countries.
- The pace of population ageing is much faster than in the past.
- All countries face major challenges to ensure that their health and social systems are ready to make the most of this demographic shift.

Adopting healthy habits and behaviors, staying involved in your community, using preventive services, managing health conditions, and understanding all your medications can contribute to a productive and meaningful life.

Cognitive Health

Cognitive health — the ability to clearly think, learn, and remember — is an important component of performing everyday activities. Cognitive health is just one aspect of overall brain health. Brain health refers to how well a person's brain functions across several areas.

Aspects of brain health include:

- Cognitive health: how well you think, learn, and remember
- Motor function: how well you make and control movements, including balance
- Emotional function: how well you interpret and respond to emotions (both pleasant and unpleasant)
- Tactile function: how well you feel and respond to sensations of touch — including pressure, pain, and temperature

Alzheimer's Disease & Related Dementias

Alzheimer's disease is the most common cause of dementia in older adults. It is a progressive brain disorder that slowly destroys memory and thinking skills. It is not a normal part of aging. Memory problems are typically one of the first signs of Alzheimer's disease. Scientists believe that a combination of genetic, lifestyle, and environmental factors influence when Alzheimer's disease begins and how it progresses. Current treatment approaches focus on helping people maintain mental function, manage behavioral symptoms, and slow or delay the symptoms of disease.

Eyes and Vision

As you age, it is normal to notice changes in your vision.

A few common changes for older adults include:

- Losing the ability to see up close
- Having trouble distinguishing colors, such as blue from black
- Needing more time to adjust to changing levels of light

The following eye problems can lead to vision loss and blindness in older adults. They may have few or no early symptoms. Regular eye exams are your best protection.

- **Age-related macular degeneration (AMD)** can harm the sharp, central vision needed to see objects clearly and to do common things like driving and reading. Your eye care professional will ask about your family history and look for signs of AMD during a dilated eye exam. Treatments are available, and special dietary supplements can help lower your chance of it getting worse.
- **Diabetic retinopathy** may occur if you have diabetes. It develops slowly, often with no early warning signs. If you have diabetes, be sure to have a dilated eye exam at least once a year. Keeping your blood sugar, blood pressure, and cholesterol under control can prevent diabetic retinopathy or slow its progress in early stages. Laser surgery in later stages can sometimes prevent it from getting worse.
- **Cataracts** are cloudy areas in the eye's lens causing blurred or hazy vision. Some cataracts stay small and don't change your eyesight much. Others become large and reduce vision. Cataract surgery can restore good vision and is a safe and common treatment. If you have a cataract, your eye care professional will watch for changes over time to see if you would benefit from surgery.
- **Glaucoma** is usually caused by too much fluid pressure inside the eye. If not treated, it can lead to vision loss and blindness. People with glaucoma often have no early symptoms or pain. You can help protect yourself by having dilated eye exams yearly. Glaucoma can be treated with prescription eye drops, lasers, or surgery.
- **Dry eye** occurs when tear glands don't work well. You may feel stinging or burning, a sandy feeling as if something is in the eye, or other discomfort. Dry eye is common as people get older, especially for women. Your eye care professional may tell you to use a home humidifier or air purifier, special eye drops (artificial tears), or ointments to treat dry eye. For more severe cases, treatment options might include prescription medication, tear duct plugs, or surgery.

Hearing

Hearing loss is a common problem caused by noise, aging, disease, and heredity. People with hearing loss may find it hard to have conversations with friends and family. They may also have trouble understanding a doctor's advice, responding to warnings, and hearing doorbells and alarms. Approximately one in three people between the ages of 65 and 74 has hearing loss, and nearly half of those older than 75 has difficulty hearing. But, some people may not want to admit they have trouble hearing.

Some people have a hearing problem and don't realize it.

You should see your doctor if you:

- Have trouble hearing over the telephone
- Find it hard to follow conversations when two or more people are talking
- Often ask people to repeat what they are saying
- Need to turn up the TV volume so loud that others complain
- Have a problem hearing because of background noise
- Think that others seem to mumble
- Can't understand when women and children speak to you

Common types of hearing loss include:

- **Sudden sensorineural hearing loss**, or sudden deafness, is a rapid loss of hearing. It can happen to a person all at once or over a period of up to 3 days. It should be considered a medical emergency. If you or someone you know experiences sudden sensorineural hearing loss, visit a doctor immediately.
- Age-related hearing loss comes on gradually as a person gets older and usually occurs in both ears. It seems to run in families and may occur because of changes in the inner ear and auditory nerve. The loss is gradual, so someone with presbycusis (age-related hearing loss) may not realize that he or she has lost some of his or her ability to hear.
- Tinnitus is also common in older people. It is typically described as ringing in the ears, but it also can sound like roaring, clicking, hissing, or buzzing. It can come and go. It might be heard in one or both ears, and it may be loud or soft. Tinnitus is sometimes the first sign of hearing loss in older adults.

Healthy Aging

Many factors influence healthy aging. Some of these, such as genetics, are not in our control. Others — like exercise, a healthy diet, going to the doctor regularly, and taking care of our mental health — are within our reach. Research supported by National Institute on Aging (NIA) and others has identified actions you can take to help manage your health, live as independently as possible, and maintain your quality of life as you age, these include both physical and mental health strategies.

Take care of your physical health:

- Get moving: Exercise and physical activity
  - Physical activity is a cornerstone of healthy aging.
  - As people age, muscle function often declines. Older adults may not have the energy to do everyday activities and can lose their independence. However, exercise can help older adults maintain muscle mass as they age.
  - A study of adults 40 and older found that taking 8,000 steps or more per day, compared to only taking 4,000 steps, was associated with a 51% lower risk of death from all causes[7].
- Healthy eating: Make smart food choices
  - Making smart food choices can help protect you from certain health problems as you age and may even help improve brain function.
  - A 2021 study analyzing the eating patterns of more than 21,000 participants found that people closely following the Mediterranean-style pattern had a significantly lower risk of sudden cardiac death[8].
  - A low-salt diet called Dietary Approaches to Stop Hypertension (DASH) has also been shown to deliver significant health benefits
- Getting a good night's sleep
  - Getting enough sleep helps you stay healthy and alert. Even though older adults need the same seven to nine hours of sleep as all adults, they often don't get enough.
  - A study, which looked at data from nearly 8,000 people, showed that those in their 50s and 60s who got six hours of sleep or less a night were at a higher risk of developing dementia later in life[9].
- Quit smoking
  - It doesn't matter how old you are or how long you've been smoking, research confirms that even if you're 60 or older and have been smoking for decades, quitting will improve your health. Quitting smoking at any age will:
    - Lower your risk of cancer, heart attack, stroke, and lung disease
    - Improve your blood circulation
    - Improve your sense of taste and smell
    - Increase your ability to exercise
    - Set a healthy example for others
- Alcohol and other substances
  - Like all adults, older adults should avoid or limit alcohol consumption. In fact, aging can lead to social and physical changes that make older adults more susceptible to alcohol misuse and abuse and more vulnerable to the consequences of alcohol.
- Go to the doctor regularly
  - Going to the doctor for regular health screenings is essential for healthy aging.
  - A 2021 study found that getting regular check-ups helps doctors catch chronic diseases early and can help patients reduce risk factors for disease, such as high blood pressure and cholesterol levels. People who went to the doctor regularly also reported improved quality of life and feelings of wellness[10].

Take care of your mental health:

- Social isolation and loneliness
  - As people age, changes such as hearing and vision loss, memory loss, disability, trouble getting around, and the loss of family and friends can make it difficult to maintain social connections. This makes older adults more likely to be socially isolated or to feel lonely.
  - A 2021 study of more than 11,000 adults older than age 70 found that loneliness was associated with a greater risk of heart disease[11].
- Stress
  - Research shows that constant stress can change the brain, affect memory, and increase the risk of developing Alzheimer's or related dementias.
  - A meta-analysis funded by the National Institute of Mental Health supports the notion that stress and anxiety rewire the brain in ways that can impact memory, decision-making, and mood[12].
- Depression and overall mood
  - Although depression is common in older adults, it can be difficult to recognize. For some older adults with depression, sadness is not their main symptom. Instead, they might feel numb or uninterested in activities and may not be as willing to talk about their feelings.
  - A 2020 longitudinal study demonstrated a link between positive mood and better cognitive control[13].
- Leisure activities and hobbies

- Your favorite activities are not only fun — they may also be good for your health. Research shows that people who participate in hobbies and social and leisure activities may be at lower risk for some health problems.
- A study showed that older adults who spent at least an hour reading or engaged in other hobbies had a decreased risk of dementia compared to those who spent less than 30 minutes a day on hobbies[14].

19.8: Dealing with Death

It is a fact that we will one day die, how will you prepare for that day?

Advance Care Planning

Advance care planning involves learning about the types of decisions that might need to be made, considering those decisions ahead of time, and then letting others know—both your family and your health care providers—about your preferences. These preferences are often put into an *advance directive*, a legal document that goes into effect only if you are incapacitated and unable to speak for yourself. An advance directive also allows you to express your values and desires related to end-of-life care. There are two main elements in an advance directive—a living will and a durable power of attorney for health care. A living will is a written document that helps you tell doctors how you want to be treated if you are dying or permanently unconscious and cannot make your own decisions about emergency treatment. A durable power of attorney for health care is a legal document naming a health care proxy, someone to make medical decisions for you at times when you are unable to do so.

Organ and Brain Donation

Data shows that 90% of adults support organ donation but only 60% are actually signed up as donors.

Organ donation is the act of taking healthy organs and tissues from one person and giving them to someone else. Making the decision to donate your organs is one of the most generous gifts you can give. There is no age limit for donation or to sign up. In 2021, one out of every three people who donated organs was over the age of 50. You're never too old to make a difference — as of 2021, the oldest organ donor in the United States was 92.

While many people think that signing up to be an organ donor includes donating their brain, the purpose and the process of brain donation are different. Rather than helping to keep others alive, such as with kidney donation, brain donation helps advance scientific research. One donated brain can make a huge impact, potentially providing information for hundreds of studies.

Why donate:

- 106,008 men, women, and children are on the national transplant waiting list.
- Every 9 minutes another person is added to the transplant waiting list.
- 17 people die each day waiting for an organ transplant.
- Every donor can save 8 lives and enhance over 75 more.

Become and offiicial organ donor

Are you ready to save lives? You can provide lifesaving organs to as many as eight people. ***Every registration counts.***

Sign Up To Be An Organ Donor

Retirement and Savings

Retirement requires a lot of planning and consideration. In addition to finances, you need to think about when and where you'll retire. Experts advise that you may need as much as 80 percent of your pre-retirement income to continue your current standard of living. The exact amount will depend on your individual needs.

As you plan, consider these important questions:

- At what age do you plan to retire?
- Can you participate in an employer's retirement savings plan? This includes 401(k) plans and traditional pension plans.

- If you have a spouse or partner, will they retire when you do?
- Where do you plan to live when you retire? Will you downsize, rent, or own your home?
- Do you expect to work part-time?
- Will you have the same medical insurance you had while working? Will your insurance coverage change?
- Do you want to travel or pursue a costly, new hobby?
- Will you qualify for social security?

Social Security provides you with a source of income when you retire or if you can't work due to a disability. It can also support your legal dependents (spouse, children, or parents) with benefits in the event of your death.

While you work, you pay Social Security taxes. This tax money goes into a trust fund that pays benefits to:

- Those who are currently retired
- To people with disabilities
- To the surviving spouses and children of workers who have died

Each year you work, you'll get credits to help you become eligible for benefits when it's time for you to retire.

