12) $\sum_{n=1}^{\infty}(-1)^{n+1}\cos^2(1/n)$

**Answer**

$\lim_{n\to\infty}\cos^2(1/n)=1$. Diverges by Divergence Test.

13) $\sum_{n=1}^{\infty}(-1)^{n+1}\ln(1/n)$

14) $\sum_{n=1}^{\infty}(-1)^{n+1}\ln(1+\frac{1}{n})$

**Answer**

Converges by alternating series test.

15) $\sum_{n=1}^{\infty}(-1)^{n+1}\frac{n^2}{1+n^4}$

16) $\sum_{n=1}^{\infty}(-1)^{n+1}\frac{n^e}{1+n^\pi}$

**Answer**

Converges conditionally by alternating series test. Does not converge absolutely by limit comparison with $p$-series, $p=\pi-e$

Solution:

17) $\sum_{n=1}^{\infty}(-1)^{n+1}2^{1/n}$

18) $\sum_{n=1}^{\infty}(-1)^{n+1}n^{1/n}$

**Answer**

Diverges; terms do not tend to zero.

19) $\sum_{n=1}^{\infty}(-1)^{n}(1-n^{1/n})$ (Hint: $n^{1/n}\approx 1+\ln(n)/n$ for large $n$.)

20) $\sum_{n=1}^{\infty}(-1)^{n+1}n\left(1-\cos\left(\frac{1}{n}\right)\right)$ (Hint: $\cos(1/n)\approx 1-1/n^2$ for large $n$.)

**Answer**

Converges by alternating series test. Does not converge absolutely by limit comparison with harmonic series.

21) $\sum_{n=1}^{\infty}(-1)^{n+1}(\sqrt{n+1}-\sqrt{n})$ (Hint: Rationalize the numerator.)

22) $\sum_{n=1}^{\infty}(-1)^{n+1}\left(\frac{1}{\sqrt{n}}-\frac{1}{\sqrt{n+1}}\right)$ (Hint: Cross-multiply then rationalize numerator.)

**Answer**

Converges absolutely by limit comparison with $p$-series, $p=3/2$, after applying the hint.

23) $\sum_{n=1}^{\infty}(-1)^{n+1}(\ln(n+1)-\ln n)$

24) $\sum_{n=1}^{\infty}(-1)^{n+1}n(\tan^{-1}(n+1)-\tan^{-1}n)$ (Hint: Use Mean Value Theorem.)

**Answer**

Converges by alternating series test since $n(\tan^{-1}(n+1)-\tan^{-1}n)$ is decreasing to zero for large $n$.Does not converge absolutely by limit comparison with harmonic series after applying hint.

25) $\sum_{n=1}^{\infty}(-1)^{n+1}((n+1)^2-n^2)$

26) $\sum_{n=1}^{\infty}(-1)^{n+1}\left(\frac{1}{n}-\frac{1}{n+1}\right)$

**Answer**

Converges absolutely, since $a_n=\frac{1}{n}-\frac{1}{n+1}$ are terms of a telescoping series.

27) $\sum_{n=1}^{\infty}\frac{\cos(n\pi)}{n}$

28) $\sum_{n=1}^{\infty}\frac{\cos(n\pi)}{n^{1/n}}$

**Answer**

Terms do not tend to zero. Series diverges by Divergence Test.

29) $\sum_{n=1}^{\infty}\frac{1}{n}\sin(\frac{n\pi}{2})$

30) $\sum_{n=1}^{\infty}\sin(n\pi/2)\sin(1/n)$

**Answer**

Converges by alternating series test. Does not converge absolutely by limit comparison with harmonic series.

**In exercises 31 - 36, use the estimate $|R_N|\le b_{N+1}$ to find a value of $N$ that guarantees that the sum of the first $N$ terms of the alternating series $\sum_{n=1}^{\infty}(-1)^{n+1}b_n$ differs from the infinite sum by at most the given error. Calculate the partial sum $S_N$ for this $N$.**

31) [Technology Required] $b_n=1/n$, error $<10^{-5}$

32) [Technology Required] $b_n=1/\ln(n), n\ge 2$, error $<10^{-1}$

**Answer**

$\ln(N+1)>10, N+1>e^{10}, N\ge 22026; S_{22026}=0.0257\ldots$

33) [Technology Required] $b_n=1/\sqrt{n}$, error $<10^{-3}$

34) [Technology Required] $b_n=1/2^n$, error $<10^{-6}$

**Answer**

$2^{N+1}>10^6$ or $N+1>6\ln(10)/\ln(2)=19.93.$ or $N\ge 19; S_{19}=0.333333969\ldots$

35) [Technology Required] $b_n=ln(1+\frac{1}{n})$, error $<10^{-3}$

36) [Technology Required] $b_n=1/n^2$, error $<10^{-6}$

**Answer**

$(N+1)^2>10^6$ or $N>999; S_{1000}\approx 0.822466.$

**For exercises 37 - 45, indicate whether each of the following statements is true or false. If the statement is false, provide an example in which it is false.**

37) If $b_n\ge 0$ is decreasing and $\lim_{n\to\infty}b_n=0$, then $\sum_{n=1}^{\infty}(b_{2n-1}-b_{2n})$ converges absolutely.

38) If $b_n\ge 0$ is decreasing, then $\sum_{n=1}^{\infty}(b_{2n-1}-b_{2n})$ converges absolutely.

**Answer**

True. $b_n$ need not tend to zero since if $c_n = b_n - \lim b_n$, then $c_{2n-1} - c_{2n} = b_{2n-1} - b_{2n}$.

39) If $b_n \geq 0$ and $\lim_{n\to\infty} b_n = 0$ then $\sum_{n=1}^{\infty}(\frac{1}{2}(b_{3n-2} + b_{3n-1}) - b_{3n})$ converges.

40) If $b_n \geq 0$ is decreasing and $\sum_{n=1}^{\infty}(b_{3n-2} + b_{3n-1} - b_{3n})$ converges then $\sum_{n=1}^{\infty} b_{3n-2}$ converges.

**Answer**

True. $b_{3n-1} - b_{3n} \geq 0$, so convergence of $\sum b_{3n-2}$ follows from the Comparison Test.

41) If $b_n \geq 0$ is decreasing and $\sum_{n=1}^{\infty}(-1)^{n-1} b_n$ converges conditionally but not absolutely, then $b_n$ does not tend to zero.

42) Let $a_n^+ = a_n$ if $a_n \geq 0$ and $a_n^- = -a_n$ if $a_n < 0$. (Also, $a_n^+ = 0$ if $a_n < 0$ and $a_n^- = 0$ if $a_n \geq 0$.) If $\sum_{n=1}^{\infty} a_n$ converges conditionally but not absolutely, then neither $\sum_{n=1}^{\infty} a_n^+$ nor $\sum_{n=1}^{\infty} a_n^-$ converge.

**Answer**

True. If one converges, then so must the other, implying absolute convergence.

43) Suppose that $a_n$ is a sequence of positive real numbers and that $\sum_{n=1}^{\infty} a_n$ converges.

44) Suppose that $b_n$ is an arbitrary sequence of ones and minus ones. Does $\sum_{n=1}^{\infty} a_n b_n$ necessarily converge?

45) Suppose that $a_n$ is a sequence such that $\sum_{n=1}^{\infty} a_n b_n$ converges for every possible sequence $b_n$ of zeros and ones. Does $\sum_{n=1}^{\infty} a_n$ converge absolutely?

**Answer**

Yes. Take $b_n = 1$ if $a_n \geq 0$ and $b_n = 0$ if $a_n < 0$. Then $\sum_{n=1}^{\infty} a_n b_n = \sum_{n:a_n \geq 0} a_n$ converges. Similarly, one can show $\sum_{n:a_n<0} a_n$ converges. Since both series converge, the series must converge absolutely.

**In exercises 46 - 49, the series do not satisfy the hypotheses of the alternating series test as stated. In each case, state which hypothesis is not satisfied. State whether the series converges absolutely.**

46) $\sum_{n=1}^{\infty}(-1)^{n+1}\frac{\sin^2 n}{n}$

47) $\sum_{n=1}^{\infty}(-1)^{n+1}\frac{\cos^2 n}{n}$

**Answer**

Not decreasing. Does not converge absolutely.

48) $1 + \frac{1}{2} - \frac{1}{3} - \frac{1}{4} + \frac{1}{5} + \frac{1}{6} - \frac{1}{7} - \frac{1}{8} + \cdots$

49) $1 + \frac{1}{2} - \frac{1}{3} + \frac{1}{4} + \frac{1}{5} - \frac{1}{6} + \frac{1}{7} + \frac{1}{8} - \frac{1}{9} + \cdots$

**Answer**

Not alternating. Can be expressed as $\sum_{n=1}^{\infty}\left(\frac{1}{3n-2} + \frac{1}{3n-1} - \frac{1}{3n}\right)$, which diverges by comparison with $\sum_{n=1}^{\infty}\frac{1}{3n-2}$.

50) Show that the alternating series $1 - \frac{1}{2} + \frac{1}{2} - \frac{1}{4} + \frac{1}{3} - \frac{1}{6} + \frac{1}{4} - \frac{1}{8} + \cdots$ does not converge. What hypothesis of the alternating series test is not met?

51) Suppose that $\sum a_n$ converges absolutely. Show that the series consisting of the positive terms $a_n$ also converges.

**Answer**

Let $a_n^+ = a_n$ if $a_n \geq 0$ and $a_n^+ = 0$ if $a_n < 0$. Then $a_n^+ \leq |a_n|$ for all $n$ so the sequence of partial sums of $a_n^+$ is increasing and bounded above by the sequence of partial sums of $|a_n|$, which converges; hence, $\sum_{n=1}^{\infty} a_n^+$ converges.

52) Show that the alternating series $\frac{2}{3} - \frac{3}{5} + \frac{4}{7} - \frac{5}{9} + \cdots$ does not converge. What hypothesis of the alternating series test is not met?

53) The formula $\cos\theta = 1 - \frac{\theta^2}{2!} + \frac{\theta^4}{4!} - \frac{\theta^6}{6!} + \cdots$ will be derived in the next chapter. Use the remainder $|R_N| \leq b_{N+1}$ to find a bound for the error in estimating $\cos\theta$ by the fifth partial sum $1 - \theta^2/2! + \theta^4/4! - \theta^6/6! + \theta^8/8!$ for $\theta = 1, \theta = \pi/6$, and $\theta = \pi$.

**Answer**

For $N = 5$ one has $| R_N | b_6 = \theta^{10}/10!$. When $\theta = 1, R_5 \leq 1/10! \approx 2.75 \times 10^{-7}$. When $\theta = \pi/6$, $R_5 \leq (\pi/6)^{10}/10! \approx 4.26 \times 10^{-10}$. When $\theta = \pi, R_5 \leq \pi^{10}/10! = 0.0258$.

54) The formula $\sin\theta = \theta - \frac{\theta^3}{3!} + \frac{\theta^5}{5!} - \frac{\theta^7}{7!} + \cdots$ will be derived in the next chapter. Use the remainder $|R_N| \leq b_{N+1}$ to find a bound for the error in estimating $\sin\theta$ by the fifth partial sum $\theta - \theta^3/3! + \theta^5/5! - \theta^7/7! + \theta^9/9!$ for $\theta = 1, \theta = \pi/6$, and $\theta = \pi$.

55) How many terms in $\cos\theta = 1 - \frac{\theta^2}{2!} + \frac{\theta^4}{4!} - \frac{\theta^6}{6!} + \cdots$ are needed to approximate $\cos 1$ accurate to an error of at most $0.00001$?

**Answer**

Let $b_n = 1/(2n-2)!$. Then $R_N \leq 1/(2N)! < 0.00001$ when $(2N)! > 10^5$ or $N = 5$ and $1 - \frac{1}{2!} + \frac{1}{4!} - \frac{1}{6!} + \frac{1}{8!} = 0.540325\ldots$, whereas $\cos 1 = 0.5403023\ldots$

56) How many terms in $\sin\theta = \theta - \frac{\theta^3}{3!} + \frac{\theta^5}{5!} - \frac{\theta^7}{7!} + \cdots$ are needed to approximate $\sin 1$ accurate to an error of at most $0.00001$?

57) Sometimes the alternating series $\sum_{n=1}^{\infty} (-1)^{n-1} b_n$ converges to a certain fraction of an absolutely convergent series $\sum_{n=1}^{\infty} b_n$ at a faster rate. Given that $\sum_{n=1}^{\infty} \frac{1}{n^2} = \frac{\pi^2}{6}$, find $S = 1 - \frac{1}{2^2} + \frac{1}{3^2} - \frac{1}{4^2} + \cdots$. Which of the series $6\sum_{n=1}^{\infty} \frac{1}{n^2}$ and $S\sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n^2}$ gives a better estimation of $\pi^2$ using $1000$ terms?

**Answer**

Let $T = \sum \frac{1}{n^2}$. Then $T - S = \frac{1}{2}T$, so $S = T/2$. $\sqrt{6 \times \sum_{n=1}^{1000} 1/n^2} = 3.140638\ldots$; $\sqrt{\frac{1}{2} \times \sum_{n=1}^{1000} (-1)^{n-1}/n^2} = 3.141591\ldots$; $\pi = 3.141592\ldots$. The alternating series is more accurate for $1000$ terms.

**The alternating series in exercises 58 & 59 converge to given multiples of $\pi$. Find the value of $N$ predicted by the remainder estimate such that the $N^{\text{th}}$ partial sum of the series accurately approximates the left-hand side to within the given error. Find the minimum $N$ for which the error bound holds, and give the desired approximate value in each case. Up to 15 decimals places, $\pi = 3.141592653589793\ldots$.**

58) [Technology Required] $\frac{\pi}{4} = \sum_{n=0}^{\infty} \frac{(-1)^n}{2n+1}$, error $< 0.0001$

59) [Technology Required] $\frac{\pi}{\sqrt{12}} = \sum_{k=0}^{\infty} \frac{(-3)^{-k}}{2k+1}$, error $< 0.0001$

**Answer**

$N = 6, S_N = 0.9068$

60) [Technology Required] The series $\sum_{n=0}^{\infty} \frac{\sin(x+\pi n)}{x+\pi n}$ plays an important role in signal processing. Show that $\sum_{n=0}^{\infty} \frac{\sin(x+\pi n)}{x+\pi n}$ converges whenever $0 < x < \pi$. (Hint: Use the formula for the sine of a sum of angles.)

61) [Technology Required] If $\sum_{n=1}^{N} (-1)^{n-1} \frac{1}{n} \to ln2$, what is $1+\frac{1}{3}+\frac{1}{5}-\frac{1}{2}-\frac{1}{4}-\frac{1}{6}+\frac{1}{7}+\frac{1}{9}+\frac{1}{11}-\frac{1}{8}-\frac{1}{10}-\frac{1}{12}+\cdots$?

**Answer**

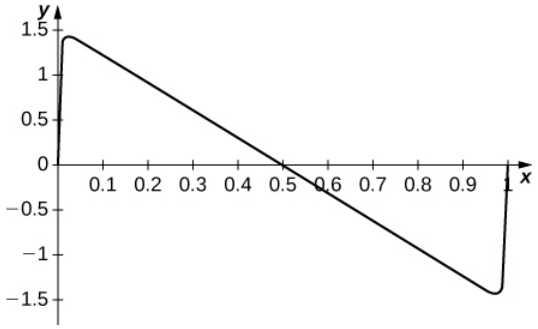
$\ln(2)$. The $n^{\text{th}}$ partial sum is the same as that for the alternating harmonic series.

62) [Technology Required] Plot the series $\sum_{n=1}^{100} \frac{\cos(2\pi n x)}{n}$ for $0 \le x < 1$. Explain why $\sum_{n=1}^{100} \frac{\cos(2\pi n x)}{n}$ diverges when $x = 0, 1$. How does the series behave for other $x$?

63) [Technology Required] Plot the series $\sum_{n=1}^{100} \frac{\sin(2\pi n x)}{n}$ for $0 \le x < 1$ and comment on its behavior

**Answer**

The series jumps rapidly near the endpoints. For $x$ away from the endpoints, the graph looks like $\pi(1/2 - x)$.



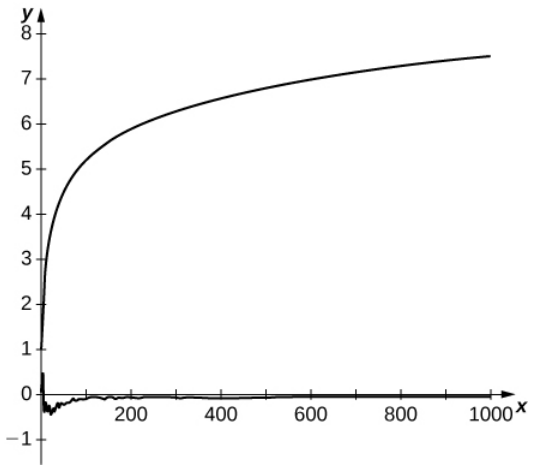
64) [Technology Required] Plot the series $\sum_{n=1}^{100} \frac{\cos(2\pi n x)}{n^2}$ for $0 \le x < 1$ and describe its graph.

65) [Technology Required] The alternating harmonic series converges because of cancelation among its terms. Its sum is known because the cancelation can be described explicitly. A random harmonic series is one of the form $\sum_{n=1}^{\infty} \frac{S_n}{n}$, where $s_n$ is a randomly generated sequence of $\pm 1's$ in which the values $\pm 1$ are equally likely to occur. Use a random number generator to produce 1000 random $\pm 1's$ and plot the partial sums $S_N = \sum_{n=1}^{N} \frac{s_n}{n}$ of your random harmonic sequence for $N = 1$ to 1000. Compare to a plot of the first 1000 partial sums of the harmonic series.

**Answer**

Here is a typical result. The top curve consists of partial sums of the harmonic series. The bottom curve plots partial sums of a random harmonic series.

https://math.libretexts.org/@go/page/175616



66) [Technology Required] Estimates of $\sum_{n=1}^{\infty} \frac{1}{n^2}$ can be accelerated by writing its partial sums as $\sum_{n=1}^{N} \frac{1}{n^2} = \sum_{n=1}^{N} \frac{1}{n(n+1)} + \sum_{n=1}^{N} \frac{1}{n^2(n+1)}$ and recalling that $\sum_{n=1}^{N} \frac{1}{n(n+1)} = 1 - \frac{1}{N+1}$ converges to one as $N \to \infty$. Compare the estimate of $\pi^2/6$ using the sums $\sum_{n=1}^{1000} \frac{1}{n^2}$ with the estimate using $1 + \sum_{n=1}^{1000} \frac{1}{n^2(n+1)}$.

67) [Technology Required] The **Euler transform** rewrites $S = \sum_{n=0}^{\infty} (-1)^n b_n$ as $S = \sum_{n=0}^{\infty} (-1)^n 2^{-n-1} \sum_{m=0}^{n} \binom{n}{m} b_{n-m}$. For the alternating harmonic series, it takes the form $\ln(2) = \sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n} = \sum_{n=1}^{\infty} \frac{1}{n2^n}$. Compute partial sums of $\sum_{n=1}^{\infty} \frac{1}{n2^n}$ until they approximate $\ln(2)$ accurate to within $0.0001$. How many terms are needed? Compare this answer to the number of terms of the alternating harmonic series are needed to estimate $\ln(2)$.

**Answer**

By the alternating series test, $|S_n - S| \le b_{n+1}$, so one needs $10^4$ terms of the alternating harmonic series to estimate $\ln(2)$ to within $0.0001$. The first $10$ partial sums of the series $\sum_{n=1}^{\infty} \frac{1}{n2^n}$ are (up to four decimals)

$0.5000, 0.6250, 0.6667, 0.6823, 0.6885, 0.6911, 0.6923, 0.6928, 0.6930, 0.6931$ and the tenth partial sum is within $0.0001$ of $\ln(2) = 0.6931\ldots$.

68) [Technology Required] In the text it was stated that a conditionally convergent series can be rearranged to converge to any number. Here is a slightly simpler, but similar, fact. If $a_n \ge 0$ is such that $a_n \to 0$ as $n \to \infty$ but $\sum_{n=1}^{\infty} a_n$ diverges, then, given any number $A$ there is a sequence $s_n$ of $\pm 1's$ such that $\sum_{n=1}^{\infty} a_n s_n \to A$. Show this for $A > 0$ as follows.

a. Recursively define $s_n$ by $s_n = 1$ if $S_{n-1} = \sum_{k=1}^{n-1} a_k s_k < A$ and $s_n = -1$ otherwise.

b. Explain why eventually $S_n \ge A$, and for any $m$ larger than this $n$, $A - a_m \le S_m \le A + a_m$.

c. Explain why this implies that $S_n \to A$ as $n \to \infty$.

# 8.7: The Ratio and Root Tests

**Learning Objectives**

- Use the Ratio Test to determine the absolute convergence of a series.
- Use the Root Test to determine the absolute convergence of a series.
- Describe a strategy for testing the convergence of a given series.

In this section, we prove the last two series convergence tests: the Ratio Test and the Root Test. These tests are particularly nice because they do not require us to find a comparable series. The Ratio Test will be especially useful in discussing power series in the next chapter. Throughout this chapter, we have seen that no single convergence test works for all series. Therefore, at the end of this section, we discuss a strategy for choosing which convergence test to use for a given series.

## Ratio Test

Consider a series $\sum_{n=1}^{\infty} a_n$. From our earlier discussion and examples, we know that $\lim_{n\to\infty} a_n = 0$ is not a sufficient condition for the series to converge. Not only do we need $a_n \to 0$, but we need $a_n \to 0$ quickly enough. For example, consider the series $\sum_{n=1}^{\infty} \frac{1}{n}$ and the series $\sum_{n=1}^{\infty} \frac{1}{n^2}$. We know that $\frac{1}{n} \to 0$ and $\frac{1}{n^2} \to 0$. However, only the series $\sum_{n=1}^{\infty} \frac{1}{n^2}$ converges. The series $\sum_{n=1}^{\infty} \frac{1}{n}$ diverges because the terms in the sequence $\left\{\frac{1}{n}\right\}$ do not approach zero fast enough as $n \to \infty$. Here, we introduce the **Ratio Test**, which provides a way of measuring how fast the terms of a series approach zero.

**Theorem: Ratio Test**

Let $\sum_{n=1}^{\infty} a_n$ be a series with nonzero terms. Let

$$\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right|.$$

i. If $0 \le \rho < 1$, then $\sum_{n=1}^{\infty} a_n$ converges absolutely.

ii. If $\rho > 1$ (or $\rho = \infty$), then $\sum_{n=1}^{\infty} a_n$ diverges.

iii. If $\rho = 1$, the test does not provide any information.

**Proof**

Let $\sum_{n=1}^{\infty} a_n$ be a series with nonzero terms.

We begin with the proof of part i. In this case, $\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| < 1$. Since $0 \le \rho < 1$, there exists $R$ such that $0 \le \rho < R < 1$. Let $\epsilon = R - \rho > 0$. By the definition of the limit of a sequence, there exists some integer $N$ such that

$$\left|\left|\frac{a_{n+1}}{a_n}\right| - \rho\right| < \epsilon, \text{ for all } n \ge N.$$

This means

$$-\epsilon < \left|\frac{a_{n+1}}{a_n}\right| - \rho < \epsilon, \text{ for all } n \ge N$$

or, written differently,

$$\left|\frac{a_{n+1}}{a_n}\right| - \rho < \epsilon, \text{ for all } n \ge N.$$

Therefore,

$$\left|\frac{a_{n+1}}{a_n}\right| < \rho + \epsilon = R, \text{ for all } n \geq N.$$

Thus,

$$\begin{aligned}
|a_{N+1}| &< R|a_N| \\
|a_{N+2}| &< R|a_{N+1}| < R^2|a_N| \\
|a_{N+3}| &< R|a_{N+2}| < R^2|a_{N+1}| < R^3|a_N| \\
|a_{N+4}| &< R|a_{N+3}| < R^2|a_{N+2}| < R^3|a_{N+1}| < R^4|a_N| \\
&\vdots
\end{aligned}$$

Since $R < 1$, the geometric series

$$\sum_{n=1}^{\infty} R^n|a_N| = R|a_N| + R^2|a_N| + R^3|a_N| + \cdots$$

converges. Since we have shown that $|a_{N+k}| < R^k|a_N|$, we can apply the Series Comparison Test and conclude that the series

$$\sum_{n=1}^{\infty} |a_{N+n}| = |a_{N+1}| + |a_{N+2}| + |a_{N+3}| + |a_{N+4}| + \cdots$$

converges. Therefore, since

$$\sum_{n=1}^{\infty} |a_n| = \sum_{n=1}^{N} |a_n| + \sum_{n=N+1}^{\infty} |a_n|,$$

where $\sum_{n=1}^{N} |a_n|$ is a finite sum and $\sum_{n=N+1}^{\infty} |a_n|$ converges, we conclude that $\sum_{n=1}^{\infty} |a_n|$ converges.

For part ii,

$$\rho = \lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| > 1.$$

Therefore, there must exist $N$ such that

$$\left|\frac{a_{n+1}}{a_n}\right| > 1$$

for all $n \geq N$. For these same values of $n$, $|a_{n+1}| > |a_n|$. Since $\sum_{n=1}^{\infty} a_n$ is a series with nonzero terms, $|a_{n+1}| > |a_n| > 0$. Hence, the sequence, $\{|a_n|\}$ is a monotonically increasing sequence of positive terms for all $n \geq N$. Thus,

$$\lim_{n\to\infty} |a_n| \neq 0.$$

This result implies

$$\lim_{n\to\infty} a_n \neq 0.$$

Hence, the series $\sum_{n=1}^{\infty} a_n$ diverges by the Divergence Test.

For part iii, we show that the test does not provide any information if $\rho = 1$ by considering the $p$−series $\sum_{n=1}^{\infty} \frac{1}{n^p}$. For any real number $p$,

$$\rho = \lim_{n\to\infty} \frac{1/(n+1)^p}{1/n^p} = \lim_{n\to\infty} \frac{n^p}{(n+1)^p} = 1.$$

However, we know that if $p \leq 1$, the $p$−series $\sum_{n=1}^{\infty} \frac{1}{n^p}$ diverges, whereas $\sum_{n=1}^{\infty} \frac{1}{n^p}$ converges if $p > 1$.

The Ratio Test is handy for series whose terms contain factorials or exponential, where the ratio of terms simplifies the expression. The Ratio Test is convenient because it does not require us to find a comparative series. The drawback is that the test sometimes does not provide any information regarding convergence.

### Example 8.7.1: Using the Ratio Test

For each of the following series, use the Ratio Test to determine whether the series converges or diverges.

a. $\sum_{n=1}^{\infty} \frac{2^n}{n!}$

b. $\sum_{n=1}^{\infty} \frac{n^n}{n!}$

c. $\sum_{n=1}^{\infty} \frac{(-1)^n (n!)^2}{(2n)!}$

**Solutions**

a. From the Ratio Test, we can see that

$$\rho = \lim_{n\to\infty} \frac{2^{n+1}/(n+1)!}{2^n/n!} = \lim_{n\to\infty} \frac{2^{n+1}}{(n+1)!} \cdot \frac{n!}{2^n}.$$

Since $(n+1)! = (n+1)\cdot n!$,

$$\rho = \lim_{n\to\infty} \frac{2}{n+1} = 0.$$

Since $\rho < 1$, the series converges (absolutely).

b. We can see that

$$\rho = \lim_{n\to\infty} \frac{(n+1)^{n+1}/(n+1)!}{n^n/n!} = \lim_{n\to\infty} \frac{(n+1)^{n+1}}{(n+1)!} \cdot \frac{n!}{n^n} = \lim_{n\to\infty} (\frac{n+1}{n})^n = \lim_{n\to\infty} (1+\frac{1}{n})^n = e.$$

Since $\rho > 1$, the series diverges.

c. Since

$$|\frac{(-1)^{n+1}((n+1)!)^2/(2(n+1))!}{(-1)^n (n!)^2/(2n)!}| = \frac{(n+1)!(n+1)!}{(2n+2)!} \cdot \frac{(2n)!}{n!n!} = \frac{(n+1)(n+1)}{(2n+2)(2n+1)}$$

we see that

$$\rho = \lim_{n\to\infty} \frac{(n+1)(n+1)}{(2n+2)(2n+1)} = \frac{1}{4}.$$

Since $\rho < 1$, the series is absolutely convergent.

### Checkpoint 8.7.1

Use the Ratio Test to determine whether the series $\sum_{n=1}^{\infty} \frac{n^3}{3^n}$ converges or diverges.

**Answer**

The series is absolutely convergent.

## Root Test

The approach of the **Root Test** is similar to that of the Ratio Test. Consider a series $\sum_{n=1}^{\infty} a_n$ such that $\lim_{n\to\infty} \sqrt[n]{|a_n|} = \rho$ for some real number $\rho$. Then for $N$ sufficiently large, $|a_N| \approx \rho^N$. Therefore, we can approximate $\sum_{n=N}^{\infty} |a_n|$ by writing

$$|a_N| + |a_{N+1}| + |a_{N+2}| + \cdots \approx \rho^N + \rho^{N+1} + \rho^{N+2} + \cdots.$$

The expression on the right-hand side is a geometric series. As in the Ratio Test, the series $\sum_{n=1}^{\infty} a_n$ converges absolutely if $0 \le \rho < 1$ and the series diverges if $\rho \ge 1$. If $\rho = 1$, the test provides no information. For example, for any $p$-series, $\sum_{n=1}^{\infty} \frac{1}{n^p}$, we see that

$$\rho = \lim_{n\to\infty} \sqrt[n]{\left|\frac{1}{n^p}\right|} = \lim_{n\to\infty} \frac{1}{n^{p/n}}.$$

To evaluate this limit, we use the natural logarithm function. Doing so, we see that

$$\begin{aligned} \ln \rho &= \ln\left(\lim_{n\to\infty} \frac{1}{n^{p/n}}\right) \\ &= \lim_{n\to\infty} \ln\left(\frac{1}{n}\right)^{p/n} \\ &= \lim_{n\to\infty} \frac{p}{n} \cdot \ln\left(\frac{1}{n}\right) \\ &= \lim_{n\to\infty} \frac{p\ln(1/n)}{n}. \end{aligned}$$

Using l'Hospital's Rule, it follows that $\ln \rho = 0$, and therefore $\rho = 1$ for all $p$. However, we know that the $p$-series only converges if $p > 1$ and diverges if $p \le 1$.

**Theorem: Root Test**

Consider the series $\sum_{n=1}^{\infty} a_n$. Let

$$\rho = \lim_{n\to\infty} \sqrt[n]{|a_n|}$$

.

i. If $0 \le \rho < 1$, then $\sum_{n=1}^{\infty} a_n$ converges absolutely.

ii. If $\rho > 1$ (or $\rho = \infty$), then $\sum_{n=1}^{\infty} a_n$ diverges.

iii. If $\rho = 1$, the test does not provide any information.

The Root Test is useful for series whose terms involve exponentials. In particular, for a series whose terms $a_n$ satisfy $|a_n| = (b_n)^n$, then $\sqrt[n]{|a_n|} = b_n$ and we need only evaluate $\lim_{n\to\infty} b_n$.

**Example 8.7.2: Using the Root Test**

For each of the following series, use the Root Test to determine whether the series converges or diverges.

a. $\sum_{n=1}^{\infty} \frac{(n^2+3n)^n}{(4n^2+5)^n}$

b. $\sum_{n=1}^{\infty} \frac{n^n}{(\ln(n))^n}$

**Solutions**

a. To apply the Root Test, we compute

$$\rho = \lim_{n\to\infty} \sqrt[n]{\frac{(n^2+3n)^n}{(4n^2+5)^n}} = \lim_{n\to\infty} \frac{n^2+3n}{4n^2+5} = \frac{1}{4}.$$

Since $\rho < 1$, the series converges absolutely.

b. We have

$$\rho = \lim_{n\to\infty} \sqrt[n]{\frac{n^n}{(\ln n)^n}} = \lim_{n\to\infty} \frac{n}{\ln n} = \infty \quad \text{by l'Hospital's Rule.}$$

Since $\rho = \infty$, the series diverges.

**? Checkpoint 8.7.2**

Use the Root Test to determine whether the series $\sum_{n=1}^{\infty} 1/n^n$ converges or diverges.

**Answer**

The series converges absolutely.

## Choosing a Convergence Test

At this point, we have a long list of convergence tests. However, not all tests can be used for all series. When given a series, we must determine which test is best. Here is a strategy for finding the best test to apply.

**Problem-Solving Strategy: Choosing a Convergence Test for a Series**

Consider a series $\sum_{n=1}^{\infty} a_n$. In the steps below, we outline a strategy for determining whether the series converges.

1. Is $\sum_{n=1}^{\infty} a_n$ a familiar series? For example, is it the harmonic series (which diverges) or the alternating harmonic series (which converges)? Is it a $p$−series or geometric series? If so, check the power $p$ or the ratio $r$ to determine if the series converges.
2. Is it an alternating series? Are we interested in absolute convergence or just convergence? If we are just interested in whether the series converges, apply the Alternating Series Test. If we are interested in absolute convergence, proceed to step **3**, considering the series of absolute values $\sum_{n=1}^{\infty} |a_n|$.
3. Is the series similar to a $p$−series or geometric series? If so, try the Series Comparison Test or Limit Comparison Test.
4. Do the terms in the series contain a factorial or power? If the terms are powers such that $a_n = (b_n)^n$, try the Root Test first. Otherwise, try the Ratio Test first.
5. Use the Divergence Test. If this test does not provide any information, try the Integral Test.

**✓ Example 8.7.3: Using Convergence Tests**

For each of the following series, determine which convergence test is best and explain why. Then, determine if the series converges or diverges. If the series is alternating, determine whether it converges absolutely, converges conditionally, or diverges.

a. $\sum_{n=1}^{\infty} \frac{n^2+2n}{n^3+3n^2+1}$

b. $\sum_{n=1}^{\infty} \frac{(-1)^{n+1}(3n+1)}{n!}$

c. $\sum_{n=1}^{\infty} \frac{e^n}{n^3}$

d. $\sum_{n=1}^{\infty} \frac{3^n}{(n+1)^n}$

**Solutions**

a. This is not a familiar series, and it is neither a $p$–series nor a geometric series. It is also not alternating; however, for large values of $n$, we approximate the series by the expression

$$\frac{n^2+2n}{n^3+3n^2+1} \approx \frac{n^2}{n^3} = \frac{1}{n}.$$

Therefore, it seems reasonable to apply the Series Comparison Test or Limit Comparison Test using the series $\sum_{n=1}^{\infty} 1/n$.

Using the Limit Comparison Test, we see that

$$\lim_{n\to\infty} \frac{(n^2+2n)/(n^3+3n^2+1)}{1/n} = \lim_{n\to\infty} \frac{n^3+2n^2}{n^3+3n^2+1} = 1.$$

Since the series $\sum_{n=1}^{\infty} 1/n$ diverges, this series diverges as well.

b. This series is not familiar; however, it is alternating. Since we are interested in absolute convergence, consider the series

$$\sum_{n=1}^{\infty} \frac{3n}{(n+1)!}.$$

The resulting series is not similar to a $p$-series or a geometric series. Still, since each term contains a factorial, we are inclined to apply the Ratio Test. We see that

$$\lim_{n\to\infty} \frac{(3(n+1))/(n+1)!}{(3n+1)/n!} = \lim_{n\to\infty} \frac{3n+3}{(n+1)!} \cdot \frac{n!}{3n+1} = \lim_{n\to\infty} \frac{3n+3}{(n+1)(3n+1)} = 0.$$

Therefore, this series converges, and we conclude that the original series converges absolutely (and, thus, converges).

c. The given series is not a familiar series, an alternating series, or a series with which there is an obvious series to compare to. Moreover, there is no factorial, and the power present is not ideal for the Root Test. Let's see about the Divergence Test.

$$\lim_{n\to\infty} \frac{e^n}{n^3} = \infty.$$

Therefore, by the Divergence Test, the series diverges.

d. This series is not a familiar series or an alternating one. There is no obvious series with which to compare this series; however, since each term is a power of $n$, we can apply the Root Test. Since

$$\lim_{n\to\infty} \sqrt[n]{\left(\frac{3}{n+1}\right)^n} = \lim_{n\to\infty} \frac{3}{n+1} = 0,$$

by the Root Test, we conclude that the series converges.

**? Checkpoint 8.7.3**

For the series $\sum_{n=1}^{\infty} \frac{2^n}{3^n+n}$, determine which convergence test is the best to use and explain why.

**Answer**

The Series Comparison Test because $\frac{2^n}{3^n+n} < \frac{2^n}{3^n}$ for all $n \in \mathbb{N}$. The Limit Comparison Test could also be used.

We summarize the convergence tests and when each can be applied in the table below. Note that while the Series Comparison Test, Limit Comparison Test, and Integral Test require the series $\sum_{n=1}^{\infty} a_n$ to have nonnegative terms, if $\sum_{n=1}^{\infty} a_n$ has negative terms, these tests can be applied to $\sum_{n=1}^{\infty} |a_n|$ to test for absolute convergence.

Summary of Convergence Tests

| Series or Test | Conclusions | Comments |
|---|---|---|
| **Divergence Test**<br>For any series $\sum_{n=1}^{\infty} a_n$, evaluate $\lim_{n\to\infty} a_n$. | • If $\lim_{n\to\infty} a_n = 0$, the test is inconclusive.<br>• If $\lim_{n\to\infty} a_n \neq 0$, the series diverges. | This test cannot prove convergence of a series. |
| **Geometric Series**<br>$\sum_{n=1}^{\infty} ar^{n-1}$ | • If $\lvert r\rvert < 1$, the series converges to $a/(1-r)$.<br>• If $\lvert r\rvert \geq 1$, the series diverges. | Any geometric series can be reindexed to be written in the form $a + ar + ar^2 + \cdots$, where $a$ is the initial term and $r$ is the common ratio. |
| **$p$-Series**<br>$\sum_{n=1}^{\infty} \frac{1}{n^p}$ | • If $p > 1$, the series converges.<br>• If $p \leq 1$, the series diverges. | For $p = 1$, we have the harmonic series $\sum_{n=1}^{\infty} 1/n$. |
| **Series Comparison Test**<br>For $\sum_{n=1}^{\infty} a_n$ with nonnegative terms, compare with a known series $\sum_{n=1}^{\infty} b_n$. | • If $a_n \leq b_n$ for all $n \geq N$ and $\sum_{n=1}^{\infty} b_n$ converges, then $\sum_{n=1}^{\infty} a_n$ converges.<br>• If $a_n \geq b_n$ for all $n \geq N$ and $\sum_{n=1}^{\infty} b_n$ diverges, then $\sum_{n=1}^{\infty} a_n$ diverges. | Typically used for a series similar to a geometric or $p$-series. It can sometimes be difficult to find an appropriate series. |
| **Limit Comparison Test**<br>For $\sum_{n=1}^{\infty} a_n$ with positive terms, compare with a series $\sum_{n=1}^{\infty} b_n$ by evaluating $L = \lim_{n\to\infty} \frac{a_n}{b_n}$. | • If $L$ is a real number and $L \neq 0$, then $\sum_{n=1}^{\infty} a_n$ and $\sum_{n=1}^{\infty} b_n$ both converge or both diverge.<br>• If $L = 0$ and $\sum_{n=1}^{\infty} b_n$ converges, then $\sum_{n=1}^{\infty} a_n$ converges.<br>• If $L = \infty$ and $\sum_{n=1}^{\infty} b_n$ diverges, then $\sum_{n=1}^{\infty} a_n$ diverges. | Typically used for a series similar to a geometric or $p$-series. Often easier to apply than the Series Comparison Test. |
| **Integral Test**<br>If there exists a positive, continuous, decreasing function $f$ such that $a_n = f(n)$ for all $n \geq N$, evaluate $\int_N^{\infty} f(x)dx$. | • $\int_N^{\infty} f(x)dx$ and $\sum_{n=1}^{\infty} a_n$ both converge or both diverge. | Limited to those series for which the corresponding function $f$ can be easily integrated. |
| **Alternating Series Test**<br>$\sum_{n=1}^{\infty} (-1)^{n+1} b_n$ or $\sum_{n=1}^{\infty} (-1)^n b_n$ | • If $b_{n+1} \leq b_n$ for all $n \geq 1$ and $b_n \to 0$, then the series converges. | Only applies to alternating series. |
| **Ratio Test**<br>For any series $\sum_{n=1}^{\infty} a_n$ with nonzero terms, let $\rho = \lim_{n\to\infty} \left\lvert \frac{a_{n+1}}{a_n} \right\rvert$ | • If $0 \leq \rho < 1$, the series converges absolutely.<br>• If $\rho > 1$ or $\rho = \infty$, the series diverges.<br>• If $\rho = 1$, the test is inconclusive. | Often used for series involving factorials or exponentials. |
| **Root Test**<br>For any series $\sum_{n=1}^{\infty} a_n$, let $\rho = \lim_{n\to\infty} \sqrt[n]{\lvert a_n\rvert}$. | • If $0 \leq \rho < 1$, the series converges absolutely.<br>• If $\rho > 1$ or $\rho = \infty$, the series diverges.<br>• If $\rho = 1$, the test is inconclusive. | Often used for series where $\lvert a_n\rvert = (b_n)^n$. |

### Series Converging to $\pi$ and $1/\pi$

Dozens of series exist that converge to $\pi$ or an algebraic expression containing $\pi$. Here, we look at several examples and compare their rates of convergence. By the rate of convergence, we mean the number of terms necessary for a partial sum to be within a certain amount of the actual value. The series representations of $\pi$ in the first two examples can be explained using **Maclaurin series**, which are discussed in the next chapter. The third example relies on material beyond the scope of this text.