Saving for retirement

Get tips for building your retirement savings in the Department of Labor's (DOL) Top 10 Ways to Prepare for Retirement

Use a retirement calculator to find out the best age to claim your Social Security benefits.

Make a plan with the Retirement Saving worksheet

19.9: End-of-Chapter Material

Key takeaways for this Chapter

- We are living much longer.
- You can easily be tricked by health fraud, so it is important to be a critical consumer of health information.
- The U.S. does not have universal healthcare, so it is important that you ensure you have healthcare either through employment, by purchasing your own insurance, or through government programs.
- Both western and eastern medicine can be helpful depending on your health status and goals.
- As you age, be aware of changes to your mind and body.
- Aging is highly dependent on your lifestyle choices.
- It is important to start planning for end of life to ensure your wishes are known.
- Plan for retirement early in your employment career to ensure you are taking the necessary steps to meet your retirement goals.

This page titled 19.9: End-of-Chapter Material is shared under a CC BY-NC 4.0 license and was authored, remixed, and/or curated by Manomita Patra and Yeny Pena-Grafton.

- 15.6: Laws of Inheritance has no license indicated.

19.10: Health Care and Aging- Optional Continued Learning

The videos below provide an opportunity to expand on your learning from the chapter. As you watch the video, make a list of what you notice and what you wonder. This is a great strategy to listen purposefully, engage with the content, and look for deeper opportunities for self growth, self-reflection, and learning.

What do you **notice**?

- How does this topic support, expand, or challenge the content in the chapter?
- How does this topic connect to health topics from other chapters?
- How does this topic connect with your prior learning, your experiences, your work, your family, or your life in general?
- How does this topic help you to more fully understand health and wellness?

What do you **wonder**?

- How has this topic sparked your curiosity?
- What would you like to know more about?
- What questions did you have as you reviewed the topic?
- What other popular and scholarly sources support or refute this topic?

Videos for continued learning and application

Note: These videos are intended to more fully reflect on health. You might agree or disagree with the videos and that is ok! Utilize these videos to critically think through the topics and identify other sources, both scholarly and popular, to convey your learning.

Essential questions to ask your future self

How healthy living nearly killed me

How humanity doubled life expectancy in a century

How the COVID-19 vaccines were created so quickly

How to find meaning after loss

How to live to be 100+

How to support yourself (and others) through grief

It's our city. Let's fix it

The emotions behind your money habits

The profound power of gratitude and "living eulogies"

The science of preserving sight

What Americans agree on when it comes to health

What I learned from 2,000 obituaries

What if our health care system kept us healthy?

What really happens to your body during menopause

What to trust in a "post-truth" world

Why do our bodies age?

This page titled 19.10: Health Care and Aging- Optional Continued Learning is shared under a CC BY-NC 4.0 license and was authored, remixed, and/or curated by Manomita Patra and Yeny Pena-Grafton.

20: WELLNESS FOR PROFESSIONALS

Welcome to Wellness for Helping Professions!

We are glad you are here! This text is designed to be a starting point for those who want to explore, understand, and improve their personal wellness, with a specific focus on those who work and care for others. The format of the course is centered around trying various self-care activities followed by reflection. Some of these activities may be ones you engage with regularly while others may allow you to step outside your comfort zone. As you engage with each of these self-care practices, it is our hope that you will learn to identify your own sources of stress, build healthier habits that help you thrive, and develop a toolbox of activities that can help ground you as you work with and care for others.

Figure : Self-care practices are essential to manage stress and keep you grounded as you work with others. (Photo by Jorge Urosa from Pexels.)

Course Goals

The course goals (learning outcomes) will be that the student will be able to:

1. **Assess** and **identify** their own wellness needs
2. **Identify** different approaches to meet different wellness needs
3. **Create** a plan for ongoing responsiveness to assess needs and implement practices for wellness
4. **Create** new habits related to wellness
5. **Demonstrate** an awareness of ethical, professional, and Christ-like behaviors related to self-care

Course Recommendations and Structure

There are some recommendations on how you can gain the most from this course:

- Be willing to commit to being an active participant in all activities, not just the 'comfortable' ones
- Set aside 1 hour each week at a consistent time to start a new module and work through and/or complete the activity
- Outside of the 1-hour class, set aside an additional minimum of 1 hour per week to practice the activity
- *Reflect* on your incorporation of that activity, the benefits and barriers to your wellness that week, and how that activity impacted your wellness
- Consider recruiting others to do this course with you. While this course is about working on your personal wellness, many of

the activities are great to do with others. Participating with a partner or a group can also help with accountability to stick to your plan!

- **DO NOT** try only the activities that are comfortable or seem interesting. **DO** try activities that push boundaries and explore new ideas!

As an introductory, exploratory course utilizing evidence-based activities, you are encouraged to try new activities and explore your own wellness and wellness needs. This course is not intended to be a long-term wellness plan, but rather, it is meant to help you develop habits that can turn into a more permanent approach to wellness. When you are able to identify activities that meet your wellness needs, we encourage you to dig deeper into those practices and expand beyond the introductory level explored in this course.

Why is this course important to the helping professions?

People who work in the helping professions are, by definition, helping others. They often have personalities that feed off of giving to others and providing care or education for those in need. However, while giving of themselves, helping professionals may not consider their own needs and are vulnerable to stress, frustration, anxiety, and fatigue. Thus, proper self-care is both a responsibility and a necessity in order to be at one's best (Radlauer-Doerfler & VanDenBerg, 2020).

To give some practical, evidence-based examples, here are several examples from research in various helping fields:

Nursing

In 2013, the American Nursing Association (ANA) launched its HealthyNurse Health Risk Appraisal. From the findings of the report, nearly every indicator showed that the health of American nurses is worse than that of the average American. This includes data showing that American nurses are more likely to be overweight, have higher levels of stress, and get less than the recommended hours of sleep (American Nurses Association, n.d.). Further, hazards such as workplace violence and musculoskeletal injuries also contributed to poorer health.

Social Work

Numerous studies have shown evidence that social workers are at risk for higher levels of burnout and stress because of their jobs (Ratcliff, 2024; Schraer, 2015). Larger organizations like the National Association of Social Workers (NASW) have changed their code of ethics (2021) to encourage proactive self-care amongst social workers to improve professional excellence, thereby recognizing the importance of mentally healthy workers.

Teaching

Teachers constantly work with students on a daily basis and are at higher risk for burnout which is often manifested physically or psychologically (Nápoles, 2021). A systematic review showed that teacher burnout was associated with headaches, illness, and voice disorders, among other physical factors (Madigan et al., 2023). Psychologically, one study showed that the proportion of teachers reporting psychological distress was twice as high as compared to a general population sample (Biron et al., 2008).

Personal Training

Personal and athletic trainers are not immune from experiencing burnout, potentially due to irregular hours and long hours (Oglesby et al., 2020). Moreover, because of the nature of the job of a personal trainer in helping people transform their bodies, personal trainers may experience higher levels of dissatisfaction with their own body and would benefit from exercises in self-compassion (Ebbeck & Austin, 2018).

Regardless of the helping profession, there is clear research and evidence that both physical and psychological issues can manifest themselves due to the work being done. To be at our optimal selves, it is vitally important that we take care of ourselves first so that we can maximize our impact on others. Our hope is that not only will you recognize your need for intentional self-care, but that you will actively engage in self-care activities to live your best life.

Reflection

What brought you to explore this course?
What has you interested in exploring wellness?

20.1: Getting Started - Assessments

Background

"You can't really know where you are going until you know where you have been"

- Maya Angelou

How do we start the exploration of wellness that is the purpose of this course? This first activity looks to set a path forward, by starting with an in-depth evaluation of where you are at now when it comes to wellness.

Princeton U Matter (n.d.) defines wellness as "not merely the absence of illness or distress, [but] a lifelong process of making decisions to live a more balanced and meaningful life" (para. 1). The first step in that process is evaluating your current state, which is similar to many models of improvement including the nursing process. The nursing process follows 5 systematic steps: assess, diagnose, plan, implement, and evaluate (Toney-Butler & Thayer, 2023). Many other helping professions have a similar approach to practice. For example, quality improvement (QI) is something frequently discussed in healthcare. While comparing oneself to healthcare may not be the most therapeutic way to start a course focused on promoting wellness, it can be helpful to borrow a few concepts from QI models. The Model for Improvement used by the Institute for Healthcare Improvement (n.d.) starts by asking three fundamental questions that can be adapted for students in this course.

Definition: The Model for Improvement

The **Model for Improvement** asks three fundamental questions:

1. What are we (am I) trying to accomplish?
2. How will we (I) know that a change is an improvement?
3. What changes can we (I) make that will result in improvement?

One way to answer these questions and complete the assessment stage of the nursing process is to use a variety of inventories or tools to gather data. These assessments can identify different wellness needs that will assist you in creating a plan to better your own wellness.

Figure : Start making changes now. (Photo by Markus Winkler from Pexels)

Activity

This week, you are going to complete a variety of assessments/inventories to gather data about your wellness needs and create individual goals for the course. Taking these assessments should help with the three questions posed in the Model for Improvement. In some ways, this week can be the hardest in the course because it asks participants to dig deeply into their experiences. This takes vulnerability, strength, and courage! Do not be discouraged if this week's activity feels heavy or difficult. Try to recognize that this marks a starting point or baseline for the adventure of this class. The goal is to help you gather data to better inform you of what your needs are and to help you evaluate how you are responding to the different activities each week!

You will complete five assessments this week:

1. Princeton U Matter
2. Social Readjustment Rating Scale OR Students' Stress Rating Scale
3. Hassles & Uplifts
4. Symptoms of Stress
5. Resting Heart Rate

Why are there so many different assessments? Each assessment measures different aspects of wellness which are discussed more in the following sections.

Materials Suggested

- Device with access to Internet (and possibly a printer) to access the assessments to be completed
- Writing utensil and paper or note app to document results
- Optional: SmartWatch for tracking heart rate
    - *Note*: You can either download and print the assessments or take them digitally. Regardless, you need to document your responses for each assessment (if appropriate) and your results to refer back to them throughout the rest of the class.

Figure : Use a laptop, paper, writing instrument, and a SmartWatch. (Photo by KATRIN BOLOVTSOVA from Pexels)

Directions

Please take the time needed to carefully fill out the following five assessments and record your results using this chart. This chart is also available as a PDF download: Assessment Summary

Assessment Summary

A table depicting each assessment with a place for scores and notes and comments.

Tool	Your Score	Notes or Comments
Princeton UMatter: Emotional		
Princeton UMatter: Environmental		
Princeton UMatter: Intellectual		
Princeton UMatter: Occupational		
Princeton UMatter: Physical		
Princeton UMatter: Social		
Princeton UMatter: Spiritual		
Social Readjustment Rating Scale OR Students' Stress Rating Scale		
Hassles & Uplifts: Hassles		
Hassles & Uplifts: Uplifts		
Symptoms of Stress		
Resting Heart Rate		

Princeton U Matter

The *Princeton UMatter Wellness Self-Assessment* prompts the user to consider their current state in 7 different dimensions

including: emotional, environmental, intellectual, occupational, physical, social, and spiritual.

Take the assessment using one of the links below:

- Electronic access to Princeton UMatter Wellness Self-Assessment (recommended for ease of use of results)
- Print version of Princeton UMatter Wellness Self-Assessment

Social Readjustment Rating Scale OR Students' Stress Rating Scale

The Social Readjustment Rating Scale (SRRS) is an updated assessment based off the 1967 Holmes and Rahe Life Stress Inventory. Its goal is to measure the impact of various life events and how susceptible you might be to a stress-induced health breakdown (Wallace et al., 2023). Similarly, the Students' Stress Rating Scale (SSRS) is a 35-item variation on the Holmes and Rahe assessment tailored to college students and stresses that they might be facing (Balamurugan & Kumaran, 2008). These assessments can be valuable in helping you identify significant events that have the possibility of affecting your wellness, as well as giving you an opportunity to think about modifiable vs non-modifiable stressors.

Pick one of the following to complete:

- Electronic access to Social Readjustment Rating Scale (recommended for ease of use of results)
- Print version of Social Readjustment Rating Scale OR Print version of Students' Stress Rating Scale Rating Scale (no electronic version available)

Hassles & Uplifts

The Hassles and Uplifts Scales (HUS) was constructed as a tool to focus on relatively minor events that happen in everyday life. This was a response to, in large part, the significance in psychological testing that the Social Readjustment Rating Scale had taken in measuring major life events (Kanner et al., 1981). While large stressors can and will happen, it is often the daily interactions or choices that impact our mood and our stress levels.

Take the assessment using the link below:

Print version of Hassles and Uplifts Scale

Note: Please read the full directions for completing the assessment to ensure you are completing the assessment accurately. After assigning a score of 0-3 for each item, add the score up for all Hassles, and then add up the score for all Uplifts.

Symptoms of Stress Table

Stress can cause many physical symptoms, some of which may be more obvious than others. The Symptoms of Stress Table can be used to identify what stress is doing to the body. Results can prompt goal setting related to those symptoms (Sairanen et al., 2024). This assessment has elements of the Calgary Symptoms of Stress Inventory (C-SOSI; Carlson & Thomas, 2007), but it is important to note that this assessment is not as comprehensive as that validated tool. The C-SOSI is primarily used by researchers to analyze data on stress symptoms in specific populations, whereas this Symptoms of Stress table is intended as a self-assessment to help identify different ways stress may be showing up in your body.

Take the assessment (found on page 2) using the link below.

Symptoms of Stress Table

To quantify this table, add up the scores as follows for each answer: Almost all day, every day (6 pts.); Once or twice daily (5 pts.); Every night or day (4 pts.); 2-3 times per week (3 pts.); Once a week (2 pts.); Once a month (1 pt.); Never (0 pts.). Record your total score in the assessment summary table.

Resting Heart Rate

Your heart rate can be used as one indicator of health and provides a quantitative piece of data to track. Many things can impact your heart rate, such as fitness level, temperature, and body position. For this course, it is particularly helpful to note that your

emotions can impact your heart rate (American Heart Association, 2025). Once you know what your resting heart rate tends to be, you can use that as a gauge to analyze if stress or emotions may be impacting you physically in any given moment.

Figure : Find your pulse on your wrist. Take your heart rate for 60 seconds. (Photo by BruceBlaus from Wikimedia Commons)

Recommendations for tracking your resting heart rate this week:

- Find a consistent time that you can check your heart rate each day. Ideally, this would be at the start of each day.
  - *Note*: If you wear a fitness tracking device, the device may do this for you.
- Take your heart rate. If you are not familiar with taking your heart rate or could use a refresher, here are some step-by-step instructions from the Mayo Clinic (2024).
- If you notice that you are feeling stressed or are experiencing heightened emotions, take a moment to check your heart rate and note any changes from your resting heart rate.

Assessment Summary

If you have not already done so, please record your assessment scores and any interesting observations or notes you had from taking these assessments: see the Assessment Summary.

Assessing wellness and stress is a complex and challenging process. Today you assessed your wellness from many different perspectives. Look back over each of the assessment tools. You will see that these tools measured wellness and stress from a variety of perspectives including:

- Physiological indicators of stress
- Your perception of what is happening in your life
- Sources of stress and frequency of hassles
- Your level of satisfaction with events in your life
- Type of life events you have experienced

Key Points

- Testing, measuring, and understanding yourself (i.e., assessment) is the first important step in developing a plan for wellness and reduction of stress.
- Stress can trigger physiological changes like an increased pulse. Symptoms of stress can include headache, muscle tension, insomnia, and a host of other warning signs. Listen to what your body is telling you as you continue through this course.
- Perception is key when assessing stress. The same situation can elicit a very different stress response in different individuals due to the individual's perception of the experience. It is okay if you experience something differently than others around

you! Be honest with yourself so you can be most responsive to your needs.
- For a balanced picture of wellness, consider all dimensions of wellness including emotional, environmental, intellectual, occupational, physical, social, and spiritual.
- No single assessment, survey, or tool can tell the whole picture when it comes to assessing your wellness. Consider the results from all of these assessments to gain a better understanding of your personal wellness needs.

Weekly Recommendation/Homework

The real impact of this activity is in **what you will do with the information you learned** about yourself. In this course, you will have the opportunity to explore different evidenced-based practices to develop a plan that is responsive to your wellness needs.

This week, continue to reflect on what you learned from the assessments. Take 5-10 minutes each day to check in with yourself about what you are feeling. Are you experiencing different physical symptoms of stress? Be attentive in listening to your body and assessing your ongoing needs.

Think about the Hassles and Uplifts assessment. Are there things that you can turn into more of uplifts? Are there hassles you can avoid or minimize? Try to be more aware of these throughout your week and repeat the assessment at least one more time to see if your results change with being more intentional about how you view each item.

Before the week is done, it is time to make some goals! Share in your reflection.

Reflection

1. Think back to the three questions from the Models for Improvement (given below) that began this section. Reflect on them in light of your scores on the assessments.
    1. What am I trying to accomplish?
    2. How will I know that a change is an improvement?
    3. What changes can I make that will result in improvement?
2. In light of your reflection, what are 3-5 specific goals that you can work towards to improve your wellness?

These reflection questions are also available as a PDF download: Weekly Recommendation/Homework - Chapter 2

20.4: Coloring

Background

Have you ever been so absorbed in a task that you lost track of time and everything else seemed to fade away? In those moments, the body and mind are fully engaged in the present, often accompanied by a sense of deep satisfaction and peace (Psychology Today, n.d.). This experience is known as flow state. More casually, this phenomenon is described as being 'in the zone,' as when a person is immersed in an activity that requires complete concentration. Flow state is desirable not only because it enhances productivity, but also because it helps reduce stress and anxiety (Flett et al., 2017). For many, moments of flow can also feel deeply spiritual, providing a sense of connection to something greater than oneself. In Christian practice, this aligns with experiences of being present with God through prayer. Professionals, artists, and athletes are just a few groups who intentionally cultivate flow to optimize their roles, crafts, or performances.

So how does flow state work, and how can you achieve it? The answer lies in neuroscience. When a person experiences the deep mind–body connection of flow, the brain releases *dopamine*, a neurotransmitter associated with pleasure, motivation, and relaxation (Ranes, 2025). This positive chemical response has led researchers to explore interventions that nurture flow for individuals facing high levels of daily stress, like health care workers or those in other helping professions.

One popular intervention that promotes flow state is coloring (Jakobsson Støre & Jakobsson, 2022). Although it may seem simple, coloring is a well-researched activity with proven health benefits. These include a reduction in anxiety and depression in addition to an increase in mindfulness, enjoyment, and creativity (Flett et al., 2017; Flicker et al., 2025; Holt et al., 2019). For health care workers such as nurses, recent research shows a significant decrease in stress symptoms after completing a structured coloring intervention (Daly et al., 2024; Kaplow et al., 2025). Coloring is also an appealing coping strategy because it is affordable, readily available, and easy to practice.

Activity

Today you will be coloring. But not just any coloring of your favorite Disney princess or comic superhero, but a specific type of coloring called *mandala coloring*.

What is a mandala? A mandala is a circular geometric design made of repeating shapes and patterns.

Why choose a mandala design for a coloring activity? Research suggests that coloring a mandala shape provides a clearly defined goal, which supports entry into flow state (Jakobsson Støre & Jakobsson, 2022).

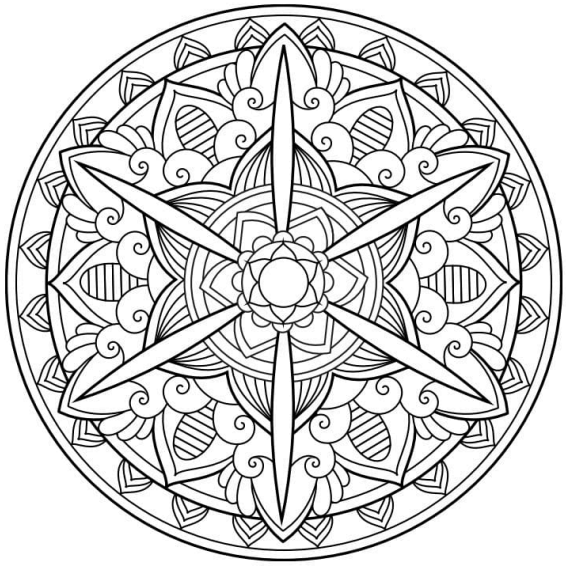

Figure : A mandala taken from the coloring book Magic Mandalas. (Illustration by Peaksel from Wikimedia Commons.)

Materials Suggested

Coloring is an outlet for creativity and emotional expression. As you choose your materials, pay attention to how you are feeling and select colors or patterns that express your current mood. If you wish to shift your mindset, select colors that inspire a positive intention for the day and invite a sense of calm.

1. A printed mandala. You can purchase mandala coloring books at a local discount or dollar store, however, they are also able to be freely printed from online. Some websites with free printable versions include:
   - Crayola
   - Monday Mandala
   - Kelly Dietrich
2. 3-5 colored pencils, crayons, or markers. Remember that repetition of color is part of the beauty of mandala art.
3. Quiet space.
4. Music (optional)

Directions

1. **Set up materials in a quiet space**. Choose an environment with minimal distractions to support deep concentration. This type of calm setting helps promote achievement of flow state.
2. **Select a time frame for your activity**. Most research studies utilize a coloring intervention of 15-20 minutes. This amount of time may be necessary to achieve flow state and attain the physiologic benefits (like reduction of anxiety and stress) that come from coloring.
3. **Begin coloring**. The strategy for coloring a mandala is highly individualized. Suggestions include coloring from center to outer ring, coloring wedge by wedge or one “slice” at a time, or filling similar shapes with the same color and then moving on to the next color. You can watch this quick tutorial of how to color a mandala

YouTube Video

This interactive element is not available in this format. Visit the link or scan the QR code to access it online.

View this YouTube Video online

Video : How to color a mandala. ("Basic tutorial for beginners on how to color a Mandala (Art Lesson 128)" by Mandala Art by Maria Hajj from YouTube.)

4. **Notice your body tension throughout the activity**. Pay attention to your posture and any tightness in your neck or shoulders. If you feel tension, consciously relax those areas and take a few deep breaths. You may find it helpful to set a timer every 4-5 minutes as a reminder to check in and release tension.
5. **Have fun**. There is no "right" way to color a mandala. The process and activity of coloring is the reward.