1. The series

$$\pi = 4\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{2n-1} = 4 - \frac{4}{3} + \frac{4}{5} - \frac{4}{7} + \frac{4}{9} - \cdots$$

was discovered by Gregory and Leibniz in the late $1600s$. This result follows from the Maclaurin series for $f(x) = \tan^{-1} x$. We will discuss this series in the next chapter.

   a. Prove that this series converges.
   b. Evaluate the partial sums $S_n$ for $n = 10, 20, 50, 100$.
   c. Use the remainder estimate for alternating series to get a bound on the error $R_n$.
   d. What is the smallest value of $N$ that guarantees $|R_N| < 0.01$? Evaluate $S_N$.

2. The series

$$\pi = 6\sum_{n=0}^{\infty} \frac{(2n)!}{2^{4n+1}(n!)^2(2n+1)}$$
$$= 6\left(\frac{1}{2} + \frac{1}{2\cdot 3}\left(\frac{1}{2}\right)^3 + \frac{1\cdot 3}{2\cdot 4\cdot 5}\cdot\left(\frac{1}{2}\right)^5 + \frac{1\cdot 3\cdot 5}{2\cdot 4\cdot 6\cdot 7}\left(\frac{1}{2}\right)^7 + \cdots\right)$$

has been attributed to Newton in the late $1600s$. The proof of this result uses the Maclaurin series for $f(x) = \sin^{-1} x$.

   a. Prove that the series converges.
   b. Evaluate the partial sums $S_n$ for $n = 5, 10, 20$.
   c. Compare $S_n$ to $\pi$ for $n = 5, 10, 20$ and discuss the number of correct decimal places.

3. The series

$$\frac{1}{\pi} = \frac{\sqrt{8}}{9801}\sum_{n=0}^{\infty} \frac{(4n)!(1103 + 26390n)}{(n!)^4 396^{4n}}$$

was discovered by **Ramanujan** in the early $1900s$. William Gosper, Jr. used this series to calculate $\pi$ to an accuracy of more than $17$ million digits in the mid-1980s. At the time, that was a world record. Since then, this series and others by Ramanujan have led mathematicians to find many other series representations for $\pi$ and $1/\pi$.

   a. Prove that this series converges.
   b. Evaluate the first term in this series. Compare this number with the value of $\pi$ from a calculating utility. To how many decimal places do these two numbers agree? What if we add the first two terms in the series?
   c. Investigate the life of Srinivasa Ramanujan (1887–1920) and write a brief summary. Ramanujan is one of the most fascinating stories in the history of mathematics. He was self-taught, with no formal training in mathematics. Yet, he contributed in highly original ways to many advanced areas of mathematics.

## Key Concepts

- For the Ratio Test, we consider

$$\rho = \lim_{n\to\infty} \left| \frac{a_{n+1}}{a_n} \right|.$$

If $\rho < 1$, the series $\sum_{n=1}^{\infty} a_n$ converges absolutely. The series diverges if $\rho > 1$. If $\rho = 1$, the test provides no information. This test is useful for series whose terms involve factorials.

- For the Root Test, we consider

$$\rho = \lim_{n\to\infty} \sqrt[n]{|a_n|}.$$

If $\rho < 1$, the series $\sum_{n=1}^{\infty} a_n$ converges absolutely. The series diverges if $\rho > 1$. If $\rho = 1$, the test provides no information. The Root Test is useful for series whose terms involve powers.

- For a series that is similar to a geometric series or **p−series,** consider one of the Comparison Tests.

---

## Glossary

**Ratio Test**

for a series $\sum_{n=1}^{\infty} a_n$ with nonzero terms, let $\rho = \lim_{n\to\infty} |a_{n+1}/a_n|$; if $0 \le \rho < 1$, the series converges absolutely; if $\rho > 1$, the series diverges; if $\rho = 1$, the test is inconclusive

**Root Test**

for a series $\sum_{n=1}^{\infty} a_n$, let $\rho = \lim_{n\to\infty} \sqrt[n]{|a_n|}$; if $0 \le \rho < 1$, the series converges absolutely; if $\rho > 1$, the series diverges; if $\rho = 1$, the test is inconclusive

# 8.7E: Exercises

**In exercises 1 - 11, use the Ratio Test to determine whether each series $\sum_{n=1}^{\infty} a_n$ converges or diverges. State if the Ratio Test is inconclusive.**

1) $\sum_{n=1}^{\infty} \frac{1}{n!}$

**Answer**

$\lim_{n\to\infty} \frac{a_{n+1}}{a_n} = 0$. Converges by the Ratio Test.

2) $\sum_{n=1}^{\infty} \frac{10^n}{n!}$

3) $\sum_{n=1}^{\infty} \frac{n^2}{2^n}$

**Answer**

$\lim_{n\to\infty} \frac{a_{n+1}}{a_n} = \lim_{n\to\infty} \frac{1}{2}\left(\frac{n+1}{n}\right)^2 = \frac{1}{2} < 1$. Converges by the Ratio Test.

4) $\sum_{n=1}^{\infty} \frac{n^{10}}{2^n}$

5) $\sum_{n=1}^{\infty} \frac{(n!)^3}{(3n)!}$

**Answer**

$\lim_{n\to\infty} \frac{a_{n+1}}{a_n} = \frac{1}{27} < 1$. Converges by the Ratio Test.

6) $\sum_{n=1}^{\infty} \frac{2^{3n}(n!)^3}{(3n)!}$

7) $\sum_{n=1}^{\infty} \frac{(2n)!}{n^{2n}}$

**Answer**

$\lim_{n\to\infty} \frac{a_{n+1}}{a_n} = \frac{4}{e^2} < 1$. Converges by the Ratio Test.

8) $\sum_{n=1}^{\infty} \frac{(2n)!}{(2n)^n}$

9) $\sum_{n=1}^{\infty} \frac{n!}{(n/e)^n}$

**Answer**

$\lim_{n\to\infty} \frac{a_{n+1}}{a_n} = 1$. Ratio Test is inconclusive.

10) $\sum_{n=1}^{\infty} \frac{(2n)!}{(n/e)^{2n}}$

11) $\sum_{n=1}^{\infty} \frac{(2^n n!)^2}{(2n)^{2n}}$

**Answer**

$\lim_{n\to\infty} \frac{a_n}{a_{n+1}} = \frac{1}{e^2} < 1$. Converges by the Ratio Test.

**In exercises 12 - 21, use the Root Test to determine whether $\sum_{n=1}^{\infty} a_n$ converges, where $a_n$ is as follows.**

12) $a_k = \left(\frac{k-1}{2k+3}\right)^k$

13) $a_k = \left(\frac{2k^2-1}{k^2+3}\right)^k$

**Answer**

$\lim_{k\to\infty} (a_k)^{1/k} = 2 > 1$. Diverges by the Root Test.

14) $a_n = \frac{(\ln n)^{2n}}{n^n}$

15) $a_n = n/2^n$

**Answer**

$\lim_{n\to\infty} (a_n)^{1/n} = 1/2 < 1$. Converges by the Root Test.

16) $a_n = n/e^n$

17) $a_k = \frac{k^e}{e^k}$

**Answer**

$\lim_{k\to\infty} (a_k)^{1/k} = 1/e < 1$. Converges by the Root Test.

18) $a_k = \frac{\pi^k}{k^\pi}$

19) $a_n = \left(\frac{1}{e} + \frac{1}{n}\right)^n$

**Answer**

$\lim_{n\to\infty} a_n^{1/n} = \lim_{n\to\infty} \frac{1}{e} + \frac{1}{n} = \frac{1}{e} < 1$. Converges by the Root Test.

20) $a_k = \frac{1}{(1+\ln k)^k}$

21) $a_n = \frac{(\ln(1+\ln n))^n}{(\ln n)^n}$

**Answer**

$\lim_{n\to\infty} a_n^{1/n} = \lim_{n\to\infty} \frac{(\ln(1+\ln n))}{(\ln n)} = 0$ by L'Hôpital's rule. Converges by the Root Test.

**In exercises 22 - 28, use either the Ratio Test or the Root Test as appropriate to determine whether the series $\sum_{k=1}^{\infty} a_k$ with given terms $a_k$ converges, or state if the test is inconclusive.**

22) $a_k = \frac{k!}{1\cdot 3\cdot 5\cdots(2k-1)}$

23) $a_k = \frac{2\cdot 4\cdot 6\cdots 2k}{(2k)!}$

**Answer**

$\lim_{k\to\infty} \frac{a_{k+1}}{a_k} = \lim_{k\to\infty} \frac{1}{2k+1} = 0$. Converges by the Ratio Test.

24) $a_k = \frac{1\cdot 4\cdot 7\cdots(3k-2)}{3^k k!}$

25) $a_n = \left(1 - \frac{1}{n}\right)^{n^2}$

**Answer**

$\lim_{n\to\infty}(a_n)^{1/n}=1/e$. Converges by the Root Test.

26) $a_k=\left(\frac{1}{k+1}+\frac{1}{k+2}+\cdots+\frac{1}{2k}\right)^k$ (Hint: Compare $a_k^{1/k}$ to $\int_k^{2k}\frac{dt}{t}$.)

27) $a_k=\left(\frac{1}{k+1}+\frac{1}{k+2}+\cdots+\frac{1}{3k}\right)^k$

**Answer**

$\lim_{k\to\infty}a_k^{1/k}=\ln(3)>1$. Diverges by the Root Test.

28) $a_n=\left(n^{1/n}-1\right)^n$

**In exercises 29 - 30, use the Ratio Test to determine whether $\sum_{n=1}^{\infty}a_n$ converges, or state if the Ratio Test is inconclusive.**

29) $\sum_{n=1}^{\infty}\frac{3^{n^2}}{2^{n^3}}$

**Answer**

$\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right|=\lim_{n\to\infty}\frac{3^{2n+1}}{2^{3n^2+3n+1}}=0$. Converges by the Ratio Test.

30) $\sum_{n=1}^{\infty}\frac{2^{n^2}}{n^n n!}$

**In exercises 31, use the root and limit Comparison Tests to determine whether $\sum_{n=1}^{\infty}a_n$ converges.**

31) $\sum_{n=1}^{\infty}\frac{1}{x_n^n}$ where $x_{n+1}=\frac{1}{2}x_n+\frac{1}{x_n}, x_1=1$ (Hint: Find limit of $x_n$.)

**Answer**

Converges by the Root Test and Limit Comparison Test since $\lim_{n\to\infty}x_n=\sqrt{2}$.

**In exercises 32 - 43, use an appropriate test to determine whether the series converges.**

32) $\sum_{n=1}^{\infty}\frac{n+1}{n^3+n^2+n+1}$

33) $\sum_{n=1}^{\infty}\frac{(-1)^{n+1}(n+1)}{n^3+3n^2+3n+1}$

**Answer**

Converges absolutely by limit comparison with **$p$–series, $p=2$.**

34) $\sum_{n=1}^{\infty}\frac{(n+1)^2}{n^3+(1.1)^n}$

35) $\sum_{n=1}^{\infty}\frac{(n-1)^n}{(n+1)^n}$

**Answer**

$\lim_{n\to\infty}a_n=1/e^2\neq 0$. Series diverges by the Divergence Test.

36) $a_n=\left(1+\frac{1}{n^2}\right)^n$ (Hint: $\left(1+\frac{1}{n^2}\right)^{n^2}\approx e$.)

37) $a_k=1/2^{\sin^2 k}$

**Answer**

Terms do not tend to zero: $a_k \geq 1/2$, since $\sin^2 x \leq 1$.

38) $a_k = 2^{-\sin(1/k)}$

39) $a_n = 1/\binom{n+2}{n}$ where $\binom{n}{k} = \frac{n!}{k!(n-k)!}$

**Answer**

$a_n = \dfrac{2}{(n+1)(n+2)}$, which converges by comparison with $p$**−series** for $p = 2$.

40) $a_k = 1/\binom{2k}{k}$

41) $a_k = 2^k/\binom{3k}{k}$

**Answer**

$a_k = \dfrac{2^k 1 \cdot 2 \cdots k}{(2k+1)(2k+2)\cdots 3k} \leq (2/3)^k$ converges by comparison with geometric series.

42) $a_k = \left(\dfrac{k}{k+\ln k}\right)^k$ $\left(\text{Hint: } a_k = \left(1+\dfrac{\ln k}{k}\right)^{-(k/\ln k)\ln k} \approx e^{-\ln k}.\right)$

43) $a_k = \left(\dfrac{k}{k+\ln k}\right)^{2k}$ $\left(\text{Hint: } a_k = \left(1+\dfrac{\ln k}{k}\right)^{-(k/\ln k)\ln k^2}.\right)$

**Answer**

$a_k \approx e^{-\ln k^2} = 1/k^2$. Series converges by limit comparison with $p$**−series**, $p = 2$.

**The series in exercises 44 - 47 converge by the Ratio Test. Use summation by parts,** $\sum_{k=1}^{n} a_k(b_{k+1} - b_k) = [a_{n+1}b_{n+1} - a_1 b_1] - \sum_{k=1}^{n} b_{k+1}(a_{k+1} - a_k)$**, to find the sum of the given series.**

44) $\sum_{k=1}^{\infty} \dfrac{k}{2^k}$ (Hint: Take $a_k = k$ and $b_k = 2^{1-k}$.)

45) $\sum_{k=1}^{\infty} \dfrac{k}{c^k}$, where $c > 1$ (Hint: Take $a_k = k$ and $b_k = c^{1-k}/(c-1)$.)

**Answer**

If $b_k = c^{1-k}/(c-1)$ and $a_k = k$, then $b_{k+1} - b_k = -c^{-k}$ and $\sum_{n=1}^{\infty} \dfrac{k}{c^k} = a_1 b_1 + \dfrac{1}{c-1}\sum_{k=1}^{\infty} c^{-k} = \dfrac{c}{(c-1)^2}$.

46) $\sum_{n=1}^{\infty} \dfrac{n^2}{2^n}$

47) $\sum_{n=1}^{\infty} \dfrac{(n+1)^2}{2^n}$

**Answer**

$6 + 4 + 1 = 11$

**The** $k^{\text{th}}$ **term of each of the following series has a factor** $x^k$**. Find the range of** $x$ **for which the Ratio Test implies that the series converges.**

48) $\sum_{k=1}^{\infty} \dfrac{x^k}{k^2}$

49) $\sum_{k=1}^{\infty} \dfrac{x^{2k}}{k^2}$

**Answer**

$|x| \leq 1$

50) $\sum_{k=1}^{\infty} \frac{x^{2k}}{3^k}$

51) $\sum_{k=1}^{\infty} \frac{x^k}{k!}$

**Answer**

$|x| < \infty$

52) Does there exist a number $p$ such that $\sum_{n=1}^{\infty} \frac{2^n}{n^p}$ converges?

53) Let $0 < r < 1$. For which real numbers $p$ does $\sum_{n=1}^{\infty} n^p r^n$ converge?

**Answer**

All real numbers $p$ by the Ratio Test.

54) Suppose that $\lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = p$. For which values of $p$ must $\sum_{n=1}^{\infty} 2^n a_n$ converge?

55) Suppose that $\lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = p$. For which values of $r > 0$ is $\sum_{n=1}^{\infty} r^n a_n$ guaranteed to converge?

**Answer**

$r < 1/p$

56) Suppose that $\left|\frac{a_{n+1}}{a_n}\right| \le (n+1)^p$ for all $n = 1, 2, \ldots$ where $p$ is a fixed real number. For which values of $p$ is $\sum_{n=1}^{\infty} n! a_n$ guaranteed to converge?

57) For which values of $r > 0$, if any, does $\sum_{n=1}^{\infty} r^{\sqrt{n}}$ converge? $\left(\text{Hint: } sum_{n=1}^{\infty} a_n = \sum_{k=1}^{\infty} \sum_{n=k^2}^{(k+1)^2-1} a_n.\right)$

**Answer**

$0 < r < 1$. Note that the ratio and Root Tests are inconclusive. Using the hint, there are $2k$ terms $r^{\sqrt{n}}$ for $k^2 \le n < (k+1)^2$, and for $r < 1$ each term is at least $r^k$. Thus, $\sum_{n=1}^{\infty} r^{\sqrt{n}} = \sum_{k=1}^{\infty} \sum_{n=k^2}^{(k+1)^2-1} r^{\sqrt{n}} \ge \sum_{k=1}^{\infty} 2k r^k$, which converges by the Ratio Test for $r < 1$. For $r \ge 1$ the series diverges by the Divergence Test.

58) Suppose that $\left|\frac{a_{n+2}}{a_n}\right| \le r < 1$ for all $n$. Can you conclude that $\sum_{n=1}^{\infty} a_n$ converges?

59) Let $a_n = 2^{-[n/2]}$ where $[x]$ is the greatest integer less than or equal to $x$. Determine whether $\sum_{n=1}^{\infty} a_n$ converges and justify your answer.

**Answer**

One has $a_1 = 1, a_2 = a_3 = 1/2, \ldots a_{2n} = a_{2n+1} = 1/2^n$. The Ratio Test does not apply because $a_{n+1}/a_n = 1$ if $n$ is even. However, $a_{n+2}/a_n = 1/2$, so the series converges according to the previous exercise. Of course, the series is just a duplicated geometric series.

**The following *advanced exercises* use a generalized Ratio Test to determine convergence of some series that arise in particular applications when tests in this chapter, including the ratio and Root Test, are not powerful enough to determine their convergence. The test states that if $\lim_{n\to\infty} \frac{a_{2n}}{a_n} < 1/2$, then $\sum a_n$ converges, while if $\lim_{n\to\infty} \frac{a_{2n+1}}{a_n} > 1/2$, then $\sum a_n$ diverges.**

60) Let $a_n = \frac{1}{4}\frac{3}{6}\frac{5}{8}\cdots\frac{2n-1}{2n+2} = \frac{1\cdot 3\cdot 5\cdots(2n-1)}{2^n(n+1)!}$. Explain why the Ratio Test cannot determine convergence of $\sum_{n=1}^{\infty} a_n$. Use the fact that $1-1/(4k)$ is increasing $k$ to estimate $\lim_{n\to\infty}\frac{a_{2n}}{a_n}$.

61) Let $a_n = \frac{1}{1+x}\frac{2}{2+x}\cdots\frac{n}{n+x}\frac{1}{n} = \frac{(n-1)!}{(1+x)(2+x)\cdots(n+x).}$ Show that $a_{2n}/a_n \le e^{-x/2}/2$. For which $x>0$ does the generalized Ratio Test imply convergence of $\sum_{n=1}^{\infty} a_n$? (Hint: Write $2a_{2n}/a_n$ as a product of $n$ factors each smaller than $1/(1+x/(2n))$.)

**Answer**

$a_{2n}/a_n = \frac{1}{2}\cdot\frac{n+1}{n+1+x}\frac{n+2}{n+2+x}\cdots\frac{2n}{2n+x}$. The inverse of the $kth$ factor is $(n+k+x)/(n+k) > 1+x/(2n)$ so the product is less than $(1+x/(2n))^{-n} \approx e^{-x/2}$. Thus for $x>0, \frac{a_{2n}}{a_n} \le \frac{1}{2}e^{-x/2}$. The series converges for $x>0$.

62) Let $a_n = \frac{n^{\ln n}}{(\ln n)^n}$. Show that $\frac{a_{2n}}{a_n} \to 0$ as $n\to\infty$.

# 8.8: Chapter 3 Review Exercises

**In exercises 1 - 2, evaluate the integrals, if possible.**

1) $\int_1^\infty \frac{1}{x^n}\,dx$, for what values of $n$ does this integral converge or diverge?

2) $\int_1^\infty \frac{e^{-x}}{x}\,dx$

**Answer**

approximately 0.2194

**In exercises 3 - 4, consider the gamma function given by $\gamma(a) = \int_0^\infty e^{-y}y^{a-1}\,dy$.**

3) Show that $\gamma(a) = (a-1)\gamma(a-1)$.

4) Extend to show that $\gamma(a) = (a-1)!$, assuming $a$ is a positive integer.

***True or False?* Justify your answer with a proof or a counterexample.**

5) If $\lim_{n\to\infty} a_n = 0$, then $\sum_{n=1}^{\infty} a_n$ converges.

**Answer**

false

6) If $\lim_{n\to\infty} a_n \neq 0$, then $\sum_{n=1}^{\infty} a_n$ diverges.

7) If $\sum_{n=1}^{\infty} |a_n|$ converges, then $\sum_{n=1}^{\infty} a_n$ converges.

**Answer**

true

8) If $\sum_{n=1}^{\infty} 2^n a_n$ converges, then $\sum_{n=1}^{\infty} (-2)^n a_n$ converges.

**Is the sequence bounded, monotone, and convergent or divergent? If it is convergent, find the limit.**

9) $a_n = \frac{3+n^2}{1-n}$

**Answer**

unbounded, not monotone, divergent

10) $a_n = \ln\left(\frac{1}{n}\right)$

11) $a_n = \frac{\ln(n+1)}{\sqrt{n+1}}$

**Answer**

bounded, monotone, convergent, **0**

12) $a_n = \frac{2^{n+1}}{5^n}$

13) $a_n = \frac{\ln(\cos n)}{n}$

**Answer**

unbounded, not monotone, divergent

**Is the series convergent or divergent?**

14) $\sum_{n=1}^{\infty} \frac{1}{n^2+5n+4}$

15) $\sum_{n=1}^{\infty} \ln\left(\frac{n+1}{n}\right)$

**Answer**

diverges

16) $\sum_{n=1}^{\infty} \frac{2^n}{n^4}$

17) $\sum_{n=1}^{\infty} \frac{e^n}{n!}$

**Answer**

converges

18) $\sum_{n=1}^{\infty} n^{-(n+1/n)}$

**Is the series convergent or divergent? If convergent, is it absolutely convergent?**

19) $\sum_{n=1}^{\infty} \frac{(-1)^n}{\sqrt{n}}$

**Answer**

converges, but not absolutely

20) $\sum_{n=1}^{\infty} \frac{(-1)^n n!}{3^n}$

21) $\sum_{n=1}^{\infty} \frac{(-1)^n n!}{n^n}$

**Answer**

converges absolutely

22) $\sum_{n=1}^{\infty} \sin\left(\frac{n\pi}{2}\right)$

23) $\sum_{n=1}^{\infty} \cos(\pi n) e^{-n}$

**Answer**

converges absolutely

**Evaluate.**

24) $\sum_{n=1}^{\infty} \frac{2^{n+4}}{7^n}$

25) $\sum_{n=1}^{\infty} \frac{1}{(n+1)(n+2)}$

**Answer**

$\frac{1}{2}$

26) A legend from India tells that a mathematician invented chess for a king. The king enjoyed the game so much he allowed the mathematician to demand any payment. The mathematician asked for one grain of rice for the first square on the chessboard, two

grains of rice for the second square on the chessboard, and so on. Find an exact expression for the total payment (in grains of rice) requested by the mathematician. Assuming there are $30,000$ grains of rice in $1$ pound, and $2000$ pounds in $1$ ton, how many tons of rice did the mathematician attempt to receive?

The following problems consider a simple population model of the housefly, which can be exhibited by the recursive formula $x_{n+1} = bx_n$, where $x_n$ is the population of houseflies at generation $n$, and $b$ is the average number of offspring per housefly who survive to the next generation. Assume a starting population $x_0$.

27) Find $\lim_{n\to\infty} x_n$ if $b > 1,\ b < 1$, and $b = 1$.

**Answer**

$\infty,\ 0,\ x_0$

28) Find an expression for $S_n = \sum_{i=0}^{n} x_i$ in terms of $b$ and $x_0$. What does it physically represent?

29) If $b = \frac{3}{4}$ and $x_0 = 100$, find $S_{10}$ and $\lim_{n\to\infty} S_n$

**Answer**

$S_{10} \approx 383, \quad \lim_{n\to\infty} S_n = 400$

30) For what values of $b$ will the series converge and diverge? What does the series converge to?

# CHAPTER OVERVIEW

## 9: Power Series

A power series (in one variable) is an infinite series. Any polynomial can be easily expressed as a power series around any center c, although most of the coefficients will be zero since a power series has infinitely many terms by definition. One can view power series as being like "polynomials of infinite degree," although power series are not polynomials. The content in this Textmap's chapter is complemented by Guichard's Calculus Textmap.

# 9.1: Power Series and Functions

**Learning Objectives**

- Identify a power series and provide examples of them.
- Determine the radius of convergence and interval of convergence of a power series.
- Use a power series to represent a function.

A power series is a series with terms involving a variable. More specifically, if the variable is $x$, then all the terms of the series involve powers of $x$. As a result, a power series can be thought of as an infinite polynomial. Power series are used to represent common functions and also to define new functions. In this section, we define power series and show how to determine when a power series converges and when it diverges. We also show how to represent certain functions using power series.

## Form of a Power Series

**Definition: Power Series**

A series of the form

$$\sum_{n=0}^{\infty} c_n x^n = c_0 + c_1 x + c_2 x^2 + \cdots$$

is called a **power series centered at $x = 0$**. A series of the form

$$\sum_{n=0}^{\infty} c_n (x-a)^n = c_0 + c_1 (x-a) + c_2 (x-a)^2 + \cdots$$

is a **power series centered at $x = a$**.

To make this definition precise, we stipulate that $x^0 = 1$ and $(x-a)^0 = 1$ even when $x = 0$ and $x = a$, respectively.[1]

The series

$$1 + x + x^2 + \cdots = \sum_{n=0}^{\infty} x^n,$$

$$\sum_{n=0}^{\infty} \frac{x^n}{n!} = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \cdots,$$

and

$$\sum_{n=0}^{\infty} n! x^n = 1 + x + 2! x^2 + 3! x^3 + \cdots$$

are all examples of power series centered at $x = 0$. The first of these is a geometric series with common ratio $r = |x|$, and we know that it converges if $|x| < 1$ and diverges if $|x| \geq 1$.

The series

$$\sum_{n=0}^{\infty} \frac{(x-2)^n}{(n+1)3^n} = 1 + \frac{x-2}{2 \cdot 3} + \frac{(x-2)^2}{3 \cdot 3^2} + \frac{(x-2)^3}{4 \cdot 3^3} + \cdots$$

is a power series centered at $x = 2$.

## Convergence of a Power Series

Since the terms in a power series involve a variable $x$, the series may converge for certain values of $x$ and diverge for other values of $x$. For a power series centered at $x = a$, the value of the series at $x = a$ is given by $c_0$. Therefore, *a power series always converges at its center*. Some power series converge only at that value of $x$. Most power series, however, converge for more than one value of

$x$. In that case, the power series either converges for all real numbers $x$ or converges for all $x$ in a finite interval. For example, the geometric series $\sum_{n=0}^{\infty} x^n$ converges for all $x$ in the interval $(-1, 1)$, but diverges for all $x$ outside that interval. We now summarize these three possibilities for a general power series.

### Theorem: Convergence of a Power Series

The power series $\sum_{n=0}^{\infty} c_n(x-a)^n$ satisfies exactly one of the following properties:

i. The series converges at $x = a$ and diverges for all $x \neq a$.
ii. The series converges for all real numbers $x$.
iii. There exists a real number $R > 0$ such that the series converges if $|x-a| < R$ and diverges if $|x-a| > R$. At the values $x$ where $|x-a| = R$, the series could converge or diverge.

**Proof**

Suppose that the power series is centered at $a = 0$.[2] We must first prove the following fact:

If there exists a real number $d \neq 0$ such that $\sum_{n=0}^{\infty} c_n d^n$ converges, then the series $\sum_{n=0}^{\infty} c_n x^n$ converges absolutely for all $x$ such that $|x| < |d|$.

Suppose, then, that $\sum_{n=0}^{\infty} c_n d^n$ converges. Then the $n^{\text{th}}$ term $c_n d^n \to 0$ as $n \to \infty$. Therefore, there exists an integer $N$ such that $|c_n d^n| \leq 1$ for all $n \geq N$. Writing

$$|c_n x^n| = |c_n d^n| \left|\frac{x}{d}\right|^n,$$

we conclude that, for all $n \geq N$,

$$|c_n x^n| \leq \left|\frac{x}{d}\right|^n.$$

The series

$$\sum_{n=N}^{\infty} \left|\frac{x}{d}\right|^n$$

is a geometric series that converges if $\left|\frac{x}{d}\right| < 1$. Therefore, by the Series Comparison Test, we conclude that $\sum_{n=N}^{\infty} c_n x^n$ also converges for $|x| < |d|$. Since we can add a finite number of terms to a convergent series, we conclude that $\sum_{n=0}^{\infty} c_n x^n$ converges for $|x| < |d|$.

With this result, we can now prove the theorem. Consider the series

$$\sum_{n=0}^{\infty} a_n x^n$$

and let $S$ be the set of real numbers for which the series converges. Suppose that the set contains only the center. That is, $S = \{0\}$. Then the series falls under case i.

Suppose that the set $S$ is the set of all real numbers. Then the series falls under case ii.

Suppose that $S \neq 0$ and $S$ is not the set of real numbers. Then there exists a real number $x^* \neq 0$ such that the series does not converge. Thus, the series cannot converge for any $x$ such that $|x| > |x^*|$. Therefore, the set $S$ must be a bounded set, meaning it must have a smallest upper bound.[3] Call that smallest upper bound $R$. Since $S \neq \{0\}$, the number $R > 0$. Therefore, the series converges for all $x$ such that $|x| < R$, and the series falls into case iii.

If a series $\sum_{n=0}^{\infty} c_n(x-a)^n$ falls into case iii., then the series converges for all $x$ such that $|x-a| < R$ for some $R > 0$, and diverges for all $x$ such that $|x-a| > R$. The series may converge or diverge at the values $x$ where $|x-a| = R$. The set of values $x$ for which the series $\sum_{n=0}^{\infty} c_n(x-a)^n$ converges is known as the **interval of convergence**. Since the series diverges for all values $x$ where $|x-a| > R$, the length of the interval of convergence is $2R$, and therefore, the radius of the interval is $R$. The value $R$ is called the **radius of convergence**.

For example, since the series $\sum_{n=0}^{\infty} x^n$ converges for all values $x$ in the interval $(-1,1)$ and diverges for all values $x$ such that $|x| \geq 1$, the interval of convergence of this series is $(-1,1)$. Since the length of the interval is $2$, the radius of convergence is $1$.

We formalize these statements in the following definition.

### Definition: Radius of Convergence

Consider the power series $\sum_{n=0}^{\infty} c_n(x-a)^n$. The set of real numbers $x$ where the series converges is called the **interval of convergence**. If there exists a real number $R > 0$ such that the series converges for $|x-a| < R$ and diverges for $|x-a| > R$, then $R$ is called the **radius of convergence**. If the series converges only at $x = a$, we say the radius of convergence is $R = 0$. If the series converges for all real numbers $x$, we say the radius of convergence is $R = \infty$ (see Figure 9.1.1).

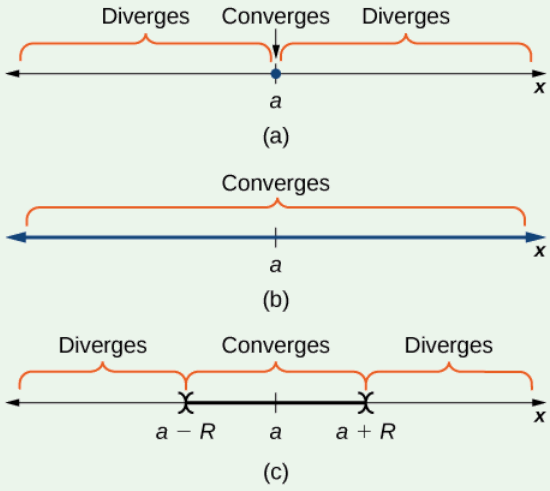

Figure 9.1.1: For a series $\sum_{n=0}^{\infty} c_n(x-a)^n$

Figure 9.1.1A: A radius of convergence of $R = 0$

Figure 9.1.1B: A radius of convergence of $R = \infty$

Figure 9.1.1C: A radius of convergence of $R$, where the series may or may not converge at the endpoints $x = a + R$ and $x = a - R$.

To determine the interval of convergence for a power series, we typically apply the Ratio Test. In Example 9.1.1, we show the three different possibilities illustrated in Figure 9.1.1.

### Example 9.1.1: Finding the Interval and Radius of Convergence

For each of the following series, find the interval and radius of convergence.

a. $\sum_{n=0}^{\infty} \frac{x^n}{n!}$

b. $\sum_{n=0}^{\infty} n! x^n$

c. $\sum_{n=0}^{\infty} \frac{(x-2)^n}{(n+1)3^n}$

**Solutions**

a. To check for convergence, apply the Ratio Test. We have

$$\begin{aligned}\rho &= \lim_{n\to\infty}\left|\frac{\frac{x^{n+1}}{(n+1)!}}{\frac{x^n}{n!}}\right| \\ &= \lim_{n\to\infty}\left|\frac{x^{n+1}}{(n+1)!}\cdot\frac{n!}{x^n}\right| \\ &= \lim_{n\to\infty}\left|\frac{x^{n+1}}{(n+1)\cdot n!}\cdot\frac{n!}{x^n}\right| \\ &= \lim_{n\to\infty}\left|\frac{x}{n+1}\right| \\ &= |x|\lim_{n\to\infty}\frac{1}{n+1} \\ &= 0 \\ &< 1\end{aligned}$$

for all values of $x$. Therefore, the series converges for all real numbers $x$. The interval of convergence is $(-\infty,\infty)$ and the radius of convergence is $R=\infty$.

b. Apply the Ratio Test. For $x\neq 0$, we see that

$$\begin{aligned}\rho &= \lim_{n\to\infty}\left|\frac{(n+1)!x^{n+1}}{n!x^n}\right| \\ &= \lim_{n\to\infty}|(n+1)x| \\ &= |x|\lim_{n\to\infty}(n+1) \\ &= \infty.\end{aligned}$$

Therefore, the series diverges for all $x\neq 0$. Since the series is centered at $x=0$, it must converge there, so it converges only for $x=0$. The interval of convergence is the single value $x=0$ and the radius of convergence is $R=0$.

c. In order to apply the Ratio Test, consider

$$\begin{aligned}\rho &= \lim_{n\to\infty}\left|\frac{\frac{(x-2)^{n+1}}{(n+2)3^{n+1}}}{\frac{(x-2)^n}{(n+1)3^n}}\right| \\ &= \lim_{n\to\infty}\left|\frac{(x-2)^{n+1}}{(n+2)3^{n+1}}\cdot\frac{(n+1)3^n}{(x-2)^n}\right| \\ &= \lim_{n\to\infty}\left|\frac{(x-2)(n+1)}{3(n+2)}\right| \\ &= \frac{|x-2|}{3}.\end{aligned}$$

The ratio $\rho<1$ if $|x-2|<3$. Since $|x-2|<3$ implies that $-3<x-2<3$, the series converges absolutely if $-1<x<5$. The ratio $\rho>1$ if $|x-2|>3$. Therefore, the series diverges if $x<-1$ or $x>5$. The Ratio Test is inconclusive if $\rho=1$. The ratio $\rho=1$ if and only if $x=-1$ or $x=5$. We need to test these values of $x$ separately. For $x=-1$, the series is given by

$$\sum_{n=0}^{\infty}\frac{(-1)^n}{n+1}=1-\frac{1}{2}+\frac{1}{3}-\frac{1}{4}+\cdots.$$

Since this is the Alternating Harmonic Series, it converges. Thus, the series converges at $x=-1$. For $x=5$, the series is given by

$$\sum_{n=0}^{\infty} \frac{1}{n+1} = 1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \ldots.$$

This is the Harmonic Series, which is divergent. Therefore, the power series diverges at $x = 5$. We conclude that the interval of convergence is $[-1, 5)$ and the radius of convergence is $R = 3$.

**? Checkpoint 9.1.1**

Find the interval and radius of convergence for the series

$$\sum_{n=1}^{\infty} \frac{x^n}{\sqrt{n}}.$$

**Answer**

The interval of convergence is $[-1, 1)$. The radius of convergence is $R = 1$.

## Representing Functions as Power Series

Being able to represent a function by an "infinite polynomial" is a powerful tool. Polynomial functions are the most manageable functions to analyze since they only involve the basic arithmetic operations of addition, subtraction, multiplication, and division. If we can represent a complicated function by an infinite polynomial, we can use the polynomial representation to differentiate or integrate it. In addition, we can use a truncated version of the polynomial expression to approximate values of the function. So, the question is:

*When can we represent a function by a power series?*

Consider again the geometric series

$$1 + x + x^2 + x^3 + \cdots = \sum_{n=0}^{\infty} x^n. \tag{9.1.1}$$

Recall that the geometric series

$$a + ar + ar^2 + ar^3 + \cdots$$

converges if and only if $|r| < 1$. In that case, it converges to $\frac{a}{1-r}$. Therefore, if $|x| < 1$, the series in Equation 9.1.1 converges to $\frac{1}{1-x}$ and we write

$$1 + x + x^2 + x^3 + \cdots = \frac{1}{1-x} \text{ for } |x| < 1.$$

As a result, we can represent the function $f(x) = \frac{1}{1-x}$ by the power series

$$1 + x + x^2 + x^3 + \cdots \text{ when } |x| < 1.$$

We now show graphically how this series provides a representation for the function $f(x) = \frac{1}{1-x}$ by comparing the graph of $f$ with the graphs of several of the partial sums of this infinite series.

**✓ Example 9.1.2: Graphing a Function and Partial Sums of its Power Series**

Sketch a graph of $f(x) = \frac{1}{1-x}$ and the graphs of the corresponding partial sums $S_N(x) = \sum_{n=0}^{N} x^n$ for $N = 2, 4, 6$ on the interval $(-1, 1)$. Comment on the approximation $S_N$ as $N$ increases.

**Solution**

From the graph in Figure 9.1.2, you see that as $N$ increases, $S_N$ becomes a better approximation for $f(x) = \frac{1}{1-x}$ for $x$ in the interval $(-1, 1)$.

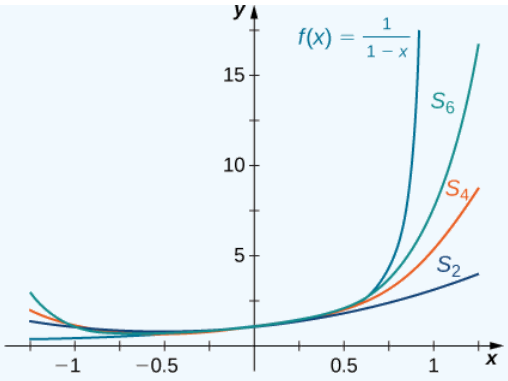

Figure **9.1.2**: The graph shows a function and three approximations by partial sums of a power series.

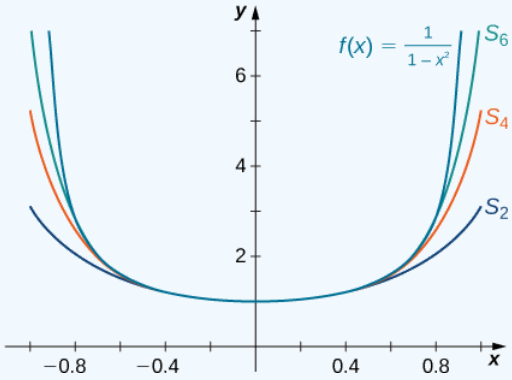
## ? Checkpoint 9.1.2

Sketch a graph of $f(x) = \frac{1}{1-x^2}$ and the corresponding partial sums $S_N(x) = \sum_{n=0}^{N} x^{2n}$ for $N = 2, 4, 6$ on the interval $(-1, 1)$.

**Answer**



Next, we consider functions involving an expression similar to the sum of a geometric series and show how to represent these functions using power series.