Alternatives/Variations

These activities may also foster flow state:

- Drawing or sketching
- Painting
- Sculpting
- Puzzles
- Journaling or creative writing
- Dancing
- Yoga

Weekly Recommendations/Homework

Spend 15-20 minutes at least 3-4 times this week coloring a mandala. As you color, pay attention to your thoughts, feelings, and any tension in your body. Choose colors that reflect your current mood or help set a positive intention for the day. You may also play soft music to enhance focus and relaxation. After each session, take a moment to reflect on how the activity influenced you physically, mentally, and spiritually.

Reflection Questions:

1. Describe any changes you noticed in the following areas when coloring this week:
Emotional, Environmental, Intellectual, Occupational, Physical, Social, and/or Spiritual

2. What benefits did you feel when coloring?

3. What, if any, barriers did you experience when coloring?

4. Do you have any additional thoughts and/or future plans for coloring?

5. What are your current stressors and do you have a wellness goal for this week?

20.5: Walking in Nature

Background

Have you ever spent some time sitting in nature surrounded by trees and found yourself feeling better? You may have actually been participating in the practice of *forest bathing* without even knowing it. Don't be alarmed - forest bathing has nothing to do with cleaning oneself in a natural stream or pond. Rather, forest bathing (also called shinrin-yoku in Japanese) is a meditative practice characterized by walking in a forest at a non-tiring pace and contemplating the natural environment (Antonelli et al., 2019). It is more than just walking in the woods though. It is the conscious and contemplative practice of using your senses - think sight, smell, feel, and sound - while being immersed in the forest (Global Wellness Institute, n.d.). Peer-reviewed evidence supports that forest bathing is capable of significantly reducing stress levels, especially stress due to studying and working activities (Antonelli et al., 2021). In general, the shorter the forest bathing session is, the smaller the effect of the intervention, but even brief visits to the forest were shown to impact individual well-being (Antonelli et al., 2021). In a separate study, 15 minutes of forest bathing showed positive short-term effects on mental health including reduction in stress and anxiety (Kotera et al., 2020).

The previous module on Breathwork presented how breath is a gift from God. In this module, we can expand the list of gifts from God by directly linking our breath to trees. Think about the perfect partnership that God created between humans and trees. Humans breath out carbon dioxide. Trees use the carbon dioxide and generate oxygen that is in return essential to human life. Humans are designed to work together with nature for the very air we share! Genesis 1:1 states: "In the beginning, God created the heavens and the earth", so this week, let us go enjoy that earth!

Figure : Forest bathing is a meditative practice. (Photo by Alex Moliski from Pexels.)

Activity

This week's activity asks you to take a trip into nature to explore and experience the world around you. Remember that the focus of this practice is not on getting a vigorous workout or hike in, but on becoming more aware of your surroundings and being curious about the world around you. To get a better sense of how to begin forest bathing and what to focus on, check out this beginner's guide from Forestry England.

Materials Suggested

- Comfortable clothing for being outdoors
- Good walking shoes

Directions

Identify a safe place to go for a walk *in a forest*. Ideally this is an actual forest versus an urban park or a cluster of trees in your backyard. Surround yourself by as many trees as possible. This can be done by oneself or with others. For the first fifteen minutes of the walk, direct your attention fully to your surroundings. Avoid conversations and use of audio. Prompt yourself to consider the following questions:

- What do I see?
- What do I hear?
- What do I smell?
- What do I taste?
- What do I feel?

As other thoughts enter your mind, gently push them aside and redirect to focus on nature and your surroundings. It may also be helpful to connect back to the breathwork you experienced earlier in the course and try some of those breathing techniques in the forest as well.

At the end of the set amount of time (aim for 15 minutes minimum), take a moment to reflect on how you feel. Then either continue your walk and engage your senses in nature or transition to a time of conversation with others or use audio (such as music, audiobooks, or podcasts). Note how these different activities each effect you. Consider when each might be useful to implement into your self-care.

Alternatives/Variations

- Grounding/Earthing - standing barefoot and/or making physical contact with the earth's surface
- Visiting a botanical gardens or greenhouse
- Exploring a meadow

Weekly Recommendations/Homework

Aim to spend a total of 2 hours in the forest this week. This can be one long visit/walk or broken down into smaller visits over multiple days. With the visit, be deliberate in considering the how you felt while you were in the forest, and how you felt after.

Reflection Questions:

1. Describe any changes you noticed in the following areas when doing forest bathing this week:
Emotional, Environmental, Intellectual, Occupational, Physical, Social, and/or Spiritual)

2. What benefits did you feel with forest bathing?

3. What, if any, barriers did you experience doing forest bathing?

4. Do you have any additional thoughts and/or future plans for forest bathing?

5. What are your current stressors and do you have a wellness goal for this week?

20.6: Reading for Fun

Background

Remembering sitting on the floor in your elementary school classroom and having the teacher read a story to you out loud? How did it feel? Does the image that comes to mind bring a sense of relaxation or comfort?

Reading for pleasure has been associated with many health benefits. One recent study found that recreational reading for college students was associated with reduced psychological distress and improved sleep over the school year (Levine et al., 2020). Critical thinking, a skill important in many college classrooms, was found to increase when students engaged in voluntary reading (Hawkins, 2012) with brain connectivity improving as well when you read a novel (Berns et al., 2013). Psychologically, a different study found that students who emotionally connected with a fictitious story were more empathetic after reading (Bal & Veltkamp, 2013). Another study presented data that reading books was associated with a 20% reduction in mortality when compared to others who did not read books (Bavishi et al., 2016).

Aside from personal health benefits, reading also is a way to expand one's own understanding of the world around them. Proverbs 4:7 (ESV) reads: "The beginning of wisdom is this: Get wisdom, and whatever you get, get insight." Isn't reading a way to get both wisdom and insight? In the helping professions, think of all the different points of views books can offer, and how that can translate to caring for others.

While there is research that provides evidence-based backing for reading for pleasure, there is a gap in evidenced-based literature regarding the potential benefits specific to nurses and other helping professions. Additional research could expand knowledge specific to how reading can help nurses and if different types of reading materials are associated with different benefits!

Figure : Reading for pleasure has many benefits. (Photo by Kaboompics.com from Pexels.)

Activity

This activity will involve you doing some reading on your own - not anything related to your academic studies, but finding something to read that you find enjoyable. For some, this could be a young adult book that you read while growing up. Or it could be a graphic novel or comic book. Or a book of poetry or a play. Or a classic novel that you have wanted to read for years. There are many different possibilities that can take you on a journey of imagination away from the daily grind of your academic studies.

Materials Suggested

- Any book of choice
  - *Note*: If this activity is being done in a class, consider inviting a guest speaker from the Library or English Education department to discuss some book recommendations

Directions

For a classroom setting:

1. Start with a discussion or reflection on how it feels to settle into reading. Share or think about memories of when a book was read out loud to you as a child or when you were able to escape to a different world reading a book.
2. Share brief book recommendations that include a 1-minute summary and why that book is recommended. Aim for a variety of options!
3. After picking a text with a strong chapter for the group to hear, settle into comfortable positions that promote relaxation. **Read the chapter out loud** (or if needed, play an audiobook). Note the book chosen can be from any background! Children's or young adult literature can work just as well as adult fiction.

For an individual:

1. Reflect on how it feels to settle into reading. Think about memories of when a book was read out loud to you as a child or when you were able to escape to a different world reading a book.
2. Spend some time (set a limit) looking up book recommendations to find a book to read this week. Use a book app like GoodReads or Story Graph to look at book options based on your preferences. Or consider a book off of the Great American Read list.
   - *Note*: It can be a physical book or an audiobook of any genre!
3. For at least 30 minutes, settle into the book. Avoid other distractions (turn your phone off) or multi-tasking. Set a timer. When done, reflect on how you feel.

Alternatives/Variations

- Read out loud to others (volunteer at a school or assisted living facility)
- Read the Bible

Weekly Recommendations/Homework

Read something not assigned for a class, for at least 1 hour this week. Consider trying reading at different times to assess how it makes you feel.

- Does reading for 5 minutes in the morning help you start your day more relaxed?
- Does reading a chapter before bed help you sleep better?
- Does listening to an audiobook during a drive make you feel different than listening to the radio or other materials?

Be creative to overcome barriers. If you have a hard time stopping reading at night, consider a book with short chapters to make it easier to set a stop point. Keep your book with you and instead of spending a few minutes scrolling on your phone, open your book during free time.

Reflection Questions

1. Describe any changes you noticed in the following areas when reading for fun this week:
Emotional, Environmental, Intellectual, Occupational, Physical, Social, and/or Spiritual

2. What benefits did you feel when reading for fun?

3. What, if any, barriers did you experience when reading for fun?

4. Do you have any additional thoughts and/or future plans for reading for fun?

5. What are your current stressors and do you have a wellness goal for this week?

20.7: Journaling

Background

Did you know that current research suggests that human beings have more than 6,000 thoughts per day? (Tseng & Poppenk, 2020). This statistic demonstrates our brain's amazing ability to engage with a complex world, but it also reveals the busyness and intricacy of our own minds. Have you ever felt like your brain is a Google search bar, with 10-15 open tabs at any given moment? Or maybe you are on autopilot, juggling a never-ending to-do list alongside responsibilities at work, school, and home. When we are bouncing from one thought to another to keep up with the current fast-paced culture, when does the mind have the opportunity to pause, reflect, and truly learn from life's experiences?

One answer to this question is through the wellness activity of journaling. Journaling is the intentional practice of writing down your thoughts and feelings to gain insight into your past, present, and future life experiences. This simple act of self-awareness has powerful, wide-ranging health benefits like lowering blood pressure, boosting immune system response, and reducing symptoms of anxiety and depression (Baikie & Wilhelm, 2005; Krpan et al., 2013; Smyth et al., 2018). Moreover, a 2023 systematic review of workplace interventions to improve well-being among health care workers concluded that gratitude journaling was an effective tool for reducing stress and depressive symptoms as well as increasing feelings of happiness (Cohen et al., 2023). Regular journaling has even been shown to decrease symptoms of burnout and trauma compassion fatigue in nurses (Dimitroff et al., 2017).

So how does the small act of journal writing lead to big changes in physical, mental, and emotional well-being? The short answer is mindfulness. By sitting down and writing your thoughts, your mind remains focused on your present situation. Even if you are writing about past experiences or fears of the future, you are naming, analyzing, and responding to current thoughts or feelings. This practice of intentional reflection is essential for self-growth and well-being.

Activity

Journaling can offer a window into your mental state and a private space to process your thoughts and feelings. It can help you regulate your emotions, track personal growth, and provide clarity in setting goals.

Figure : Writing your thoughts helps you remain focused on your current situation. (Photo by Alina Vilchenko from Pexels.)

Materials Suggested

Because journaling is a form of self-expression, the materials you select should reflect your preferences and personality. Feel free to get as creative as you want and choose supplies with various colors and textures. If a digital journal entry is preferred, then consider logging your entries in a different color or style font.

- Writing utensil
- Paper or notebook
- Computer or tablet (if doing the activity digitally)

Directions

1. **Choose a space that is free from distraction and promotes feelings of relaxation and comfort.** Journaling is an introspective and reflective practice. The ideal setting for this activity allows your mind time and space to explore personal thoughts and feelings without interruption. This could be in a quiet room in your home, sitting in your car, or traveling on public transportation. It could be at a local coffee shop or even a breakroom during a shift at work. One of the best parts of this wellness activity is that it can be done at any time and at any place as long as it works for you.
2. **Choose a time frame for your activity.** Set a goal for the minimum amount of time you want to journal, but allow yourself the flexibility to journal beyond that time limit. Journal writing sessions of 10-20 minutes in length are most common, but health benefits are possible with as little as two minutes of daily journal time (Burton & King, 2008). Journaling time may vary depending on your daily circumstances and wellness needs.
3. **Begin journaling.** Write your thoughts and feelings down on paper or type them on your tablet/computer. You can write down whatever flows naturally from your mind in this moment or choose from one of the following writing prompts suggested by *Psychology Today* (Martin, 2024):
    - What are you worried about right now?
    - What events happened today and how do you feel about them?
    - What are three things that you are grateful for and why?
    - What is a situation that you can't stop thinking about?
    - Discuss a happy memory and reflect on why it makes you happy.
    - Write about something that makes you feel angry, sad, or afraid.
    - Discuss a problem that you want to solve and possible solutions.
4. **Consider using a reflective model.** The Gibbs Model of Reflection (1988) is a helpful tool for journal writing. This six-stage cycle guides the exploration of an individual's experience with emphasis on fostering personal and professional development (Butler, 2024).

Alternatives/Variations

Consider these different forms of writing to express your thoughts and feelings. Review the associated links to gain deeper insight into these variations on journaling.

1. **Reflective writing**
    - Reflective Practice Toolkit, University of Cambridge
    - Reflective Writing, Australian National University
2. **Gratitude journaling**
    - Gratitude Journal: 35 Ideas for Getting Started
3. Learn How to Write Expressively (and heal yourself):

YouTube Video

This interactive element is not available in this format. Visit the link or scan the QR code to access it online.

View this YouTube Video online

Video : Learn how to write expressively. ("Nelda Shorts | James Pennebaker | How to write expressively and heal yourself" by Nelda Studios from YouTube.)

Weekly Recommendations/Homework

Review your daily and weekly schedule to dedicate time for journaling. The goal is to write a daily journal entry. The timing of this activity should be the best fit for your schedule. For some people, this might look like journaling at the same time every day with your morning coffee or before bed. For others, the time for journal writing will vary depending on when your schedule allows for those precious moments of solitude. Whenever you find the time, the most important part of journaling is committing consistent minutes each day to the practice of allowing thoughts and feelings to flow from the mind to paper (or computer/tablet).

Reflection Questions

1. Describe any changes you noticed in the following areas when journaling this week:
Emotional, Environmental, Intellectual, Occupational, Physical, Social, and/or Spiritual

2. What benefits did you feel when journaling?

3. What, if any, barriers did you experience when journaling?

4. Do you have any additional thoughts and/or future plans for journaling?

5. What are your current stressors and do you have a wellness goal for this week?

20.8: Sleep

Background

Sleep is an essential part of life. The National Sleep Foundation (2020) recommends that the average adult should sleep 7-9 hours per night. People who get the recommended amount of sleep are more likely to flourish in their day-to-day life (National Sleep Foundation, 2025). Despite knowing how important sleep is, many helping professionals and college students struggle to get adequate sleep. 77.4% of one sample population of hundreds of nurses had a poor quality of sleep, with night shift nurses having more sleep problems than others (Khatony et al., 2020). In a different study, 87% of intensive care unit (ICU) nurses experienced poor sleep quality which affected their professional quality of life (Mansouri et al., 2025). Related to college students, 60% of surveyed students reported experiencing sleep disturbances which affected their physical and psychological health (Lund et al., 2010).

Many factors can impact sleep. One significant factor is the use of electronic devices. A study reported that 97.3% of medical students used a blue light-emitting device at bedtime with a mean duration of screen time being 1 hour and 50 minutes per night. More than half of the students had their sleep interrupted to check messages (Jniene et al., 2019). Healthcare workers are at risk for sleeping disturbances for several reasons including shift work, work-related schedules, stress, and the type of care they provide for other people. Other factors that can impact sleep include one's activity level, alcohol use, caffeine use, stress, and environment.

In the past decade, both the American Nurses Association and the American Academy of Nursing have released position statements on the importance of addressing fatigue, sleep, work, and safety for nurses (Weaver, 2024). Research supports that there is a strong link between sleep disturbances and burnout in nurses (Ren et al., 2025). Nurses who are not getting enough sleep are also at increased risk for many infections like the common cold, pneumonia, bronchitis, sinusitis, and gastrointestinal infections (Hartveit Hosøy et al., 2025). Sleep also impacts the care that healthcare workers can provide others, directly impacting safety for both the nurse and patient as well as overall quality of care. Likewise, poor sleep has many negative impacts on students, including impaired memory, reduced cognitive function, decreased motivation and focus, and increased stress and anxiety (TrueLearn, 2025). Some good news is that while the average college student has a significant need for improved sleep, this population is also more responsive to sleep related interventions (Saruhanjan, et al., 2020).

How does God feel about sleep? In Genesis 2:2 (NLT), we read that "On the seventh day God had finished his work of creation, so he rested from all his work." Even God rested! With all that in mind, this week the focus is on sleep!

Activity

Who doesn't love a good sleep? This week, we are going to assess the length and quality of our sleep using the Pittsburgh Sleep Quality Index (PSQI). This evidence-based assessment helps people measure their sleep quality. From these results, you will identify ways to modify your sleeping patterns. This will mostly be done by setting some sleep-related goals for the week and tracking them. And hopefully, with these modifications, your overall wellness will be improved as well!

Figure : Sleep is essential for your wellbeing. (Photo by Jasmine Pang from Pexels.)

Materials Suggested

- Paper, pencil, or electronic device for documenting
- *Optional*: Sleep aids such as eye masks, ear plugs, noise machines, or sleep tracking devices like a smart watch

Directions

Pittsburgh Sleep Quality Index

The Pittsburgh Sleep Quality Index (Buysse et al., 1989) is an evidence-based assessment that helps people measure their sleep quality. It contains 19 questions (plus a few more if you sleep with a partner) with a scoring rubric as well.

Take the assessment using one of the links below:

- Electronic access to Pittsburgh Sleep Quality Index (PSQI) (recommended for ease of use of results)
- Print version of Pittsburg Sleep Quality Index PSQI

Note: If you use the print version, you will also need the scoring rubric as well.

For both the digital or print version, a final PSQI score less than or equal to (≤) 5 is associated with good sleep quality. A score greater than (>) 5 is associated with poor sleep quality.

Evidence-Based Sleep Interventions

There are numerous evidence-based interventions that can help with the quality of your sleep. An example of a research study that investigated different inventions tested relaxation, music therapy, and the use of earplugs/eye masks (Ashghab et al., 2024). But there are many more options to consider!

This exercise will help you set a few goals for the week. Consider each of the following interventions and what it could look like for you to try it out this week. If it is something you want to commit to, place a checkmark in the check column. As you go, write specific goals for you and your plans as appropriate, such as "Last coffee for the day is at 12pm" or "Set bed time alert for 11pm."

This chart is also available as a PDF download: Sleep Interventions

Intervention	Check	Comments about specific goal
Physical Environment		
Turn off all lights when going to sleep		
Change lights remaining on in sleeping area to red-light or non-blue light		
Adjust electronic devices off of blue light for night use		
Regulate room temperature		
Insert ear plugs		
Wear an eye mask		
Aromatherapy: Use lavender or damask rose extract		
Sleep with phone away from bed		
Set phone to “sleep mode” each night		
Turn off all non-essential notifications for phone apps		
Activity Considerations		
Set a consistent time to go to bed with a phone alert for this time		
Set a consistent time to wake up		
Avoid napping during the day		
No caffeine for at least 6 hours before bed		

No alcohol for at least 3 hours before bed		
Work out for at least 20 minutes during the day at least 1 hour before bed		
No use of blue light electronics (phone, tablet, computer, TV) at least 1 hour before bed		
Start a routine that excludes electronics or TV for consistent approach to bedtime		
Relaxation Techniques		
Pre-bed muscle relaxation or body scan		
Sleep yoga		
Sleep-focused meditation		
No going to bed feeling stressed, angry, upset, or nervous. Resolve feelings before getting into bed.		
No thinking, planning, or worrying in bed.		
Other		

Resources for Interventions

To assist you in coming up with some sleep interventions or learning more about the different interventions mentioned in the chart, here are some additional resources that may be of assistance (see Gupta et al., 2023 for more specifics about many of these interventions):

Physical Environment:

- Temperature control: Regulate room temperature to personal preference for comfort
- Lighting control: Turn off all lights; use blackout curtains; wear an eye mask
- Sound control: Use ear plugs; use a sound/noise machine
- Different type of sheets
- Use aromatherapy like lavender or damask rose extract

Activity Considerations:

- Try to set a schedule that allows for a consistent time of going to bed and getting out of bed each day
- Avoid daytime napping or reduce the nap to less than 2 hours
- Avoid caffeine for at least 6 hours prior to bedtime (Drake et al., 2013)
- Avoid alcohol at least 3 hours prior to bedtime or consider abstaining altogether (Bryan & Singh, 2025)
- Avoid exercising to the point of sweating within 1 hour of going to bed; Keep track of when and how exercise impacts your sleep
- Avoid use of any blue light (phone, computer, tablets, TV) for at least 1 hour before bed

Relaxation Techniques:

- Avoid going to bed feeling stressed, angry, upset or nervous; try to avoid thinking, planning, or worrying in bed
- Apps/websites that can help you relax including *Calm*, *Balance*, relaxing music playlists on Spotify, Apple Music, or YouTube
- Muscle relaxation
- Body scan meditations

- Walk in Nature
- Journaling

Weekly Recommendations/Homework

After considering the different resources for intervention, write three different sleep goals that you can incorporate this week. In addition, you will be tracking and logging your sleep each day using a sleep diary. Fill out the sleep diary as directed each morning and night for one consecutive week.

Print version of a Sleep Diary

Reflection:

1. Describe any changes you noticed in the following areas with focusing on sleep this week:
Emotional, Environmental, Intellectual, Occupational, Physical, Social, and/or Spiritual

2. What benefits did you feel with focusing on sleep?

3. What, if any, barriers did you experience focusing on sleep?

4. Do you have any additional thoughts and/or future plans for focusing on sleep?

5. What are your current stressors and do you have a wellness goal for this week?

20.9: Strength Training

Background

For many years, I worked as a labor and delivery nurse. It was a very physically demanding job. I could be on my feet for an entire 12- (or 14- or 16-) hour shift. I assist in heavy lifting to care for patients with limited mobility related to epidurals or surgery. Helping patients deliver might include holding a leg or working in an awkward position to meet the patient's needs. I witnessed and felt the toll that this type of work took on not only my body, but the other nurses around me. Unfortunately, many colleagues suffered from injuries, chronic back pain, and even sometimes the need for spinal surgery.

My experience is not unique. Nursing has been documented as the occupation with the highest prevalence of heavy lifting, which is noted as the most significant risk factor for the development of musculoskeletal injuries, especially to the lower back (Tariq et al., 2023). As such, it is no surprise that nurses have a higher-than-average risk of sustaining musculoskeletal problems related to their work. For a first hand story of a nurse lifting injury, you can read more in the article "The nurse who could lift" (Jones, 2017).

Nurses often engage in the actions of bending, reaching, extended periods of walking and standing, heavy lifting, and moving patients. These activities make nurses especially vulnerable to back injuries, fatigue, slips, trips, and falls (Dressner & Kissinger, 2018). In their report which used data from 2016, 27.7% (5,490 cases) of the days-away-from-work cases involving RNs resulted from injuries to the back and required a median recovery time of 7 days. These injuries occurred at an incidence rate greater than the rate of back injuries for all occupations (Dressner & Kissinger, 2018). Physicians and physical therapists also have been documented to have a prevalence of back issues, though not quite as high as nurses (Tariq et al., 2023).