## ✓ Example 9.1.3: Representing a Function with a Power Series

Use a power series to represent each of the following functions $f$. Find the interval of convergence.

a. $f(x) = \frac{1}{1+x^3}$
b. $f(x) = \frac{x^2}{4-x^2}$

**Solutions**

a. You should recognize this function $f$ as the sum of a geometric series, because

$$\frac{1}{1+x^3} = \frac{1}{1-(-x^3)}.$$

Using the fact that, for $|r| < 1$, $\frac{a}{1-r}$ is the sum of the geometric series

$$\sum_{n=0}^{\infty} ar^n = a + ar + ar^2 + \cdots,$$

we see that, for $|-x^3| < 1$,

$$\begin{aligned}\frac{1}{1+x^3} &= \frac{1}{1-(-x^3)}\\ &= \sum_{n=0}^{\infty}(-x^3)^n\\ &= 1-x^3+x^6-x^9+\cdots.\end{aligned}$$

Since this series converges if and only if $|-x^3|<1$, the interval of convergence is $(-1,1)$, and we have

$$\frac{1}{1+x^3}=1-x^3+x^6-x^9+\cdots \text{ for } |x|<1.$$

b. This function is not in the exact form of a sum of a geometric series. However, we can relate $f$ to a geometric series with a little algebraic manipulation. By factoring $4$ out of the two terms in the denominator, we obtain

$$\begin{aligned}\frac{x^2}{4-x^2} &= \frac{x^2}{4(\frac{1-x^2}{4})}\\ &= \frac{x^2}{4(1-(\frac{x}{2})^2)}.\end{aligned}$$

Therefore, we have

$$\begin{aligned}\frac{x^2}{4-x^2} &= \frac{x^2}{4(1-(\frac{x}{2})^2)}\\ &= \frac{\frac{x^2}{4}}{1-(\frac{x}{2})^2}\\ &= \sum_{n=0}^{\infty}\frac{x^2}{4}\left(\frac{x}{2}\right)^{2n}.\end{aligned}$$

The series converges as long as $|(\frac{x}{2})^2|<1$ (note that when $|(\frac{x}{2})^2|=1$ the series does not converge). Solving this inequality, we conclude that the interval of convergence is $(-2,2)$ and

$$\begin{aligned}\frac{x^2}{4-x^2} &= \sum_{n=0}^{\infty}\frac{x^{2n+2}}{4^{n+1}}\\ &= \frac{x^2}{4}+\frac{x^4}{4^2}+\frac{x^6}{4^3}+\cdots\end{aligned}$$

for $|x|<2$.

**? Checkpoint 9.1.3**

Represent the function $f(x)=\frac{x^3}{2-x}$ using a power series and find the interval of convergence.

**Answer**

$\sum_{n=0}^{\infty}\frac{x^{n+3}}{2^{n+1}}$ with interval of convergence $(-2,2)$

In the remaining sections of this chapter, we will show ways of deriving power series representations for many other functions. We also show how we can use these representations to evaluate, differentiate, and integrate various functions.

## Footnotes

[1] It is *incredibly* important to understand that $0^0$ is still considered indeterminate for all other purposes within Mathematics. Defining $x^0=1$ even when $x=0$ is a useful but unique convention for power series.

[2] For a series centered at a value of $a$ other than zero, the result follows by letting $y=x-a$ and considering the series

$$\sum_{n=0}^{\infty} c_n y^n.$$

[3] This fact follows from the **Least Upper Bound Property** for the real numbers, which is beyond the scope of this text and is covered in real analysis courses.

## Key Concepts

- For a power series centered at $x = a$, one of the following three properties hold:
  - i. The power series converges only at $x = a$. In this case, we say that the radius of convergence is $R = 0$.
  - ii. The power series converges for all real numbers $x$. In this case, we say that the radius of convergence is $R = \infty$.
  - iii. There is a real number R such that the series converges for $|x - a| < R$ and diverges for $|x - a| > R$. In this case, the radius of convergence is $R$.
- If a power series converges on a finite interval, the series may or may not converge at the endpoints.
- The Ratio Test may often be used to determine the radius of convergence.
- The geometric series $\sum_{n=0}^{\infty} x^n = \frac{1}{1-x}$ for $|x| < 1$ allows us to represent certain functions using geometric series.

## Key Equations

- **Power series centered at $x = 0$**

$$\sum_{n=0}^{\infty} c_n x^n = c_0 + c_1 x + c_2 x^2 + \ldots n$$

- **Power series centered at $x = a$**

$$\sum_{n=0}^{\infty} c_n (x-a)^n = c_0 + c_1 (x-a) + c_2 (x-a)^2 + \ldots$$

## Glossary

**interval of convergence**

the set of real numbers $x$ for which a power series converges

**power series**

a series of the form $\sum_{n=0}^{\infty} c_n x^n$ is a power series centered at $x = 0$; a series of the form $\sum_{n=0}^{\infty} c_n (x-a)^n$ is a power series centered at $x = a$

**radius of convergence**

if there exists a real number $R > 0$ such that a power series centered at $x = a$ converges for $|x - a| < R$ and diverges for $|x - a| > R$, then $R$ is the radius of convergence; if the power series only converges at $x = a$, the radius of convergence is $R = 0$; if the power series converges for all real numbers $x$, the radius of convergence is $R = \infty$

# 9.1E: Exercises

**In exercises 1 - 4, state whether each statement is true, or give an example to show that it is false.**

1) If $\sum_{n=1}^{\infty} a_n x^n$ converges, then $a_n x^n \to 0$ as $n \to \infty$.

**Answer**

True. If a series converges then its terms tend to zero.

2) $\sum_{n=1}^{\infty} a_n x^n$ converges at $x = 0$ for any real numbers $a_n$.

3) Given any sequence $a_n$, there is always some $R > 0$, possibly very small, such that $\sum_{n=1}^{\infty} a_n x^n$ converges on $(-R, R)$.

**Answer**

False. It would imply that $a_n x^n \to 0$ for $|x| < R$. If $a_n = n^n$, then $a_n x^n = (nx)^n$ does not tend to zero for any $x \neq 0$.

4) If $\sum_{n=1}^{\infty} a_n x^n$ has radius of convergence $R > 0$ and if $|b_n| \leq |a_n|$ for all $n$, then the radius of convergence of $\sum_{n=1}^{\infty} b_n x^n$ is greater than or equal to $R$.

5) Suppose that $\sum_{n=0}^{\infty} a_n (x-3)^n$ converges at $x = 6$. At which of the following points must the series also converge? Use the fact that if $\sum a_n (x-c)^n$ converges at $x$, then it converges at any point closer to $c$ than $x$.

a. $x = 1$

b. $x = 2$

c. $x = 3$

d. $x = 0$

e. $x = 5.99$

f. $x = 0.000001$

**Answer**

It must converge on $(0, 6]$ and hence at: a. $x = 1$; b. $x = 2$; c. $x = 3$; d. $x = 0$; e. $x = 5.99$; and f. $x = 0.000001$.

6) Suppose that $\sum_{n=0}^{\infty} a_n (x+1)^n$ converges at $x = -2$. At which of the following points must the series also converge? Use the fact that if $\sum a_n (x-c)^n$ converges at $x$, then it converges at any point closer to $c$ than $x$.

a. $x = 2$

b. $x = -1$

c. $x = -3$

d. $x = 0$

e. $x = 0.99$

f. $x = 0.000001$

**In the following exercises, suppose that $\left|\frac{a_{n+1}}{a_n}\right| \to 1$ as $n \to \infty$. Find the radius of convergence for each series.**

7) $\sum_{n=0}^{\infty} a_n 2^n x^n$

**Answer**

$$\left|\frac{a_{n+1}2^{n+1}x^{n+1}}{a_n 2^n x^n}\right| = 2|x|\left|\frac{a_{n+1}}{a_n}\right| \to 2|x| \text{ so } R = \tfrac{1}{2}$$

8) $\sum_{n=0}^{\infty} \frac{a_n x^n}{2^n}$

9) $\sum_{n=0}^{\infty} \frac{a_n \pi^n x^n}{e^n}$

**Answer**

$$\left|\frac{a_{n+1}(\frac{\pi}{e})^{n+1}x^{n+1}}{a_n(\frac{\pi}{e})^n x^n}\right| = \frac{\pi|x|}{e}\left|\frac{a_{n+1}}{a_n}\right| \to \frac{\pi|x|}{e} \text{ so } R = \tfrac{e}{\pi}$$

10) $\sum_{n=0}^{\infty} \frac{a_n(-1)^n x^n}{10^n}$

11) $\sum_{n=0}^{\infty} a_n(-1)^n x^{2n}$

**Answer**

$$\left|\frac{a_{n+1}(-1)^{n+1}x^{2n+2}}{a_n(-1)^n x^{2n}}\right| = |x^2|\left|\frac{a_{n+1}}{a_n}\right| \to |x^2| \text{ so } R = 1$$

12) $\sum_{n=0}^{\infty} a_n(-4)^n x^{2n}$

**In exercises 13 - 22, find the radius of convergence $R$ and interval of convergence for $\sum a_n x^n$ with the given coefficients $a_n$.**

13) $\sum_{n=1}^{\infty} \frac{(2x)^n}{n}$

**Answer**

$a_n = \frac{2^n}{n}$ so $\frac{a_{n+1}x}{a_n} \to 2x$. so $R = \frac{1}{2}$. When $x = \frac{1}{2}$ the series is harmonic and diverges. When $x = -\frac{1}{2}$ the series is alternating harmonic and converges. The interval of convergence is $I = \left[-\frac{1}{2}, \frac{1}{2}\right)$.

14) $\sum_{n=1}^{\infty} (-1)^n \frac{x^n}{\sqrt{n}}$

15) $\sum_{n=1}^{\infty} \frac{nx^n}{2^n}$

**Answer**

$a_n = \frac{n}{2^n}$ so $\frac{a_{n+1}x}{a_n} \to \frac{x}{2}$ so $R = 2$. When $x = \pm 2$ the series diverges by the Divergence Test. The interval of convergence is $I = (-2, 2)$.

16) $\sum_{n=1}^{\infty} \frac{nx^n}{e^n}$

17) $\sum_{n=1}^{\infty} \frac{n^2 x^n}{2^n}$

**Answer**

$a_n = \frac{n^2}{2^n}$ so $R = 2$. When $x = \pm 2$ the series diverges by the Divergence Test. The interval of convergence is $I = (-2, 2)$.

18) $\sum_{k=1}^{\infty} \frac{k^e x^k}{e^k}$

19) $\sum_{k=1}^{\infty} \frac{\pi^k x^k}{k^\pi}$

**Answer**

$a_k = \frac{\pi^k}{k^\pi}$ so $R = \frac{1}{\pi}$. When $x = \pm\frac{1}{\pi}$ the series is an absolutely convergent $p$-series. The interval of convergence is $I = \left[-\frac{1}{\pi}, \frac{1}{\pi}\right]$.

20) $\sum_{n=1}^{\infty} \frac{x^n}{n!}$

21) $\sum_{n=1}^{\infty} \frac{10^n x^n}{n!}$

**Answer**

$a_n = \frac{10^n}{n!}, \frac{a_{n+1}x}{a_n} = \frac{10x}{n+1} \to 0 < 1$ so the series converges for all $x$ by the Ratio Test and $I = (-\infty, \infty)$.

22) $\sum_{n=1}^{\infty} (-1)^n \frac{x^n}{\ln(2n)}$

**In exercises 23 - 28, find the radius of convergence of each series.**

23) $\sum_{k=1}^{\infty} \frac{(k!)^2 x^k}{(2k)!}$

**Answer**

$a_k = \frac{(k!)^2}{(2k)!}$ so $\frac{a_{k+1}}{a_k} = \frac{(k+1)^2}{(2k+2)(2k+1)} \to \frac{1}{4}$ so $R = 4$

24) $\sum_{n=1}^{\infty} \frac{(2n)! x^n}{n^{2n}}$

25) $\sum_{k=1}^{\infty} \frac{k!}{1 \cdot 3 \cdot 5 \cdots (2k-1)} x^k$

**Answer**

$a_k = \frac{k!}{1 \cdot 3 \cdot 5 \cdots (2k-1)}$ so $\frac{a_{k+1}}{a_k} = \frac{k+1}{2k+1} \to \frac{1}{2}$ so $R = 2$

26) $\sum_{k=1}^{\infty} \frac{2 \cdot 4 \cdot 6 \cdots 2k}{(2k)!} x^k$

27) $\sum_{n=1}^{\infty} \frac{x^n}{\binom{2n}{n}}$ where $\binom{n}{k} = \frac{n!}{k!(n-k)!}$

**Answer**

$a_n = \frac{1}{\binom{2n}{n}}$ so $\frac{a_{n+1}}{a_n} = \frac{\left((n+1)!\right)^2}{(2n+2)!} \frac{2n!}{(n!)^2} = \frac{(n+1)^2}{(2n+2)(2n+1)} \to \frac{1}{4}$ so $R = 4$

28) $\sum_{n=1}^{\infty} \sin^2 n x^n$

**In exercises 29 - 32, use the Ratio Test to determine the radius of convergence of each series.**

29) $\sum_{n=1}^{\infty} \frac{(n!)^3}{(3n)!} x^n$

**Answer**

$\frac{a_{n+1}}{a_n} = \frac{(n+1)^3}{(3n+3)(3n+2)(3n+1)} \to \frac{1}{27}$ so $R = 27$

30) $\sum_{n=1}^{\infty} \frac{2^{3n}(n!)^3}{(3n)!} x^n$

31) $\sum_{n=1}^{\infty} \frac{n!}{n^n} x^n$

**Answer**

$a_n = \frac{n!}{n^n}$ so $\frac{a_{n+1}}{a_n} = \frac{(n+1)!}{n!} \frac{n^n}{(n+1)^{n+1}} = (\frac{n}{n+1})^n \to \frac{1}{e}$ so $R = e$

32) $\sum_{n=1}^{\infty} \frac{(2n)!}{n^{2n}} x^n$

**In the following exercises, given that $\frac{1}{1-x} = \sum_{n=0}^{\infty} x^n$ with convergence in $(-1,1)$, find the power series for each function with the given center $a$, and identify its interval of convergence.**

33) $f(x) = \frac{1}{x}; a = 1$ (Hint: $\frac{1}{x} = \frac{1}{1-(1-x)}$)

**Answer**

$f(x) = \sum_{n=0}^{\infty} (1-x)^n$ on $I = (0,2)$

34) $f(x) = \frac{1}{1-x^2}; a = 0$

35) $f(x) = \frac{x}{1-x^2}; a = 0$

**Answer**

$\sum_{n=0}^{\infty} x^{2n+1}$ on $I = (-1,1)$

36) $f(x) = \frac{1}{1+x^2}; a = 0$

37) $f(x) = \frac{x^2}{1+x^2}; a = 0$

**Answer**

$\sum_{n=0}^{\infty} (-1)^n x^{2n+2}$ on $I = (-1,1)$

38) $f(x) = \frac{1}{2-x}; a = 1$

39) $f(x) = \frac{1}{1-2x}; a = 0.$

**Answer**

$\sum_{n=0}^{\infty} 2^n x^n$ on $(-\frac{1}{2}, \frac{1}{2})$

40) $f(x) = \frac{1}{1-4x^2}; a = 0$

41) $f(x) = \frac{x^2}{1-4x^2}; a = 0$

**Answer**

$\sum_{n=0}^{\infty} 4^n x^{2n+2}$ on $(-\frac{1}{2}, \frac{1}{2})$

42) $f(x) = \frac{x^2}{5-4x+x^2}; a = 2$

**Use the result of exercise 43 to find the radius of convergence of the given series in the subsequent exercises (44 - 47).**

43) Explain why, if $|a_n|^{1/n} \to r > 0$, then $|a_n x^n|^{1/n} \to |x| r < 1$ whenever $|x| < \frac{1}{r}$ and, therefore, the radius of convergence of $\sum_{n=1}^{\infty} a_n x^n$ is $R = \frac{1}{r}$.

**Answer**

$|a_n x^n|^{1/n} = |a_n|^{1/n}|x| \to |x| r$ as $n \to \infty$ and $|x| r < 1$ when $|x| < \frac{1}{r}$. Therefore, $\sum_{n=1}^{\infty} a_n x^n$ converges when $|x| < \frac{1}{r}$ by the $n^{\text{th}}$ Root Test.

44) $\sum_{n=1}^{\infty} \frac{x^n}{n^n}$

45) $\sum_{k=1}^{\infty} \left(\frac{k-1}{2k+3}\right)^k x^k$

**Answer**

$a_k = \left(\frac{k-1}{2k+3}\right)^k$ so $(a_k)^{1/k} \to \frac{1}{2} < 1$ so $R = 2$

46) $\sum_{k=1}^{\infty} (\frac{2k^2-1}{k^2+3})^k x^k$

47) $\sum_{n=1}^{\infty} a_n = (n^{1/n} - 1)^n x^n$

**Answer**

$a_n = (n^{1/n} - 1)^n$ so $(a_n)^{1/n} \to 0$ so $R = \infty$

48) Suppose that $p(x) = \sum_{n=0}^{\infty} a_n x^n$ such that $a_n = 0$ if $n$ is even. Explain why $p(x) = p(-x)$.

49) Suppose that $p(x) = \sum_{n=0}^{\infty} a_n x^n$ such that $a_n = 0$ if $n$ is odd. Explain why $p(x) = -p(-x)$.

**Answer**

We can rewrite $p(x) = \sum_{n=0}^{\infty} a_{2n+1} x^{2n+1}$ and $p(x) = p(-x)$ since $x^{2n+1} = -(-x)^{2n+1}$.

50) Suppose that $p(x) = \sum_{n=0}^{\infty} a_n x^n$ converges on $(-1, 1]$. Find the interval of convergence of $p(Ax)$.

51) Suppose that $p(x) = \sum_{n=0}^{\infty} a_n x^n$ converges on $(-1, 1]$. Find the interval of convergence of $p(2x - 1)$.

**Answer**

If $x \in [0, 1]$, then $y = 2x - 1 \in [-1, 1]$ so $p(2x - 1) = p(y) = \sum_{n=0}^{\infty} a_n y^n$ converges.

**In the following exercises, suppose that $p(x) = \sum_{n=0}^{\infty} a_n x^n$ satisfies $\lim_{n\to\infty} \frac{a_{n+1}}{a_n} = 1$ where $a_n \geq 0$ for each $n$. State whether each series converges on the full interval $(-1, 1)$, or if there is not enough information to draw a conclusion. Use the Comparison Test when appropriate.**

52) $\sum_{n=0}^{\infty} a_n x^{2n}$

53) $\sum_{n=0}^{\infty} a_{2n} x^{2n}$

**Answer**

Converges on $(-1, 1)$ by the Ratio Test

54) $\sum_{n=0}^{\infty} a_{2n}x^n$ (Hint:$x = \pm\sqrt{x^2}$)

55) $\sum_{n=0}^{\infty} a_{n^2}x^{n^2}$ (Hint: Let $b_k = a_k$ if $k = n^2$ for some $n$, otherwise $b_k = 0$.)

**Answer**

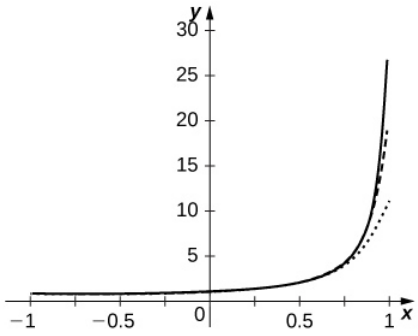
Consider the series $\sum b_k x^k$ where $b_k = a_k$ if $k = n^2$ and $b_k = 0$ otherwise. Then $b_k \le a_k$ and so the series converges on $(-1, 1)$ by the Comparison Test.

56) Suppose that $p(x)$ is a polynomial of degree $N$. Find the radius and interval of convergence of $\sum_{n=1}^{\infty} p(n)x^n$.

57) [Technology Required] Plot the graphs of $\frac{1}{1-x}$ and of the partial sums $S_N = \sum_{n=0}^{N} x^n$ for $n = 10, 20, 30$ on the interval $[-0.99, 0.99]$. Comment on the approximation of $\frac{1}{1-x}$ by $S_N$ near $x = -1$ and near $x = 1$ as $N$ increases.

**Answer**

The approximation is more accurate near $x = -1$. The partial sums follow $\frac{1}{1-x}$ more closely as $N$ increases but are never accurate near $x = 1$ since the series diverges there.

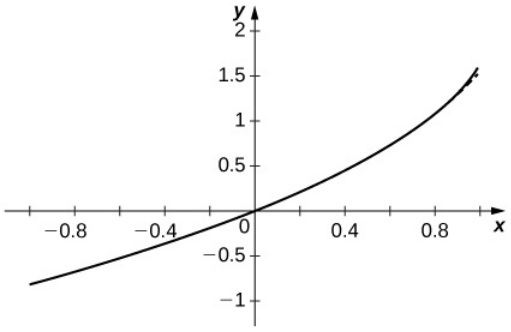


58) [Technology Required] Plot the graphs of $-\ln(1-x)$ and of the partial sums $S_N = \sum_{n=1}^{N} \frac{x^n}{n}$ for $n = 10, 50, 100$ on the interval $[-0.99, 0.99]$. Comment on the behavior of the sums near $x = -1$ and near $x = 1$ as $N$ increases.

59) [Technology Required] Plot the graphs of the partial sums $S_n = \sum_{n=1}^{N} \frac{x^n}{n^2}$ for $n = 10, 50, 100$ on the interval $[-0.99, 0.99]$. Comment on the behavior of the sums near $x = -1$ and near $x = 1$ as $N$ increases.

**Answer**

The approximation appears to stabilize quickly near both $x = \pm 1$.



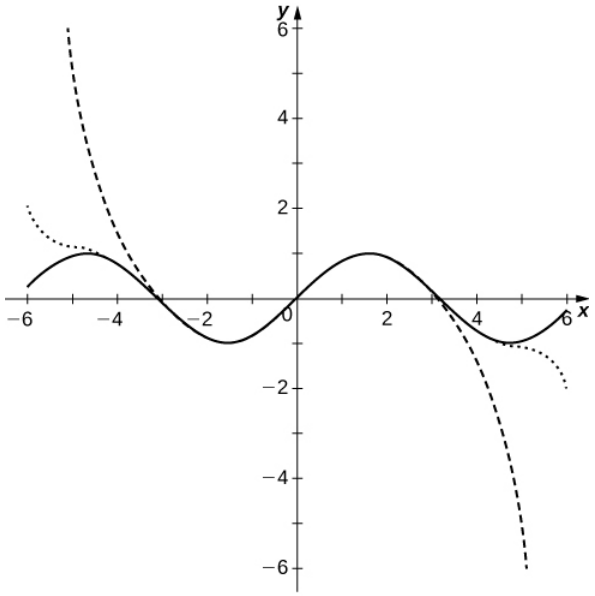
https://math.libretexts.org/@go/page/175622

60) [Technology Required] Plot the graphs of the partial sums $S_N = \sum_{n=1}^{N} (\sin n) x^n$ for $n = 10, 50, 100$ on the interval $[-0.99, 0.99]$. Comment on the behavior of the sums near $x = -1$ and near $x = 1$ as $N$ increases.

61) [Technology Required] Plot the graphs of the partial sums $S_N = \sum_{n=0}^{N} (-1)^n \frac{x^{2n+1}}{(2n+1)!}$ for $n = 3, 5, 10$ on the interval $[-2\pi, 2\pi]$. Comment on how these plots approximate $\sin x$ as $N$ increases.

**Answer**

The polynomial curves have roots close to those of $\sin x$ up to their degree and then the polynomials diverge from $\sin x$.



62) [Technology Required] Plot the graphs of the partial sums $S_N = \sum_{n=0}^{N} (-1)^n \frac{x^{2n}}{(2n)!}$ for $n = 3, 5, 10$ on the interval $[-2\pi, 2\pi]$. Comment on how these plots approximate $\cos x$ as $N$ increases.

# 9.2: Properties of Power Series

**Learning Objectives**

- Combine power series by addition or subtraction.
- Create a new power series by multiplying by a power of the variable, multiplying by a constant, or by substitution.
- Multiply two power series together.
- Differentiate and integrate power series term-by-term.

In the preceding section on power series and functions, we showed how to represent certain functions using power series. This section discusses how power series can be combined, differentiated, or integrated to create new power series. This is particularly useful for a couple of reasons. First, it allows us to find power series representations for certain elementary functions by writing those functions in terms of functions with known power series. For example, given the power series representation for $f(x) = \frac{1}{1-x}$, we can find a power series representation for $f'(x) = \frac{1}{(1-x)^2}$. Second, creating a power series allows us to define new functions that cannot be written in terms of elementary functions. This capability is handy for solving differential equations for which there is no solution in terms of elementary functions.

## Combining Power Series

If we have two power series with the same interval of convergence, we can add or subtract the two series to create a new one with the same interval of convergence. Similarly, we can multiply a power series by a power of $x$ or evaluate a power series at $x^m$ for a positive integer $m$ to create a new power series (we did this a little bit in the previous section). Being able to do this allows us to find power series representations for certain functions by using power series representations of other functions. For example, since we know the power series representation for $f(x) = \frac{1}{1-x}$, we can find power series representations for related functions, such as

$$y = \frac{3x}{1-x^2}$$

and

$$y = \frac{1}{(x-1)(x-3)}.$$

In the theorem below, we state results regarding the addition or subtraction of two power series, compositions involving power series, and multiplication of a power series by a power of the variable. For simplicity, we state the theorem for power series centered at $x = 0$. Similar results hold for power series centered at $x = a$.

**Theorem: Combining Power Series**

Suppose that the two power series $\sum_{n=0}^{\infty} c_n x^n$ and $\sum_{n=0}^{\infty} d_n x^n$ converge to the functions $f$ and $g$, respectively, on a common interval $I$. Then, the following statements are true.

i. The power series $\sum_{n=0}^{\infty} (c_n x^n \pm d_n x^n)$ converges to $f \pm g$ on $I$.

ii. For any integer $m \geq 0$ and any real number $b$, the power series $\sum_{n=0}^{\infty} b x^m c_n x^n$ converges to $b x^m f(x)$ on $I$.

iii. For any integer $m \geq 0$ and any real number $b$, the series $\sum_{n=0}^{\infty} c_n (bx^m)^n$ converges to $f(bx^m)$ for all $x$ such that $bx^m$ is in $I$.

**Proof**

We prove $i$ for the case of the series $\sum_{n=0}^{\infty} (c_n x^n + d_n x^n)$. Suppose that $\sum_{n=0}^{\infty} c_n x^n$ and $\sum_{n=0}^{\infty} d_n x^n$ converge to the functions $f$ and $g$, respectively, on the interval $I$. Let $x$ be a point in $I$ and let $S_N(x)$ and $T_N(x)$ denote the $N^{\text{th}}$ partial sums of the series

$\sum_{n=0}^{\infty} c_n x^n$ and $\sum_{n=0}^{\infty} d_n x^n$, respectively. Then the sequence $\{S_N(x)\}$ converges to $f(x)$ and the sequence $\{T_N(x)\}$ converges to $g(x)$. Furthermore, the $N^{\text{th}}$ partial sum of $\sum_{n=0}^{\infty}(c_n x^n + d_n x^n)$ is

$$\begin{aligned}\sum_{n=0}^{N}(c_n x^n + d_n x^n) &= \sum_{n=0}^{N} c_n x^n + \sum_{n=0}^{N} d_n x^n \\ &= S_N(x) + T_N(x).\end{aligned}$$

Because

$$\begin{aligned}\lim_{N\to\infty}(S_N(x) + T_N(x)) &= \lim_{N\to\infty} S_N(x) + \lim_{N\to\infty} T_N(x) \\ &= f(x) + g(x),\end{aligned}$$

we conclude that the series $\sum_{n=0}^{\infty}(c_n x^n + d_n x^n)$ converges to $f(x) + g(x)$.

We examine products of power series in a later theorem.

**Caution: Common Interval of Convergence Required**

As with all of the theorems in this section, the two series in question must share a common interval of convergence; **however**, these theorems hold over the *intersection* of the respective intervals of convergence for the given series. Thus, if one series converges on $(-4, 7)$ and the other converges on $[-1, 10)$, the theorems from this section would apply to the common interval of convergence, $[-1, 7)$.

We begin by showing several applications of the previous theorem and how to find the interval of convergence of a power series given the interval of convergence of a related power series.

**Example 9.2.1: Combining Power Series**

Suppose that $\sum_{n=0}^{\infty} a_n x^n$ is a power series whose interval of convergence is $(-1, 1)$, and suppose that $\sum_{n=0}^{\infty} b_n x^n$ is a power series whose interval of convergence is $(-2, 2)$

a. Find the interval of convergence of the series $\sum_{n=0}^{\infty}(a_n x^n + b_n x^n)$.

b. Find the interval of convergence of the series $\sum_{n=0}^{\infty} a_n 3^n x^n$.

**Solutions**

a. Since the interval $(-1, 1)$ is a common interval of convergence of the series $\sum_{n=0}^{\infty} a_n x^n$ and $\sum_{n=0}^{\infty} b_n x^n$, the interval of convergence of the series $\sum_{n=0}^{\infty}(a_n x^n + b_n x^n)$ is $(-1, 1)$.

b. Since $\sum_{n=0}^{\infty} a_n x^n$ is a power series centered at zero with radius of convergence $1$, it converges for all $x$ in the interval $(-1, 1)$. By the previous theorem, the series

$$\sum_{n=0}^{\infty} a_n 3^n x^n = \sum_{n=0}^{\infty} a_n (3x)^n$$

converges if $3x$ is in the interval $(-1, 1)$. Hence, the series converges for all $x$ in the interval $\left(-\frac{1}{3}, \frac{1}{3}\right)$.

**? Checkpoint 9.2.1**

Suppose that $\sum_{n=0}^{\infty} a_n x^n$ has an interval of convergence of $(-1,1)$. Find the interval of convergence of $\sum_{n=0}^{\infty} a_n \left(\frac{x}{2}\right)^n$.

**Answer**

Interval of convergence is $(-2,2)$.

In the next example, we show how to construct power series for functions related to $f$. Specifically, we consider functions related to the function $f(x) = \frac{1}{1-x}$ and we use the fact that

$$\frac{1}{1-x} = \sum_{n=0}^{\infty} x^n = 1 + x + x^2 + x^3 + \cdots$$

for $|x| < 1$.

**✓ Example 9.2.2: Constructing Power Series from Known Power Series**

Use the power series representation for $f(x) = \frac{1}{1-x}$ to construct a power series for each of the following functions. Find the interval of convergence of the power series.

a. $f(x) = \frac{3x}{1+x^2}$
b. $f(x) = \frac{1}{(x-1)(x-3)}$

**Solutions**

a. First write $f(x)$ as

$$f(x) = 3x\left(\frac{1}{1-(-x^2)}\right).$$

Using the power series representation for $f(x) = \frac{1}{1-x}$ and parts ii. and iii. of the previous theorem, we find that a power series representation for $f$ is given by

$$\sum_{n=0}^{\infty} 3x(-x^2)^n = \sum_{n=0}^{\infty} 3(-1)^n x^{2n+1}.$$

Since the interval of convergence of the series for $\frac{1}{1-x}$ is $(-1,1)$, the interval of convergence for this new series is the set of real numbers $x$ such that $|x^2| < 1$. Therefore, the interval of convergence is $(-1,1)$.

b. To find the power series representation, use partial fractions to write $f(x) = \frac{1}{(x-1)(x-3)}$ as the sum of two fractions. We have

$$\frac{1}{(x-1)(x-3)} = \frac{-1/2}{x-1} + \frac{1/2}{x-3} = \frac{1/2}{1-x} - \frac{1/2}{3-x} = \frac{1/2}{1-x} - \frac{1/6}{1-\frac{x}{3}}.$$

First, we obtain

$$\frac{1/2}{1-x} = \sum_{n=0}^{\infty} \frac{1}{2} x^n \text{ for } |x| < 1.$$

Then, we have

$$\frac{1/6}{1-x/3} = \sum_{n=0}^{\infty} \frac{1}{6}\left(\frac{x}{3}\right)^n \text{ for } |x| < 3.$$

Since we are combining these two power series, the interval of convergence of the difference must be the smaller of these two intervals. Using this fact, we have

$$\frac{1}{(x-1)(x-3)} = \sum_{n=0}^{\infty} \left(\frac{1}{2} - \frac{1}{6 \cdot 3^n}\right) x^n$$

where the interval of convergence is $(-1,1)$.

**Checkpoint 9.2.2**

Use the series for $f(x)=\frac{1}{1-x}$ on $|x|<1$ to construct a series for $\frac{1}{(1-x)(x-2)}$. Determine the interval of convergence.

**Answer**

$\sum_{n=0}^{\infty}\left(-1+\frac{1}{2^{n+1}}\right)x^n$. The interval of convergence is $(-1,1)$.

In Example **9.2.2**, we showed how to find power series for specific functions. In Example **9.2.3**, we show how to do the opposite: given a power series, determine which function it represents.

**Example 9.2.3: Finding the Function Represented by a Given Power Series**

Consider the power series $\sum_{n=0}^{\infty}2^nx^n$. Find the function $f$ represented by this series. Determine the interval of convergence of the series.

**Solution**

Writing the given series as

$$\sum_{n=0}^{\infty}2^nx^n=\sum_{n=0}^{\infty}(2x)^n,$$

we can recognize this series as the power series for

$$f(x)=\frac{1}{1-2x}.$$

Since this is a geometric series, the series converges if and only if $|2x|<1$. Therefore, the interval of convergence is $\left(-\frac{1}{2},\frac{1}{2}\right)$.

**Checkpoint 9.2.3**

Find the function represented by the power series $\sum_{n=0}^{\infty}\frac{1}{3^n}x^n$. Determine its interval of convergence.

**Answer**

$f(x)=\frac{3}{3-x}$. The interval of convergence is $(-3,3)$.

When winning the lottery, an individual can sometimes receive winnings in one lump sum or smaller payments over fixed intervals. For example, you could receive 20 million dollars today or 1.5 million each year for the next 20 years. Which is the better deal?

Luckily, our new knowledge will allow us to use series to compare values of payments over time with a lump sum payment today. We will compute how much future payments are worth in today's dollars, assuming we can invest winnings and earn interest. The value of future payments in today's dollars is known as the **present value** of those payments.

**Example 9.2.4: Present Value of Future Winnings**

Suppose you win the lottery and are given the following three options:

- Receive 20 million dollars today;
- Receive 1.5 million dollars per year over the next 20 years; or
- Receive 1 million dollars per year indefinitely (being passed on to your heirs).

Which is the best deal, assuming the annual interest rate is 5%? We answer this by working through the following sequence of questions.

a. How much is the 1.5 million dollars received annually over 20 years worth in terms of today's dollars, assuming an annual interest rate of 5%?
b. Use the answer to part a. to find a general formula for the **present value** of payments of $C$ dollars received each year over the next $n$ years, assuming an average annual interest rate $r$.
c. Find a formula for the present value if annual payments of $C$ dollars continue indefinitely, assuming an average annual interest rate $r$.
d. Use the answer to part c. to determine the present value of 1 million dollars paid annually indefinitely.
e. Use your answers to parts a. and d. to determine which of the three options is best.

Figure **9.2.1**: (credit: modification of work by Robert Huffstutter, Flickr)

**Solutions**

a. Consider the payment of 1.5 million dollars made at the end of the first year. If you receive that payment today instead of one year from now, you could invest that money and earn 5% interest. Therefore, the present value of that money $P_1$ satisfies $P_1(1+0.05) = 1.5$ million dollars. We conclude that

$$P_1 = \frac{1.5}{1.05} = 1.429 \text{ million dollars.}$$

Similarly, consider the payment of 1.5 million dollars made at the end of the second year. If you receive that payment today, you could invest that money for two years, earning 5% interest compounded annually. Therefore, the present value of that money $P_2$ satisfies $P_2(1+0.05)^2 = 1.5$ million dollars. We conclude that

$$P_2 = 1.5(1.05)^2 = 1.361 \text{ million dollars.}$$

The value of the future payments today is the sum of the present values $P_1$, $P_2$, ..., $P_{20}$ of each of those annual payments. The present value $P_k$ satisfies

$$P_k = \frac{1.5}{(1.05)^k}.$$

Therefore,

$$P = \frac{1.5}{1.05} + \frac{1.5}{(1.05)^2} + \ldots + \frac{1.5}{(1.05)^{20}} = 18.693 \text{ million dollars.}$$

b. Using the result from part a., we see that the present value $P$ of $C$ dollars paid annually for $n$ years, assuming an annual interest rate $r$, is given by

$$P = \frac{C}{1+r} + \frac{C}{(1+r)^2} + \cdots + \frac{C}{(1+r)^n} \text{ dollars.}$$

c. Using the result from part b. we see that the present value of an annuity that continues indefinitely is given by the infinite series

$$P = \sum_{n=0}^{\infty} \frac{C}{(1+r)^{n+1}}.$$

We can view the present value as a power series in $r$, which converges as long as $\left|\frac{1}{1+r}\right| < 1$. Since $r > 0$, this series converges. Rewriting the series as

$$P = \frac{C}{(1+r)} \sum_{n=0}^{\infty} \left(\frac{1}{1+r}\right)^n,$$

we recognize this series as the power series for

$$f(r) = \frac{1}{1-\left(\frac{1}{1+r}\right)} = \frac{1}{\left(\frac{r}{1+r}\right)} = \frac{1+r}{r}.$$

We conclude that the present value of this annuity is

$$P = \frac{C}{1+r} \cdot \frac{1+r}{r} = \frac{C}{r}.$$

d. From the result to part c., we conclude that the present value $P$ of $C = 1$ million dollars paid out every year indefinitely, assuming an annual interest rate $r = 0.05$, is given by

$$P = \frac{1}{0.05} = 20$$

million dollars.

e. From part a., we see that receiving 1.5 million dollars over 20 years is worth 18.693 million dollars in today's dollars. From part d., we see that indefinitely receiving $1 million annually is worth $20 million in today's dollars. Therefore, either receiving a lump sum payment of $20 million today or receiving $1 million indefinitely have the same present value.

## Multiplication of Power Series

We can also create new power series by multiplying power series. Multiplying two power series provides another way of finding power series representations for functions. The way we multiply them is similar to how we multiply polynomials. For example, suppose we want to multiply

$$\sum_{n=0}^{\infty} c_n x^n = c_0 + c_1 x + c_2 x^2 + \cdots$$

and

$$\sum_{n=0}^{\infty} d_n x^n = d_0 + d_1 x + d_2 x^2 + \cdots.$$

It appears that the product should satisfy

$$\begin{aligned}\left(\sum_{n=0}^{\infty} c_n x^n\right)\left(\sum_{n=-0}^{\infty} d_n x^n\right) &= (c_0 + c_1 x + c_2 x^2 + \cdots) \cdot (d_0 + d_1 x + d_2 x^2 + \cdots) \\ &= c_0 d^0 + (c_1 d^0 + c_0 d^1)x + (c_2 d^0 + c_1 d^1 + c_0 d^2)x^2 + \cdots.\end{aligned}$$

In the following theorem, we state the main result regarding multiplying power series, showing that if $\sum_{n=0}^{\infty} c_n x^n$ and $\sum_{n=0}^{\infty} d_n x^n$ converge on a common interval $I$, then we can multiply the series in this way, and the resulting series also converges on the interval $I$.

### Theorem: Product of Power Series

Suppose that the power series $\sum_{n=0}^{\infty} c_n x^n$ and $\sum_{n=0}^{\infty} d_n x^n$ converge to $f$ and $g$, respectively, on a common interval $I$. Let

$$e_n = c_0 d_n + c_1 d_{n-1} + c_2 d_{n-2} + \cdots + c_{n-1} d_1 + c_n d_0 = \sum_{k=0}^{n} c_k d_{n-k}.$$

Then

$$\left(\sum_{n=0}^{\infty} c_n x^n\right)\left(\sum_{n=0}^{\infty} d_n x^n\right) = \sum_{n=0}^{\infty} e_n x^n$$

and

$$\sum_{n=0}^{\infty} e_n x^n \text{ converges to } f(x)\cdot g(x) \text{ on } I.$$

The series $\sum_{n=0}^{\infty} e_n x^n$ is known as the **Cauchy product** of the series $\sum_{n=0}^{\infty} c_n x^n$ and $\sum_{n=0}^{\infty} d_n x^n$.[1]

We omit the proof of this theorem as it is beyond the level of this text and is typically covered in a more advanced course. We now provide an example of this theorem by finding the power series representation for

$$f(x) = \frac{1}{(1-x)(1-x^2)}$$

using the power series representations for

$$y = \frac{1}{1-x} \text{ and } y = \frac{1}{1-x^2}.$$

### Example 9.2.5: Multiplying Power Series

Multiply the power series representation

$$\frac{1}{1-x} = \sum_{n=0}^{\infty} x^n = 1 + x + x^2 + x^3 + \cdots$$

for $|x| < 1$ with the power series representation

$$\frac{1}{1-x^2} = \sum_{n=0}^{\infty} \left(x^2\right)^n = 1 + x^2 + x^4 + x^6 + \cdots$$

for $|x| < 1$ to construct a power series for $f(x) = \frac{1}{(1-x)(1-x^2)}$ on the interval $(-1, 1)$.