These startling statistics should be used as a call for nurses to consider modifiable and non-modifiable risk factors for musculoskeletal injuries and preventative steps that can be taken proactively. Physical activity helps nurses reduce stress, build stamina, and inspire healthier lifestyles. While nurses often stay active throughout the day, many do not meet the recommended exercise guidelines (American Nurses Association, n.d.). Strength training is one highly impactful approach to helping prepare the body for the physical demands of nursing (Barrington Orthopedic, 2021). Strength training has numerous benefits that may include bone strengthening, weight management, quality of life improvement, chronic condition management, and even sharpened thinking skills (Mayo Clinic, 2023). Strength training can be done through different methods such as weight lifting or resistance training. Resistance training is defined as "a form of exercise that increases muscular strength and endurance by exercising a muscle or muscle group against external resistance" (Cave, n.d., para. 2). It is associated with improved blood pressure, glycemic index, lipids, and body composition. It also has been associated with enhanced sleep quality and reduced symptoms of depression and anxiety (Paluch et al., 2023). Similarly, weightlifting is a common form of exercise used to improve strength and power (Morris et al., 2022). While this training is often associated with athletes, there are definite benefits to consider for healthcare professionals with physically demanding jobs. Like so many other areas of wellness, research specific to the short- and long- term benefits of weightlifting and resistance training *specific to nurses or those in helping professions* is limited. However, there is plenty of evidence-based support for the health benefits of these activities to the general adult population.

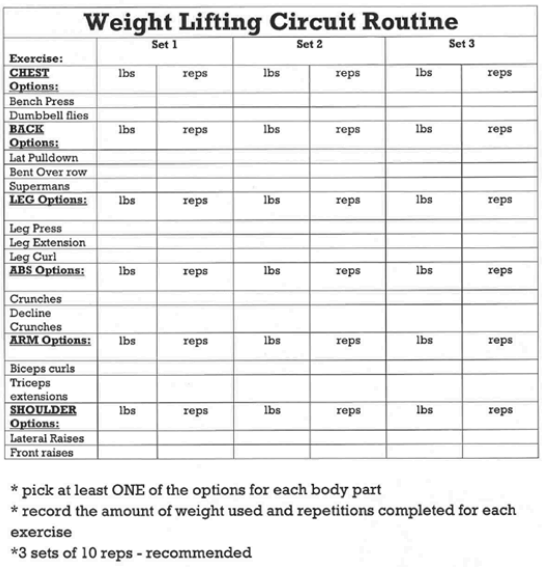
When considering how important the body is as a tool for healthcare professionals, perhaps the Bible can provide further inspiration. 1 Corinthians 6:19-20 (NIV) reads: "Do you not know that your bodies are temples of the Holy Spirit, who is in you, whom you have received from God? You are not your own; you were bought at a price. Therefore, honor God with your bodies." Providing care for others as a healthcare worker seems like an excellent way to honor God with your body. Taking that one step further, providing care for your own body so that you can provide care for others seems like another excellent way to honor God with the gift that is your body. Let those words serve as motivation as you tackle this week's physical activity!

Activity

This week, you are going to move!! The goal is to complete a total body weightlifting circuit routine. If you are completely new to the gym/fitness center, that is okay! Do not stress. Here are some tips for nurses or others in helping professions who are just getting started in the gym (Healthy Nurse, Healthy Nation, 2024). Every fitness center should have personnel that are trained in the use of gym equipment and can help you get started. Don't be afraid to ask! Really, most people are happy to share their knowledge! Or consider asking a classmate, friend, or family member to join you for this week's activity.

Figure : The body is a temple. (Photo by The Lazy Artist Gallery from Pexels.)

Materials Suggested



1. Athletic shoes. Supportive footwear matters!
2. Athletic clothing: A loose-fitting T-shirt or tank top and shorts are recommended
3. A fitness center with weight training equipment
   - If you are a student, you are encouraged to explore your school's fitness facility.
   - If you do not have direct access to a fitness center as a student, explore what your community has to offer. Perhaps there is a local recreational center, community center, or fitness center that offers free trial memberships for the week.
   - If you do not have access to a fitness center, you can explore options to workout from home via free online resources. YouTube has a number of alternative options or paid-from-home fitness workouts (examples below). Make sure the workouts include a focus on strength training or muscle building, though, to differentiate from other activities like yoga, walking, biking, or running.

Directions

Please note that if you have any concerns about physical activity, consult your healthcare provider.

1. To start, do a 5 minute warm up which might include one of the following activities:
   - Brisk walking
   - Jog
   - Jumping jacks
   - Elliptical
2. Next, move to weights. You can either use free weights or a machine. If you are not sure how to use either, do not be afraid to ask for help! If you are a beginner, you may also benefit from more information about weight lifting.
3. You should pick at least one option from each of the major muscle groups. Start with a weight level that allows you to feel comfortable lifting that weight at least 10 times with proper form.
   - Each controlled movement is called a repetition (rep, for short).
   - Performing the controlled movement 10 times (or 10 reps) is considered 1 set.
   - After 1 set, you should take a short break (generally, 30-90 seconds depending on your goals).
   - The goal is to complete 3 sets (30 total reps) for each muscle group.
     - Once you have done three sets for all of the major muscle areas, you have completed a circuit.
   - If you are easily able to complete 10 reps for 3 sets, you might consider either increasing to 15 or 20 reps for a set or increasing the weight the next time you do a set.

For this week, you can record your weights and reps on the Weight Lifting Circuit Routine worksheet, available for PDF download: Weight Lifting Circuit Routine worksheet

Weight Lifting Circuit Routine

Exercise:	Set 1		Set 2		Set 3	
CHEST Options:	lbs	reps	lbs	reps	lbs	reps
Bench Press						
Dumbbell flies						
BACK Options:	lbs	reps	lbs	reps	lbs	reps
Lat Pulldown						
Bent Over row						
Supermans						
LEG Options:	lbs	reps	lbs	reps	lbs	reps
Leg Press						
Leg Extension						
Leg Curl						
ABS Options:	lbs	reps	lbs	reps	lbs	reps
Crunches						
Decline Crunches						
ARM Options:	lbs	reps	lbs	reps	lbs	reps
Biceps curls						
Triceps extensions						
SHOULDER Options:	lbs	reps	lbs	reps	lbs	reps
Lateral Raises						
Front raises						

* pick at least ONE of the options for each body part
* record the amount of weight used and repetitions completed for each exercise
*3 sets of 10 reps - recommended

Figure : Weight Lifting Circuit Route. (Used with permission from Dr. Shari Jurgens.)

Tips for a successful strength training experience

- Gently stretch your muscles after completing your work out
- Make sure to drink lots of water and stay hydrated

Alternatives/Variations

If a fitness center is not an option for you, here is an example of a weightlifting workout that you can do at home if you have access to some dumbbells.

Weekly Recommendations/Homework

The goal for this week is to complete 3 circuit workouts. If you did one circuit during class today, congratulations! Look at your calendar and plan for two more sessions, scheduled at least 1 day apart. Track each of your sets with weight and reps and note how you feel during and after each session!

Reflection:

1. Describe any changes you noticed in the following areas with strength training:
Emotional, Environmental, Intellectual, Occupational, Physical, Social, and/or Spiritual

2. What benefits did you feel with strength training?

3. What, if any, barriers did you experience using strength training?

4. Do you have any additional thoughts and/or future plans for strength training?

5. What are your current stressors and do you have a wellness goal for this week?

20.10: Games

Background

Take a moment to imagine each of the following scenarios:

- Rolling a *Yahtzee* during game night
- Competing as part of a team in a sporting event
- Landing on "Free Parking" during a fierce round of *Monopoly*
- Laughing through a round of charades

Figure : Playing games together can improve physical and psychological health. (Photos by ClickerHappy from Pexels (left), Philip Taylor ptmoney.com from Flikr (right).)

Did any of those scenarios bring to mind a positive memory? Hopefully one or two! All these scenarios have elements of social interaction through playing a game. The saying "fun and games" implies the innate connection between participating in games and finding joy. If you dig a little deeper into that concept, research shows that the health benefits of playing games are plentiful. Some of the benefits may come from the game itself, while other benefits may relate to participating in a social interaction.

Social interaction is important for health. Studies have shown that being socially active is associated with less stress and depression, lower blood pressure, smaller waist circumference and body mass index, and better overall cortisol levels (Barbieri, 2021). Social interaction, also identified as "social and community context", has been identified to be one of the five primary social determinants of health as defined by the Centers for Disease Control and Prevention (CDC, 2024). These health determinants are non-medical factors that are most likely to influence health outcomes in the general population.

Games can be one specific approach to social interaction. In one recent study, data suggested that table-top, role-playing games can result in reduced general anxiety, social anxiety, and improved social skills (Varrette et al., 2022). A different 20-year, population-based study found the risk for dementia was 15% lower in participants who regularly participated in playing board games (Dartigues et al., 2013). A published systematic review incorporated 83 studies about “board games” and outlined health benefits that ranged from decreased heart rate variability and panic attacks to increased gray-matter in the brain and lower depression scores (Nakao, 2019). But board games are not the only game that showed positive effects. Barbieri (2021) reported that individuals who participated in organized sports self-reported that they had improved physical and psychological health.

"Health and games" is not as catchy to say as "fun and games", but the proof of the health benefits are impressive! And remember, people were designed by God as social beings. In Genesis 2:18 (NASB), "the Lord God said, 'It is not good for the man to be alone'.” In Matthew 18:20 (NIV), Jesus states that “where two or three gather in my name, there am I with them." Was Jesus talking about playing board games? No. Did God create Eve specifically to throw around an apple? Probably not! However, humans **were** created to be together and playing games can be just one potentially positive way to do that.

Activity

As you might be able to guess, today you will be playing a game of your choice. Games offer the opportunity for social interaction and the ability to learn life skills that can be applied in other areas of life. Whatever game is chosen, though, have fun!!

Materials Suggested

- A game of your choice
- A person or group of people to play your game with

Directions

Find another person or a group and play a game together! The only requirement is that it *must be with someone else* (no single-player Solitaire or playing a game on your phone!). It is recommended that you play the game in person, but if absolutely necessary there are apps or online games that can allow for live social interaction while playing with others.

The options for games are endless! A few favorites from a recent unofficial survey include:

- Dutch Blitz card game
- Sequence
- Candyland
- Jackbox
- Hilarium
- Kickball
- Tag

Remember that you can also play games that don't have a winner and loser (particularly if you either get too competitive or don't like competition). There are many cooperative games where you work together with others to achieve some task including:

- Pandemic
- Max
- Tower building
- Telephone
- 5-Word Story

Alternatives/Variations

- Gathering together to prepare a meal
- Being part of a team
- Taking a walk with friends

Exercise

Weekly Recommendations/Homework

The activity this week is to play a game. Try to schedule at least two additional social gatherings around a game this week or you can achieve this through one longer game session. If doing more than one session, try a different game and see if that makes any difference on how you feel.

Reflection Questions

1. Describe any changes you noticed in the following areas when gathering for a game:
    - Emotional
    - Environmental
    - Intellectual
    - Occupational
    - Physical
    - Social
    - Spiritual
2. What benefits did you feel while playing a game with others?
3. What, if any, barriers did you experience when playing a game with others?
4. Do you have any additional thoughts and/or future plans for playing a game with others?
5. What are your current stressors and do you have a wellness goal for this week?