**Solution**

We need to multiply

$$(1 + x + x^2 + x^3 + \cdots)(1 + x^2 + x^4 + x^6 + \cdots).$$

We note that this product will have a constant term and terms for $x$, $x^2$, $x^3$, and so on. Hence, we see that the product is given by

$$\begin{aligned}(1 + x + x^2 + x^3 + \cdots)(1 + x^2 + x^4 + x^6 + \cdots) &= 1 + x + (1+1)x^2 + (1+1)x^3 + (1+1+1)x^4 + (1+1+1)x^5 + \cdots \\ &= 1 + x + 2x^2 + 2x^3 + 3x^4 + 3x^5 + \cdots.\end{aligned}$$

Since the series for $y = \frac{1}{1-x}$ and $y = \frac{1}{1-x^2}$ both converge on the interval $(-1, 1)$, the series for the product also converges on the interval $(-1, 1)$.

### Note: The Expansion of Products of Power Series

As you progress in Mathematics, there will be a few moments (specifically, in Differential Equations) when you must find the product of two power series. It's a common convention to list the expansion's first three or four nonzero terms.

**? Checkpoint 9.2.5**

Multiply the series $\frac{1}{1-x} = \sum_{n=0}^{\infty} x^n$ by itself to construct a series for $\frac{1}{(1-x)(1-x)}$.

**Answer**

$1 + 2x + 3x^2 + 4x^3 + \cdots$

## Differentiating and Integrating Power Series

Consider a power series $\sum_{n=0}^{\infty} c_n x^n = c_0 + c_1 x + c_2 x^2 + \cdots$ that converges on some interval $I$, and let $f$ be the function defined by this series. Here we address two questions about $f$:

1. Is $f$ differentiable, and if so, how do we determine the derivative $f'$?
2. How do we evaluate the indefinite integral $\int f(x)\,dx$?

We know we can evaluate the derivative by differentiating each term separately for a polynomial with a finite number of terms. Similarly, we can evaluate the indefinite integral by integrating each term separately. We show we can do the same for *convergent* power series. That is, if

$$f(x) = c_n x^n = c_0 + c_1 x + c_2 x^2 + \cdots$$

converges on some interval $I$, then

$$f'(x) = c_1 + 2c_2 x + 3c_3 x^2 + \cdots$$

and

$$\int f(x)\,dx = C + c_0 x + c_1 \frac{x^2}{2} + c_2 \frac{x^3}{3} + \cdots.$$

Evaluating the derivative and indefinite integral in this way is called **term-by-term differentiation of a power series** and **term-by-term integration of a power series**, respectively.

The ability to differentiate and integrate power series term-by-term also allows us to use known power series representations to find power series representations for other functions. For example, given the power series for $f(x) = \frac{1}{1-x}$, we can differentiate term-by-term to find the power series for $f'(x) = \frac{1}{(1-x)^2}$. Similarly, using the power series for $g(x) = \frac{1}{1+x}$, we can integrate term-by-term to find the power series for $G(x) = \ln(1+x)$, an antiderivative of $g$. We show how to do this in Example **9.2.6** and Example **9.2.7**. First, we state the following theorem, which provides the main result regarding power series differentiation and integration.

**Theorem: Term-by-Term Differentiation and Integration for Power Series**

Suppose that the power series $\sum_{n=0}^{\infty} c_n (x-a)^n$ converges on the interval $(a-R, a+R)$ for some $R > 0$. Let $f$ be the function defined by the series

$$f(x) = \sum_{n=0}^{\infty} c_n (x-a)^n = c_0 + c_1(x-a) + c_2(x-a)^2 + c_3(x-a)^3 + \cdots$$

for $|x-a| < R$. Then $f$ is differentiable on the interval $(a-R, a+R)$ and we can find $f'$ by differentiating the series term-by-term:

$$f'(x) = \sum_{n=1}^{\infty} n c_n (x-a)^{n-1} = c_1 + 2c_2(x-a) + 3c_3(x-a)^2 + \cdots$$

for $|x-a| < R$. Also, to find $\int f(x)\,dx$, we can integrate the series term-by-term. The resulting series converges on $(a-R, a+R)$, and we have

$$\int f(x)\,dx = C + \sum_{n=0}^{\infty} c_n \frac{(x-a)^{n+1}}{n+1} = C + c_0(x-a) + c_1\frac{(x-a)^2}{2} + c_2\frac{(x-a)^3}{3} + \cdots$$

for $|x-a| < R$.

This result's proof is omitted and beyond the text's scope. Note that although this theorem guarantees the same radius of convergence when a power series is differentiated or integrated term-by-term, it says nothing about what happens at the endpoints. The differentiated and integrated power series may behave differently at the endpoints than the original series. We see this behavior in the next examples.

### Example 9.2.6: Differentiating Power Series

a. Use the power series representation

$$f(x) = \frac{1}{1-x} = \sum_{n=0}^{\infty} x^n = 1 + x + x^2 + x^3 + \cdots$$

for $|x| < 1$ to find a power series representation for

$$g(x) = \frac{1}{(1-x)^2}$$

on the interval $(-1, 1)$. Determine whether the resulting series converges at the endpoints.

b. Use the result of part a. to evaluate the sum of the series $\sum_{n=0}^{\infty} \frac{n+1}{4^n}$.

**Solutions**

a. Since $g(x) = \frac{1}{(1-x)^2}$ is the derivative of $f(x) = \frac{1}{1-x}$, we can find a power series representation for $g$ by differentiating the power series for $f$ term-by-term. The result is

$$\begin{aligned} g(x) &= \frac{1}{(1-x)^2} \\ &= \frac{d}{dx}\left(\frac{1}{1-x}\right) \\ &= \sum_{n=0}^{\infty} \frac{d}{dx}(x^n) \\ &= \frac{d}{dx}(1 + x + x^2 + x^3 + \cdots) \\ &= 0 + 1 + 2x + 3x^2 + 4x^3 + \cdots \\ &= \sum_{n=0}^{\infty} (n+1)x^n \end{aligned}$$

for $|x| < 1$. Theorem 9.2.1 does not guarantee anything about the behavior of this series at the endpoints. Testing the endpoints by using the Divergence Test, we find that the series diverges at both endpoints $x = \pm 1$.

b. From part a. we know that

$$\sum_{n=0}^{\infty} (n+1)x^n = \frac{1}{(1-x)^2}.$$

Therefore,

$$\begin{aligned}\sum_{n=0}^{\infty}\frac{n+1}{4^n} &= \sum_{n=0}^{\infty}(n+1)\left(\frac{1}{4}\right)^n \\ &= \frac{1}{\left(1-\frac{1}{4}\right)^2} \\ &= \frac{1}{\left(\frac{3}{4}\right)^2} \\ &= \frac{16}{9}\end{aligned}$$

**? Checkpoint 9.2.6**

Differentiate the series $\frac{1}{(1-x)^2} = \sum_{n=0}^{\infty}(n+1)x^n$ term-by-term to find a power series representation for $\frac{2}{(1-x)^3}$ on the interval $(-1,1)$.

**Answer**

$$\sum_{n=0}^{\infty}(n+2)(n+1)x^n$$

**✓ Example 9.2.7: Integrating Power Series**

For each of the following functions $f$, find a power series representation for $f$ by integrating the power series for $f'$ and find its interval of convergence.

a. $f(x) = \ln(1+x)$
b. $f(x) = \tan^{-1}x$

**Solutions**

a. For $f(x) = \ln(1+x)$,the derivative is $f'(x) = \frac{1}{1+x}$. We know that

$$\frac{1}{1+x} = \frac{1}{1-(-x)} = \sum_{n=0}^{\infty}(-x)^n = 1 - x + x^2 - x^3 + \cdots$$

for $|x| < 1$. To find a power series for $f(x) = \ln(1+x)$, we integrate the series term-by-term.

$$\int f'(x)\,dx = \int (1 - x + x^2 - x^3 + \cdots)\,dx = C + x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \cdots$$

Since $f(x) = \ln(1+x)$ is an antiderivative of $\frac{1}{1+x}$, it remains to solve for the constant $C$. Since $\ln(1+0) = 0$, we have $C = 0$. Therefore, a power series representation for $f(x) = \ln(1+x)$ is

$$\ln(1+x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \cdots = \sum_{n=1}^{\infty}(-1)^{n+1}\frac{x^n}{n} \text{ for } |x| < 1.$$

Theorem 9.2.1 does not guarantee anything about the behavior of this power series at the endpoints. However, checking the endpoints, we find that at $x = 1$, the series is the Alternating Harmonic Series, which converges. Also, at $x = -1$, the series is the Harmonic Series, which diverges. It is important to note that, even though this series converges at $x = 1$, we cannot guarantee that the series converges to $\ln(2)$. In fact, the series converges $\ln(2)$, but showing this fact requires more advanced techniques.[2] The interval of convergence is $(-1, 1]$.

b. The derivative of $f(x) = \tan^{-1}x$ is $f'(x) = \frac{1}{1+x^2}$. We know that

$$\frac{1}{1+x^2} = \frac{1}{1-(-x^2)} = \sum_{n=0}^{\infty}(-x^2)^n = 1 - x^2 + x^4 - x^6 + \cdots$$

for $|x| < 1$. To find a power series for $f(x) = \tan^{-1}x$, we integrate this series term-by-term.

$$\int f'(x)\,dx = \int (1 - x^2 + x^4 - x^6 + \cdots)\,dx = C + x - \frac{x^3}{3} + \frac{x^5}{5} - \frac{x^7}{7} + \cdots.$$

Since $\tan^{-1}(0) = 0$, we have $C = 0$. Therefore, a power series representation for $f(x) = \tan^{-1} x$ is

$$\tan^{-1} x = x - \frac{x^3}{3} + \frac{x^5}{5} - \frac{x^7}{7} + \cdots = \sum_{n=0}^{\infty} (-1)^n \frac{x^{2n+1}}{2n+1}$$

for $|x| < 1$. Again, Theorem 9.2.1 does not guarantee anything about the convergence of this series at the endpoints. However, checking the endpoints and using the Alternating Series Test, we find that the series converges at $x = 1$ and $x = -1$. As discussed in the footnote to part a., using Abel's Theorem, it can be shown that the series converges to $\tan^{-1}(1)$ and $\tan^{-1}(-1)$ at $x = 1$ and $x = -1$, respectively. Thus, the interval of convergence is $[-1, 1]$.

**? Checkpoint 9.2.7**

Integrate the power series $\ln(1+x) = \sum_{n=1}^{\infty} (-1)^{n+1} \frac{x^n}{n}$ term-by-term to evaluate $\int \ln(1+x)\,dx$.

**Answer**

$$\sum_{n=2}^{\infty} \frac{(-1)^n x^n}{n(n-1)}$$

Up to this point, we have shown several techniques for finding power series representations for functions. However, how do we know that these power series are unique? That is, given a function $f$ and a power series for $f$ at $a$, is it possible that there is a different power series for $f$ at $a$ that we could have found if we had used a different technique? The answer to this question is no. This fact should not seem surprising if we consider power series as polynomials with infinite terms. Intuitively, if

$$c_0 + c_1 x + c_2 x^2 + \cdots = d_0 + d_1 x + d_2 x^2 + \cdots$$

for all values $x$ in some open interval $I$ about zero, then the coefficients $c_n$ should equal $d_n$ for $n \geq 0$. We now state this result formally.

**Theorem: Uniqueness of Power Series**

Let $\sum_{n=0}^{\infty} c_n (x-a)^n$ and $\sum_{n=0}^{\infty} d_n (x-a)^n$ be two convergent power series such that

$$\sum_{n=0}^{\infty} c_n (x-a)^n = \sum_{n=0}^{\infty} d_n (x-a)^n$$

for all $x$ in an open interval containing $a$. Then $c_n = d_n$ for all $n \geq 0$.

**Proof**

Let

$$\begin{aligned} f(x) &= c_0 + c_1(x-a) + c_2(x-a)^2 + c_3(x-a)^3 + \cdots \\ &= d_0 + d_1(x-a) + d_2(x-a)^2 + d_3(x-a)^3 + \cdots. \end{aligned}$$

Then $f(a) = c_0 = d_0$. By Theorem 9.2.3, we can differentiate both series term-by-term. Therefore,

$$\begin{aligned} f'(x) &= c_1 + 2c_2(x-a) + 3c_3(x-a)^2 + \cdots \\ &= d_1 + 2d_2(x-a) + 3d_3(x-a)^2 + \cdots, \end{aligned}$$

and thus, $f'(a) = c_1 = d_1$. Similarly,

$$\begin{aligned} f''(x) &= 2c_2 + 3 \cdot 2c_3(x-a) + \cdots \\ &= 2d_2 + 3 \cdot 2d_3(x-a) + \cdots \end{aligned}$$

implies that $f''(a) = 2c_2 = 2d_2$, and therefore, $c_2 = d_2$. More generally, for any integer $n \geq 0$, $f^{(n)}(a) = n!c_n = n!d_n$, and consequently, $c_n = d_n$ for all $n \geq 0$.

In this section, we have shown how to find power series representations for certain functions using various algebraic operations, differentiation, or integration. However, we are still limited in the functions for which we can find power series representations. Next, by introducing the Taylor series, we show how to find power series representations for many more functions.

## Footnotes

[1] This theorem is included for completeness; however, your instructor might "approximate" this theorem (which is perfectly fine) by stating that the product of two convergent power series is best computed by finding the first three or four lowest powers of the product. That is,

$$\begin{aligned} \left(\sum_{n=0}^{\infty} c_n x^n\right)\left(\sum_{n=0}^{\infty} d_n x^n\right) &= \left(c_0 + c_1 x + c_2 x^2 + \cdots\right)\left(d_0 + d_1 x + d_2 x^2 + \cdots\right) \\ &= c_0 d_0 + \left(c_0 d_1 + c_1 d_0\right) x + \left(c_0 d_2 + c_1 d_1 + c_2 d_0\right) x^2 + \cdots \end{aligned}$$

[2] Abel's Theorem, covered in more advanced texts, deals with this more technical point.

## Key Concepts

- Given two power series $\sum_{n=0}^{\infty} c_n x^n$ and $\sum_{n=0}^{\infty} d_n x^n$ that converge to functions $f$ and $g$ on a common interval $I$, the sum and difference of the two series converge to $f \pm g$, respectively, on $I$. In addition, for any real number $b$ and integer $m \geq 0$, the series $\sum_{n=0}^{\infty} b x^m c_n x^n$ converges to $b x^m f(x)$ and the series $\sum_{n=0}^{\infty} c_n (b x^m)^n$ converges to $f(b x^m)$ whenever $b x^m$ is in the interval $I$.
- Given two power series that converge on an interval $(-R, R)$, the Cauchy product of the two power series converges on the interval $(-R, R)$.
- Given a power series that converges to a function $f$ on an interval $(-R, R)$, the series can be differentiated term-by-term and the resulting series converges to $f'$ on $(-R, R)$. The series can also be integrated term-by-term and the resulting series converges to $\int f(x)\,dx$ on $(-R, R)$.

## Glossary

**term-by-term differentiation of a power series**

a technique for evaluating the derivative of a power series $\sum_{n=0}^{\infty} c_n (x-a)^n$ by considering the derivative of each term separately to create the new power series $\sum_{n=1}^{\infty} n c_n (x-a)^{n-1}$

**term-by-term integration of a power series**

a technique for integrating a power series $\sum_{n=0}^{\infty} c_n (x-a)^n$ by integrating each term separately to create the new power series $C + \sum_{n=0}^{\infty} c_n \frac{(x-a)^{n+1}}{n+1}$

# 9.2E: Exercises

1) If $f(x)=\sum_{n=0}^{\infty}\frac{x^n}{n!}$ and $g(x)=\sum_{n=0}^{\infty}(-1)^n\frac{x^n}{n!}$, find the power series of $\frac{1}{2}\big(f(x)+g(x)\big)$ and of $\frac{1}{2}\big(f(x)-g(x)\big)$.

**Answer**

$$\frac{1}{2}\big(f(x)+g(x)\big)=\sum_{n=0}^{\infty}\frac{x^{2n}}{(2n)!} \text{ and } \frac{1}{2}\big(f(x)-g(x)\big)=\sum_{n=0}^{\infty}\frac{x^{2n+1}}{(2n+1)!}.$$

2) If $C(x)=\sum_{n=0}^{\infty}\frac{x^{2n}}{(2n)!}$ and $S(x)=\sum_{n=0}^{\infty}\frac{x^{2n+1}}{(2n+1)!}$, find the power series of $C(x)+S(x)$ and of $C(x)-S(x)$.

**In exercises 3 - 6, use partial fractions to find the power series of each function.**

3) $\frac{4}{(x-3)(x+1)}$

**Answer**

$$\frac{4}{(x-3)(x+1)}=\frac{1}{x-3}-\frac{1}{x+1}=-\frac{1}{3(1-\frac{x}{3})}-\frac{1}{1-(-x)}=-\frac{1}{3}\sum_{n=0}^{\infty}\left(\frac{x}{3}\right)^n-\sum_{n=0}^{\infty}(-1)^nx^n=\sum_{n=0}^{\infty}\left((-1)^{n+1}-\frac{1}{3n+1}\right)x^n$$

4) $\frac{3}{(x+2)(x-1)}$

5) $\frac{5}{(x^2+4)(x^2-1)}$

**Answer**

$$\frac{5}{(x^2+4)(x^2-1)}=\frac{1}{x^2-1}-\frac{1}{4}\frac{1}{1+(\frac{x}{2})^2}=-\sum_{n=0}^{\infty}x^{2n}-\frac{1}{4}\sum_{n=0}^{\infty}(-1)^n\left(\frac{x}{2}\right)^n=\sum_{n=0}^{\infty}\left((-1)+(-1)^{n+1}\frac{1}{2^{n+2}}\right)x^{2n}$$

6) $\frac{30}{(x^2+1)(x^2-9)}$

**In exercises 7 - 10, express each series as a rational function.**

7) $\sum_{n=1}^{\infty}\frac{1}{x^n}$

**Answer**

$$\frac{1}{x}\sum_{n=0}^{\infty}\frac{1}{x^n}=\frac{1}{x}\cdot\frac{1}{1-\frac{1}{x}}=\frac{1}{x-1}$$

8) $\sum_{n=1}^{\infty}\frac{1}{x^{2n}}$

9) $\sum_{n=1}^{\infty}\frac{1}{(x-3)^{2n-1}}$

**Answer**

$$\frac{1}{x-3}\cdot\frac{1}{1-\frac{1}{(x-3)^2}}=\frac{x-3}{(x-3)^2-1}$$

10) $\sum_{n=1}^{\infty}\left(\frac{1}{(x-3)^{2n-1}}-\frac{1}{(x-2)^{2n-1}}\right)$

**Exercises 11 - 16 explore applications of *annuities*.**

11) Calculate the present values $P$ of an annuity in which \$10,000 is to be paid out annually for a period of 20 years, assuming interest rates of $r=0.03$, $r=0.05$, and $r=0.07$.

**Answer**

$P = P_1 + \cdots + P_{20}$ where $P_k = 10,000\dfrac{1}{(1+r)^k}$. Then $P = 10,000\displaystyle\sum_{k=1}^{20}\frac{1}{(1+r)^k} = 10,000\frac{1-(1+r)^{-20}}{r}$. When $r = 0.03,\ P \approx 10,000 \times 14.8775 = 148,775$. When $r = 0.05,\ P \approx 10,000 \times 12.4622 = 124,622$. When $r = 0.07,\ P \approx 105,940$.

12) Calculate the present values $P$ of annuities in which \$9,000 is to be paid out annually perpetually, assuming interest rates of $r = 0.03$, $r = 0.05$ and $r = 0.07$.

13) Calculate the annual payouts $C$ to be given for 20 years on annuities having present value \$100,000 assuming respective interest rates of $r = 0.03$, $r = 0.05$, and $r = 0.07$.

**Answer**

In general, $P = \dfrac{C(1-(1+r)^{-N})}{r}$ for $N$ years of payouts, or $C = \dfrac{Pr}{1-(1+r)^{-N}}$. For $N = 20$ and $P = 100,000$, one has $C = 6721.57$ when $r = 0.03$; $C = 8024.26$ when $r = 0.05$; and $C \approx 9439.29$ when $r = 0.07$.

14) Calculate the annual payouts $C$ to be given perpetually on annuities having present value \$100,000 assuming respective interest rates of $r = 0.03$, $r = 0.05$, and $r = 0.07$.

15) Suppose that an annuity has a present value $P = 1$ **million dollars.** What interest rate $r$ would allow for perpetual annual payouts of \$50,000?

**Answer**

In general, $P = \dfrac{C}{r}$. Thus, $r = \dfrac{C}{P} = 5 \times \frac{10^4}{10^6} = 0.05$.

16) Suppose that an annuity has a present value $P = 10$ **million dollars.** What interest rate $r$ would allow for perpetual annual payouts of \$100,000?

**In exercises 17 - 20, express the sum of each power series in terms of geometric series, and then express the sum as a rational function.**

17) $x + x^2 - x^3 + x^4 + x^5 - x^6 + \cdots$ (Hint: Group powers $x^{3k}$, $x^{3k-1}$, and $x^{3k-2}$.)

**Answer**

$$(x + x^2 - x^3)(1 + x^3 + x^6 + \cdots) = \frac{x + x^2 - x^3}{1 - x^3}$$

18) $x + x^2 - x^3 - x^4 + x^5 + x^6 - x^7 - x^8 + \cdots$ (Hint: Group powers $x^{4k}$, $x^{4k-1}$, etc.)

19) $x - x^2 - x^3 + x^4 - x^5 - x^6 + x^7 - \cdots$ (Hint: Group powers $x^{3k}$, $x^{3k-1}$, and $x^{3k-2}$.)

**Answer**

$$(x - x^2 - x^3)(1 + x^3 + x^6 + \cdots) = \frac{x - x^2 - x^3}{1 - x^3}$$

20) $\dfrac{x}{2} + \dfrac{x^2}{4} - \dfrac{x^3}{8} + \dfrac{x^4}{16} + \dfrac{x^5}{32} - \dfrac{x^6}{64} + \cdots$ (Hint: Group powers $\left(\dfrac{x}{2}\right)^{3k}$, $\left(\dfrac{x}{2}\right)^{3k-1}$, and $\left(\dfrac{x}{2}\right)^{3k-2}$.)

**In exercises 21 - 24, find the power series of $f(x)g(x)$ given $f$ and $g$ as defined.**

21) $f(x) = 2\displaystyle\sum_{n=0}^{\infty} x^n, g(x) = \sum_{n=0}^{\infty} nx^n$

**Answer**

$a_n = 2$, $b_n = n$ so $c_n = \displaystyle\sum_{k=0}^{n} b_k a_{n-k} = 2\sum_{k=0}^{n} k = (n)(n+1)$ and $f(x)g(x) = \displaystyle\sum_{n=1}^{\infty} n(n+1)x^n$

22) $f(x) = \displaystyle\sum_{n=1}^{\infty} x^n,\ g(x) = \sum_{n=1}^{\infty} \frac{1}{n}x^n$. Express the coefficients of $f(x)g(x)$ in terms of $H_n = \displaystyle\sum_{k=1}^{n} \frac{1}{k}$.

23) $f(x) = g(x) = \displaystyle\sum_{n=1}^{\infty} \left(\frac{x}{2}\right)^n$

**Answer**

$a_n = b_n = 2^{-n}$ so $c_n = \sum_{k=1}^{n} b_k a_{n-k} = 2^{-n} \sum_{k=1}^{n} 1 = \frac{n}{2^n}$ and $f(x)g(x) = \sum_{n=1}^{\infty} n \left(\frac{x}{2}\right)^n$

24) $f(x) = g(x) = \sum_{n=1}^{\infty} nx^n$

**In exercises 25 - 26, differentiate the given series expansion of $f$ term-by-term to obtain the corresponding series expansion for the derivative of $f$.**

25) $f(x) = \frac{1}{1+x} = \sum_{n=0}^{\infty} (-1)^n x^n$

**Answer**

The derivative of $f$ is $-\frac{1}{(1+x)^2} = -\sum_{n=0}^{\infty} (-1)^n (n+1) x^n$.

26) $f(x) = \frac{1}{1-x^2} = \sum_{n=0}^{\infty} x^{2n}$

**In exercises 27 - 28, integrate the given series expansion of $f$ term-by-term from zero to $x$ to obtain the corresponding series expansion for the indefinite integral of $f$.**

27) $f(x) = \frac{2x}{(1+x^2)^2} = \sum_{n=1}^{\infty} (-1)^n (2n) x^{2n-1}$

**Answer**

The indefinite integral of $f$ is $\frac{1}{1+x^2} = \sum_{n=0}^{\infty} (-1)^n x^{2n}$.

28) $f(x) = \frac{2x}{1+x^2} = 2\sum_{n=0}^{\infty} (-1)^n x^{2n+1}$

**In exercises 29 - 32, evaluate each infinite series by identifying it as the value of a derivative or integral of geometric series.**

29) Evaluate $\sum_{n=1}^{\infty} \frac{n}{2^n}$ as $f'\left(\frac{1}{2}\right)$ where $f(x) = \sum_{n=0}^{\infty} x^n$.

**Answer**

$$f(x) = \sum_{n=0}^{\infty} x^n = \frac{1}{1-x};\ f'(\frac{1}{2}) = \sum_{n=1}^{\infty} \frac{n}{2^{n-1}} = \frac{d}{dx}(1-x)^{-1}\Big|_{x=1/2} = \frac{1}{(1-x)^2}\Big|_{x=1/2} = 4 \text{ so } \sum_{n=1}^{\infty} \frac{n}{2^n} = 2.$$

30) Evaluate $\sum_{n=1}^{\infty} \frac{n}{3^n}$ as $f'\left(\frac{1}{3}\right)$ where $f(x) = \sum_{n=0}^{\infty} x^{6n}$.

31) Evaluate $\sum_{n=2}^{\infty} \frac{n(n-1)}{2^n}$ as $f''\left(\frac{1}{2}\right)$ where $f(x) = \sum_{n=0}^{\infty} x^n$.

**Answer**

$$f(x) = \sum_{n=0}^{\infty} x^n = \frac{1}{1-x};\ f''\left(\frac{1}{2}\right) = \sum_{n=2}^{\infty} \frac{n(n-1)}{2^{n-2}} = \frac{d^2}{dx^2}(1-x)^{-1}\Big|_{x=1/2} = \frac{2}{(1-x)^3}\Big|_{x=1/2} = 16 \text{ so } \sum_{n=2}^{\infty} n\frac{(n-1)}{2^n} = 4.$$

32) Evaluate $\sum_{n=0}^{\infty} \frac{(-1)^n}{n+1}$ as $\int_0^1 f(t)\,dt$ where $f(x) = \sum_{n=0}^{\infty} (-1)^n x^{2n} = \frac{1}{1+x^2}$.

**In exercises 33 - 39, given that $\frac{1}{1-x} = \sum_{n=0}^{\infty} x^n$, use term-by-term differentiation or integration to find power series for each function centered at the given point.**

33) $f(x) = \ln x$ centered at $x = 1$ (Hint: $x = 1 - (1-x)$)

**Answer**

$$\int \sum (1-x)^n\,dx = \int \sum (-1)^n (x-1)^n\,dx = \sum \frac{(-1)^n (x-1)^{n+1}}{n+1}$$

34) $\ln(1-x)$ at $x=0$

35) $\ln(1-x^2)$ at $x=0$

**Answer**

$$-\int_{t=0}^{x^2} \frac{1}{1-t}\,dt = -\sum_{n=0}^{\infty} \int_0^{x^2} t^n dx - \sum_{n=0}^{\infty} \frac{x^{2(n+1)}}{n+1} = -\sum_{n=1}^{\infty} \frac{x^{2n}}{n}$$

36) $f(x) = \dfrac{2x}{(1-x^2)^2}$ at $x=0$

37) $f(x) = \tan^{-1}(x^2)$ at $x=0$

**Answer**

$$\int_0^{x^2} \frac{dt}{1+t^2} = \sum_{n=0}^{\infty} (-1)^n \int_0^{x^2} t^{2n}dt = \sum_{n=0}^{\infty} (-1)^n \frac{t^{2n+1}}{2n+1}\,|_{t=0}^{x^2} = \sum_{n=0}^{\infty} (-1)^n \frac{x^{4n+2}}{2n+1}$$

38) $f(x) = \ln(1+x^2)$ at $x=0$

39) $f(x) = \displaystyle\int_0^x \ln t\,dt$ where $\ln(x) = \displaystyle\sum_{n=1}^{\infty} (-1)^{n-1} \frac{(x-1)^n}{n}$

**Answer**

Term-by-term integration gives $\displaystyle\int_0^x \ln t\,dt = \sum_{n=1}^{\infty} (-1)^{n-1} \frac{(x-1)^{n+1}}{n(n+1)} = \sum_{n=1}^{\infty} (-1)^{n-1} \left(\frac{1}{n} - \frac{1}{n+1}\right)(x-1)^{n+1} = (x-1)\ln x + \displaystyle\sum_{n=2}^{\infty} (-1)^n \frac{(x-1)^n}{n} = x\ln x - x.$

40) [Technology Required] Evaluate the power series expansion $\ln(1+x) = \displaystyle\sum_{n=1}^{\infty} (-1)^{n-1} \frac{x^n}{n}$ at $x=1$ to show that $\ln(2)$ is the sum of the alternating harmonic series. Use the alternating series test to determine how many terms of the sum are needed to estimate $\ln(2)$ accurate to within $0.001$, and find such an approximation.

41) [Technology Required] Subtract the infinite series of $\ln(1-x)$ from $\ln(1+x)$ to get a power series for $\ln\left(\dfrac{1+x}{1-x}\right)$. Evaluate at $x = \frac{1}{3}$. What is the smallest $N$ such that the $N^{\text{th}}$ partial sum of this series approximates $\ln(2)$ with an error less than $0.001$?

**Answer**

We have $\ln(1-x) = -\displaystyle\sum_{n=1}^{\infty} \frac{x^n}{n}$ so $\ln(1+x) = \displaystyle\sum_{n=1}^{\infty} (-1)^{n-1} \frac{x^n}{n}$. Thus, $\ln\left(\dfrac{1+x}{1-x}\right) = \displaystyle\sum_{n=1}^{\infty} \left(1+(-1)^{n-1}\right)\frac{x^n}{n} = 2\sum_{n=1}^{\infty} \frac{x^{2n-1}}{2n-1}$.

When $x = \frac{1}{3}$ we obtain $\ln(2) = 2\displaystyle\sum_{n=1}^{\infty} \frac{1}{3^{2n-1}(2n-1)}$. We have $2\displaystyle\sum_{n=1}^{3} \frac{1}{3^{2n-1}(2n-1)} = 0.69300\ldots$, while $2\displaystyle\sum_{n=1}^{4} \frac{1}{3^{2n-1}(2n-1)} = 0.69313\ldots$ and $\ln(2) = 0.69314\ldots$; therefore, $N=4$.

**In exercises 42 - 45, using a substitution if indicated, express each series in terms of elementary functions and find the radius of convergence of the sum.**

42) $\displaystyle\sum_{k=0}^{\infty} (x^k - x^{2k+1})$

43) $\displaystyle\sum_{k=1}^{\infty} \frac{x^{3k}}{6k}$

**Answer**

$\displaystyle\sum_{k=1}^{\infty} \frac{x^k}{k} = -\ln(1-x)$ so $\displaystyle\sum_{k=1}^{\infty} \frac{x^{3k}}{6k} = -\frac{1}{6}\ln(1-x^3)$. The radius of convergence is equal to $1$ by the Ratio Test.

44) $\sum_{k=1}^{\infty}(1+x^2)^{-k}$ using $y=\dfrac{1}{1+x^2}$

45) $\sum_{k=1}^{\infty}2^{-kx}$ using $y=2^{-x}$

**Answer**

If $y=2^{-x}$, then $\sum_{k=1}^{\infty}y^k=\dfrac{y}{1-y}=\dfrac{2^{-x}}{1-2^{-x}}=\dfrac{1}{2^x-1}$. If $a_k=2^{-kx}$, then $\dfrac{a_{k+1}}{a_k}=2^{-x}<1$ when $x>0$. So the series converges for all $x>0$.

46) Show that, up to powers $x^3$ and $y^3$, $E(x)=\sum_{n=0}^{\infty}\dfrac{x^n}{n!}$ satisfies $E(x+y)=E(x)E(y)$.

47) Differentiate the series $E(x)=\sum_{n=0}^{\infty}\dfrac{x^n}{n!}$ term-by-term to show that $E(x)$ is equal to its derivative.

**Answer**

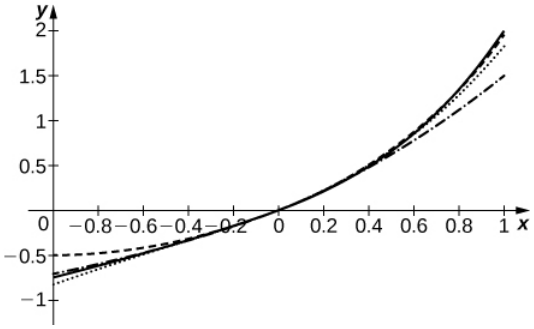
Answers will vary.

48) Show that if $f(x)=\sum_{n=0}^{\infty}a_nx^n$ is a sum of even powers, that is, $a_n=0$ if $n$ is odd, then $F=\int_0^x f(t)\,dt$ is a sum of odd powers, while if $I$ is a sum of odd powers, then $F$ is a sum of even powers.

49) [Technology Required] Suppose that the coefficients an of the series $\sum_{n=0}^{\infty}a_nx^n$ are defined by the recurrence relation $a_n=\dfrac{a_{n-1}}{n}+\dfrac{a_{n-2}}{n(n-1)}$. For $a_0=0$ and $a_1=1$, compute and plot the sums $S_N=\sum_{n=0}^{N}a_nx^n$ for $N=2,3,4,5$ on $[-1,1]$.

**Answer**

The solid curve is $S_5$. The dashed curve is $S_2$, dotted is $S_3$, and dash-dotted is $S_4$



50) [Technology Required] Suppose that the coefficients an of the series $\sum_{n=0}^{\infty}a_nx^n$ are defined by the recurrence relation $a_n=\dfrac{a_{n-1}}{\sqrt{n}}-\dfrac{a_{n-2}}{\sqrt{n(n-1)}}$. For $a_0=1$ and $a_1=0$, compute and plot the sums $S_N=\sum_{n=0}^{N}a_nx^n$ for $N=2,3,4,5$ on $[-1,1]$.

51) [Technology Required] Given the power series expansion $\ln(1+x)=\sum_{n=1}^{\infty}(-1)^{n-1}\dfrac{x^n}{n}$, determine how many terms $N$ of the sum evaluated at $x=-1/2$ are needed to approximate $\ln(2)$ accurate to within $1/1000$. Evaluate the corresponding partial sum $\sum_{n=1}^{N}(-1)^{n-1}\dfrac{x^n}{n}$.

**Answer**

When $x=-\dfrac{1}{2}$, $-\ln(2)=\ln\left(\dfrac{1}{2}\right)=-\sum_{n=1}^{\infty}\dfrac{1}{n2^n}$. Since $\sum_{n=11}^{\infty}\dfrac{1}{n2^n}<\sum_{n=11}^{\infty}\dfrac{1}{2^n}=\dfrac{1}{2^{10}}$, one has $\sum_{n=1}^{10}\dfrac{1}{n2^n}=0.69306\ldots$ whereas $\ln(2)=0.69314\ldots$; therefore, $N=10$.

52) [Technology Required] Given the power series expansion $\tan^{-1}(x) = \sum_{k=0}^{\infty}(-1)^k \frac{x^{2k+1}}{2k+1}$, use the alternating series test to determine how many terms $N$ of the sum evaluated at $x = 1$ are needed to approximate $\tan^{-1}(1) = \frac{\pi}{4}$ accurate to within $1/1000$. Evaluate the corresponding partial sum $\sum_{k=0}^{N}(-1)^k \frac{x^{2k+1}}{2k+1}$.

53) [Technology Required] Recall that $\tan^{-1}\left(\frac{1}{\sqrt{3}}\right) = \frac{\pi}{6}$. Assuming an exact value of $\frac{1}{\sqrt{3}}$), estimate $\frac{\pi}{6}$ by evaluating partial sums $S_N\left(\frac{1}{\sqrt{3}}\right)$ of the power series expansion $\tan^{-1}(x) = \sum_{k=0}^{\infty}(-1)^k \frac{x^{2k+1}}{2k+1}$ at $x = \frac{1}{\sqrt{3}}$. What is the smallest number $N$ such that $6S_N\left(\frac{1}{\sqrt{3}}\right)$ approximates $\pi$ accurately to within $0.001$? How many terms are needed for accuracy to within $0.00001$?

**Answer**

$6S_N\left(\frac{1}{\sqrt{3}}\right) = 2\sqrt{3}\sum_{n=0}^{N}(-1)^n \frac{1}{3^n(2n+1)}$. One has $\pi - 6S_4\left(\frac{1}{\sqrt{3}}\right) = 0.00101\ldots$ and $\pi - 6S_5\left(\frac{1}{\sqrt{3}}\right) = 0.00028\ldots$ so $N = 5$ is the smallest partial sum with accuracy to within $0.001$. Also, $\pi - 6S_7\left(\frac{1}{\sqrt{3}}\right) = 0.00002\ldots$ while $\pi - 6S_8\left(\frac{1}{\sqrt{3}}\right) = -0.000007\ldots$ so $N = 8$ is the smallest $N$ to give accuracy to within $0.00001$.

# 9.3: Taylor and Maclaurin Series

**Learning Objectives**

- Describe the procedure for finding a Taylor polynomial of a given order for a function.
- Explain the meaning and significance of Taylor's theorem with remainder.
- Estimate the remainder for a Taylor series approximation of a given function.

In the previous two sections, we discussed how to find power series representations for certain types of functions - specifically, functions related to geometric series. Here, we discuss power series representations for other types of functions. In particular, we address the following questions: Which functions can be represented by power series, and how do we find such representations? Suppose we can find a power series representation for a particular function $f$, and the series converges on some interval. How do we prove that the series converges to $f$?

## Overview of Taylor and Maclaurin Series

Consider a function $f$ that has a power series representation at $x = a$. Then the series has the form

$$\sum_{n=0}^{\infty} c_n(x-a)^n = c_0 + c_1(x-a) + c_2(x-a)^2 + \cdots. \tag{9.3.1}$$

What should the coefficients be? For now, we ignore convergence issues but instead focus on what the series should be if one exists. We return to discuss convergence later in this section. If the series in Equation 9.3.1 is a representation for $f$ at $x = a$, we certainly want the series to equal $f(a)$ at $x = a$. Evaluating the series at $x = a$, we see that

$$\sum_{n=0}^{\infty} c_n(x-a)^n = c_0 + c_1(a-a) + c_2(a-a)^2 + \cdots = c_0. \tag{9.3.2}$$

Thus, the series equals $f(a)$ if the coefficient $c_0 = f(a)$. In addition, we would like the first derivative of the power series to equal $f'(a)$ at $x = a$. Differentiating Equation 9.3.2 term-by-term, we see that

$$\frac{d}{dx}\left(\sum_{n=0}^{\infty} c_n(x-a)^n\right) = c_1 + 2c_2(x-a) + 3c_3(x-a)^2 + \cdots. \tag{9.3.3}$$

Therefore, at $x = a$, the derivative is

$$\frac{d}{dx}\left(\sum_{n=0}^{\infty} c_n(x-a)^n\right) = c_1 + 2c_2(a-a) + 3c_3(a-a)^2 + \cdots = c_1. \tag{9.3.4}$$

Hence, the derivative of the series equals $f'(a)$ if the coefficient $c_1 = f'(a)$. Continuing in this way, we look for coefficients $c_n$ such that all the derivatives of the power series in Equation 9.3.4 will agree with all the corresponding derivatives of $f$ at $x = a$. The second and third derivatives of Equation 9.3.3 are given by

$$\frac{d^2}{dx^2}\left(\sum_{n=0}^{\infty} c_n(x-a)^n\right) = 2c_2 + 3\cdot 2c_3(x-a) + 4\cdot 3c_4(x-a)^2 + \cdots$$

and

$$\frac{d^3}{dx^3}\left(\sum_{n=0}^{\infty} c_n(x-a)^n\right) = 3\cdot 2c_3 + 4\cdot 3\cdot 2c_4(x-a) + 5\cdot 4\cdot 3c_5(x-a)^2 + \cdots.$$

Therefore, at $x = a$, the second and third derivatives

$$\frac{d^2}{dx^2}\left(\sum_{n=0}^{\infty} c_n(x-a)^n\right) = 2c_2 + 3\cdot 2c_3(a-a) + 4\cdot 3c_4(a-a)^2 + \cdots = 2c_2$$

and

$$\frac{d^3}{dx^3}\left(\sum_{n=0}^{\infty} c_n(x-a)^n\right) = 3\cdot 2c_3 + 4\cdot 3\cdot 2c_4(a-a) + 5\cdot 4\cdot 3c_5(a-a)^2 + \cdots = 3\cdot 2c_3$$

equal $f''(a)$ and $f'''(a)$, respectively, if $c_2 = \frac{f''(a)}{2}$ and $c_3 = \frac{f'''(a)}{3\cdot 2}$. More generally, we see that if $f$ has a power series representation at $x = a$, then the coefficients should be given by $c_n = \frac{f^{(n)}(a)}{n!}$. That is, the series should be

$$\sum_{n=0}^{\infty} \frac{f^{(n)}(a)}{n!}(x-a)^n = f(a) + f'(a)(x-a) + \frac{f''(a)}{2!}(x-a)^2 + \frac{f'''(a)}{3!}(x-a)^3 + \cdots$$

This power series for $f$ is known as the **Taylor series for $f$ at $a$**. If $x = 0$, then this series is known as the **Maclaurin series** for $f$. We formalize these statements using the following definition.