20.11: Choose your Own Adventure

The previous chapters have covered a variety of evidenced-based wellness activities. However, it would be impossible to cover ALL the options for wellness and self-care that are available in the world! The purpose of this chapter is to provide a transition space for you to follow the same structure as the previous activities, but to explore an activity that has not been covered yet. By doing this, you get to experience and learn about another activity of your choosing, but you also begin the evolution of continuing to explore your wellness without exact directions of what is required of you for that week.

How do you know what activity to consider this week? Perhaps there is an activity that you have been curious about or have considered trying. Or maybe there is something that you have never wanted to do, but now you feel ready to step outside of your comfort zone and do something completely different! This week, that choice is yours!

Activity

For each of the previous modules, we have included a foundation of evidence-based practice that shows the wellness benefits for the chosen activity. With modern technology, this might seem pretty easy, but sometimes the "ease" of information can actually make finding evidence-based information harder to discern. Not all evidence is created equal!

Finding good information begins with finding authoritative and credible research, often called ***peer-reviewed research***. Peer-reviewed research is exactly what it sounds like - research that other scholars (or peers) in the field review to ensure that information and data is accurate. Research that goes through this process is considered higher quality and more credible than information that is not peer-reviewed. This does not mean, though, that you should avoid all non-peer-reviewed research when searching for evidence-based information. There are some really good and helpful websites that are not peer-reviewed. However, the majority of information around your activity should be strongly rooted in evidence-based practice.

There are a few ways you can go about finding evidence-based information. If you are a current college student, you most likely have access to research databases through your institution's library. If you have never been shown how to access databases, don't be afraid to ask your librarian for help! Biased opinion here, but I think librarians are pretty nice and a great resource when help is needed!

Some examples of subscription databases for finding wellness-related research could include:

- CINAHL (Cumulative Index to Nursing and Allied Health Literature)
- MEDLINE
- Cochrane Library
- OVID

If you are not a current student, don't worry! PubMed is a freely-available, online database that contains wellness-related content and is published by the United States National Library of Medicine (NLM) and the National Institutes of Health (NIH). A basic search for "wellness" retrieved over 7 million results (as of 2025)! And the majority of it is peer-reviewed which makes it a good source for evidence-based information.

Alternatively, a public library may have access to academic information through some of their database content. Google Scholar could be yet another option, but not everything in the search results is peer-reviewed, so use caution if this is the direction you take.

Once you find a good source of information related to the activity you are considering, you might be ready to engage in the activity or you might find that it leads you to dig deeper into the research. Either way is okay. If you are digging deeper, you might try different databases or look into the references found in your first source.

This activity can be done individually, but if done in a class setting, it can also be a group project. For a group project, it is recommended that every member of the team be responsible for providing at least one peer-reviewed resource.

Figure : Librarians can help you find evidence-based information. (Photo by Kampus Production from Pexels.)

- Computer with access to Internet to:
  - Brainstorm wellness activity ideas
  - Search scholarly databases
  - Gather supporting resources

Once you have found some information supporting a wellness activity, it is time to act. Using the same structure as the other modules, it is recommended that you spend 1 hour learning and trying the activity as an introduction. If this is being done as part of a group project or class, adjust the time to fit the class schedule. For example, you might consider limiting each group to 10 minutes for introduction of the topic and class participation in a mini-activity session.

Since this is a choose your own adventure, the possibilities for alternatives and variations are nearly infinite. In case you are experiencing a bit of a block in trying to pick an activity, here are some possibilities to consider:

- Pet therapy
- Drum circle
- Using a sauna
- Aromatherapy
- Tactile stimulation (e.g., kinetic sand)
- Zen gardening
- Athletic competition
- Volunteering
- Trying a new hobby like crocheting

Weekly Recommendations/Homework

Incorporate the activity into your week for at least 1 additional hour.

Also, consider sharing your activity with the authors of this text. Feel free to contact them with the activity you chose! Maybe it could become a new chapter in the future!

Reflection Questions

1. Describe any changes you noticed in the following areas when doing your activity this week:
    - Emotional
    - Environmental
    - Intellectual
    - Occupational
    - Physical
    - Social
    - Spiritual
2. What benefits did you feel with your activity?
3. What, if any, barriers did you experience with your activity?
4. Do you have any additional thoughts and/or future plans for for your activity?
5. What are your current stressors and do you have a wellness goal for this week?

20.12: Reassessment

Reassessment

Congratulations! You have made it through a number of activities that focused on giving you opportunities to explore different approaches to research-based wellness. These activities were intended to help you learn about self-care strategies and hopefully more about yourself as well.

One of the most common research study designs is often called pre-test/post-test. In this design, a researcher gives an assessment to a person, provides them with an intervention, and then retests to see if there was any significant change. At the beginning of this text, you did a number of assessments meant to give you a baseline or starting point for how well you were doing around self-care, stress management, and wellness. The various wellness activities over the past weeks were the intervention. And now it is time to retest! After all, what would a wellness course that is grounded in evidence-based research be without doing our own individualized assessments?

Activity

This week, you will repeat the assessments that you completed for the first activity. As a reminder, there were five assessments that you took during the first activitiy and will take again this week:

1. Princeton U Matter
2. Social Readjustment Rating Scale OR Students' Stress Rating Scale
3. Hassles & Uplifts
4. Symptoms of Stress
5. Resting Heart Rate

It should be noted at this point that you should **NOT** go back and look at your initial results until **AFTER** you have taken these assessments again for the second time. Doing so could introduce bias into your responses which could lead to inaccurate results and conclusions. The goal is to assess as you are in your present state.

Materials Suggested

- Device with access to Internet (and possibly a printer) to access the assessments to be completed.
- Writing utensil and paper or note app to document results
- Optional: SmartWatch for tracking heart rate

Note: You can either download and print the assessments or take them digitally. Regardless, you need to document your responses for each assessment (if appropriate) for your reflection

---

Directions

Please take the time needed to carefully fill out the five assessments and record your results using the Assessment Summary. As a reminder, it is also recommended that you **NOT** look at the results of your initial assessments until after you have retaken all of your assessments. The chart is also available as a PDF download: Assessment Summary

Assessment Summary

A table depicting each assessment, a place for scores and notes and comments.

Tool	Your Score	Notes or Comments
Princeton UMatter: Emotional		
Princeton UMatter: Environmental		
Princeton UMatter: Intellectual		
Princeton UMatter: Occupational		
Princeton UMatter: Physical		
Princeton UMatter: Social		
Princeton UMatter: Spiritual		
Social Readjustment Rating Scale OR Students' Stress Rating Scale		
Hassle & Uplift: Hassle		
Hassle & Uplift: Uplift		
Symptoms of Stress		
Resting Heart Rate		

Princeton U Matter

The *Princeton UMatter Wellness Self-Assessment* prompts the user to consider their current state in 7 different dimensions including: emotional, environmental, intellectual, occupational, physical, social, and spiritual.

Take the assessment using one of the links below:

- Electronic access to Princeton UMatter Wellness Self-Assessment (recommended for ease of use of results)
- Print version of Princeton UMatter Wellness Self-Assessment

Social Readjustment Rating Scale OR Students' Stress Rating Scale

The Social Readjustment Rating Scale (SRRS) or Students' Stress Rating Scale (SSRS) measure the impact of various life events on your well-being.

Pick one of the following to complete:

- Electronic access to Social Readjustment Rating Scale (recommended for ease of use of results)
- Print version of Social Readjustment Rating Scale OR Print version of Students' Stress Rating Scale Rating Scale (no electronic version available)

Hassles & Uplifts

The Hassles and Uplifts Scales (HUS) was constructed as a tool to focus on relatively minor events that happen in everyday life.

Take the assessment using the link below:

Print version of Hassles and Uplifts Scale

Note: Please read the full directions for completing the assessment to ensure you are completing the assessment accurately. After assigning a score of 0-3 for each item, add the score up for all Hassles, and then add up the score for all Uplifts.

Symptoms of Stress Table

The Symptoms of Stress Table can be used to identify what stress is doing to the body.

Take the assessment (found on page 2) using the link below.

Symptoms of Stress Table

To quantify this table, add up the scores as follows for each answer: Almost all day, every day (6 pts); Once or twice daily (5 pts.); Every night or day (4 pts.); 2-3 times per week (3 pts.); Once a week (2 pts.); Once a month (1 pt.); Never (0 pts.). Record your total score in the assessment summary table.

Resting Heart Rate

Your heart rate can be used as one indicator of health and provides a quantitative piece of data to track.

Figure : Find your pulse on your wrist. Take your heart rate for 60 seconds. (Photo by BruceBlaus from Wikimedia Commons)

Take your heart rate. If you are not familiar with taking your heart rate or could use a refresher, here are some step-by-step instructions from the Mayo Clinic.

Assessment Summary

If you have not already done so, please record your assessment scores and any interesting observations or notes you had from taking these assessments again: see the Assessment Summary.

Now is the time for you to look back at the results from your initial Assessment Summary. Where possible, consider both your overall score as well as individual item or question comparisons to note the smaller changes that you had.

- What stayed the same between your initial assessments and today's assessments?
- What was different between your initial assessments and today's assessments?

Reflection

Perhaps you have seen some of the improvements you were hoping for, such as a decrease in a physical symptom or better emotional regulation. If so, that is great! However, it is also possible that the scores indicated that you have MORE stress now than when you started. Remember that there are a lot of "unseen" factors that can play a role in assessment and lower scores may not always indicate that things are "worse". For example, if you are taking these assessments around finals week as a college student, some of your scores might be higher, showing the stressors that come with the end of the semester. For other scores, they may be lower due to the removal of certain life stressors or fears. The numbers alone do not tell the whole picture.

It is important to continue to reflect on the why behind the numbers. Use the questions below to reflect on the changes that you noticed between the initial and current assessment.

1. What implications or "take aways" do you notice after comparing the assessment summaries?
    - Why did things stay the same or why did they change?
    - What life circumstances have changed since you took the initial assessment? For the good or for the worse?
    - What changes are more subtle and nuanced reflecting a consistent perspective on your wellness?
2. What changes do you notice in your own understanding of yourself and how you analyze the results?
    - Are you more connected with what you are feeling and the stress-related triggers you experience?

These reflection questions are also available as a PDF download: Reassessment Reflection - Chapter 13

20.13: Closing and Reflection

"What we call the beginning is often the end
And to make and end is to make a beginning.
The end is where we start from."

T. S. Eliot from Little Gidding

In starting this journey of exploring your wellness, you ended the routine you were doing before and made a new beginning. Now you are at a different end - the end of the structure this text provided - but you have the opportunity to be at a new beginning where you can continue with habits and wellness activities that are intentional and responsive to your needs. As noted at the outset of this text, the real impact is in **what you will do with the information you learned** about yourself. The goal of this closing section is to help you process what you have learned and think about new goals you can set going forward.

Near the beginning of this text, you did an in-depth evaluation of your wellness. You were prompted to consider three questions coming from the Model for Improvement:

1. What am I trying to accomplish?
2. How will I know that a change is an improvement?
3. What changes can I make that will result in improvement?

Do these questions sound familiar? Hopefully! Because they are the key questions of this text. They provide a system and structure that can be used for improvement, not only personally related to wellness, but in many professional and vocational settings as well. They can help with both big and small decisions and are a framework for improvement.