**Definition: Maclaurin and Taylor series**

If $f$ has derivatives of all orders at $x = a$, then the **Taylor series for the function $f$ at $a$** is

$$\sum_{n=0}^{\infty} \frac{f^{(n)}(a)}{n!}(x-a)^n = f(a) + f'(a)(x-a) + \frac{f''(a)}{2!}(x-a)^2 + \cdots + \frac{f^{(n)}(a)}{n!}(x-a)^n + \cdots$$

The Taylor series for $f$ at $0$ is known as the **Maclaurin series** for $f$.

Later in this section, we will show examples of finding Taylor series and discuss conditions under which the Taylor series for a function will converge to that function. Here, we state an important result. Recall that power series representations are unique. Therefore, if a function $f$ has a power series at $a$, then it must be the Taylor series for $f$ at $a$.

**Theorem: Uniqueness of Taylor Series**

If a function $f$ has a power series at $a$ that converges to $f$ on some open interval containing $a$, then that power series is the Taylor series for $f$ at $a$.

The proof follows directly from that which was discussed previously.

To determine if a Taylor series converges, we need to look at its sequence of partial sums. These partial sums are finite polynomials, known as **Taylor polynomials**. These are the focus of the next subsection.

## Taylor Polynomials

The $n^{\text{th}}$ partial sum of the Taylor series for a function $f$ at $a$ is known as the **$n^{\text{th}}$-degree Taylor polynomial**. For example, the $0^{\text{th}}$, $1^{\text{st}}$, $2^{\text{nd}}$, and $3^{\text{rd}}$ partial sums of the Taylor series are given by

$$\begin{aligned}
p_0(x) &= f(a)\\
p_1(x) &= f(a) + f'(a)(x-a)\\
p_2(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2!}(x-a)^2\\
p_3(x) &= f(a) + f'(a)(x-a) + \frac{f''(a)}{2!}(x-a)^2 + \frac{f'''(a)}{3!}(x-a)^3
\end{aligned}$$

respectively. These partial sums are known as the $0^{\text{th}}$, $1^{\text{st}}$, $2^{\text{nd}}$, and $3^{\text{rd}}$ degree Taylor polynomials of $f$ at $a$, respectively. If $x = 0$, then these polynomials are known as **Maclaurin polynomials** for $f$. Below, we formally define Taylor and Maclaurin polynomials for a function $f$.

**Definition: Taylor and Maclaurin Polynomials**

If $f$ has $n$ derivatives at $x = a$, then the **$n^{\text{th}}$-degree Taylor polynomial** of $f$ at $a$ is

$$p_n(x) = f(a) + f'(a)(x-a) + \frac{f''(a)}{2!}(x-a)^2 + \frac{f'''(a)}{3!}(x-a)^3 + \cdots + \frac{f^{(n)}(a)}{n!}(x-a)^n.$$

The $n^{\text{th}}$-degree Taylor polynomial for $f$ at $0$ is known as the **$n^{\text{th}}$-degree Maclaurin polynomial** for $f$.

We now show how to use this definition to find several Taylor polynomials for $f(x) = \ln x$ at $x = 1$.

### Example 9.3.1: Finding Taylor Polynomials

Find the Taylor polynomials $p_0$, $p_1$, $p_2$, and $p_3$ for $f(x) = \ln x$ at $x = 1$. Use graphing technology to compare the graph of $f$ with the graphs of $p_0$, $p_1$, $p_2$, and $p_3$.

**Solution**

To find these Taylor polynomials, we need to evaluate $f$ and its first three derivatives at $x = 1$.

$$\begin{aligned} f(x) &= \ln x \implies f(1) = 0 \\ f'(x) &= \frac{1}{x} \implies f'(1) = 1 \\ f''(x) &= -\frac{1}{x^2} \implies f''(1) = -1 \\ f'''(x) &= \frac{2}{x^3} \implies f'''(1) = 2 \end{aligned}$$

Therefore,

$$\begin{aligned} p_0(x) &= f(1) &&= 0, \\ p_1(x) &= f(1) + f'(1)(x-1) &&= x - 1, \\ p_2(x) &= f(1) + f'(1)(x-1) + \frac{f''(1)}{2}(x-1)^2 &&= (x-1) - \frac{1}{2}(x-1)^2 \\ p_3(x) &= f(1) + f'(1)(x-1) + \frac{f''(1)}{2}(x-1)^2 + \frac{f'''(1)}{3!}(x-1)^3 &&= (x-1) - \frac{1}{2}(x-1)^2 + \frac{1}{3}(x-1)^3 \end{aligned}$$

The graphs of $y = f(x)$ and the first three Taylor polynomials are shown in Figure 9.3.1.

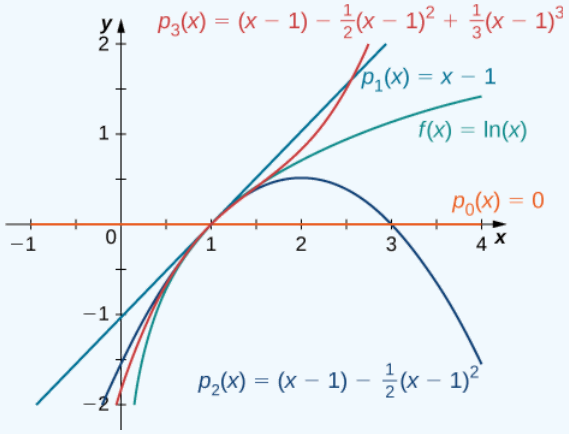

Figure 9.3.1: The function $y = \ln x$ and the Taylor polynomials $p_0, p_1, p_2$ and $p_3$ at $x = 1$ are plotted on this graph.

### Checkpoint 9.3.1

Find the Taylor polynomials $p_0$, $p_1$, $p_2$, and $p_3$ for $f(x) = \frac{1}{x^2}$ at $x = 1$.

**Answer**

$$\begin{aligned} p_0(x) &= 1 \\ p_1(x) &= 1-2(x-1) \\ p_2(x) &= 1-2(x-1)+3(x-1)^2 \\ p_3(x) &= 1-2(x-1)+3(x-1)^2-4(x-1)^3 \end{aligned}$$

We now show how to find Maclaurin polynomials for $e^x$, $\sin x$, and $\cos x$. As stated above, Maclaurin polynomials are Taylor polynomials centered at zero.

### Example 9.3.2: Finding Maclaurin Polynomials

For each of the following functions, find formulas for the Maclaurin polynomials $p_0$, $p_1$, $p_2$, and $p_3$. Find a formula for the $n^{\text{th}}$-degree Maclaurin polynomial and write it using sigma notation. Use graphing technology to compare the graphs of $p_0$, $p_1$, $p_2$, and $p_3$ with $f$.

a. $f(x)=e^x$
b. $f(x)=\sin x$
c. $f(x)=\cos x$

**Solutions**

a. Since $f(x)=e^x$,we know that $f(x)=f'(x)=f''(x)=\cdots=f^{(n)}(x)=e^x$ for all positive integers $n$. Therefore,

$$f(0)=f'(0)=f''(0)=\cdots=f^{(n)}(0)=1$$

for all positive integers $n$. Therefore, we have

$$\begin{aligned} p_0(x) &= f(0) &&= 1, \\ p_1(x) &= f(0)+f'(0)x &&= 1+x, \\ p_2(x) &= f(0)+f'(0)x+\frac{f''(0)}{2!}x^2 &&= 1+x+\frac{1}{2}x^2 \\ p_3(x) &= f(0)+f'(0)x+\frac{f''(0)}{2}x^2+\frac{f'''(0)}{3!}x^3 &&= 1+x+\frac{1}{2}x^2+\frac{1}{3!}x^3, \\ &\vdots \quad \vdots \quad \vdots && \vdots \quad \vdots \\ p_n(x) &= f(0)+f'(0)x+\frac{f''(0)}{2}x^2+\frac{f'''(0)}{3!}x^3+\cdots+\frac{f^{(n)}(0)}{n!}x^n &&= 1+x+\frac{x^2}{2!}+\frac{x^3}{3!}+\cdots+\frac{x^n}{n!} \end{aligned}$$

This last line could be written as

$$p_n(x)=\sum_{k=0}^{n}\frac{x^k}{k!}.$$

The function and the first three Maclaurin polynomials are shown in Figure 9.3.2.

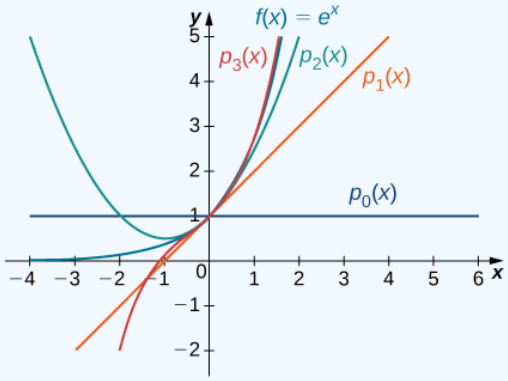

Figure 9.3.2: *The graph shows the function $y=e^x$ and the Maclaurin polynomials $p_0$, $p_1$, $p_2$, and $p_3$.*

b. For $f(x) = \sin x$, the values of the function and its first four derivatives at $x = 0$ are given as follows:

$$\begin{aligned} f(x) &= \sin x \implies f(0) = 0 \\ f'(x) &= \cos x \implies f'(0) = 1 \\ f''(x) &= -\sin x \implies f''(0) = 0 \\ f'''(x) &= -\cos x \implies f'''(0) = -1 \\ f^{(4)}(x) &= \sin x \implies f^{(4)}(0) = 0. \end{aligned}$$

Since the fourth derivative is $\sin x$, the pattern repeats. That is, $f^{(2m)}(0) = 0$ and $f^{(2m+1)}(0) = (-1)^m$ for $m \geq 0$. Thus, we have

$$\begin{aligned} p_0(x) &= 0, \\ p_1(x) &= 0 + x = x, \\ p_2(x) &= 0 + x + 0 = x, \\ p_3(x) &= 0 + x + 0 - \frac{1}{3!}x^3 = x - \frac{x^3}{3!}, \\ p_4(x) &= 0 + x + 0 - \frac{1}{3!}x^3 + 0 = x - \frac{x^3}{3!}, \\ p_5(x) &= 0 + x + 0 - \frac{1}{3!}x^3 + 0 + \frac{1}{5!}x^5 = x - \frac{x^3}{3!} + \frac{x^5}{5!}, \end{aligned}$$

and for $m \geq 0$,

$$p_{2m+1}(x) = p_{2m+2}(x) = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \cdots + (-1)^m \frac{x^{2m+1}}{(2m+1)!} = \sum_{k=0}^{m} (-1)^k \frac{x^{2k+1}}{(2k+1)!}.$$

Graphs of the function and its Maclaurin polynomials are shown in Figure 9.3.3.

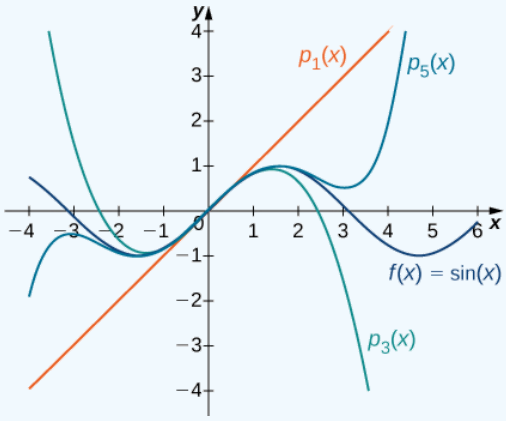

Figure 9.3.3: *The graph shows the function $y = \sin x$ and the Maclaurin polynomials $p_1$, $p_3$, and $p_5$.*

c. For $f(x) = \cos x$, the values of the function and its first four derivatives at $x = 0$ are given as follows:

$$\begin{aligned} f(x) &= \cos x \implies f(0) = 1 \\ f'(x) &= -\sin x \implies f'(0) = 0 \\ f''(x) &= -\cos x \implies f''(0) = -1 \\ f'''(x) &= \sin x \implies f'''(0) = 0 \\ f^{(4)}(x) &= \cos x \implies f^{(4)}(0) = 1. \end{aligned}$$

Since the fourth derivative is $\sin x$, the pattern repeats. In other words, $f^{(2m)}(0) = (-1)^m$ and $f^{(2m+1)} = 0$ for $m \geq 0$. Therefore,

$$
\begin{aligned}
p_0(x) &= 1, \\
p_1(x) &= 1+0 = 1, \\
p_2(x) &= 1+0-\frac{1}{2!}x^2 = 1-\frac{x^2}{2!}, \\
p_3(x) &= 1+0-\frac{1}{2!}x^2+0 = 1-\frac{x^2}{2!}, \\
p_4(x) &= 1+0-\frac{1}{2!}x^2+0+\frac{1}{4!}x^4 = 1-\frac{x^2}{2!}+\frac{x^4}{4!}, \\
p_5(x) &= 1+0-\frac{1}{2!}x^2+0+\frac{1}{4!}x^4+0 = 1-\frac{x^2}{2!}+\frac{x^4}{4!},
\end{aligned}
$$

and for $n \geq 0$,

$$p_{2m}(x) = p_{2m+1}(x) = 1-\frac{x^2}{2!}+\frac{x^4}{4!}-\cdots+(-1)^m\frac{x^{2m}}{(2m)!} = \sum_{k=0}^{m}(-1)^k\frac{x^{2k}}{(2k)!}.$$

Graphs of the function and the Maclaurin polynomials appear in Figure 9.3.4.

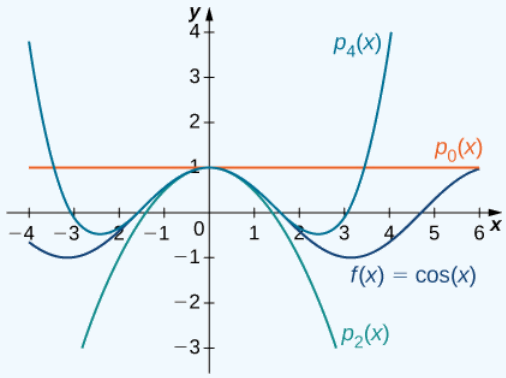

Figure 9.3.4: *The function $y = \cos x$ and the Maclaurin polynomials $p_0$, $p_2$, and $p_4$ are plotted on this graph.*

**? Checkpoint 9.3.2**

Find formulas for the Maclaurin polynomials $p_0$, $p_1$, $p_2$, and $p_3$ for $f(x) = \frac{1}{1+x}$.

Find a formula for the $n^{\text{th}}$-degree Maclaurin polynomial. Write your answer using sigma notation.

**Answer**

$$p_0(x) = 1;\ p_1(x) = 1-x;\ p_2(x) = 1-x+x^2;\ p_3(x) = 1-x+x^2-x^3;\ p_n(x) = 1-x+x^2-x^3+\cdots+(-1)^n x^n = \sum_{k=0}^{n}(-1)^k x^k$$

## Taylor's Theorem with Remainder

Recall that the $n^{\text{th}}$-degree Taylor polynomial for a function $f$ at $a$ is the $n^{\text{th}}$ partial sum of the Taylor series for $f$ at $a$. Therefore, to determine if the Taylor series converges, we need to determine whether the sequence of Taylor polynomials $\{p_n\}$ converges. However, not only do we want to know if the sequence of Taylor polynomials converges, we want to know if *it converges to* $f$. To answer this question, we define the remainder $R_n(x)$ as

$$R_n(x) = f(x) - p_n(x).$$

For the sequence of Taylor polynomials to converge to $f$, we need the remainder, $R_n$, to converge to zero. To determine if $R_n$ converges to zero, we introduce **Taylor's Theorem with Remainder** (also known as **Taylor's Remainder Theorem**). Not only is this theorem useful in proving that a Taylor series converges to its related function, but it will also allow us to quantify how well the $n^{\text{th}}$-degree Taylor polynomial approximates the function.

Here we look for a bound on $|R_n|$. Consider the simplest case: $n = 0$. Let $p_0$ be the $0^{\text{th}}$-degree Taylor polynomial at $a$ for a function $f$. The remainder $R_0$ satisfies

$$R_0(x) = f(x) - p_0(x) = f(x) - f(a).$$

If $f$ is differentiable on an interval $I$ containing $a$ and $x$, then by the Mean Value Theorem there exists a real number $c$ between $a$ and $x$ such that $f(x) - f(a) = f'(c)(x - a)$. Therefore,

$$R_0(x) = f'(c)(x - a).$$

Using the Mean Value Theorem in a similar argument, we can show that if $f$ is $n$ times differentiable on an interval $I$ containing $a$ and $x$, then the $n^{\text{th}}$ remainder $R_n$ satisfies

$$R_n(x) = \frac{f^{(n+1)}(c)}{(n+1)!}(x - a)^{n+1}$$

for some real number $c$ between $a$ and $x$. It is important to note that the value $c$ in the numerator above is not the center $a$, but rather an unknown value $c$ between $a$ and $x$. This formula allows us to get a bound on the remainder $R_n$. If we happen to know that $|f^{(n+1)}(x)|$ is bounded by some real number $M$ on this interval $I$, then

$$|R_n(x)| \leq \frac{M}{(n+1)!}|x - a|^{n+1}$$

for all $x$ in the interval $I$.

We now state Taylor's theorem, which provides the formal relationship between a function $f$ and its $n^{\text{th}}$-degree Taylor polynomial $p_n(x)$. This theorem allows us to bound the error when using a Taylor polynomial to approximate a function value. It will be important in proving that a Taylor series for $f$ converges to $f$.

### Theorem: Taylor's Theorem with Remainder

Let $f$ be a function that can be differentiated $n + 1$ times on an interval $I$ containing the real number $a$. Let $p_n$ be the $n^{\text{th}}$-degree Taylor polynomial of $f$ at $a$ and let

$$R_n(x) = f(x) - p_n(x)$$

be the $n^{\text{th}}$ remainder. Then for each $x$ in the interval $I$, there exists a real number $c$ between $a$ and $x$ such that

$$R_n(x) = \frac{f^{(n+1)}(c)}{(n+1)!}(x - a)^{n+1}.$$

If there exists a real number $M$ such that $|f^{(n+1)}(x)| \leq M$ for all $x \in I$, then

$$|R_n(x)| \leq \frac{M}{(n+1)!}|x - a|^{n+1}$$

for all $x$ in $I$.

**Proof**

Fix a point $x \in I$ and introduce the function $g$ such that

$$g(t) = f(x) - f(t) - f'(t)(x - t) - \frac{f''(t)}{2!}(x - t)^2 - \cdots - \frac{f^{(n)}(t)}{n!}(x - t)^n - R_n(x)\frac{(x - t)^{n+1}}{(x - a)^{n+1}}.$$

We claim that $g$ satisfies the criteria of Rolle's Theorem. Since $g$ is a polynomial function (in $t$), it is a differentiable function. Also, $g$ is zero at $t = a$ and $t = x$ because

$$\begin{aligned} g(a) &= f(x) - f(a) - f'(a)(x-a) - \frac{f''(a)}{2!}(x-a)^2 + \cdots + \frac{f^{(n)}(a)}{n!}(x-a)^n - R_n(x) \\ &= f(x) - p_n(x) - R_n(x) \\ &= 0, \\ g(x) &= f(x) - f(x) - 0 - \cdots - 0 \\ &= 0. \end{aligned}$$

Therefore, $g$ satisfies Rolle's Theorem, and consequently, there exists $c$ between $a$ and $x$ such that $g'(c) = 0$. We now calculate $g'$. Using the Product Rule, we note that

$$\frac{d}{dt}\left[\frac{f^{(n)}(t)}{n!}(x-t)^n\right] = -\frac{f^{(n)}(t)}{(n-1)!}(x-t)^{n-1} + \frac{f^{(n+1)}(t)}{n!}(x-t)^n.$$

Consequently,

$$\begin{aligned} g'(t) &= -f'(t) + [f'(t) - f''(t)(x-t)] + \left[f''(t)(x-t) - \frac{f'''(t)}{2!}(x-t)^2\right] + \cdots \\ &\quad + \left[\frac{f^{(n)}(t)}{(n-1)!}(x-t)^{n-1} - \frac{f^{(n+1)}(t)}{n!}(x-t)^n\right] + (n+1)R_n(x)\frac{(x-t)^n}{(x-a)^{n+1}} \end{aligned}$$

Notice that there is a telescoping effect. Therefore,

$$g'(t) = -\frac{f^{(n+1)}(t)}{n!}(x-t)^n + (n+1)R_n(x)\frac{(x-t)^n}{(x-a)^{n+1}}.$$

By Rolle's Theorem, we conclude that there exists a number $c$ between $a$ and $x$ such that $g'(c) = 0$. Since

$$g'(c) = -\frac{f^{(n+1)}(c)}{n!}(x-c)^n + (n+1)R_n(x)\frac{(x-c)^n}{(x-a)^{n+1}}$$

we conclude that

$$-\frac{f^{(n+1)}(c)}{n!}(x-c)^n + (n+1)R_n(x)\frac{(x-c)^n}{(x-a)^{n+1}} = 0.$$

Adding the first term on the left-hand side to both sides of the equation and dividing both sides of the equation by $n+1$, we conclude that

$$R_n(x) = \frac{f^{(n+1)}(c)}{(n+1)!}(x-a)^{n+1}$$

as desired. From this fact, it follows that if there exists $M$ such that $|f^{(n+1)}(x)| \leq M$ for all $x$ in $I$, then

$$|R_n(x)| \leq \frac{M}{(n+1)!}|x-a|^{n+1}.$$

Not only does Taylor's Theorem allow us to prove that a Taylor series converges to a function, but it also allows us to estimate the accuracy of Taylor polynomials in approximating function values. We begin by looking at linear and quadratic approximations of $f(x) = \sqrt[3]{x}$ at $x = 8$ and determine how accurate these approximations are at estimating $\sqrt[3]{11}$.

### Example 9.3.3: Using Linear and Quadratic Approximations to Estimate Function Values

Consider the function $f(x) = \sqrt[3]{x}$.

a. Find the first and second Taylor polynomials for $f$ at $x = 8$. Use a graphing utility to compare these polynomials with $f$ near $x = 8$.
b. Use these two polynomials to estimate $\sqrt[3]{11}$.
c. Use Taylor's theorem to bound the error.

**Solutions**

a. For $f(x) = \sqrt[3]{x}$, the values of the function and its first two derivatives at $x = 8$ are as follows:

$$\begin{aligned} f(x) &= \sqrt[3]{x}, \quad \Rightarrow \quad f(8) = 2 \\ f'(x) &= \frac{1}{3x^{2/3}}, \quad \Rightarrow \quad f'(8) = \frac{1}{12} \\ f''(x) &= \frac{-2}{9x^{5/3}}, \quad \Rightarrow \quad f''(8) = -\frac{1}{144}. \end{aligned}$$

Thus, the first and second Taylor polynomials at $x = 8$ are given by

$$\begin{aligned} p_1(x) &= f(8) + f'(8)(x-8) \\ &= 2 + \frac{1}{12}(x-8) \\ p_2(x) &= f(8) + f'(8)(x-8) + \frac{f''(8)}{2!}(x-8)^2 \\ &= 2 + \frac{1}{12}(x-8) - \frac{1}{288}(x-8)^2. \end{aligned}$$

The function and the Taylor polynomials are shown in Figure 9.3.5.

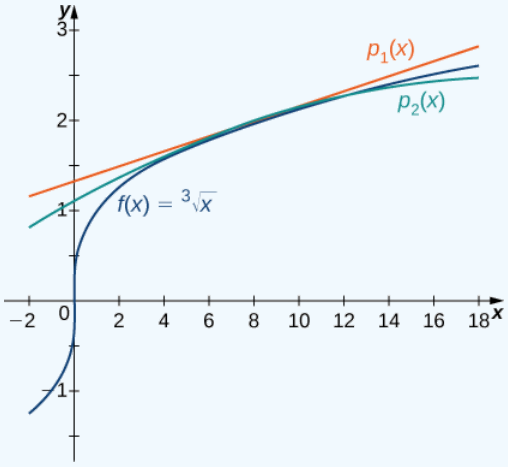

Figure 9.3.5: *The graphs of $f(x) = \sqrt[3]{x}$ and the linear and quadratic approximations $p_1(x)$ and $p_2(x)$*

b. Using the first Taylor polynomial at $x = 8$, we can estimate

$$\sqrt[3]{11} \approx p_1(11) = 2 + \frac{1}{12}(11-8) = 2.25.$$

Using the second Taylor polynomial at $x = 8$, we obtain

$$\sqrt[3]{11} \approx p_2(11) = 2 + \frac{1}{12}(11-8) - \frac{1}{288}(11-8)^2 = 2.21875.$$

c. There exists a $c$ in the interval $(8, 11)$ such that the remainder when approximating $\sqrt[3]{11}$ by the first Taylor polynomial satisfies

$$R_1(11) = \frac{f''(c)}{2!}(11-8)^2.$$

We do not know the exact value of $c$, so we find an upper bound on $R_1(11)$ by determining the maximum value of $f''$ on the interval $(8, 11)$. Since $f''(x) = -\frac{2}{9x^{5/3}}$, the largest value for $|f''(x)|$ on that interval occurs at $x = 8$. Using the fact that $f''(8) = -\frac{1}{144}$, we obtain

$$|R_1(11)| \leq \frac{1}{144 \cdot 2!}(11-8)^2 = 0.03125.$$

Similarly, to estimate $R_2(11)$, we use the fact that

$$R_2(11) = \frac{f'''(c)}{3!}(11-8)^3.$$

Since

$$f'''(x) = \frac{10}{27x^{8/3}},$$

the maximum value of $f'''$ on the interval $(8, 11)$ is $f'''(8) \approx 0.0014468$. Therefore, we have

$$|R_2(11)| \leq \frac{0.0011468}{3!}(11-8)^3 \approx 0.0065104.$$

## Checkpoint 9.3.3

Find the first and second Taylor polynomials for $f(x) = \sqrt{x}$ at $x = 4$. Use these polynomials to estimate $\sqrt{6}$. Use Taylor's theorem to bound the error.

**Answers**

$p_1(x) = 2 + \frac{1}{4}(x-4); p_2(x) = 2 + \frac{1}{4}(x-4) - \frac{1}{64}(x-4)^2; p_1(6) = 2.5; p_2(6) = 2.4375;$

$|R_1(6)| \leq 0.0625; |R_2(6)| \leq 0.015625$

## Example 9.3.4: Approximating $\sin x$ Using Maclaurin Polynomials

From Example 9.3.2b, the Maclaurin polynomials for $\sin x$ are given by

$$p_{2m+1}(x) = p_{2m+2}(x) = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \cdots + (-1)^m \frac{x^{2m+1}}{(2m+1)!}$$

for $m = 0, 1, 2, \ldots$.

a. Use the fifth Maclaurin polynomial for $\sin x$ to approximate $\sin\left(\frac{\pi}{18}\right)$ and bound the error.
b. For what values of $x$ does the fifth Maclaurin polynomial approximate $\sin x$ to within $0.0001$?

**Solutions**

a. The fifth Maclaurin polynomial is

$$p_5(x) = x - \frac{x^3}{3!} + \frac{x^5}{5!}.$$

Using this polynomial, we can estimate as follows:

$$\sin\left(\frac{\pi}{18}\right) \approx p_5\left(\frac{\pi}{18}\right) = \frac{\pi}{18} - \frac{1}{3!}\left(\frac{\pi}{18}\right)^3 + \frac{1}{5!}\left(\frac{\pi}{18}\right)^5 \approx 0.173648.$$

To estimate the error, use the fact that the sixth Maclaurin polynomial is $p_6(x) = p_5(x)$ and calculate a bound on $R_6(\frac{\pi}{18})$. By Note, the remainder is

$$R_6\left(\frac{\pi}{18}\right) = \frac{f^{(7)}(c)}{7!}\left(\frac{\pi}{18}\right)^7$$

for some $c$ between 0 and $\frac{\pi}{18}$. Using the fact that $|f^{(7)}(x)| \leq 1$ for all $x$, we find that the magnitude of the error is at most

$$\frac{1}{7!} \cdot \left(\frac{\pi}{18}\right)^7 \leq 9.8 \times 10^{-10}.$$

b. We need to find the values of $x$ such that

$$\frac{1}{7!}|x|^7 \leq 0.0001.$$

Solving this inequality for $x$, we have that the fifth Maclaurin polynomial gives an estimate to within $0.0001$ as long as $|x| < 0.907$.

**Checkpoint 9.3.4**

Use the fourth Maclaurin polynomial for $\cos x$ to approximate $\cos\left(\frac{\pi}{12}\right)$.

**Answer**

0.96593

Now that we can bound the remainder $R_n(x)$, we can use this bound to prove that a Taylor series for $f$ at a converges to $f$.

## Representing Functions with Taylor and Maclaurin Series

We now discuss issues of convergence for Taylor series. We begin by showing how to find a Taylor series for a function and how to find its interval of convergence.

**Example 9.3.5: Finding a Taylor Series**

Find the Taylor series for $f(x) = \frac{1}{x}$ at $x = 1$. Determine the interval of convergence.

**Solution**

For $f(x) = \frac{1}{x}$, the values of the function and its first four derivatives at $x = 1$ are

$$\begin{aligned} f(x) &= \frac{1}{x} \quad \Rightarrow \quad f(1) = 1 \\ f'(x) &= -\frac{1}{x^2} \quad \Rightarrow \quad f'(1) = -1 \\ f''(x) &= \frac{2}{x^3} \quad \Rightarrow \quad f''(1) = 2! \\ f'''(x) &= -\frac{3 \cdot 2}{x^4} \quad \Rightarrow \quad f'''(1) = -3! \\ f^{(4)}(x) &= \frac{4 \cdot 3 \cdot 2}{x^5} \quad \Rightarrow \quad f^{(4)}(1) = 4!. \end{aligned}$$

That is, we have $f^{(n)}(1) = (-1)^n n!$ for all $n \geq 0$. Therefore, the Taylor series for $f$ at $x = 1$ is given by

$$\sum_{n=0}^{\infty} \frac{f^{(n)}(1)}{n!}(x-1)^n = \sum_{n=0}^{\infty} (-1)^n (x-1)^n.$$

To find the interval of convergence, we use the Ratio Test. We find that

$$\frac{|a_{n+1}|}{|a_n|} = \frac{|\,(-1)^{n+1}(x-1)^{n+1}\,|}{|(-1)^n(x-1)^n|} = |x-1|.$$

Thus, the series converges if $|x-1| < 1$. That is, the series converges for $0 < x < 2$. Next, we need to check the endpoints. At $x = 2$, we see that

$$\sum_{n=0}^{\infty} (-1)^n (2-1)^n = \sum_{n=0}^{\infty} (-1)^n$$

diverges by the Divergence Test. Similarly, at $x = 0$,

$$\sum_{n=0}^{\infty} (-1)^n (0-1)^n = \sum_{n=0}^{\infty} (-1)^{2n} = \sum_{n=0}^{\infty} 1$$

diverges. Therefore, the interval of convergence is $(0, 2)$.

**Checkpoint 9.3.5**

Find the Taylor series for $f(x) = \frac{1}{2x}$ at $x = 2$ and determine its interval of convergence.

**Answer**

$\frac{1}{2}\sum_{n=0}^{\infty}\left(\frac{2-x}{2}\right)^n$. The interval of convergence is $(0, 4)$.

We know that the Taylor series found in this example converges on the interval $(0, 2)$, but how do we know it converges to $f$? We consider this question in more generality in a moment. Still, for this example, we can answer this question by writing

$$f(x) = \frac{1}{x} = \frac{1}{1-(1-x)}.$$

That is, $f$ can be represented by the geometric series $\sum_{n=0}^{\infty}(1-x)^n$. Since this is a geometric series, it converges to $\frac{1}{x}$ as long as $|1 - x| < 1$. Therefore, the Taylor series found in Example 9.3.5 does converge to $f(x) = \frac{1}{x}$ on $(0, 2)$.

We now consider the more general question: if a Taylor series for a function $f$ converges on some interval, how can we determine if it converges to $f$? To answer this question, recall that a series converges to a particular value if and only if its sequence of partial sums converges to that value. Given a Taylor series for $f$ at $a$, the $n^{\text{th}}$ partial sum is given by the $n^{\text{th}}$-degree Taylor polynomial $p_n$. Therefore, to determine if the Taylor series converges to $f$, we need to determine whether

$$\lim_{n\to\infty} p_n(x) = f(x).$$

Since the remainder $R_n(x) = f(x) - p_n(x)$, the Taylor series converges to $f$ if and only if

$$\lim_{n\to\infty} R_n(x) = 0.$$

We now state this theorem formally.

**Theorem: Convergence of Taylor Series**

Suppose that $f$ has derivatives of all orders on an interval $I$ containing $a$. Then the Taylor series

$$\sum_{n=0}^{\infty}\frac{f^{(n)}(a)}{n!}(x-a)^n$$

converges to $f(x)$ for all $x$ in $I$ if and only if

$$\lim_{n\to\infty} R_n(x) = 0$$

for all $x$ in $I$.

With this theorem, we can prove that a Taylor series for $f$ at $a$ converges to $f$ if we can prove that the remainder $R_n(x) \to 0$. To prove that $R_n(x) \to 0$, we typically use the bound

$$|R_n(x)| \le \frac{M}{(n+1)!}|x-a|^{n+1}$$

from Taylor's Theorem with Remainder.

In the next example, we find the Maclaurin series for $e^x$ and $\sin x$ and show that these series converge to the corresponding functions for all real numbers by proving that the remainders $R_n(x) \to 0$ for all real numbers $x$.

## Example 9.3.6: Finding Maclaurin Series

For each of the following functions, find the Maclaurin series and its interval of convergence. Use the Convergence of Taylor Series theorem to prove that the Maclaurin series for $f$ converges to $f$ on that interval.

a. $e^x$

b. $\sin x$

**Solutions**

a. a. Using the $n^{\text{th}}$-degree Maclaurin polynomial for $e^x$ found in Example 9.3.2a., we find that the Maclaurin series for $e^x$ is given by

$$\sum_{n=0}^{\infty} \frac{x^n}{n!}.$$

To determine the interval of convergence, we use the Ratio Test. Since

$$\frac{|a_{n+1}|}{|a_n|} = \frac{|x|^{n+1}}{(n+1)!} \cdot \frac{n!}{|x|^n} = \frac{|x|}{n+1},$$

we have

$$\lim_{n\to\infty} \frac{|a_{n+1}|}{|a_n|} = \lim_{n\to\infty} \frac{|x|}{n+1} = 0$$

for all $x$. Therefore, the series converges absolutely for all $x$, and thus, the interval of convergence is $(-\infty, \infty)$. To show that the series converges to $e^x$ for all $x$, we use the fact that $f^{(n)}(x) = e^x$ for all $n \geq 0$ and $e^x$ is an increasing function on $(-\infty, \infty)$. Therefore, for any real number $b$, the maximum value of $e^x$ for all $|x| \leq b$ is $e^b$. Thus,

$$|R_n(x)| \leq \frac{e^b}{(n+1)!}|x|^{n+1}.$$

Since we just showed that

$$\sum_{n=0}^{\infty} \frac{|x|^n}{n!}$$

converges for all $x$, by the Divergence Test, we know that

$$\lim_{n\to\infty} \frac{|x|^{n+1}}{(n+1)!} = 0$$

for any real number $x$. By combining this fact with the Squeeze Theorem, the result is $\lim_{n\to\infty} R_n(x) = 0$.

b. Using the $n^{\text{th}}$-degree Maclaurin polynomial for $\sin x$ found in Example 9.3.2b., we find that the Maclaurin series for $\sin x$ is given by

$$\sum_{n=0}^{\infty} (-1)^n \frac{x^{2n+1}}{(2n+1)!}.$$

In order to apply the Ratio Test, consider

$$\begin{aligned} \frac{|a_{n+1}|}{|a_n|} &= \frac{|x|^{2n+3}}{(2n+3)!} \cdot \frac{(2n+1)!}{|x|^{2n+1}} \\ &= \frac{|x|^2}{(2n+3)(2n+2)}. \end{aligned}$$

Since

$$\lim_{n\to\infty} \frac{|x|^2}{(2n+3)(2n+2)} = 0$$

for all $x$, we obtain the interval of convergence as $(-\infty, \infty)$. To show that the Maclaurin series converges to $\sin x$, look at $R_n(x)$. For each $x$ there exists a real number $c$ between $0$ and $x$ such that

$$R_n(x) = \frac{f^{(n+1)}(c)}{(n+1)!}x^{n+1}.$$

Since $|f^{(n+1)}(c)| \leq 1$ for all integers $n$ and all real numbers $c$, we have

$$|R_n(x)| \leq \frac{|x|^{n+1}}{(n+1)!}$$

for all real numbers $x$. Using the same idea as in part a., the result is $\lim_{n\to\infty} R_n(x) = 0$ for all $x$, and therefore, the Maclaurin series for $\sin x$ converges to $\sin x$ for all real $x$.

**? Checkpoint 9.3.6**

Find the Maclaurin series for $f(x) = \cos x$. Use the Ratio Test to show that the interval of convergence is $(-\infty, \infty)$. Show that the Maclaurin series converges to $\cos x$ for all real numbers $x$.

**Answer**

$$\sum_{n=0}^{\infty} \frac{(-1)^n x^{2n}}{(2n)!}$$

By the Ratio Test, the interval of convergence is $(-\infty, \infty)$. Since $|R_n(x)| \leq \frac{|x|^{n+1}}{(n+1)!}$, the series converges to $\cos x$ for all real $x$.

## Deriving New Maclaurin Series from Known Series

At this point, we have derived Maclaurin series for exponential, trigonometric, and logarithmic functions. In Table **9.3.1**, we summarize the results of these series. We remark that the convergence of the Maclaurin series for $f(x) = \ln(1+x)$ at the endpoint $x = 1$ and the Maclaurin series for $f(x) = \tan^{-1} x$ at the endpoints $x = 1$ and $x = -1$ relies on a more advanced theorem than we present here. (Refer to Abel's Theorem for a discussion of this more technical point.)

Table **9.3.1**: Maclaurin Series for Common Functions

| Function | Maclaurin Series | Interval of Convergence |
|---|---|---|
| $f(x) = \frac{1}{1-x}$ | $\sum_{n=0}^{\infty} x^n$ | $-1 < x < 1$ |
| $f(x) = e^x$ | $\sum_{n=0}^{\infty} \frac{x^n}{n!}$ | $-\infty < x < \infty$ |
| $f(x) = \sin x$ | $\sum_{n=0}^{\infty} (-1)^n \frac{x^{2n+1}}{(2n+1)!}$ | $-\infty < x < \infty$ |
| $f(x) = \cos x$ | $\sum_{n=0}^{\infty} (-1)^n \frac{x^{2n}}{(2n)!}$ | $-\infty < x < \infty$ |
| $f(x) = \ln(1+x)$ | $\sum_{n=1}^{\infty} (-1)^{n-1} \frac{x^n}{n}$ | $-1 < x \leq 1$ |
| $f(x) = \tan^{-1} x$ | $\sum_{n=0}^{\infty} (-1)^n \frac{x^{2n+1}}{2n+1}$ | $-1 \leq x \leq 1$ |

Earlier in the chapter, we showed how you could combine power series to create new power series. Here we use these properties, combined with the Maclaurin series in Table **9.3.1**, to create Maclaurin series for other functions.

### Example 9.3.7: Deriving Maclaurin Series from Known Series

Find the Maclaurin series of each of the following functions by using one of the series listed in Table 9.3.1.

a. $f(x) = \cos\sqrt{x}$
b. $f(x) = \sinh x$

**Solutions**

a. Using the Maclaurin series for $\cos x$ we find that the Maclaurin series for $\cos\sqrt{x}$ is given by

$$\sum_{n=0}^{\infty} \frac{(-1)^n(\sqrt{x})^{2n}}{(2n)!} = \sum_{n=0}^{\infty} \frac{(-1)^n x^n}{(2n)!} = 1 - \frac{x}{2!} + \frac{x^2}{4!} - \frac{x^3}{6!} + \frac{x^4}{8!} - \cdots.$$

This series converges to $\cos\sqrt{x}$ for all $x$ in the domain of $\cos\sqrt{x}$; that is, for all $x \geq 0$.

b. To find the Maclaurin series for $\sinh x$, we use the fact that

$$\sinh x = \frac{e^x - e^{-x}}{2}.$$

Using the Maclaurin series for $e^x$, we see that the $n^{\text{th}}$ term in the Maclaurin series for $\sinh x$ is given by

$$\frac{x^n}{n!} - \frac{(-x)^n}{n!}.$$

For $n$ even, this term is zero. For $n$ odd, this term is $\frac{2x^n}{n!}$. Therefore, the Maclaurin series for $\sinh x$ has only odd-order terms and is given by

$$\sum_{n=0}^{\infty} \frac{x^{2n+1}}{(2n+1)!} = x + \frac{x^3}{3!} + \frac{x^5}{5!} + \cdots.$$

### Exercise 9.3.7

Find the Maclaurin series for $\sin(x^2)$.

**Answer**

$$\sum_{n=0}^{\infty} \frac{(-1)^n x^{4n+2}}{(2n+1)!}$$

## Revisiting Limits

At this point, many students feel a sense of frustration at not knowing why Maclaurin and Taylor series are a required investigation in Calculus. In truth, the functions encountered in applications of science and engineering are often not the "nice" functions you have been dealing with since Algebra. It is more often the case that you are not going to be dealing with explicit functions at all and, instead, will only have datasets and regressions (neither of which are the focus of a traditional Calculus course).

To illustrate some of the flexibility we gain by having Taylor (and Maclaurin) series, we reach back to our first investigation in Differential Calculus - limits.

### Example 9.3.8: Determining the Value of a Limit

Evaluate the limit using a series.

$$\lim_{x \to 0} \frac{\sin(x) - x + \frac{1}{6}x^3}{x^5}$$

**Solution**

Since this is an indeterminate limit of the form $0/0$, we could easily use l'Hospital's Rule to find its value; however, using a mathematical tool (like l'Hospital's Rule) simply because we have "always done it that way" closes our minds to the possibilities of other, more efficient, methods. Recall, from Example **9.3.6***b*, that

$$\sin(x) = \sum_{n=0}^{\infty} (-1)^n \frac{x^{2n+1}}{(2n+1)!} = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \frac{x^9}{9!} - \cdots$$

for all $x \in \mathbb{R}$. Therefore,

$$\begin{aligned}
\lim_{x\to 0} \frac{\sin(x) - x - \frac{1}{6}x^3}{x^5} &= \lim_{x\to 0} \frac{\sum_{n=0}^{\infty} (-1)^n \frac{x^{2n+1}}{(2n+1)!} - x + \frac{1}{6}x^3}{x^5} \\
&= \lim_{x\to 0} \frac{\left(x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \frac{x^9}{9!} - \cdots\right) - x + \frac{1}{6}x^3}{x^5} \\
&= \lim_{x\to 0} \frac{\cancel{x} - \cancel{\frac{1}{6}x^3} + \frac{x^5}{120} - \frac{x^7}{7!} + \frac{x^9}{9!} - \cdots - \cancel{x} + \cancel{\frac{1}{6}x^3}}{x^5} \\
&= \lim_{x\to 0} \frac{\frac{x^5}{120} - \frac{x^7}{7!} + \frac{x^9}{9!} - \cdots}{x^5} \\
&= \lim_{x\to 0} \frac{1}{120} - \frac{x^2}{7!} + \frac{x^4}{9!} - \cdots \\
&= \frac{1}{120}
\end{aligned}$$

The lazy student might look at the amount of work performed in Example **9.3.8** and feel inclined to use l'Hospital's Rule instead. In doing so, they miss a golden opportunity to "streamline" their Calculus skills. In truth, the savvy student (once familiarized with the Maclaurin series of the sine) would immediately recognize the polynomial in the numerator of the limit as the opposite of the first two terms of the Maclaurin series expansion of the sine. Knowing the remaining terms of said expansion are $\frac{1}{5!}x^5 - \frac{1}{7!}x^7 + \cdots$, the student would visualize the cancellation of the $x^5$ between numerator and denominator - leaving $\frac{1}{5!} - (\text{some number})x^2 + (\text{some number})x^4 - \cdots$. All the variable terms would tend to zero leaving $\frac{1}{5!} = \frac{1}{120}$.

**? Exercise 9.3.8**

Evaluate the limit using a series.

$$\lim_{x\to 0} \frac{1 + x + \frac{1}{2}x^2 - e^x}{x^3}$$

**Answer**

$-\frac{1}{6}$

## Revisiting Integration

In terms of complexity, evaluating limits and differentiating functions is much easier than integration. For example, the limit

$$\lim_{x\to\infty} x^2 e^{-x^2} = 0$$

and the derivative

$$\frac{d}{dx} x^2 e^{-x^2} = 2xe^{-x^2} - 2x^3 e^{-x^2} = 2xe^{-x^2}(1-x)(1+x)$$

are simple affairs at this point. However, up to this point, evaluating the definite integral

$$\int_0^{0.5} x^2 e^{-x^2}\, dx$$

is a disaster without using numerical integration techniques.

Truly, it is for integration that Taylor and Maclaurin series are profoundly useful. Specifically, power series can be used to evaluate integrals involving functions whose antiderivatives cannot be expressed using elementary functions. By **elementary function**, we mean a function that can be written using a finite number of algebraic combinations or compositions of exponential, logarithmic, trigonometric, or power functions. We remark that the term "elementary function" is not synonymous with noncomplicated function. For example, the function $f(x) = \sqrt{x^2 - 3x} + e^{x^3} - \sin(5x + 4)$ is an elementary function, although not a particularly simple-looking function. Any integral of the form $\int f(x)\,dx$ where the antiderivative of $f$ cannot be written as an elementary function is considered a **non-elementary integral**.

Non-elementary integrals cannot be evaluated using the basic integration techniques discussed earlier. One way to evaluate such integrals is by expressing the integrand as a power series and integrating term by term. We demonstrate this technique by considering $\int x^2 e^{-x^2}\,dx$.

### Example 9.3.9: Integration Involving Maclaurin Series

a. Represent $\int x^2 e^{-x^2}\,dx$ as an infinite series.

b. Evaluate the definite integral to within 0.0000001.

$$\int_0^{0.5} x^2 e^{-x^2}\,dx$$

**Solution**

a. We begin by noting that

$$x^2 e^{-x^2} = x^2 \sum_{n=0}^{\infty} \frac{(-x^2)^n}{n!} = x^2 \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n}}{n!} = \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n+2}}{n!}.$$

Hence,

$$\begin{aligned} \int x^2 e^{-x^2}\,dx &= \int \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n+2}}{n!} \\ &= C + \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n+3}}{n!(2n+3)} \end{aligned}$$

b. Using the result from part a, we get

$$\begin{aligned} \int_0^{0.5} x^2 e^{-x^2}\,dx &= \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n+3}}{n!(2n+3)}\Bigg|_0^{0.5} \\ &= \sum_{n=0}^{\infty} \frac{(-1)^n \left(\frac{1}{2}\right)^{2n+3}}{n!(2n+3)} - \sum_{n=0}^{\infty} \frac{(-1)^n (0)^{2n+3}}{n!(2n+3)} \\ &= \sum_{n=0}^{\infty} \frac{(-1)^n}{n!(2n+3)2^{2n+3}} \end{aligned}$$

If we let $b_n = \frac{1}{n!(2n+3)2^{2n+3}}$, then

$$\lim_{n\to\infty} b_n = \lim_{n\to\infty} \frac{1}{n!(2n+3)2^{2n+3}} = 0.$$

Moreover,

$$(n+1)!(2(n+1)+3)2^{2(n+1)+3} = (n+1)!(2n+5)2^{2n+5} > n!(2n+3)2^{2n+3}$$

and so

$$\frac{1}{(n+1)!(2(n+1)+3)2^{2(n+1)+3}} < \frac{1}{n!(2n+3)2^{2n+3}} \implies b_{n+1} < b_n.$$

Hence, the sequence, $\{b_n\}$, is decreasing. As such, the series converges by the Alternating Series Test. The error in approximating the value of this series is bounded by $b_{n+1}$. Therefore, we want

$$b_{n+1} < 0.0000001 \implies \frac{1}{(n+1)!(2(n+1)+3)2^{2(n+1)+3}} < 0.0000001$$

Sadly, the best way to determine the value of $n$ satisfying this inequality is to try $n = 1, 2, 3, \ldots$ until we get the left side to be less than $0.0000001 = 10^{-7}$. Using the **TABLE** feature in Desmos, we see that $n = 4$ will work fine.

| $x_1$ | $\frac{1}{(x_1+1)!(2x_1+5)2^{(2x_1+5)}}$ |
|---|---|
| 1 | $5.580357 \times 10^{-4}$ |
| 2 | $3.616898 \times 10^{-5}$ |
| 3 | $1.84955 \times 10^{-6}$ |
| 4 | $7.82502 \times 10^{-8}$ |

Hence,

$$\int_0^{0.5} x^2 e^{-x^2}\,dx = \sum_{n=0}^{\infty} \frac{(-1)^n}{n!(2n+3)2^{2n+3}} \approx \sum_{n=0}^{4} \frac{(-1)^n}{n!(2n+3)2^{2n+3}} \approx 0.03594038$$

**? Exercise 9.3.9**

a. Express $\int e^{-x^2}\,dx$ as an infinite series.

b. Evaluate $\int_0^1 e^{-x^2}\,dx$ to within an error of $0.01$.

**Answer**

a. $$C + \sum_{n=0}^{\infty} (-1)^n \frac{x^{2n+1}}{(2n+1)n!} = C + x - \frac{x^3}{3} + \frac{x^5}{5(2!)} - \frac{x^7}{7(3!)} + \cdots + (-1)^n \frac{x^{2n+1}}{(2n+1)n!} + \cdots$$

b. Using the result from part a. we have

$$\int_0^1 e^{-x^2}\,dx = 1 - \frac{1}{3} + \frac{1}{10} - \frac{1}{42} + \frac{1}{216} - \cdots.$$

The sum of the first four terms is approximately $0.74$. By the Alternating Series Test, this estimate is accurate to within an error of less than $\frac{1}{216} \approx 0.0046296 < 0.01$.

## Identifying Series

Once we get used to the *forms* of specific Maclaurin series (see Table **9.3.1**), we can sometimes worked backwards and identify a function given its power series. To be clear, this requires some comfort with the Maclaurin series we have derived thus far.

**✓ Example 9.3.10**

Find the sum of the series.

$$\sum_{n=0}^{\infty} \frac{(-1)^{n+1}\pi^{2n+1}}{7 \cdot 3^{2n}(2n)!}$$

**Solution**

We begin by noting that the given series is very close to the form of the Maclaurin series for the cosine,

$$\cos(x) = \sum_{n=0}^{\infty} (-1)^n \frac{x^{2n}}{(2n)!}.$$

Performing some manipulations (specifically, to obtain the necessary powers in the Maclaurin series for the cosine), we get

$$\begin{aligned} \sum_{n=0}^{\infty} \frac{(-1)^{n+1}\pi^{2n+1}}{7 \cdot 3^{2n}(2n)!} &= -\frac{\pi}{7} \sum_{n=0}^{\infty} \frac{(-1)^n \pi^{2n}}{3^{2n}(2n)!} \\ &= -\frac{\pi}{7} \sum_{n=0}^{\infty} \frac{(-1)^n \left(\frac{\pi}{3}\right)^{2n}}{(2n)!} \\ &= -\frac{\pi}{7} \cos\left(\tfrac{\pi}{3}\right) \\ &= -\frac{\pi}{14} \end{aligned}$$

**? Exercise 9.3.10**

Find the sum of the series.

$$\sum_{n=0}^{\infty} \frac{2^{n-1}}{3^{n+1} n!}$$

**Answer**

$\frac{1}{6}e^{2/3}$

**Proving that $e$ is Irrational**

In this project, we use the Maclaurin polynomials for $e^x$ to prove that $e$ is irrational. The proof relies on supposing that $e$ is rational and arriving at a contradiction. Therefore, in the following steps, we suppose $e = r/s$ for some integers $r$ and $s$ where $s \neq 0$.

1. Write the Maclaurin polynomials $p_0(x), p_1(x), p_2(x), p_3(x), p_4(x)$ for $e^x$. Evaluate $p_0(1), p_1(1), p_2(1), p_3(1), p_4(1)$ to estimate $e$.
2. Let $R_n(x)$ denote the remainder when using $p_n(x)$ to estimate $e^x$. Therefore, $R_n(x) = e^x - p_n(x)$, and $R_n(1) = e - p_n(1)$. Assuming that $e = \frac{r}{s}$ for integers $r$ and $s$, evaluate $R_0(1), R_1(1), R_2(1), R_3(1), R_4(1)$.
3. Using the results from part 2, show that for each remainder $R_0(1), R_1(1), R_2(1), R_3(1), R_4(1)$, we can find an integer $k$ such that $kR_n(1)$ is an integer for $n = 0, 1, 2, 3, 4$.
4. Write down the formula for the $n^{\text{th}}$-degree Maclaurin polynomial $p_n(x)$ for $e^x$ and the corresponding remainder $R_n(x)$. Show that $sn!R_n(1)$ is an integer.
5. Use Taylor's theorem to write down an explicit formula for $R_n(1)$. Conclude that $R_n(1) \neq 0$, and therefore, $sn!R_n(1) \neq 0$.
6. Use Taylor's theorem to find an estimate on $R_n(1)$. Use this estimate combined with the result from part 5 to show that $|sn!R_n(1)| < \frac{se}{n+1}$. Conclude that if $n$ is large enough, then $|sn!R_n(1)| < 1$. Therefore, $sn!R_n(1)$ is an integer with magnitude less than 1. Thus, $sn!R_n(1) = 0$. But from part 5, we know that $sn!R_n(1) \neq 0$. We have arrived at a contradiction, and consequently, the original supposition that e is rational must be false.

## Key Concepts

- Taylor polynomials are used to approximate functions near a value $x = a$. Maclaurin polynomials are Taylor polynomials at $x = 0$.

- The $n^{\text{th}}$-degree Taylor polynomials for a function $f$ are the partial sums of the Taylor series for $f$.
- If a function $f$ has a power series representation at $x = a$, then it is given by its Taylor series at $x = a$.
- A Taylor series for $f$ converges to $f$ if and only if $\lim_{n\to\infty} R_n(x) = 0$ where $R_n(x) = f(x) - p_n(x)$.
- The Taylor series for $e^x$, $\sin x$, and $\cos x$ converge to the respective functions for all real x.

## Key Equations

- **Taylor series for the function $f$ at the point $x = a$**

$$\sum_{n=0}^{\infty} \frac{f^{(n)}(a)}{n!}(x-a)^n = f(a) + f'(a)(x-a) + \frac{f''(a)}{2!}(x-a)^2 + \cdots + \frac{f^{(n)}(a)}{n!}(x-a)^n + \cdots$$

## Glossary

**Maclaurin polynomial**

a Taylor polynomial centered at 0; the $n^{\text{th}}$-degree Taylor polynomial for $f$ at 0 is the $n^{\text{th}}$-degree Maclaurin polynomial for $f$

**Maclaurin series**

a Taylor series for a function $f$ at $x = 0$ is known as a Maclaurin series for $f$

**Taylor polynomials**

the $n^{\text{th}}$-degree Taylor polynomial for $f$ at $x = a$ is $p_n(x) = f(a) + f'(a)(x-a) + \frac{f''(a)}{2!}(x-a)^2 + \cdots + \frac{f^{(n)}(a)}{n!}(x-a)^n$

**Taylor series**

a power series at $a$ that converges to a function $f$ on some open interval containing $a$.

**Taylor's theorem with remainder**

for a function $f$ and the $n^{\text{th}}$-degree Taylor polynomial for $f$ at $x = a$, the remainder $R_n(x) = f(x) - p_n(x)$ satisfies $R_n(x) = \frac{f^{(n+1)}(c)}{(n+1)!}(x-a)^{n+1}$

for some $c$ between $x$ and $a$; if there exists an interval $I$ containing $a$ and a real number $M$ such that $|f^{(n+1)}(x)| \leq M$ for all $x$ in $I$, then $|R_n(x)| \leq \frac{M}{(n+1)!}|x-a|^{n+1}$

# 9.3E: Exercises

## Taylor Polynomials

**In exercises 1 - 8, find the Taylor polynomials of degree two approximating the given function centered at the given point.**

1) $f(x) = 1 + x + x^2$ at $a = 1$

2) $f(x) = 1 + x + x^2$ at $a = -1$

**Answer**

$f(-1) = 1;\ f'(-1) = -1;\ f''(-1) = 2; \quad p_2(x) = 1 - (x+1) + (x+1)^2$

3) $f(x) = \cos(2x)$ at $a = \pi$

4) $f(x) = \sin(2x)$ at $a = \frac{\pi}{2}$

**Answer**

$f'(x) = 2\cos(2x);\ f''(x) = -4\sin(2x); \quad p_2(x) = -2(x - \frac{\pi}{2})$

5) $f(x) = \sqrt{x}$ at $a = 4$

6) $f(x) = \ln x$ at $a = 1$

**Answer**

$f'(x) = \dfrac{1}{x};\ f''(x) = -\dfrac{1}{x^2}; \quad p_2(x) = 0 + (x-1) - \frac{1}{2}(x-1)^2$

7) $f(x) = \dfrac{1}{x}$ at $a = 1$

8) $f(x) = e^x$ at $a = 1$

**Answer**

$p_2(x) = e + e(x-1) + \dfrac{e}{2}(x-1)^2$

## Taylor Remainder Theorem

**In exercises 9 - 14, verify that the given choice of $n$ in the remainder estimate $|R_n| \le \dfrac{M}{(n+1)!}(x-a)^{n+1}$, where $M$ is the maximum value of $| f^{(n+1)}(z) |$ on the interval between $a$ and the indicated point, yields $|R_n| \le \frac{1}{1000}$. Find the value of the Taylor polynomial $p_n$ of $f$ at the indicated point.**

9) [Technology Required] $\sqrt{10};\ a = 9,\ n = 3$

10) [Technology Required] $(28)^{1/3};\ a = 27,\ n = 1$

**Answer**

$\dfrac{d^2}{dx^2}x^{1/3} = -\dfrac{2}{9x^{5/3}} \ge -0.00092\ldots$ when $x \ge 28$ so the remainder estimate applies to the linear approximation $x^{1/3} \approx p_1(27) = 3 + \dfrac{x-27}{27}$, which gives $(28)^{1/3} \approx 3 + \frac{1}{27} = 3.0\overline{37}$, while $(28)^{1/3} \approx 3.03658$.

11) [Technology Required] $\sin(6);\ a = 2\pi,\ n = 5$

12) [Technology Required] $e^2;\ a = 0,\ n = 9$

**Answer**

Using the estimate $\dfrac{2^{10}}{10!} < 0.000283$ we can use the Taylor expansion of order 9 to estimate $e^x$ at $x = 2$. as $e^2 \approx p_9(2) = 1 + 2 + \frac{2^2}{2} + \frac{2^3}{6} + \cdots + \frac{2^9}{9!} = 7.3887$ \ldots whereas $e^2 \approx 7.3891$.

13) [Technology Required] $\cos(\frac{\pi}{5});\ a=0,\ n=4$

14) [Technology Required] $\ln(2);\ a=1,\ n=1000$

**Answer**

Since $\frac{d^n}{dx^n}(\ln x)=(-1)^{n-1}\frac{(n-1)!}{x^n}, R_{1000}\approx\frac{1}{1001}$. One has $p_{1000}(1)=\sum_{n=1}^{1000}\frac{(-1)^{n-1}}{n}\approx 0.6936$ whereas $\ln(2)\approx 0.6931\cdots$.

## Approximating Definite Integrals Using Taylor Series

15) Integrate the approximation $\sin t\approx t-\frac{t^3}{6}+\frac{t^5}{120}-\frac{t^7}{5040}$ evaluated at $\pi$t to approximate $\int_0^1\frac{\sin\pi t}{\pi t}\,dt$.

16) Integrate the approximation $e^x\approx 1+x+\frac{x^2}{2}+\cdots+\frac{x^6}{720}$ evaluated at $-x^2$ to approximate $\int_0^1 e^{-x^2}\,dx$.

**Answer**

$\int_0^1\left(1-x^2+\frac{x^4}{2}-\frac{x^6}{6}+\frac{x^8}{24}-\frac{x^{10}}{120}+\frac{x^{12}}{720}\right)dx=1-\frac{1^3}{3}+\frac{1^5}{10}-\frac{1^7}{42}+\frac{1^9}{9\cdot 24}-\frac{1^{11}}{120\cdot 11}+\frac{1^{13}}{720\cdot 13}\approx 0.74683$ whereas $\int_0^1 e^{-x^2}dx\approx 0.74682$.

## More Taylor Remainder Theorem Problems

**In exercises 17 - 20, find the smallest value of $n$ such that the remainder estimate $|R_n|\le\frac{M}{(n+1)!}(x-a)^{n+1}$, where $M$ is the maximum value of $|f^{(n+1)}(z)|$ on the interval between $a$ and the indicated point, yields $|R_n|\le\frac{1}{1000}$ on the indicated interval.**

17) $f(x)=\sin x$ on $[-\pi,\pi],\ a=0$

18) $f(x)=\cos x$ on $[-\frac{\pi}{2},\frac{\pi}{2}],\ a=0$

**Answer**

Since $f^{(n+1)}(z)$ is $\sin z$ or $\cos z$, we have $M=1$. Since $|x-0|\le\frac{\pi}{2}$, we seek the smallest $n$ such that $\frac{\pi^{n+1}}{2^{n+1}(n+1)!}\le 0.001$. The smallest such value is $n=7$. The remainder estimate is $R_7\le 0.00092$.

19) $f(x)=e^{-2x}$ on $[-1,1], a=0$

20) $f(x)=e^{-x}$ on $[-3,3], a=0$

**Answer**

Since $f^{(n+1)}(z)=\pm e^{-z}$ one has $M=e^3$. Since $|x-0|\le 3$, one seeks the smallest $n$ such that $\frac{3^{n+1}e^3}{(n+1)!}\le 0.001$. The smallest such value is $n=14$. The remainder estimate is $R_{14}\le 0.000220$.

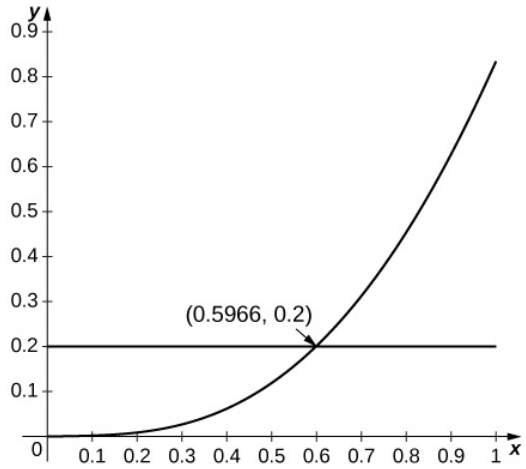
**In exercises 21 - 24, the maximum of the right-hand side of the remainder estimate $|R_1|\le\frac{max|f''(z)|}{2}R^2$ on $[a-R,a+R]$ occurs at $a$ or $a\pm R$. Estimate the maximum value of $R$ such that $\frac{max|f''(z)|}{2}R^2\le 0.1$ on $[a-R,a+R]$ by plotting this maximum as a function of $R$.**

21) [Technology Required] $e^x$ approximated by $1+x,\ a=0$

22) [Technology Required] $\sin x$ approximated by $x,\ a=0$

**Answer**

Since $\sin x$ is increasing for small $x$ and since $\frac{d^2}{dx^2}(\sin x)=-\sin x$, the estimate applies whenever $R^2\sin(R)\le 0.2$, which applies up to $R=0.596$.

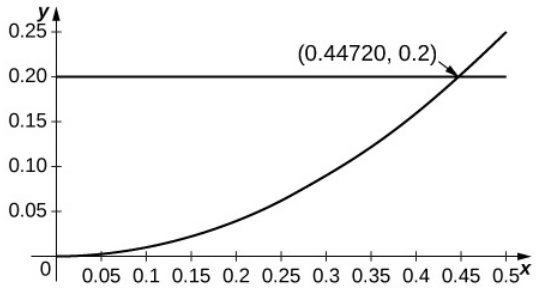


23) [Technology Required] $\ln x$ approximated by $x-1,\ a=1$

24) [Technology Required] $\cos x$ approximated by $1,\ a=0$

**Answer**

Since the second derivative of $\cos x$ is $-\cos x$ and since $\cos x$ is decreasing away from $x=0$, the estimate applies when $R^2 \cos R \leq 0.2$ or $R \leq 0.447$.



## Taylor Series

**In exercises 25 - 35, find the Taylor series of the given function centered at the indicated point.**

25) $f(x)=x^4$ at $a=-1$

26) $f(x)=1+x+x^2+x^3$ at $a=-1$

**Answer**

$(x+1)^3-2(x+1)^2+2(x+1)$

27) $f(x)=\sin x$ at $a=\pi$

28) $f(x)=\cos x$ at $a=2\pi$

**Answer**

Values of derivatives are the same as for $x=0$ so $\cos x=\sum_{n=0}^{\infty}(-1)^n\frac{(x-2\pi)^{2n}}{(2n)!}$

29) $f(x)=\sin x$ at $x=\frac{\pi}{2}$

30) $f(x)=\cos x$ at $x=\frac{\pi}{2}$

**Answer**

$\cos(\frac{\pi}{2}) = 0,\ -\sin(\frac{\pi}{2}) = -1$ so $\cos x = \sum_{n=0}^{\infty} (-1)^{n+1} \frac{(x-\frac{\pi}{2})^{2n+1}}{(2n+1)!}$, which is also $-\cos(x-\frac{\pi}{2})$.

31) $f(x) = e^x$ at $a = -1$

32) $f(x) = e^x$ at $a = 1$

**Answer**

The derivatives are $f^{(n)}(1) = e$, so $e^x = e\sum_{n=0}^{\infty} \frac{(x-1)^n}{n!}$.

33) $f(x) = \frac{1}{(x-1)^2}$ at $a = 0$ (Hint: Differentiate the Taylor Series for $\frac{1}{1-x}$.)

34) $f(x) = \frac{1}{(x-1)^3}$ at $a = 0$

**Answer**

$$\frac{1}{(x-1)^3} = -\frac{1}{2}\frac{d^2}{dx^2}\left(\frac{1}{1-x}\right) = -\sum_{n=0}^{\infty}\left(\frac{(n+2)(n+1)x^n}{2}\right)$$

35) $F(x) = \int_0^x \cos(\sqrt{t})\,dt;$ where $f(t) = \sum_{n=0}^{\infty} (-1)^n \frac{t^n}{(2n)!}$ at a=0 (Note: $f$ is the Taylor series of $\cos(\sqrt{t})$.)

**In exercises 36 - 44, compute the Taylor series of each function around $x = 1$.**

36) $f(x) = 2 - x$

**Answer**

$2 - x = 1 - (x-1)$

37) $f(x) = x^3$

38) $f(x) = (x-2)^2$

**Answer**

$((x-1)-1)^2 = (x-1)^2 - 2(x-1) + 1$

39) $f(x) = \ln x$

40) $f(x) = \frac{1}{x}$

**Answer**

$$\frac{1}{1-(1-x)} = \sum_{n=0}^{\infty} (-1)^n (x-1)^n$$

41) $f(x) = \frac{1}{2x - x^2}$

42) $f(x) = \frac{x}{4x - 2x^2 - 1}$

**Answer**

$$x\sum_{n=0}^{\infty} 2^n (1-x)^{2n} = \sum_{n=0}^{\infty} 2^n (x-1)^{2n+1} + \sum_{n=0}^{\infty} 2^n (x-1)^{2n}$$

43) $f(x) = e^{-x}$

44) $f(x) = e^{2x}$

**Answer**

$$e^{2x} = e^{2(x-1)+2} = e^2 \sum_{n=0}^{\infty} \frac{2^n (x-1)^n}{n!}$$

**[Technology Required] In exercises 45 - 48, identify the value of $x$ such that the given series $\sum_{n=0}^{\infty} a_n$ is the value of the Maclaurin series of $f(x)$ at $x$. Approximate the value of $f(x)$ using $S_{10} = \sum_{n=0}^{10} a_n$.**

45) $\sum_{n=0}^{\infty} \frac{1}{n!}$

46) $\sum_{n=0}^{\infty} \frac{2^n}{n!}$

**Answer**

$x = e^2; \quad S_{10} = \frac{34,913}{4725} \approx 7.3889947$

47) $\sum_{n=0}^{\infty} \frac{(-1)^n (2\pi)^{2n}}{(2n)!}$

48) $\sum_{n=0}^{\infty} \frac{(-1)^n (2\pi)^{2n+1}}{(2n+1)!}$

**Answer**

$\sin(2\pi) = 0; \quad S_{10} = 8.27 \times 10^{-5}$

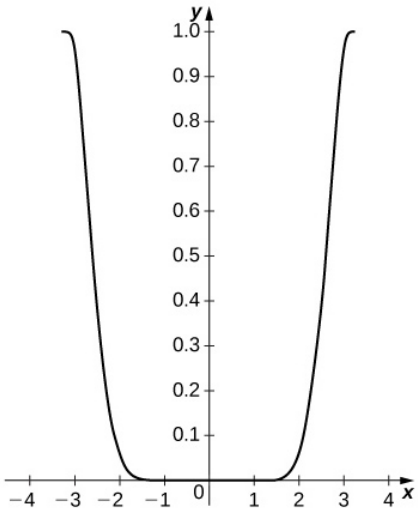
**In exercises 49 - 52 use the functions $S_5(x) = x - \frac{x^3}{6} + \frac{x^5}{120}$ and $C_4(x) = 1 - \frac{x^2}{2} + \frac{x^4}{24}$ on $[-\pi, \pi]$.**

49) [Technology Required] Plot $\sin^2 x - (S_5(x))^2$ on $[-\pi, \pi]$. Compare the maximum difference with the square of the Taylor remainder estimate for $\sin x$.

50) [Technology Required] Plot $\cos^2 x - (C_4(x))^2$ on $[-\pi, \pi]$. Compare the maximum difference with the square of the Taylor remainder estimate for $\cos x$.

**Answer**

The difference is small on the interior of the interval but approaches 1 near the endpoints. The remainder estimate is $|R_4| = \frac{\pi^5}{120} \approx 2.552$.



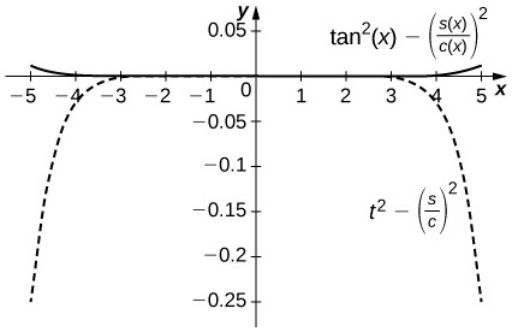
51) [Technology Required] Plot $|2S_5(x)C_4(x) - \sin(2x)|$ on $[-\pi, \pi]$.

https://math.libretexts.org/@go/page/175626

52) [Technology Required] Compare $\frac{S_5(x)}{C_4(x)}$ on $[-1,1]$ to $\tan x$. Compare this with the Taylor remainder estimate for the approximation of $\tan x$ by $x+\frac{x^3}{3}+\frac{2x^5}{15}$.

**Answer**

The difference is on the order of $10^{-4}$ on $[-1,1]$ while the Taylor approximation error is around $0.1$ near $\pm 1$. The top curve is a plot of $\tan^2 x - \left(\frac{S_5(x)}{C_4(x)}\right)^2$ and the lower dashed plot shows $t^2 - \left(\frac{S_5}{C_4}\right)^2$.



53) [Technology Required] Plot $e^x - e_4(x)$ where $e_4(x) = 1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24}$ on $[0,2]$. Compare the maximum error with the Taylor remainder estimate.

54) (Taylor approximations and root finding.) Recall that Newton's method $x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}$ approximates solutions of $f(x) = 0$ near the input $x_0$.

a. If $f$ and $g$ are inverse functions, explain why a solution of $g(x) = a$ is the value $f(a)$ of $f$.

b. Let $p_N(x)$ be the $N^{\text{th}}$ degree Maclaurin polynomial of $e^x$. Use Newton's method to approximate solutions of $p_N(x) - 2 = 0$ for $N = 4, 5, 6$.

c. Explain why the approximate roots of $p_N(x) - 2 = 0$ are approximate values of $\ln(2)$.

**Answer**

a. Answers will vary.

b. The following are the $x_n$ values after $10$ iterations of Newton's method to approximation a root of $p_N(x) - 2 = 0$: for $N = 4, x = 0.6939...$; for $N = 5, x = 0.6932...$; for $N = 6, x = 0.69315...$; . (Note: $\ln(2) = 0.69314...$)

c. Answers will vary.

## Evaluating Limits using Taylor Series

**In exercises 55 - 58, use the fact that if $q(x) = \sum_{n=1}^{\infty} a_n (x-c)^n$ converges in an interval containing $c$, then $\lim_{x \to c} q(x) = a_0$ to evaluate each limit using Taylor series.**

55) $\lim_{x \to 0} \frac{\cos x - 1}{x^2}$

56) $\lim_{x \to 0} \frac{\ln(1-x^2)}{x^2}$

**Answer**

$\frac{\ln(1-x^2)}{x^2} \to -1$

57) $\lim_{x \to 0} \frac{e^{x^2} - x^2 - 1}{x^4}$

58) $\lim_{x \to 0^+} \frac{\cos(\sqrt{x}) - 1}{2x}$

**Answer**

$$\frac{\cos(\sqrt{x})-1}{2x} \approx \frac{(1-\frac{x}{2}+\frac{x^2}{4!}-\cdots)-1}{2x} \to -\frac{1}{4}$$

# 9.4: The Binomial Theorem and Applications of Taylor Series

**Learning Objectives**

- Write the terms of the binomial series.
- Recognize the Taylor series expansions of common functions.
- Recognize and apply techniques to find the Taylor series for a function.
- Use Taylor series to evaluate non-elementary integrals.

In the preceding section, we defined Taylor series and showed how to find the Taylor series for several common functions by explicitly calculating the coefficients of the Taylor polynomials. We also showed how to use those Taylor series to derive Taylor series for other functions. We then showed how power series can be used to evaluate integrals when the antiderivative of the integrand cannot be expressed in terms of elementary functions. We now venture into the final discussion surrounding Taylor series - expansions of powers of expressions involving two terms.

## The Binomial Series

Our first goal in this section is to determine the Maclaurin series for the function $f(x) = (1+x)^r$ for all real numbers $r$. The Maclaurin series for this function is known as the **binomial series**. We begin by considering the simplest case: $r$ is a non-negative integer. We recall that, for $r = 0, 1, 2, 3, 4,\ f(x) = (1+x)^r$ can be written as

$$\begin{aligned} f(x) &= (1+x)^0 = 1, \\ f(x) &= (1+x)^1 = 1+x, \\ f(x) &= (1+x)^2 = 1+2x+x^2, \\ f(x) &= (1+x)^3 = 1+3x+3x^2+x^3, \\ f(x) &= (1+x)^4 = 1+4x+6x^2+4x^3+x^4. \end{aligned}$$

The expressions on the right-hand side are known as **binomial expansions** and the coefficients are known as **binomial coefficients**. More generally, for any nonnegative integer $r$, the binomial coefficient of $x^n$ in the binomial expansion of $(1+x)^r$ is given by

$$\binom{r}{n} = \frac{r!}{n!(r-n)!} \tag{9.4.1}$$

and

$$\begin{aligned} f(x) &= (1+x)^r \\ &= \binom{r}{0} + \binom{r}{1}x + \binom{r}{2}x^2 + \binom{r}{3}x^3 + \cdots + \binom{r}{r-1}x^{r-1} + \binom{r}{r}x^r \\ &= \sum_{n=0}^{r} \binom{r}{n} x^n. \end{aligned} \tag{9.4.2}$$

For example, using this formula for $r = 5$, we see that

$$\begin{aligned} f(x) &= (1+x)^5 \\ &= \binom{5}{0}1 + \binom{5}{1}x + \binom{5}{2}x^2 + \binom{5}{3}x^3 + \binom{5}{4}x^4 + \binom{5}{5}x^5 \\ &= \frac{5!}{0!5!}1 + \frac{5!}{1!4!}x + \frac{5!}{2!3!}x^2 + \frac{5!}{3!2!}x^3 + \frac{5!}{4!1!}x^4 + \frac{5!}{5!0!}x^5 \\ &= 1 + 5x + 10x^2 + 10x^3 + 5x^4 + x^5. \end{aligned}$$

We now consider the case when the exponent $r$ is any real number, not necessarily a non-negative integer. If $r$ is *not* a nonnegative integer, then $f(x) = (1+x)^r$ cannot be written as a finite polynomial. However, we can find a power series for $f$. Specifically, we

look for the Maclaurin series for $f$. To do this, we find the derivatives of $f$ and evaluate them at $x = 0$.

$$\begin{aligned}
f(x) &= (1+x)^r && \Longrightarrow && f(0) &= 1\\
f'(x) &= r(1+x)^{r-1} && \Longrightarrow && f'(0) &= r\\
f''(x) &= r(r-1)(1+x)^{r-2} && \Longrightarrow && f''(0) &= r(r-1)\\
f'''(x) &= r(r-1)(r-2)(1+x)^{r-3} && \Longrightarrow && f'''(0) &= r(r-1)(r-2)\\
f^{(n)}(x) &= r(r-1)(r-2)\cdots(r-n+1)(1+x)^{r-n} && \Longrightarrow && f^{(n)}(0) &= r(r-1)(r-2)\cdots(r-n+1)
\end{aligned}$$

We conclude that the coefficients in the binomial series are given by

$$\frac{f^{(n)}(0)}{n!} = \frac{r(r-1)(r-2)\cdots(r-n+1)}{n!}. \tag{9.4.3}$$

We note that if $r$ is a non-negative integer, then the $(r+1)^{\text{st}}$ derivative $f^{(r+1)}$ is the zero function, and the series terminates. In addition, if $r$ is a non-negative integer, then the coefficients in Equation 9.4.3 agree with those from Equation 9.4.1, and the formula for the binomial series agrees with Equation 9.4.2 for the finite binomial expansion. More generally, to denote the binomial coefficients for any real number $r$, we define

$$\binom{r}{n} = \frac{(r-1)(r-2)\cdots(r-n+1)}{n!}.$$

With this notation, we can write the binomial series for $(1+x)^r$ as

$$\sum_{n=0}^{\infty}\binom{r}{n}x^n = 1 + rx + \frac{r(r-1)}{2!}x^2 + \cdots + \frac{r(r-1)\cdots(r-n+1)}{n!}x^n + \cdots. \tag{9.4.4}$$

We now need to determine the interval of convergence for the binomial series Equation 9.4.4. To do so, we apply the Ratio Test. Consequently, we consider

$$\begin{aligned}
\frac{|a_{n+1}|}{|a_n|} &= \frac{|r(r-1)(r-2)\cdots(r-n)||x|^{n+1}}{(n+1)!}\cdot\frac{n}{|r(r-1)(r-2)\cdots(r-n+1)||x|^n}\\
&= \frac{|r-n||x|}{|n+1|}.
\end{aligned}$$

Since

$$\lim_{n\to\infty}\frac{|a_{n+1}|}{|a_n|} = |x| < 1$$

if and only if $|x| < 1$, we conclude that the interval of convergence for the binomial series is $(-1, 1)$. The behavior at the endpoints depends on $r$. It can be shown that, for $r \geq 0$, the series converges at both endpoints; for $-1 < r < 0$, the series converges at $x = 1$ and diverges at $x = -1$; and for $r < -1$, the series diverges at both endpoints. The binomial series does converge to $(1+x)^r$ in $(-1, 1)$ for all real numbers $r$, but proving this fact by showing that the remainder $R_n(x) \to 0$ is difficult.

It's time to summarize this in a formal definition.

**Definition: Binomial Series**

For any real number $r$, the Maclaurin series for $f(x) = (1+x)^r$ is called the **binomial series**. It converges to $f$ for $|x| < 1$, and we write

$$(1+x)^r = \sum_{n=0}^{\infty}\binom{r}{n}x^n = 1 + rx + \frac{r(r-1)}{2!}x^2 + \cdots + r\frac{(r-1)\cdots(r-n+1)}{n!}x^n + \cdots$$

for $|x| < 1$.

We can use this definition to find the binomial series for $f(x) = \sqrt{1+x}$ and use the series to approximate $\sqrt{1.5}$.

## Example 9.4.1: Finding Binomial Series

a. Find the binomial series for $f(x) = \sqrt{1+x}$.

b. Use the third-order Maclaurin polynomial $p_3(x)$ to estimate $\sqrt{1.5}$. Use Taylor's Theorem to bound the error. Use graphing technology to compare the graphs of $f$ and $p_3$.