In Weekly Recommendation/Homework 2.1 of this text, you were asked to reflect on the three questions and come up with 3-5 specific goals that you could work towards to improve your wellness. Additionally, most of the wellness activities had a reflection question that also asked for a wellness goal. Go back and find your responses to both the initial reflection prompt and the weekly goals and consider the following questions in light of your earlier responses.

- How did you progress in meeting the overall goals you set?
- Have the changes you made been an improvement based on your initial goals/reflection?
- Why do you think you were able to meet that goal? Or why didn't you meet that goal?
- Consider some of your weekly goals from the reflections. Were you successful in meeting some of these weekly goals?
- How did those weekly goals help you (or did not help you) meet the larger goals?

Lastly, we would gently encourage you to set some new goals that reflect your learning and development.

- What are your future plans for wellness?

Closing

One of the objectives of this text is to help you assess and identify your own wellness needs. At the end of each week's activity, we encouraged you to reflect on the information you learned and notice changes that you were experiencing. How do you feel? Do you feel more in touch with your body, mind, and spirit? Do you feel more equipped to be responsive to your wellness needs? In case it was not clear:

Your reflection matters.

A space for reflection can provide the opportunity to routinely check in and continue moving forward with a growth mindset that both recognizes how far you have already come and what path you want to continue going forward with in the future. Including a time in your daily routine - even 5 minutes - to check-in with your mind, body, and spirit is key to living a life that is balanced.

Wellness is a journey! Exploring wellness activities can and should be a life-long pursuit. Our hope is that this text has given you tools to live this balanced life and that not only will you integrate some of these activities into your own life, but that you will share what you have learned with others. Nothing in this text has to be a secret! By sharing and teaching others, it will help to instill the concepts that you have learned deeper into your core and provide a richer, fuller life experience.

May the Lord bless you on your journey.

Figure 20.13.1: The Lord bless you and keep you; the Lord make His face shine upon you, and be gracious to you; the Lord lift up His countenance upon you, and give you his peace. (Image by Dr. Michael D. Evans from Facebook.)

- Video 4 – [microbiome] The Plant Microbiome: Managing the plant microbiome (3.3) by iMooX at licenced under Creative Commons Attribution-ShareAlike 4.0 International. (https://creativecommons.org/licenses/...)

Pollution and Bioremediation

- Video 1 – [microbiome] Microbiome and Planetary Health (6.1) by iMooX at licenced under Creative Commons Attribution-ShareAlike 4.0 International. (https://creativecommons.org/licenses/...)
- Video 2 – [microbiome] Microbiome and SDGs (6.2) by iMooX at licenced under Creative Commons Attribution-ShareAlike 4.0 International. (https://creativecommons.org/licenses/...)

Forensic Microbiomes

- Figure 1 – A summary of possible sources of forensically relevant microbiota identified by the literature review by Robinson et al., 2021 licensed under the terms of the Creative Commons Attribution License (CC BY).

Case study #1 – The Farmer's Flu

Part I – Background and Problem

- Video 1 – Raising temperatures: the immunology of influenza by British Society for Immunology under a Creative Commons Attribution License (reuse allowed)
- Article 1: Respiratory Viral Infection-Induced Microbiome Alterations and Secondary Bacterial Pneumonia by Hanada et al., 2018 under CC BY 4.0 license
- Article 2 – Allergic inflammation alters the lung microbiome and hinders synergistic co-infection with H1N1 influenza virus and Streptococcus pneumoniae in C57BL/6 mice by LeMessurier et al., 2019 under CC BY 4.0 license
- Figure 1 – Antigenic Shift of the Flu Virus by NIAID licensed under CC BY 2.0 license

Part II – Approach, Implementation, Reasoning

- Video 1 – Influenza Virus – Viral entry and fusion inhibitor by iCAP Université Claude Bernard Lyon 1 under a Creative Commons Attribution License (reuse allowed)
- Article 1 – The respiratory microbiome and susceptibility to influenza virus infection by Lee et al., 2019 under CC BY 4.0 license
- Article 2 – Secondary Bacterial Infections in Patients With Viral Pneumonia by Manohar et al., 2020 under CC BY 4.0 license
- Article 3 – Patterns in the longitudinal oropharyngeal microbiome evolution related to ventilator-associated pneumonia by Sommerstein et al., 2019 under CC BY 4.0 license

Part III – Discussion

- Article 1 – The distribution of microbiomes and resistomes across farm environments in conventional and organic dairy herds in Pennsylvania by Pitta et al., 2020 under CC BY 4.0
- Article 2 – Antimicrobial use and production system shape the fecal, environmental, and slurry resistomes of pig farms by Mencía-Ares et al., 2020 under CC BY 4.0
- Article 3 – Influence of Pig Farming on the Human Nasal Microbiota: Key Role of Airborne Microbial Communities by Kraemer et al., 2018 under CC BY 4.0
- Video 1 – Fact Check: Agriculture and Antibiotic Resistance by Livestock & Poultry Environ. Learning Community under a Creative Commons Attribution License (reuse allowed)
- Article 4 – Incidence, outcome, and risk factors for recurrence of nosocomial Clostridioides difficile infection in adults: A prospective cohort study by Karaoui et al., 2020 under CC BY-NC-ND 4.0
- Video 2 – Antibiotics and the Digestive Microbiota | Jean Carlet by World Economic Forum under a Creative Commons Attribution License (reuse allowed)

Part IV – Resolution

- Article 1 – Basic Characterization of Natural Transformation in a Highly Transformable Haemophilus parasuis Strain SC1401 by Dai et al., 2019 under CC BY 4.0
- Video 1 – Microbiota and Vaccines – Eric Brown by National Human Genome Research Institute under a Creative Commons Attribution Liscence (reuse allowed)
- Article 2 – The Gut-Lung Axis in Health and Respiratory Diseases: A Place for Inter-Organ and Inter-Kingdom Crosstalks by Enaud et al., 2020 under CC BY 4.0
- Article 3 – Translating Lung Microbiome Profiles into the Next-Generation Diagnostic Gold Standard for Pneumonia: a Clinical Investigator's Perspective by Kitsios, 2018 under CC BY 4.0

Case study #2 – The Land is Sick

Part I – Background and Problem

- Figure 1 – Coffee exports by country 2019-20 by Dylan Parks. Data source: International Coffee Organization
- Figure 2 – A world map of countries by coffee production, 2019 by Cbahrs licensed under CC BY-SA 4.0

- Article 1 – The Bacterial Microbiome of *Meloidogyne*-Based Disease Complex in Coffee and Tomato by Lamelas et al., 2020 licensed under the terms of the Creative Commons Attribution License (CC BY).
- Article 2 – A review of three major fungal diseases of *Coffea Arabica* L. in the rainforests of Ethiopia and progress in breeding for resistance in Kenya by Hindorf and Omondi, 2011 licensed under CC BY-NC-ND 3.0
- Article 3 – Structure and Dynamics of the Gut Bacterial Community Across the Developmental Stages of the Coffee Berry Borer, *Hypothenemus hampei* by Mejía-Alvarado et al., 2021 licensed under the terms of the Creative Commons Attribution License (CC BY).
- Video 1 – The biggest threats to the coffee industry by Startup to Storefront licensed under a Creative Commons Attribution License (reuse allowed)
- Video 2 – #1 Specialty coffee and the price crisis | Producer Crossover 2019 by Coffee Circle licensed under a Creative Commons Attribution License (reuse allowed)

Part II – Approach, Implementation, Reasoning

- Article 1 – Prokaryotic diversity in the rhizosphere of organic, intensive, and transitional coffee farms in Brazil by Caldwell et al., 2015 licensed under a Creative Commons Attribution-ShareAlike 4.0 International (CC BY-SA 4.0) license.
- Article 2 – A metagenomics approach in the evaluation of the soil microbiome in coffee plantations under organic and conventional production in tropical agroecosystems by Rodriguez et al., 2020 licensed under a Creative Commons Attribution-NonCommercial 4.0 International License.
- Video 1 – #2 Producer Crossover 2019 by Coffee Circle licensed under a Creative Commons Attribution License (reuse allowed)
- Video 2 – How countries farm and make coffee differently by Startup to Storefront licensed under a Creative Commons Attribution License (reuse allowed)

Part III – Discussion

- Figure 1 – Shade grown coffee in Guatamala by John Blake under Public Domain
- Figure 2. Sun-grown coffee plantation in Brazil by Knase caption adapted by Dylan Parks licensed under the Creative CommonsAttribution 3.0 Germany license.
- Video 1 – #3 The future of the price crisis by Coffee Circle licensed under a Creative Commons Attribution License (reuse allowed)
- Video 2 – How coffee destroys the environment by Startup to Storefront licensed under a Creative Commons Attribution License (reuse allowed)
- Article 1 – Root endophytes of coffee (*Coffea Arabica*): Variation across climatic gradients and relationships with functional traits by Fulthorpe et al., 2020 licensed under Creative Commons Attribution License (CC BY).
- Article 2 – Brazilian Coffee Production and the Future Microbiome and Mycotoxin Profile Considering the Climate Change Scenario by dos Santos et al., 2021 licensed under the terms and conditions of the Creative Commons Attribution (CC BY) license.
- Article 3 – Effects of environmental factors on microbiota of fruits and soil of *Coffea arabica* in Brazil by Veloso et al., 2020 licensed under the terms and conditions of the Creative Commons Attribution (CC BY) license.

Part IV – Resolution

- Article 1 – Coffee Microbiota and Its Potential Use in Sustainable Crop Management. A Review by Duong et al., 2020 licensed under the terms of the Creative Commons Attribution License (CC BY).
- Article 2 – Soil fungal communities differ between shaded and sun-intensive coffee plantations in El Salvador by Rao et al., 2020 licensed under the Creative Commons CC0 public domain dedication.
- Article 3 – https://www.frontiersin.org/articles/10.3389/fpubh.2018.00235/full by Trinh et al., 2018 licensed under the terms of the Creative Commons Attribution License (CC BY).
- Video 1 – Teaching coffee farmers about the birds and the bees by VOA Learning English licensed under a Creative Commons Attribution License (reuse allowed)

Derivative Notes

Minor revisions not noted below include editing language for clarity, length, and flow as well as corrections to and additions of hyperlinks and citations. Other revisions not listed below include removing first person language and references to sections of the text that were not included in the book/article.

Analyzing Microbiomes

- Excerpt taken from Findley and Grice, 2014 available under the Creative Commons CC0 public domain dedication:

Environmental Metagenomics

- Chapter taken from Hozzein, 2020 available under the Creative Commons Attribution 3.0 License.

Environmental Nutrient Cycling and Human Health

- Embedded article by Ochoa-Hueso, 2017 licensed under the terms of the Creative Commons Attribution License (CC BY).

Ocean Microbiome and Marine Life

- Embedded article by Apprill, 2017 licensed under the terms of the Creative Commons Attribution License (CC BY).

Soil Microbiomes

- Embedded article by Ray et al., 2020 licensed under the terms of the Creative Commons Attribution License (CC BY).

Plant Microbiomes

- Embedded article by Dastogeer et al., 2020 licensed under the terms of the Creative Commons Attribution License (CC BY).

Pollution and Bioremediation

- Embedded article by Jaiswal and Shukla, 2020 licensed under the terms of the Creative Commons Attribution License (CC BY).
    - Grammar and syntax edits made under the section ‘Ecological Safety & Risk Assessment’.

Forensic Microbiomes

- Embedded article by Robinson et al., 2021 licensed under the terms of the Creative Commons Attribution License (CC BY).