**Solutions**

a. Here $r = \frac{1}{2}$. Using the definition for the binomial series, we obtain

$$\begin{aligned}\sqrt{1+x} &= 1 + \frac{1}{2}x + \frac{(1/2)(-1/2)}{2!}x^2 + \frac{(1/2)(-1/2)(-3/2)}{3!}x^3 + \cdots \\ &= 1 + \frac{1}{2}x - \frac{1}{2!}\frac{1}{2^2}x^2 + \frac{1}{3!}\frac{1\cdot 3}{2^3}x^3 - \cdots + \frac{(-1)^{n+1}}{n!}\frac{1\cdot 3\cdot 5\cdots(2n-3)}{2^n}x^n + \cdots \\ &= 1 + \sum_{n=1}^{\infty}\frac{(-1)^{n+1}}{n!}\frac{1\cdot 3\cdot 5\cdots(2n-3)}{2^n}x^n.\end{aligned}$$

b. From the result in part a., the third-order Maclaurin polynomial is

$$p_3(x) = 1 + \frac{1}{2}x - \frac{1}{8}x^2 + \frac{1}{16}x^3.$$

Therefore,

$$\sqrt{1.5} = \sqrt{1+0.5} \approx 1 + \frac{1}{2}(0.5) - \frac{1}{8}(0.5)^2 + \frac{1}{16}(0.5)^3 \approx 1.2266.$$

From Taylor's Theorem, the error satisfies

$$R_3(0.5) = \frac{f^{(4)}(c)}{4!}(0.5)^4$$

for some $c$ between $0$ and $0.5$. Since $f^{(4)}(x) = -\frac{15}{2^4(1+x)^{7/2}}$, and the maximum value of $|f^{(4)}(x)|$ on the interval $(0, 0.5)$ occurs at $x = 0$, we have

$$|R_3(0.5)| \le \frac{15}{4!2^4}(0.5)^4 \approx 0.00244.$$

The function and the Maclaurin polynomial $p_3$ are graphed in Figure 9.4.1.

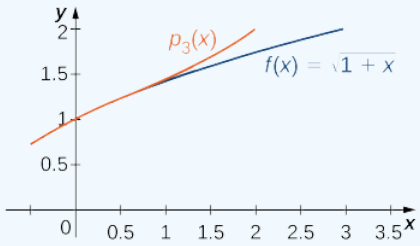

Figure 9.4.1: The third-order Maclaurin polynomial $p_3(x)$ provides a good approximation for $f(x) = \sqrt{1+x}$ for $x$ near zero.

## Checkpoint 9.4.1

Find the binomial series for $f(x) = \frac{1}{(1+x)^2}$.

**Answer**

$$\sum_{n=0}^{\infty}(-1)^n(n+1)x^n$$

## A Summary of Common Functions Expressed as Taylor Series

As in Section 4.3, we summarize the common Maclaurin series we have derived up to this point.

Table **9.4.1**: Maclaurin Series for Common Functions

| Function | Maclaurin Series | Interval of Convergence |
|---|---|---|
| $f(x)=\frac{1}{1-x}$ | $\sum_{n=0}^{\infty} x^n$ | $-1<x<1$ |
| $f(x)=e^x$ | $\sum_{n=0}^{\infty} \frac{x^n}{n!}$ | $-\infty<x<\infty$ |
| $f(x)=\sin x$ | $\sum_{n=0}^{\infty} (-1)^n \frac{x^{2n+1}}{(2n+1)!}$ | $-\infty<x<\infty$ |
| $f(x)=\cos x$ | $\sum_{n=0}^{\infty} (-1)^n \frac{x^{2n}}{(2n)!}$ | $-\infty<x<\infty$ |
| $f(x)=\ln(1+x)$ | $\sum_{n=1}^{\infty} (-1)^{n-1} \frac{x^n}{n}$ | $-1<x\leq 1$ |
| $f(x)=\tan^{-1} x$ | $\sum_{n=0}^{\infty} (-1)^n \frac{x^{2n+1}}{2n+1}$ | $-1\leq x\leq 1$ |
| $f(x)=(1+x)^r$ | $\sum_{n=0}^{\infty} \binom{r}{n} x^n$ | $-1<x<1$ |

We showed previously in this chapter how power series can be differentiated term-by-term to create a new power series. In Example **9.4.2**, we differentiate the binomial series for $\sqrt{1+x}$ term by term to find the binomial series for $\frac{1}{\sqrt{1+x}}$. Note that we could construct the binomial series for $\frac{1}{\sqrt{1+x}}$ directly from the definition, but differentiating the binomial series for $\sqrt{1+x}$ is an easier calculation.

### Example 9.4.2: Differentiating a Series to Find a New Series

Use the binomial series for $\sqrt{1+x}$ to find the binomial series for $\frac{1}{\sqrt{1+x}}$.

**Solution**

The two functions are related by

$$\frac{d}{dx}\sqrt{1+x}=\frac{1}{2\sqrt{1+x}},$$

so the binomial series for $\frac{1}{\sqrt{1+x}}$ is given by

$$\frac{1}{\sqrt{1+x}}=2\frac{d}{dx}\sqrt{1+x}=1+\sum_{n=1}^{\infty}\frac{(-1)^n}{n!}\frac{1\cdot 3\cdot 5\cdots(2n-1)}{2^n}x^n.$$

### Checkpoint 9.4.2

Find the binomial series for $f(x)=\frac{1}{(1+x)^{3/2}}$

**Answer**

$$\sum_{n=1}^{\infty}\frac{(-1)^n}{n!}\frac{1\cdot 3\cdot 5\cdots(2n-1)}{2^n}x^n$$

In this example, we differentiated a known Taylor series to construct a Taylor series for another function. The ability to differentiate power series term-by-term makes them a powerful tool for solving differential equations.

## Applications Involving Taylor Series

### Probability

Taylor and Maclaurin series are used frequently when encountering non-elementary integrals. For example, the integral $\int e^{-x^2}\,dx$ arises often in probability theory. Specifically, it is used when studying data sets that are normally distributed, meaning the data values lie under a bell-shaped curve. For example, if a set of data values is normally distributed with mean $\mu$ and standard deviation $\sigma$, then the probability that a randomly chosen value lies between $x = a$ and $x = b$ is given by

$$\frac{1}{\sigma\sqrt{2\pi}}\int_a^b e^{-(x-\mu)^2/(2\sigma^2)}\,dx. \tag{9.4.5}$$

(See Figure 9.4.2.)

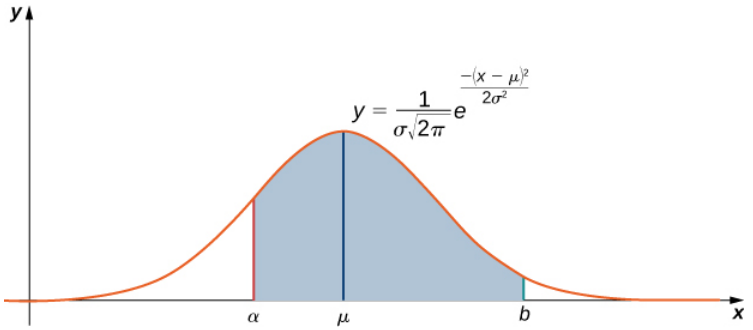

Figure 9.4.2: If data values are normally distributed with mean $\mu$ and standard deviation $\sigma$, the probability that a randomly selected data value is between $a$ and $b$ is the area under the curve $y = \frac{1}{\sigma\sqrt{2\pi}}e^{-(x-\mu)^2/(2\sigma^2)}$ between $x = a$ and $x = b$.

To simplify this integral, we typically let $z = \frac{x-\mu}{\sigma}$. This quantity $z$ is the data value's $z$ score. With this simplification, integral Equation 9.4.5 becomes

$$\frac{1}{\sqrt{2\pi}}\int_{(a-\mu)/\sigma}^{(b-\mu)/\sigma} e^{-z^2/2}\,dz.$$

In Example 9.4.3, we show how we can use this integral in calculating probabilities.

**Example 9.4.3: Using Maclaurin Series to Approximate a Probability**

Suppose a set of standardized test scores are normally distributed with mean $\mu = 100$ and standard deviation $\sigma = 50$. Use Equation 9.4.5 and the first six terms in the Maclaurin series for $e^{-x^2/2}$ to approximate the probability that a randomly selected test score is between $x = 100$ and $x = 200$. Use the Alternating Series Test to determine how accurate your approximation is.

**Solution**

Since $\mu = 100$, $\sigma = 50$, and we are trying to determine the area under the curve from $a = 100$ to $b = 200$, integral Equation 9.4.5 becomes

$$\frac{1}{\sqrt{2\pi}}\int_0^2 e^{-z^2/2}\,dz.$$

The Maclaurin series for $e^{-x^2/2}$ is given by

$$\begin{aligned} e^{-x^2/2} &= \sum_{n=0}^{\infty}\frac{\left(-\frac{x^2}{2}\right)^n}{n!} \\ &= 1-\frac{x^2}{2^1\cdot 1!}+\frac{x^4}{2^2\cdot 2!}-\frac{x^6}{2^3\cdot 3!}+\cdots+(-1)^n\frac{x^{2n}}{2^n\cdot n}!+\cdots \\ &= \sum_{n=0}^{\infty}(-1)^n\frac{x^{2n}}{2^n\cdot n!}. \end{aligned}$$

Therefore,

$$\begin{aligned}\frac{1}{\sqrt{2\pi}}\int e^{-z^2/2}\,dz &= \frac{1}{\sqrt{2\pi}}\int\left(1-\frac{z^2}{2^1\cdot 1!}+\frac{z^4}{2^2\cdot 2!}-\frac{z^6}{2^3\cdot 3!}+\cdots+(-1)^n\frac{z^{2n}}{2^n\cdot n!}+\cdots\right)dz\\ &= \frac{1}{\sqrt{2\pi}}\left(C+z-\frac{z^3}{3\cdot 2^1\cdot 1!}+\frac{z^5}{5\cdot 2^2\cdot 2!}-\frac{z^7}{7\cdot 2^3\cdot 3!}+\cdots+(-1)^n\frac{z^{2n+1}}{(2n+1)2^n\cdot n!}+\cdots\right)\end{aligned}$$

$$\frac{1}{\sqrt{2\pi}}\int_0^2 e^{-z^2/2}\,dz = \frac{1}{\sqrt{2\pi}}\left(2-\frac{8}{6}+\frac{32}{40}-\frac{128}{336}+\frac{512}{3456}-\frac{2^{11}}{11\cdot 2^5\cdot 5!}+\cdots\right)$$

Using the first five terms, we estimate that the probability is approximately 0.4922. By the Alternating Series Test, we see that this estimate is accurate to within

$$\frac{1}{\sqrt{2\pi}}\frac{2^{13}}{13\cdot 2^6\cdot 6!}\approx 0.00546.$$

**Analysis**

The probability that a data value is within two standard deviations of the mean is approximately $95\%$. Here, we calculated the probability that a data value is between the mean and two standard deviations above the mean, so the estimate should be around $47.5\%$. The estimate, combined with the bound on the accuracy, falls within this range.

**? Checkpoint 9.4.3**

Use the first five terms of the Maclaurin series for $e^{-x^2/2}$ to estimate the probability that a randomly selected test score is between $100$ and $150$. Use the Alternating Series Test to determine the accuracy of this estimate.

**Answer**

The estimate is approximately $0.3414$. This estimate is accurate to within $0.0000094$.

## Elliptical Integrals

Another application in which a non-elementary integral arises involves the period of a pendulum. The integral is

$$\int_0^{\pi/2}\frac{d\theta}{\sqrt{1-k^2\sin^2\theta}}.$$

An integral of this form is known as an **elliptic integral** of the first kind. Elliptic integrals originally arose when trying to calculate the arc length of an ellipse. We now show how to use power series to approximate this integral.

**✓ Example 9.4.4: Period of a Pendulum**

The period of a pendulum is the time it takes for a pendulum to make one complete back-and-forth swing. For a pendulum with length $L$ that makes a maximum angle $\theta_{max}$ with the vertical, its period $T$ is given by

$$T=4\sqrt{\frac{L}{g}}\int_0^{\pi/2}\frac{d\theta}{\sqrt{1-k^2\sin^2\theta}}$$

where $g$ is the acceleration due to gravity and $k=\sin\left(\frac{\theta_{max}}{2}\right)$ (see Figure 9.4.3). (We note that this formula for the period arises from a non-linearized model of a pendulum. In some cases, for simplification, a linearized model is used, and $\sin\theta$ is approximated by $\theta$.)

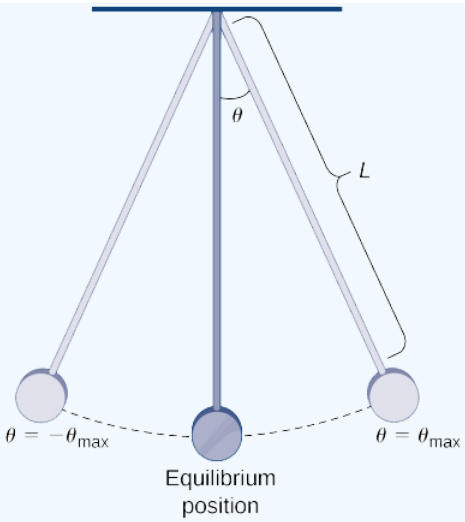

Figure 9.4.3: This pendulum has length $L$ and makes a maximum angle $\theta_{max}$ with the vertical.

Use the binomial series

$$\frac{1}{\sqrt{1+x}} = 1 + \sum_{n=1}^{\infty} \frac{(-1)^n}{n!} \frac{1 \cdot 3 \cdot 5 \cdots (2n-1)}{2^n} x^n$$

to estimate the period of this pendulum. Specifically, approximate the period of the pendulum if

a. you use only the first term in the binomial series, and
b. you use the first two terms in the binomial series.

**Solution**

We use the binomial series, replacing x with $-k^2 \sin^2 \theta$. Then we can write the period as

$$T = 4\sqrt{\frac{L}{g}} \int_0^{\pi/2} \left(1 + \frac{1}{2}k^2 \sin^2 \theta + \frac{1 \cdot 3}{2!2^2} k^4 \sin^4 \theta + \cdots\right) d\theta.$$

a. Using just the first term in the integrand, the first-order estimate is

$$T \approx 4\sqrt{\frac{L}{g}} \int_0^{\pi/2} d\theta = 2\pi\sqrt{\frac{L}{g}}.$$

If $\theta_{max}$ is small, then $k = \sin\left(\frac{\theta_{max}}{2}\right)$ is small. This is a good estimate when $k$ is small. To justify this claim, consider

$$\int_0^{\pi/2} \left(1 + \frac{1}{2}k^2 \sin^2 \theta + \frac{1 \cdot 3}{2!2^2} k^4 \sin^4 \theta + \cdots\right) d\theta.$$

Since $|\sin x| \leq 1$, this integral is bounded by

$$\int_0^{\pi/2} \left(\frac{1}{2}k^2 + \frac{1.3}{2!2^2}k^4 + \cdots\right) d\theta \; < \; \frac{\pi}{2}\left(\frac{1}{2}k^2 + \frac{1 \cdot 3}{2!2^2}k^4 + \cdots\right).$$

Furthermore, it can be shown that each coefficient on the right-hand side is less than 1 and, therefore, that this expression is bounded by

$$\frac{\pi k^2}{2}(1 + k^2 + k^4 + \cdots) = \frac{\pi k^2}{2} \cdot \frac{1}{1-k^2},$$

which is small for $k$ small.

b. For larger values of $\theta_{max}$, we can approximate $T$ by using more terms in the integrand. By using the first two terms in the integral, we arrive at the estimate

$$T \approx 4\sqrt{\frac{L}{g}}\int_0^{\pi/2}\left(1+\frac{1}{2}k^2\sin^2\theta\right)d\theta = 2\pi\sqrt{\frac{L}{g}}\left(1+\frac{k^2}{4}\right).$$

## Recentering Polynomials

One of the most useful applications of Taylor series occurs in Differential Equations. A polynomial centered at $0$ can always be **recentered** at another point using Taylor series. To showcase how this is done, let

$$P(x) = a_n x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0.$$

By computing the derivatives of $P$ at $a$, we get the recentered polynomial

$$P(x) = \sum_{n=0}^{\infty}\frac{P^{(n)}(a)}{n!}(x-a)^n = P(a) + P'(a)(x-a) + \frac{P''(a)}{2!}(x-a)^2 + \cdots.$$

The usefulness of recentering polynomials cannot be overstated; however, to describe the reasons at this point is moot (it suffices to say that it is important). Let's see how this works in practice.

### Example 9.4.5

Recenter the polynomial at $a = -3$.

$$P(x) = x^6 - x^4 + x^3 + x - 2.$$

**Solution**

We begin by making a table of derivatives and their values at $a = -3$.

$$\begin{aligned}
P(-3) &= 616\\
P'(x) &= 6x^5 - 4x^3 + 3x^2 + 1 \implies P'(-3) = -1322\\
P''(x) &= 30x^4 - 12x^2 + 6x \implies P''(-3) = 2304\\
P'''(x) &= 120x^3 - 24x + 6 \implies P'''(-3) = -3162\\
P^{(4)}(x) &= 360x^2 - 24 \implies P^{(4)}(-3) = 3216\\
P^{(5)}(x) &= 720x \implies P^{(5)}(-3) = -2160\\
P^{(6)}(x) &= 720 \implies P^{(6)}(-3) = 720\\
P^{(n)}(x) &= 0 \quad \text{for} \quad n \geq 7
\end{aligned}$$

Therefore,

$$\begin{aligned}
P(x) &= \sum_{n=0}^{\infty}\frac{P^{(n)}}{n!}(x-a)^n\\
&= 616 - 1322(x+3) + \frac{2304}{2!}(x+3)^2 - \frac{3162}{3!}(x+3)^3 + \frac{3216}{4!}(x+3)^4 - \frac{2160}{5!}(x+3)^5 + \frac{720}{6!}(x+3)^6\\
&= 616 - 1322(x+3) + 1152(x+3)^2 - 527(x+3)^3 + 134(x+3)^4 - 18(x+3)^5 + (x+3)^6
\end{aligned}$$

Since $P$ is a polynomial with a finite number of terms, the radius of convergence is always $\infty$.

### Exercise 9.4.5

Recenter

$$P(x) = x^5 + 2x^3 + x$$

at $a = 2$.

**Answer**

$P(x) = 50 + 105(x-2) + 92(x-2)^2 + 42(x-2)^3 + 10(x-2)^4 + (x-2)^5$.

## Building Data Models

Our final application involves data given at a single point. If we know the quantity of something at a given time, how quickly that quantity changes at that moment, how quickly that change changes, and so on, we can use Taylor series to build a polynomial model of the underlying dataset. Let's transition that language into Mathematics.

If we know $P(a)$, $P'(a)$, $P''(a)$, and so on, then we can build a model of the data (that works locally) using the Taylor series

$$P(x) = \sum_{n=0}^{\infty} \frac{P^{(n)}(a)}{n!}(x-a)^n = P(a) + P'(a)(x-a) + P''(a)(x-a)^2 + \cdots.$$

The fact that we will only have a finite amount of information will keep this polynomial restricted to a finite number of terms. Moreover, this limitation means that our model will only be predictive in "real-world" situations for a short time; however, this still can be very useful.

**Example 9.4.6**

The price of a certain stock is currently (at this very moment) at \$23.10. If, based on computer models, we know this price is increasing at a rate of \$12.93 per day, this rate is increasing at a rate of \$0.50 per day (squared), and the rate of this is decreasing at \$0.24 per day (cubed), build a model that can be used to predict the price of the stock in 5 minutes.

**Solution**

We are given a single data point and three of its derivatives. That is, if we let $p(t)$ be the price of the stock at time $t$, we were given

$$\begin{aligned} p(0) &= 23.10 \\ p'(0) &= 12.93 \\ p''(0) &= 0.50 \\ p'''(0) &= -0.24 \end{aligned}$$

Therefore, we can build a model for the price using a Taylor polynomial.

$$P_3(t) = \sum_{n=0}^{3} \frac{p^{(n)}(0)}{n!}(t-0)^n = 23.10 + 12.93t + \frac{0.50}{2!}t^2 - \frac{0.24}{3!}t^3 = 23.10 + 12.93t + 0.25t^2 - 0.04t^3$$

Since $t$ is in terms of days, the predicted value of the stock in 5 minutes using this model is

$$P_3\left(\frac{5}{1440}\right) \approx 23.14$$

Thus, we can expect the stock to rise by \$0.04 in the next five minutes.

To be honest, Example 9.4.6 might be a little too immersed in fantasy to be realistic; however, the impact of being able to predict future values given "dense" information at a single point (a value and the values of several derivatives at that point) should imply many uses.

The applications of Taylor series in this section are intended to highlight their importance. In general, Taylor series are helpful because they allow us to represent known functions using polynomials, thus providing a tool for approximating function values and estimating complicated integrals. In addition, they will enable us to define new functions as power series, thus providing us with a powerful tool for solving differential equations.

## Key Concepts

- The binomial series is the Maclaurin series for $f(x) = (1+x)^r$. It converges for $|x| < 1$.
- Taylor series for functions can often be derived by algebraic operations with a known Taylor series or by differentiating or integrating a known Taylor series.
- Power series can be used to solve differential equations.
- Taylor series can be used to help approximate integrals that cannot be evaluated by other means.

---

## Glossary

**binomial series**

the Maclaurin series for $f(x) = (1+x)^r$; it is given by $(1+x)^r = \sum_{n=0}^{\infty} \binom{r}{n} x^n = 1 + rx + \frac{r(r-1)}{2!}x^2 + \cdots + \frac{r(r-1)\cdots(r-n+1)}{n!}x^n + \cdots$ for $|x| < 1$

**non-elementary integral**

an integral for which the antiderivative of the integrand cannot be expressed as an elementary function

# 9.4E: Exercises

**In exercises 1 - 4, use appropriate substitutions to write down the Maclaurin series for the given binomial.**

1) $(1-x)^{1/3}$

2) $(1+x^2)^{-1/3}$

**Answer**

$$(1+x^2)^{-1/3}=\sum_{n=0}^{\infty}\left(n^{-\frac{1}{3}}\right)x^{2n}$$

3) $(1-x)^{1.01}$

4) $(1-2x)^{2/3}$

**Answer**

$$(1-2x)^{2/3}=\sum_{n=0}^{\infty}(-1)^n 2^n\left(n^{\frac{2}{3}}\right)x^n$$

**In exercises 5 - 12, use the substitution $(b+x)^r=(b+a)^r\left(1+\dfrac{x-a}{b+a}\right)^r$ in the binomial expansion to find the Taylor series of each function with the given center.**

5) $\sqrt{x+2}$ at $a=0$

6) $\sqrt{x^2+2}$ at $a=0$

**Answer**

$$\sqrt{2+x^2}=\sum_{n=0}^{\infty}2^{(1/2)-n}\left(n^{\frac{1}{2}}\right)x^{2n};(|x^2|<2)$$

7) $\sqrt{x+2}$ at $a=1$

8) $\sqrt{2x-x^2}$ at $a=1$ (Hint: $2x-x^2=1-(x-1)^2$)

**Answer**

$$\sqrt{2x-x^2}=\sqrt{1-(x-1)^2}\text{ so }\sqrt{2x-x^2}=\sum_{n=0}^{\infty}(-1)^n\left(n^{\frac{1}{2}}\right)(x-1)^{2n}$$

9) $(x-8)^{1/3}$ at $a=9$

10) $\sqrt{x}$ at $a=4$

**Answer**

$$\sqrt{x}=2\sqrt{1+\tfrac{x-4}{4}}\text{ so }\sqrt{x}=\sum_{n=0}^{\infty}2^{1-2n}\left(n^{\frac{1}{2}}\right)(x-4)^n$$

11) $x^{1/3}$ at $a=27$

12) $\sqrt{x}$ at $x=9$

**Answer**

$$\sqrt{x}=\sum_{n=0}^{\infty}3^{1-3n}\left(n^{\frac{1}{2}}\right)(x-9)^n$$

**In exercises 13 - 14, use the binomial theorem to estimate each number, computing enough terms to obtain an estimate accurate to an error of at most $1/1000$.**

13) [Technology Required] $(15)^{1/4}$ using $(16-x)^{1/4}$

14) [Technology Required] $(1001)^{1/3}$ using $(1000+x)^{1/3}$

**Answer**

$10(1+\frac{x}{1000})^{1/3}=\sum_{n=0}^{\infty}10^{1-3n}\binom{\frac{1}{3}}{n}x^n$. Using, for example, a fourth-degree estimate at $x=1$ gives $(1001)^{1/3}$ $\approx 10\left(1+\left(1^{\frac{1}{3}}\right)10^{-3}+\left(2^{\frac{1}{3}}\right)10^{-6}+\left(3^{\frac{1}{3}}\right)10^{-9}+\left(3^{\frac{1}{3}}\right)10^{-12}\right)=10\left(1+\frac{1}{3.10^3}-\frac{1}{9.10^6}+\frac{5}{81.10^9}-\frac{10}{243.10^{12}}\right)=10.00333222...$ whereas $(1001)^{1/3}=10.00332222839093...$. Two terms would suffice for three-digit accuracy.

**In exercises 15 - 18, use the binomial approximation $\sqrt{1-x}\approx 1-\frac{x}{2}-\frac{x^2}{8}-\frac{x^3}{16}-\frac{5x^4}{128}-\frac{7x^5}{256}$ for $|x|<1$ to approximate each number. Compare this value to the value given by a scientific calculator.**

15) [Technology Required] $\frac{1}{\sqrt{2}}$ using $x=\frac{1}{2}$ in $(1-x)^{1/2}$

16) [Technology Required] $\sqrt{5}=5\times\frac{1}{\sqrt{5}}$ using $x=\frac{4}{5}$ in $(1-x)^{1/2}$

**Answer**

The approximation is $2.3152$; the CAS value is $2.23...$.

17) [Technology Required] $\sqrt{3}=\frac{3}{\sqrt{3}}$ using $x=\frac{2}{3}$ in $(1-x)^{1/2}$

18) [Technology Required] $\sqrt{6}$ using $x=\frac{5}{6}$ in $(1-x)^{1/2}$

**Answer**

The approximation is $2.583...$; the CAS value is $2.449...$.

19) Integrate the binomial approximation of $\sqrt{1-x}$ to find an approximation of $\int_0^x\sqrt{1-t}\,dt$.

20) [Technology Required] Recall that the graph of $\sqrt{1-x^2}$ is an upper semicircle of radius 1. Integrate the binomial approximation of $\sqrt{1-x^2}$ up to order 8 from $x=-1$ to $x=1$ to estimate $\frac{\pi}{2}$.

**Answer**

$\sqrt{1-x^2}=1-\frac{x^2}{2}-\frac{x^4}{8}-\frac{x^6}{16}-\frac{5x^8}{128}+\cdots$. Thus $\int_{-1}^{1}\sqrt{1-x^2}\,dx=\left[x-\frac{x^3}{6}-\frac{x^5}{40}-\frac{x^7}{7\cdot 16}-\frac{5x^9}{9\cdot 128}+\cdots\right]\Big|_{-1}^{1}\approx 2-\frac{1}{3}-\frac{1}{20}-\frac{1}{56}-\frac{10}{9\cdot 128}+error=1.590...$ whereas $\frac{\pi}{2}=1.570...$

**In exercises 21 - 24, use the expansion $(1+x)^{1/3}=1+\frac{1}{3}x-\frac{1}{9}x^2+\frac{5}{81}x^3-\frac{10}{243}x^4+\cdots$ to write the first five terms (not necessarily a quartic polynomial) of each expression.**

21) $(1+4x)^{1/3};\ a=0$

22) $(1+4x)^{4/3};\ a=0$

**Answer**

$(1+x)^{4/3}=(1+x)(1+\frac{1}{3}x-\frac{1}{9}x^2+\frac{5}{81}x^3-\frac{10}{243}x^4+\cdots)=1+\frac{4x}{3}+\frac{2x^2}{9}-\frac{4x^3}{81}+\frac{5x^4}{243}+\cdots$

23) $(3+2x)^{1/3};\ a=-1$

24) $(x^2+6x+10)^{1/3};\ a=-3$

**Answer**

$(1+(x+3)^2)^{1/3}=1+\frac{1}{3}(x+3)^2-\frac{1}{9}(x+3)^4+\frac{5}{81}(x+3)^6-\frac{10}{243}(x+3)^8+\cdots$

25) Use $(1+x)^{1/3}=1+\frac{1}{3}x-\frac{1}{9}x^2+\frac{5}{81}x^3-\frac{10}{243}x^4+\cdots$ with $x=1$ to approximate $2^{1/3}$.

26) Use the approximation $(1-x)^{2/3}=1-\frac{2x}{3}-\frac{x^2}{9}-\frac{4x^3}{81}-\frac{7x^4}{243}-\frac{14x^5}{729}+\cdots$ for $|x|<1$ to approximate $2^{1/3}=2.2^{-2/3}$.

**Answer**

Twice the approximation is $1.260...$ whereas $2^{1/3}=1.2599...$.

27) Find the $25^{\text{th}}$ derivative of $f(x) = (1+x^2)^{13}$ at $x = 0$.

28) Find the $99^{\text{th}}$ derivative of $f(x) = (1+x^4)^{25}$.

**Answer**

$f^{(99)}(0) = 0$

**In exercises 29 - 36, find the Maclaurin series of each function.**

29) $f(x) = xe^{2x}$

30) $f(x) = 2^x$

**Answer**

$$\sum_{n=0}^{\infty} \frac{(\ln(2)x)^n}{n!}$$

31) $f(x) = \dfrac{\sin x}{x}$

32) $f(x) = \dfrac{\sin(\sqrt{x})}{\sqrt{x}}, (x > 0),$

**Answer**

For $x > 0$, $\sin(\sqrt{x}) = \displaystyle\sum_{n=0}^{\infty} (-1)^n \frac{x^{(2n+1)/2}}{\sqrt{x}(2n+1)!} = \sum_{n=0}^{\infty} (-1)^n \frac{x^n}{(2n+1)!}.$

33) $f(x) = \sin(x^2)$

34) $f(x) = e^{x^3}$

**Answer**

$$e^{x^3} = \sum_{n=0}^{\infty} \frac{x^{3n}}{n!}$$

35) $f(x) = \cos^2 x$ using the identity $\cos^2 x = \frac{1}{2} + \frac{1}{2}\cos(2x)$

36) $f(x) = \sin^2 x$ using the identity $\sin^2 x = \frac{1}{2} - \frac{1}{2}\cos(2x)$

**Answer**

$$\sin^2 x = -\sum_{k=1}^{\infty} \frac{(-1)^k 2^{2k-1} x^{2k}}{(2k)!}$$

**In exercises 37 - 44, find the Maclaurin series of $F(x) = \displaystyle\int_0^x f(t)\,dt$ by integrating the Maclaurin series of $f$ term by term. If $f$ is not strictly defined at zero, you may substitute the value of the Maclaurin series at zero.**

37) $F(x) = \displaystyle\int_0^x e^{-t^2}\,dt;\ f(t) = e^{-t^2} = \sum_{n=0}^{\infty} (-1)^n \frac{t^{2n}}{n!}$

38) $F(x) = \tan^{-1} x;\ f(t) = \dfrac{1}{1+t^2} = \displaystyle\sum_{n=0}^{\infty} (-1)^n t^{2n}$

**Answer**

$$\tan^{-1} x = \sum_{k=0}^{\infty} \frac{(-1)^k x^{2k+1}}{2k+1}$$

39) $F(x) = \tanh^{-1} x;\ f(t) = \dfrac{1}{1-t^2} = \displaystyle\sum_{n=0}^{\infty} t^{2n}$

40) $F(x) = \sin^{-1} x;\ f(t) = \dfrac{1}{\sqrt{1-t^2}} = \displaystyle\sum_{k=0}^{\infty} \binom{k^{\frac{1}{2}}}{} \frac{t^{2k}}{k!}$

**Answer**

$$\sin^{-1} x = \sum_{n=0}^{\infty} \left(n^{\frac{1}{2}}\right) \frac{x^{2n+1}}{(2n+1)n!}$$

41) $F(x) = \int_0^x \frac{\sin t}{t}\, dt;\ f(t) = \frac{\sin t}{t} = \sum_{n=0}^{\infty} (-1)^n \frac{t^{2n}}{(2n+1)!}$

42) $F(x) = \int_0^x \cos\left(\sqrt{t}\right)\, dt;\ f(t) = \sum_{n=0}^{\infty} (-1)^n \frac{x^n}{(2n)!}$

**Answer**

$$F(x) = \sum_{n=0}^{\infty} (-1)^n \frac{x^{n+1}}{(n+1)(2n)!}$$

43) $F(x) = \int_0^x \frac{1-\cos t}{t^2}\, dt;\ f(t) = \frac{1-\cos t}{t^2} = \sum_{n=0}^{\infty} (-1)^n \frac{t^{2n}}{(2n+2)!}$

44) $F(x) = \int_0^x \frac{\ln(1+t)}{t}\, dt;\ f(t) = \sum_{n=0}^{\infty} (-1)^n \frac{t^n}{n+1}$

**Answer**

$$F(x) = \sum_{n=1}^{\infty} (-1)^{n+1} \frac{x^n}{n^2}$$

**In exercises 45 - 52, compute at least the first three nonzero terms (not necessarily a quadratic polynomial) of the Maclaurin series of $f$.**

45) $f(x) = \sin\left(x + \frac{\pi}{4}\right) = \sin x \cos\left(\frac{\pi}{4}\right) + \cos x \sin\left(\frac{\pi}{4}\right)$

46) $f(x) = \tan x$

**Answer**

$$x + \frac{x^3}{3} + \frac{2x^5}{15} + \cdots$$

47) $f(x) = \ln(\cos x)$

48) $f(x) = e^x \cos x$

**Answer**

$$1 + x - \frac{x^3}{3} - \frac{x^4}{6} + \cdots$$

49) $f(x) = e^{\sin x}$

50) $f(x) = \sec^2 x$

**Answer**

$$1 + x^2 + \frac{2x^4}{3} + \frac{17x^6}{45} + \cdots$$

51) $f(x) = \tanh x$

52) $f(x) = \frac{\tan\sqrt{x}}{\sqrt{x}}$ (see expansion for $\tan x$)

**Answer**

Using the expansion for $\tan x$ gives $1 + \frac{x}{3} + \frac{2x^2}{15}$.

**In exercises 53 - 56, find the radius of convergence of the Maclaurin series of each function.**

53) $\ln(1+x)$

54) $\frac{1}{1+x^2}$

**Answer**

$\frac{1}{1+x^2} = \sum_{n=0}^{\infty}(-1)^n x^{2n}$ so $R = 1$ by the Ratio Test.

55) $\tan^{-1} x$

56) $\ln(1+x^2)$

**Answer**

$\ln(1+x^2) = \sum_{n=1}^{\infty}\frac{(-1)^{n-1}}{n}x^{2n}$ so $R = 1$ by the Ratio Test.

57) Find the Maclaurin series of $\sinh x = \frac{e^x - e^{-x}}{2}$.

58) Find the Maclaurin series of $\cosh x = \frac{e^x + e^{-x}}{2}$.

**Answer**

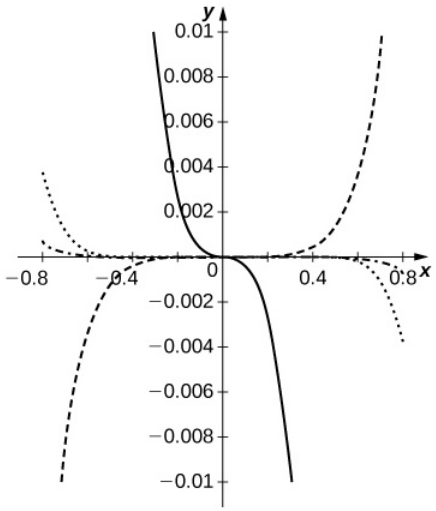
Add series of $e^x$ and $e^{-x}$ term by term. Odd terms cancel and $\cosh x = \sum_{n=0}^{\infty}\frac{x^{2n}}{(2n)!}$.

59) Differentiate term by term the Maclaurin series of $\sinh x$ and compare the result with the Maclaurin series of $\cosh x$.

60) [Technology Required] Let $S_n(x) = \sum_{k=0}^{n}(-1)^k\frac{x^{2k+1}}{(2k+1)!}$ and $C_n(x) = \sum_{n=0}^{n}(-1)^k\frac{x^{2k}}{(2k)!}$ denote the respective Maclaurin polynomials of degree $2n+1$ of $\sin x$ and degree $2n$ of $\cos x$. Plot the errors $\frac{S_n(x)}{C_n(x)} - \tan x$ for $n = 1, .., 5$ and compare them to $x + \frac{x^3}{3} + \frac{2x^5}{15} + \frac{17x^7}{315} - \tan x$ on $(-\frac{\pi}{4}, \frac{\pi}{4})$.

**Answer**

The ratio $\frac{S_n(x)}{C_n(x)}$ approximates $\tan x$ better than does $p_7(x) = x + \frac{x^3}{3} + \frac{2x^5}{15} + \frac{17x^7}{315}$ for $N \geq 3$. The dashed curves are $\frac{S_n}{C_n} - \tan x$ for $n = 1, 2$. The dotted curve corresponds to $n = 3$, and the dash-dotted curve corresponds to $n = 4$. The solid curve is $p_7 - \tan x$.



61) Use the identity $2\sin x \cos x = \sin(2x)$ to find the power series expansion of $\sin^2 x$ at $x = 0$. (Hint: Integrate the Maclaurin series of $\sin(2x)$ term by term.)

https://math.libretexts.org/@go/page/175628

62) If $y = \sum_{n=0}^{\infty} a_n x^n$, find the power series expansions of $xy'$ and $x^2y''$.

**Answer**

By the term-by-term differentiation theorem, $y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$ so $y' = \sum_{n=1}^{\infty} n a_n x^{n-1} xy' = \sum_{n=1}^{\infty} n a_n x^n$, whereas $y' = \sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}$ so $xy'' = \sum_{n=2}^{\infty} n(n-1) a_n x^n$.

63) [Technology Required] Suppose that a set of standardized test scores is normally distributed with mean $\mu = 100$ and standard deviation $\Sigma = 10$. Set up an integral that represents the probability that a test score will be between $90$ and $110$ and use the integral of the degree $10$ Maclaurin polynomial of $\frac{1}{\sqrt{2\pi}} e^{-x^2/2}$ to estimate this probability.

**Answer**

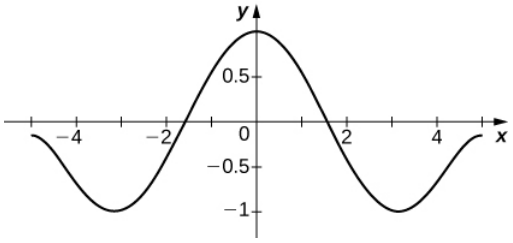
The probability is $p = \frac{1}{\sqrt{2\pi}} \int_{(a-\mu)/\Sigma}^{(b-\mu)/\Sigma} e^{-x^2/2}\, dx$ where $a = 90$ and $b = 100$, that is, $p = \frac{1}{\sqrt{2\pi}} \int_{-1}^{1} e^{-x^2/2}\, dx$
$= \frac{1}{\sqrt{2\pi}} \int_{-1}^{1} \sum_{n=0}^{5} (-1)^n \frac{x^{2n}}{2^n n!}\, dx = \frac{2}{\sqrt{2\pi}} \sum_{n=0}^{5} (-1)^n \frac{1}{(2n+1)2^n n!} \approx 0.6827.$

64) [Technology Required] Suppose that a set of standardized test scores is normally distributed with mean $\mu = 100$ and standard deviation $\Sigma = 10$. Set up an integral that represents the probability that a test score will be between $70$ and $130$ and use the integral of the degree $50$ Maclaurin polynomial of $\frac{1}{\sqrt{2\pi}} e^{-x^2/2}$ to estimate this probability.

65) [Technology Required] Suppose that $\sum_{n=0}^{\infty} a_n x^n$ converges to a function $f(x)$ such that $f(0) = 1$, $f'(0) = 0$, and $f''(x) = -f(x)$. Find a formula for $a_n$ and plot the partial sum $S_N$ for $N = 20$ on $[-5, 5]$.

**Answer**

As in the previous problem one obtains $a_n = 0$ if $n$ is odd and $a_n = -(n+2)(n+1)a_{n+2}$ if $n$ is even, so $a_0 = 1$ leads to $a_{2n} = \frac{(-1)^n}{(2n)!}$.



66) [Technology Required] Suppose that $\sum_{n=0}^{\infty} a_n x^n$ converges to a function $f(x)$ such that $f(0) = 0$, $f'(0) = 1$, and $f''(x) = -f(x)$. Find a formula for an and plot the partial sum $S_N$ for $N = 10$ on $[-5, 5]$.

**The error in approximating the integral $\int_a^b f(t)\, dt$ by that of a Taylor approximation $\int_a^b Pn(t)\, dt$ is at most $\int_a^b R_n(t)\, dt$. In exercises 67 - 68, the Taylor remainder estimate $R_n \le \frac{M}{(n+1)!}|x-a|^{n+1}$ guarantees that the integral of the Taylor polynomial of the given order approximates the integral of $f$ with an error less than $\frac{1}{10}$.**

a. Evaluate the integral of the appropriate Taylor polynomial and verify that it approximates the CAS value with an error less than $\frac{1}{100}$.

b. Compare the accuracy of the polynomial integral estimate with the remainder estimate.

67) [Technology Required] $\int_0^{\pi} \frac{\sin t}{t}\, dt$; $P_s = 1 - \frac{x^2}{3!} + \frac{x^4}{5!} - \frac{x^6}{7!} + \frac{x^8}{9!}$ (You may assume that the absolute value of the ninth derivative of $\frac{\sin t}{t}$ is bounded by $0.1$.)

**Answer**

a. (Proof)

b. We have $R_s \le \frac{0.1}{(9)!}\pi^9 \approx 0.0082 < 0.01$. We have $\int_0^{\pi}\left(1-\frac{x^2}{3!}+\frac{x^4}{5!}-\frac{x^6}{7!}+\frac{x^8}{9!}\right)dx = \pi - \frac{\pi^3}{3\cdot 3!}+\frac{\pi^5}{5\cdot 5!}-\frac{\pi^7}{7\cdot 7!}+\frac{\pi^9}{9\cdot 9!}$ $= 1.852...$, whereas $\int_0^{\pi}\frac{\sin t}{t}\,dt = 1.85194...$, so the actual error is approximately $0.00006$.

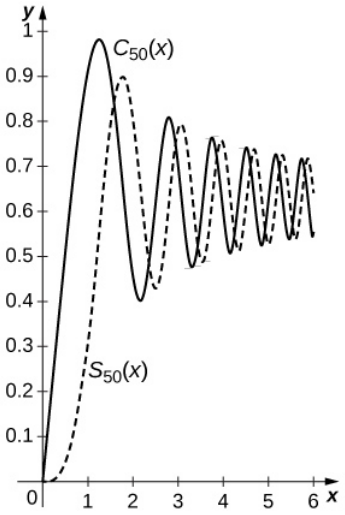
68) [Technology Required] $\int_0^2 e^{-x^2}\,dx;\ p_{11} = 1-x^2+\frac{x^4}{2}-\frac{x^6}{3!}+\cdots-\frac{x^{22}}{11!}$ (You may assume that the absolute value of the $23^{\text{rd}}$ derivative of $e^{-x^2}$ is less than $2\times 10^{14}$.)

**The following exercises (69-70) deal with *Fresnel integrals*.**

69) The Fresnel integrals are defined by $C(x) = \int_0^x \cos(t^2)\,dt$ and $S(x) = \int_0^x \sin(t^2)\,dt$. Compute the power series of $C(x)$ and $S(x)$ and plot the sums $C_N(x)$ and $S_N(x)$ of the first $N = 50$ nonzero terms on $[0, 2\pi]$.

**Answer**

Since $\cos(t^2) = \sum_{n=0}^{\infty}(-1)^n\frac{t^{4n}}{(2n)!}$ and $\sin(t^2) = \sum_{n=0}^{\infty}(-1)^n\frac{t^{4n+2}}{(2n+1)!}$, one has $S(x) = \sum_{n=0}^{\infty}(-1)^n\frac{x^{4n+3}}{(4n+3)(2n+1)!}$ and $C(x)$ $= \sum_{n=0}^{\infty}(-1)^n\frac{x^{4n+1}}{(4n+1)(2n)!}$. The sums of the first $50$ nonzero terms are plotted below with $C_{50}(x)$ the solid curve and $S_{50}(x)$ the dashed curve.



70) [Technology Required] The Fresnel integrals are used in design applications for roadways and railways and other applications because of the curvature properties of the curve with coordinates $(C(t), S(t))$. Plot the curve $(C_{50}, S_{50})$ for $0 \le t \le 2\pi$, the coordinates of which were computed in the previous exercise.

71) Estimate $\int_0^{1/4}\sqrt{x-x^2}\,dx$ by approximating $\sqrt{1-x}$ using the binomial approximation $1-\frac{x}{2}-\frac{x^2}{8}-\frac{x^3}{16}-\frac{5x^4}{2128}-\frac{7x^5}{256}$.

**Answer**

$\int_0^{1/4}\sqrt{x}\left(1-\frac{x}{2}-\frac{x^2}{8}-\frac{x^3}{16}-\frac{5x^4}{128}-\frac{7x^5}{256}\right)dx = \frac{2}{3}2^{-3}-\frac{1}{2}\frac{2}{5}2^{-5}-\frac{1}{8}\frac{2}{7}2^{-7}-\frac{1}{16}\frac{2}{9}2^{-9}-\frac{5}{128}\frac{2}{11}2^{-11}-\frac{7}{256}\frac{2}{13}2^{-13}$ $= 0.0767732...$ whereas $\int_0^{1/4}\sqrt{x-x^2}\,dx = 0.076773$.

72) [Technology Required] Use Newton's approximation of the binomial $\sqrt{1-x^2}$ to approximate $\pi$ as follows. The circle centered at $(\frac{1}{2}, 0)$ with radius $\frac{1}{2}$ has upper semicircle $y = \sqrt{x}\sqrt{1-x}$. The sector of this circle bounded by the $x$-axis between $x = 0$ and $x = \frac{1}{2}$ and by the line joining $(\frac{1}{4}, \frac{\sqrt{3}}{4})$ corresponds to $\frac{1}{6}$ of the circle and has area $\frac{\pi}{24}$. This sector is the union of a right triangle with height $\frac{\sqrt{3}}{4}$ and base $\frac{1}{4}$ and the region below the graph between $x = 0$ and $x = \frac{1}{4}$. To find the area of this region you can write $y$

$= \sqrt{x}\sqrt{1-x} = \sqrt{x} \times (\text{binomial expansion of} \sqrt{1-x})$ and integrate term by term. Use this approach with the binomial approximation from the previous exercise to estimate $\pi$.

73) Use the approximation $T \approx 2\pi\sqrt{\frac{L}{g}}(1+\frac{k^2}{4})$ to approximate the period of a pendulum having length $10$ meters and maximum angle $\theta_{max} = \frac{\pi}{6}$ where $k = \sin\left(\frac{\theta_{max}}{2}\right)$. Compare this with the small angle estimate $T \approx 2\pi\sqrt{\frac{L}{g}}$.

**Answer**

$T \approx 2\pi\sqrt{\frac{10}{9.8}}\left(1+\frac{\sin^2(\theta/12)}{4}\right) \approx 6.453$ seconds. The small angle estimate is $T \approx 2\pi\sqrt{\frac{10}{9.8}} \approx 6.347$. The relative error is around $2$ percent.

74) Suppose that a pendulum is to have a period of $2$ seconds and a maximum angle of $\theta_{max} = \frac{\pi}{6}$. Use $T \approx 2\pi\sqrt{\frac{L}{g}}\left(1+\frac{k^2}{4}\right)$ to approximate the desired length of the pendulum. What length is predicted by the small angle estimate $T \approx 2\pi\sqrt{\frac{L}{g}}$?

75) Evaluate $\int_0^{\pi/2} \sin^4\theta \; d\theta$ in the approximation $T = 4\sqrt{\frac{L}{g}}\int_0^{\pi/2}\left(1+\frac{1}{2}k^2\sin^2\theta+\frac{3}{8}k^4\sin^4\theta+\cdots\right) d\theta$ to obtain an improved estimate for $T$.

**Answer**

$\int_0^{\pi/2} \sin^4\theta \, d\theta = \frac{3\pi}{16}$. Hence $T \approx 2\pi\sqrt{\frac{L}{g}}\left(1+\frac{k^2}{4}+\frac{9}{256}k^4\right)$.

76) [Technology Required] An equivalent formula for the period of a pendulum with amplitude $\theta_{max}$ is $T(\theta_{max}) = 2\sqrt{2}\sqrt{\frac{L}{g}}\int_0^{\theta_{max}} \frac{d\theta}{\sqrt{\cos\theta-\cos(\theta_{max})}}$ where $L$ is the pendulum length and $g$ is the gravitational acceleration constant. When $\theta_{max} = \frac{\pi}{3}$ we get $\frac{1}{\sqrt{\cos t - 1/2}} \approx \sqrt{2}\left(1+\frac{t^2}{2}+\frac{t^4}{3}+\frac{181t^6}{720}\right)$. Integrate this approximation to estimate $T(\frac{\pi}{3})$ in terms of $L$ and $g$. Assuming $g = 9.806$ meters per second squared, find an approximate length $L$ such that $T(\frac{\pi}{3}) = 2$ seconds.

## 9.5: Chapter 4 Review Exercises

**True or False? In exercises 1 - 4, justify your answer with a proof or a counterexample.**

1) If the radius of convergence for a power series $\sum_{n=0}^{\infty} a_n x^n$ is $5$, then the radius of convergence for the series $\sum_{n=1}^{\infty} n a_n x^{n-1}$ is also $5$.

**Answer**

True

2) Power series can be used to show that the derivative of $e^x$ is $e^x$. (Hint: Recall that $e^x = \sum_{n=0}^{\infty} \frac{1}{n!} x^n$.)

3) For small values of $x$, $\sin x \approx x$.

**Answer**

True

4) The radius of convergence for the Maclaurin series of $f(x) = 3^x$ is $3$.

**In exercises 5 - 8, find the radius of convergence and the interval of convergence for the given series.**

5) $\sum_{n=0}^{\infty} n^2 (x-1)^n$

**Answer**

ROC: $1$; IOC: $(0, 2)$

6) $\sum_{n=0}^{\infty} \frac{x^n}{n^n}$

7) $\sum_{n=0}^{\infty} \frac{3n x^n}{12^n}$

**Answer**

ROC: $12$; IOC: $(-16, 8)$

8) $\sum_{n=0}^{\infty} \frac{2^n}{e^n} (x-e)^n$

**In exercises 9 - 10, find the power series representation for the given function. Determine the radius of convergence and the interval of convergence for that series.**

9) $f(x) = \frac{x^2}{x+3}$

**Answer**

$\sum_{n=0}^{\infty} \frac{(-1)^n}{3^{n+1}} x^n$; ROC: $3$; IOC: $(-3, 3)$

10) $f(x) = \frac{8x+2}{2x^2 - 3x + 1}$

**In exercises 11 - 12, find the power series for the given function using term-by-term differentiation or integration.**

11) $f(x) = \tan^{-1}(2x)$

**Answer**

integration: $\sum_{n=0}^{\infty} \frac{(-1)^n}{2n+1} (2x)^{2n+1}$

12) $f(x) = \dfrac{x}{(2+x^2)^2}$

**In exercises 13 - 14, evaluate the Taylor series expansion of degree four for the given function at the specified point. What is the error in the approximation?**

13) $f(x) = x^3 - 2x^2 + 4, \quad a = -3$

**Answer**

$p_4(x) = (x+3)^3 - 11(x+3)^2 + 39(x+3) - 41$; exact

14) $f(x) = e^{1/(4x)}, \quad a = 4$

**In exercises 15 - 16, find the Maclaurin series for the given function.**

15) $f(x) = \cos(3x)$

**Answer**

$$\sum_{n=0}^{\infty} \frac{(-1)^n (3x)^{2n}}{2n!}$$

16) $f(x) = \ln(x+1)$

**In exercises 17 - 18, find the Taylor series at the given value.**

17) $f(x) = \sin x, \quad a = \frac{\pi}{2}$

**Answer**

$$\sum_{n=0}^{\infty} \frac{(-1)^n}{(2n)!} \left(x - \frac{\pi}{2}\right)^{2n}$$

18) $f(x) = \dfrac{3}{x}, \quad a = 1$

**In exercises 19 - 20, find the Maclaurin series for the given function.**

19) $f(x) = e^{-x^2} - 1$

**Answer**

$$\sum_{n=1}^{\infty} \frac{(-1)^n}{n!} x^{2n}$$

20) $f(x) = \cos x - x \sin x$

**In exercises 21 - 23, find the Maclaurin series for $F(x) = \int_0^x f(t)\, dt$ by integrating the Maclaurin series of $f(x)$ term by term.**

21) $f(x) = \dfrac{\sin x}{x}$

**Answer**

$$F(x) = \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)(2n+1)!} x^{2n+1}$$

22) $f(x) = 1 - e^x$

23) Use power series to prove **Euler's formula:** $e^{ix} = cosx + isinx$

**Answer**

Answers may vary.

**Exercises 24 - 26 consider problems of *annuity payments*.**

24) For annuities with a present value of $1 million, calculate the annual payouts given over 25 years assuming interest rates of $1\%, 5\%$, and $10\%$.

25) A lottery winner has an annuity that has a present value of $10 million. What interest rate would they need to live on perpetual annual payments of $\$250,000$?

**Answer**

$2.5\%$

26) Calculate the necessary present value of an annuity in order to support annual payouts of $\$15,000$ given over 25 years assuming interest rates of $1\%, 5\%$,and $10\%$.

# CHAPTER OVERVIEW

## 10: Parametric Equations and Polar Coordinates

Parametric equations define a group of quantities as functions of one or more independent variables called parameters. Parametric equations are commonly used to express the coordinates of the points that make up a geometric object such as a curve or surface, in which case the equations are collectively called a parametric representation or parameterization. The polar coordinate system is a two-dimensional coordinate system in which each point on a plane is determined by a distance from a reference point and an angle from a reference direction. The reference point (analogous to the origin of a Cartesian system) is called the pole, and the ray from the pole in the reference direction is the polar axis. The distance from the pole is called the radial coordinate or radius, and the angle is called the angular coordinate, polar angle, or azimuth

# 10.1: Chapter 5 Review Exercises

***True or False?* Justify your answer with a proof or a counterexample.**

1) The rectangular coordinates of the point $\left(4, \frac{5\pi}{6}\right)$ are $\left(2\sqrt{3}, -2\right)$.

2) The equations $x = \cosh(3t),\ y = 2\sinh(3t)$ represent a hyperbola.

**Answer**

True

3) The arc length of the spiral given by $r = \dfrac{\theta}{2}$ for $0 \le \theta \le 3\pi$ is $\frac{9}{4}\pi^3$ units.

4) Given $x = f(t)$ and $y = g(t)$, if $\dfrac{dx}{dy} = \dfrac{dy}{dx}$, then $f(t) = g(t) + C$, where $C$ is a constant.

**Answer**

False. Imagine $y = t + 1,\ x = -t + 1$.

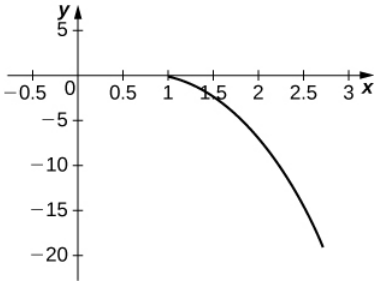
**In exercises 5 -8, sketch the parametric curve and eliminate the parameter to find the Cartesian equation of the curve.**

5) $x = 1 + t,\ y = t^2 - 1, \quad -1 \le t \le 1$

6) $x = e^t,\ y = 1 - e^{3t}, \quad 0 \le t \le 1$

**Answer**

$y = 1 - x^3$

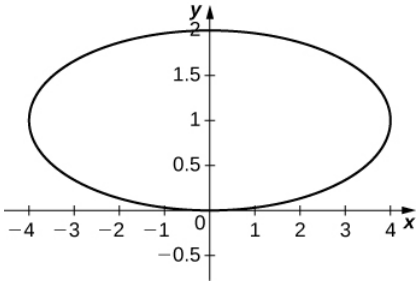


7) $x = \sin\theta,\ y = 1 - \csc\theta, \quad 0 \le \theta \le 2\pi$

8) $x = 4\cos\phi,\ y = 1 - \sin\phi, \quad 0 \le \phi \le 2\pi$

**Answer**

$\dfrac{x^2}{16} + (y-1)^2 = 1$



**In exercises 9 - 10, sketch the polar curve and determine what type of symmetry exists, if any.**

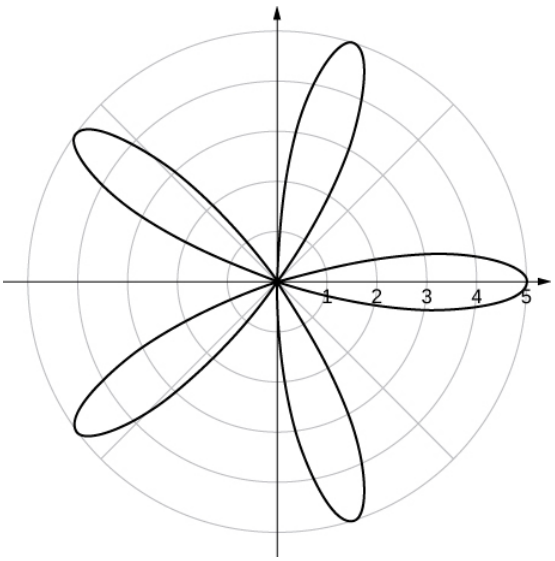
9) $r = 4\sin\left(\frac{\theta}{3}\right)$

https://math.libretexts.org/@go/page/175641

10) $r = 5\cos(5\theta)$

**Answer**

Symmetric about polar axis



**In exercises 11 - 12, find the polar equation for the curve given as a Cartesian equation.**

11) $x + y = 5$

12) $y^2 = 4 + x^2$

**Answer**

$$r^2 = \frac{4}{\sin^2\theta - \cos^2\theta}$$

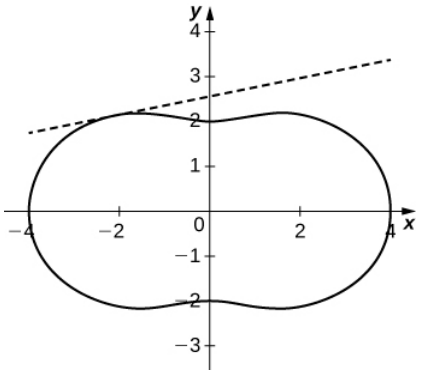
**In exercises 13 - 14, find the equation of the tangent line to the given curve. Graph both the function and its tangent line.**

13) $x = \ln(t),\ y = t^2 - 1,\ t = 1$

14) $r = 3 + \cos(2\theta),\ \theta = \frac{3\pi}{4}$

**Answer**

$y = \frac{3\sqrt{2}}{2} + \frac{1}{5}\left(x + \frac{3\sqrt{2}}{2}\right)$



15) Find $\frac{dy}{dx}$, $\frac{dx}{dy}$, and $\frac{d^2x}{dy^2}$ of $y = (2 + e^{-t}),\ x = 1 - \sin t$

**In exercises 16 -17, find the area of the region.**

16) $x = t^2,\ y = \ln(t),\quad 0 \le t \le e$

**Answer**

$\frac{e^2}{2}$ units$^2$

17) $r = 1 - \sin\theta$ in the first quadrant

**In exercises 18 - 19, find the arc length of the curve over the given interval.**

18) $x = 3t + 4,\ y = 9t - 2,\quad 0 \le t \le 3$

**Answer**

$9\sqrt{10}$ units

19) $r = 6\cos\theta,\quad 0 \le \theta \le 2\pi$. Check your answer by geometry.

**In exercises 20 - 22, find the Cartesian equation describing the given shapes.**

20) A parabola with focus $(2, -5)$ and directrix $x = 6$

**Answer**

$(y+5)^2 = -8x + 32$

21) An ellipse with a major axis length of 10 and foci at $(-7, 2)$ and $(1, 2)$

22) A hyperbola with vertices at $(3, -2)$ and $(-5, -2)$ and foci at $(-2, -6)$ and $(-2, 4)$

**Answer**

$\frac{(y+1)^2}{16} - \frac{(x+2)^2}{9} = 1$

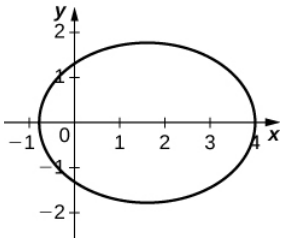
**In exercises 23 - 25, determine the eccentricity and identify the conic. Sketch the conic.**

23) $r = \frac{6}{1 + 3\cos\theta}$

24) $r = \frac{4}{3 - 2\cos\theta}$

**Answer**

$e = \frac{2}{3}$, ellipse



25) $r = \frac{7}{5 - 5\cos\theta}$

26) Determine the Cartesian equation describing the orbit of Pluto, the most eccentric orbit around the Sun. The length of the major axis is 39.26 AU and minor axis is 38.07 AU. What is the eccentricity?

**Answer**

$\frac{y^2}{19.03^2} + \frac{x^2}{19.63^2} = 1,\quad e = 0.2447$

27) The C/1980 E1 comet was observed in 1980. Given an eccentricity of $1.057$ and a perihelion (point of closest approach to the Sun) of $3.364$ AU, find the Cartesian equations describing the comet's trajectory. Are we guaranteed to see this comet again? (Hint: Consider the Sun at point $(0,0)$.)

# 10.2: Parametric Equations

**Learning Objectives**

- Plot a curve described by parametric equations.
- Convert the parametric equations of a curve into the form $y = f(x)$.
- Recognize the parametric equations of basic curves, such as a line and a circle.
- Recognize the parametric equations of a cycloid.

This section examines parametric equations and their graphs. In the two-dimensional coordinate system, parametric equations are useful for describing curves that are not necessarily functions. The parameter is an independent variable that both $x$ and $y$ depend on. As the parameter increases, the values of $x$ and $y$ trace a path along a plane curve. For example, if the parameter is $t$ (a common choice), then $t$ might represent time. Then, $x$ and $y$ are defined as functions of time, and $(x(t), y(t))$ can describe the position in the plane of a given object as it moves along a curved path.

## Parametric Equations and Their Graphs

Consider the orbit of Earth around the Sun. Our year lasts approximately 365.25 days, but we will use 365 days for this discussion. On January 1 of each year, the physical location of Earth with respect to the Sun is nearly the same, except for leap years, when the lag introduced by the extra $\frac{1}{4}$ day of orbiting time is built into the calendar. We call January 1 "day 1" of the year. Then, for example, day 31 is January 31, day 59 is February 28, and so on.

The day number in a year can be considered a variable that determines Earth's position in its orbit. As Earth revolves around the Sun, its physical location changes relative to the Sun. After one full year, we are back where we started, and a new year begins. According to Kepler's laws of planetary motion, the shape of the orbit is elliptical, with the Sun at one focus of the ellipse. We study this idea in more detail in Conic Sections.

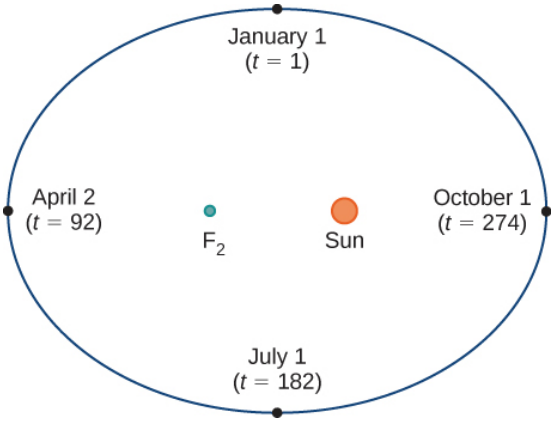

Figure 10.2.1: Earth's orbit around the Sun in one year.

Figure 10.2.1 depicts Earth's orbit around the Sun during one year. The point labeled $F_2$ is one of the ellipse's foci; the other focus is occupied by the Sun. Suppose we superimpose coordinate axes over this graph. In that case, we can assign ordered pairs to each point on the ellipse (Figure 10.2.2). Then, each $x$- and $y$-value on the graph is a value of position as a function of time. Therefore, each point on the graph corresponds to a value of Earth's position as a function of time.

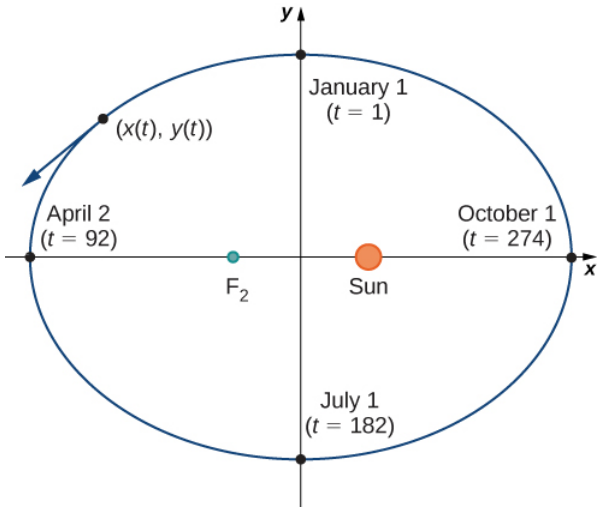

Figure 10.2.2: Coordinate axes superimposed on the orbit of Earth.

We can determine the functions for $x(t)$ and $y(t)$, thereby **parametrizing** (also called **parameterizing**) the orbit of Earth around the Sun. The variable $t$ is called an **independent parameter** and, in this context, represents time relative to the beginning of each year.

Any curve in the $(x, y)$ plane can be represented parametrically. The equations that are used to define the curve are called **parametric equations**.

### Definition: Parametric Equations

If $x$ and $y$ are continuous functions of $t$ on an interval $I$, then the equations

$$x = x(t)$$

and

$$y = y(t)$$

are called **parametric equations** and $t$ is called the **parameter**. The set of points $(x, y)$ obtained as $t$ varies over the interval $I$ is called the graph of the **parametric equations**. The graph of parametric equations is called a **parametric curve**, or **plane curve**, and is denoted by $C$.

Notice in this definition that $x$ and $y$ are used in two ways. The first is as functions of the independent variable $t$. As $t$ varies over the interval $I$, the functions $x(t)$ and $y(t)$ generate a set of ordered pairs $(x, y)$. This set of ordered pairs generates the graph of the parametric equations. This usage of $x$ and $y$ as coordinates in a set of ordered pairs is the second interpretation of $x$ and $y$. It is important to distinguish the variables $x$ and $y$ from the functions $x(t)$ and $y(t)$.

### Example 10.2.1: Graphing a Parametrically Defined Curve

Sketch the curves described by the following parametric equations:

a. $x(t) = t - 1, \quad y(t) = 2t + 4, \quad \text{for } -3 \le t \le 2$
b. $x(t) = t^2 - 3, \quad y(t) = 2t + 1, \quad \text{for } -2 \le t \le 3$
c. $x(t) = 4\cos t, \quad y(t) = 4\sin t, \quad \text{for } 0 \le t \le 2\pi$

**Solutions**

a. To create a graph of this curve, first set up a table of values. Since the independent variable in both $x(t)$ and $y(t)$ is $t$, let $t$ appear in the first column. Then $x(t)$ and $y(t)$ will appear in the second and third columns of the table.

| $t$ | $x(t)$ | $y(t)$ |
|---|---|---|
| −3 | −4 | −2 |
| −2 | −3 | 0 |
| −1 | −2 | 2 |
| 0 | −1 | 4 |
| 1 | 0 | 6 |
| 2 | 1 | 8 |

The second and third columns in this table provide a set of points to be plotted. The graph of these points appears in Figure **10.2.3**. The arrows on the graph indicate the **orientation** of the graph. This is the direction that a point moves on the graph as $t$ varies from $-3$ to $2$.

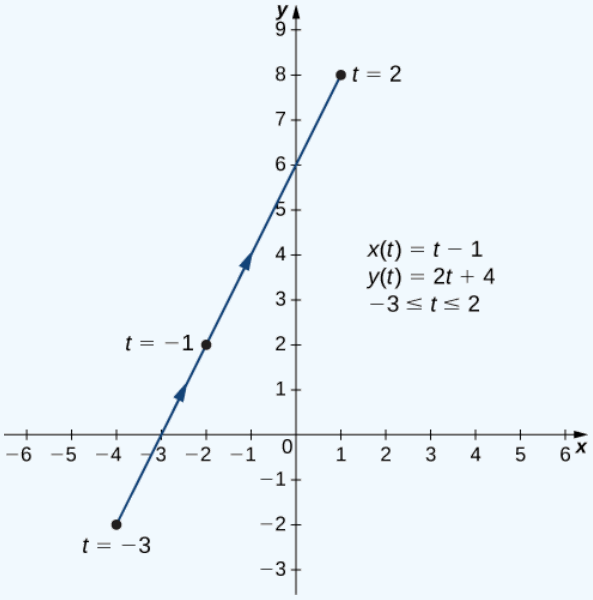

Figure **10.2.3**: Graph of the plane curve described by the parametric equations in part a.

b. To create a graph of this curve, again set up a table of values.

| $t$ | $x(t)$ | $y(t)$ |
|---|---|---|
| −2 | 1 | −3 |
| −1 | −2 | −1 |
| 0 | −3 | 1 |
| 1 | −2 | 3 |
| 2 | 1 | 5 |
| 3 | 6 | 7 |

The second and third columns in this table give a set of points to be plotted (Figure **10.2.4**). The first point on the graph (corresponding to $t = -2$) has coordinates $(1, -3)$, and the last point (corresponding to $t = 3$) has coordinates $(6, 7)$. As $t$ progresses from $-2$ to $3$, the point on the curve travels along a parabola. The direction the point moves is again called orientation and is indicated on the graph.

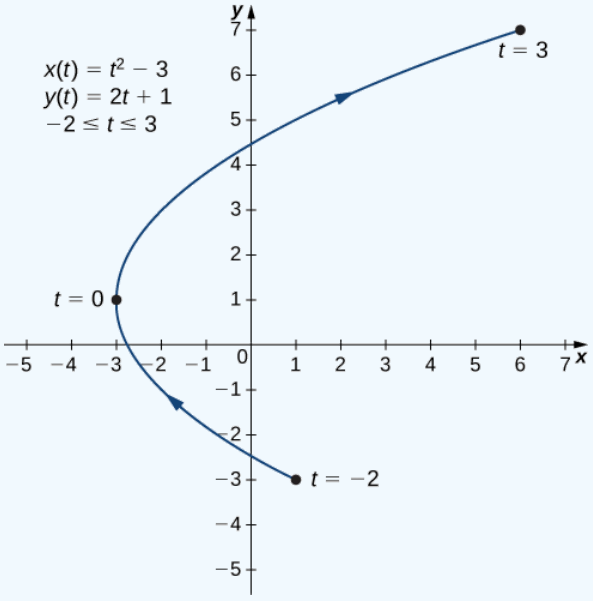

Figure 10.2.4: Graph of the plane curve described by the parametric equations in part b.

c. In this case, use multiples of $\pi/6$ for $t$ and create another table of values:

| $t$ | $x(t)$ | $y(t)$ | $t$ | $x(t)$ | $y(t)$ |
|---|---|---|---|---|---|
| 0 | 4 | 0 | $\frac{7\pi}{6}$ | $-2\sqrt{3} \approx -3.5$ | -2 |
| $\frac{\pi}{6}$ | $2\sqrt{3} \approx 3.5$ | 2 | $\frac{4\pi}{3}$ | $-2$ | $-2\sqrt{3} \approx -3.5$ |
| $\frac{\pi}{3}$ | 2 | $2\sqrt{3} \approx 3.5$ | $\frac{3\pi}{2}$ | 0 | $-4$ |
| $\frac{\pi}{2}$ | 0 | 4 | $\frac{5\pi}{3}$ | 2 | $-2\sqrt{3} \approx -3.5$ |
| $\frac{2\pi}{3}$ | $-2$ | $2\sqrt{3} \approx 3.5$ | $\frac{11\pi}{6}$ | $2\sqrt{3} \approx 3.5$ | -2 |
| $\frac{5\pi}{6}$ | $-2\sqrt{3} \approx -3.5$ | 2 | $2\pi$ | 4 | 0 |
| $\pi$ | $-4$ | 0 | | | |

The graph of this plane curve appears in the following graph.

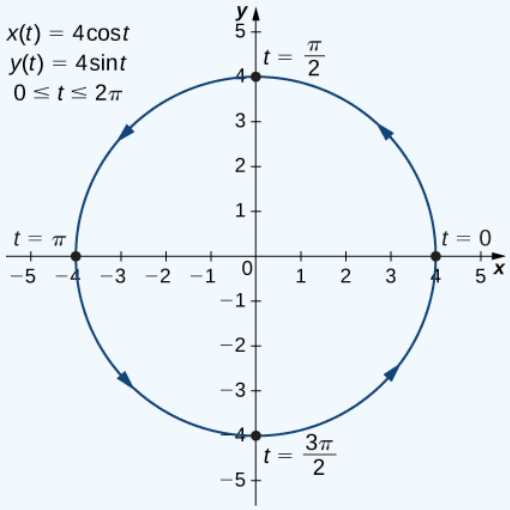

Figure 10.2.5: Graph of the plane curve described by the parametric equations in part c.

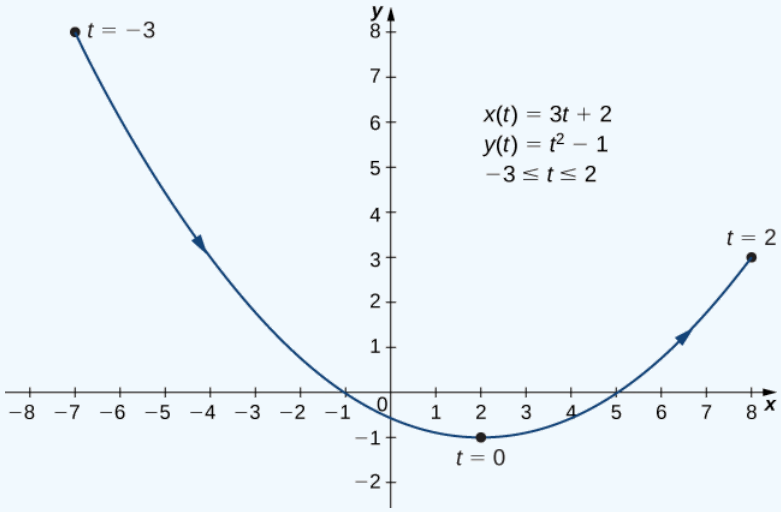
This is the graph of a circle with radius $4$ centered at the origin, with a counterclockwise orientation. The starting point and ending points of the curve both have coordinates $(4,0)$.

**? Checkpoint 10.2.1**

Sketch the curve described by the parametric equations

$$x(t) = 3t + 2, \quad y(t) = t^2 - 1, \quad \text{for } -3 \le t \le 2.$$

**Answer**



## Eliminating the Parameter

To better understand the graph of a curve represented parametrically, it is helpful to rewrite the two equations as a single equation relating the variables $x$ and $y$. Then, we can apply any previous knowledge of equations of curves in the plane to identify the curve. For example, the equations describing the plane curve in Example $10.2.1b$ are

$$x(t) = t^2 - 3 \tag{10.2.1}$$

$$y(t) = 2t + 1 \tag{10.2.2}$$

over the region $-2 \le t \le 3$.

Solving Equation 10.2.2 for $t$ gives

$$t = \frac{y-1}{2}.$$

This can be substituted into Equation 10.2.1:

$$x = \left(\frac{y-1}{2}\right)^2 - 3 \tag{10.2.3}$$

$$= \frac{y^2 - 2y + 1}{4} - 3 \tag{10.2.4}$$

$$= \frac{y^2 - 2y - 11}{4}. \tag{10.2.5}$$

Equation 10.2.5 describes $x$ as a function of $y$. These steps give an example of eliminating the parameter. The graph of this function is a parabola opening to the right (Figure $10.2.4$). Recall that the plane curve started at $(1,-3)$ and ended at $(6,7)$. These terminations were due to the restriction on the parameter $t$.

## Example 10.2.2: Eliminating the Parameter

Eliminate the parameter for each plane curve described by the following parametric equations and describe the resulting graph.

a. $x(t) = \sqrt{2t+4}, \quad y(t) = 2t+1, \quad \text{for } -2 \le t \le 6$

b. $x(t) = 4\cos t, \quad y(t) = 3\sin t, \quad \text{for } 0 \le t \le 2\pi$

**Solution**

a. To eliminate the parameter, we can solve either of the equations for $t$. For example, solving the first equation for $t$ gives

$$\begin{aligned} x &= \sqrt{2t+4} \\ \Rightarrow \quad x^2 &= 2t+4 \\ \Rightarrow \quad x^2-4 &= 2t \\ \Rightarrow \quad t &= \frac{x^2-4}{2}. \end{aligned}$$

Note that when we square both sides, it is important to observe that $x \ge 0$. Substituting $t = \frac{x^2-4}{2}$ into $y(t)$ yields

$$\begin{aligned} y(t) &= 2t+1 \\ \Rightarrow \quad y &= 2\left(\frac{x^2-4}{2}\right)+1 \\ \Rightarrow \quad y &= x^2-4+1 \\ \Rightarrow \quad y &= x^2-3. \end{aligned}$$

This is the equation of a parabola opening upward. There is, however, a domain restriction because of the limits on the parameter $t$. When $t = -2$, $x = \sqrt{2(-2)+4} = 0$, and when $t = 6$, $x = \sqrt{2(6)+4} = 4$. The graph of this plane curve follows.

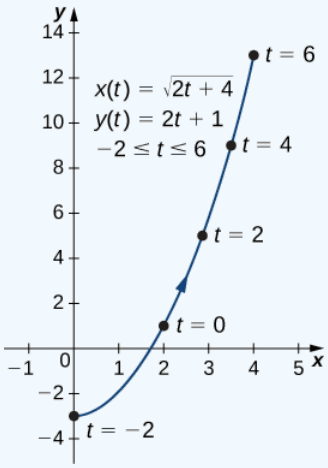


Figure 10.2.6: Graph of the plane curve described by the parametric equations in part a.

b. Sometimes, it is necessary to be creative in eliminating the parameter. The parametric equations for this example are

$$x(t) = 4\cos t$$

and

$$y(t) = 3\sin t.$$

Solving either equation for $t$ directly is not advisable because sine and cosine are not one-to-one functions. However, dividing the first equation by 4 and the second equation by 3 (and suppressing the $t$) gives us

$$\cos t = \frac{x}{4}$$

and

$$\sin t = \frac{y}{3}.$$

Now use the Pythagorean Identity $\cos^2 t + \sin^2 t = 1$ and replace the expressions for $\sin t$ and $\cos t$ with the equivalent expressions in terms of $x$ and $y$. This gives

$$\begin{aligned} \left(\frac{x}{4}\right)^2 + \left(\frac{y}{3}\right)^2 &= 1 \\ \Rightarrow \qquad \frac{x^2}{16} + \frac{y^2}{9} &= 1. \end{aligned}$$

This is the equation of a horizontal ellipse centered at the origin, with semi-major axis $4$ and semi-minor axis $3$, as shown in the following graph.

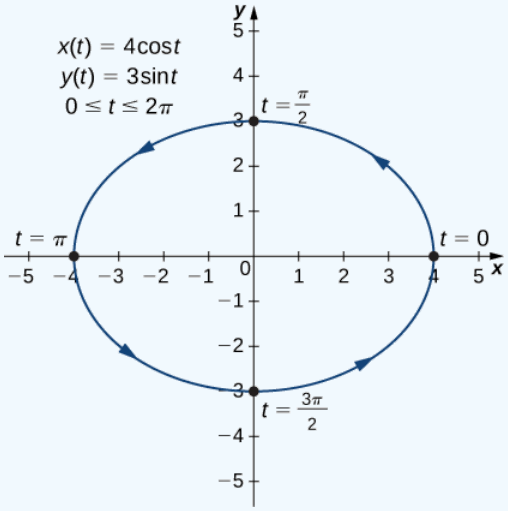

Figure 10.2.7: Graph of the plane curve described by the parametric equations in part b.

As $t$ progresses from $0$ to $2\pi$, a point on the curve traverses the ellipse once in a counterclockwise direction. Recall from the section opener that the orbit of Earth around the Sun is also elliptical. This is a perfect example of using parametrized curves to model real-world phenomena.

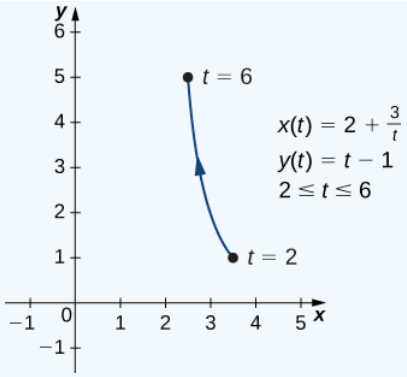
## ? Checkpoint 10.2.2

Eliminate the parameter for the plane curve defined by the following parametric equations and describe the resulting graph.

$$x(t) = 2 + \frac{3}{t}, \quad y(t) = t - 1, \quad \text{for } 2 \le t \le 6$$

**Answer**

$x = 2 + \frac{3}{y+1}$, or $y = -1 + \frac{3}{x-2}$. This equation describes a portion of a rectangular hyperbola centered at $(2, -1)$.



So far, we have seen the method of eliminating the parameter, assuming we know a set of parametric equations that describe a plane curve. What if we start with the equation of a curve and determine a pair of parametric equations for that curve? This can be done in many ways for a given curve. The process is known as **parametrization of a curve**.

### Example 10.2.3: Parametrizing a Curve

Find two different pairs of parametric equations to represent the graph of $y = 2x^2 - 3$.

**Solution**

First, it is always possible to parametrize a curve by defining $x(t) = t$, then replacing $x$ with $t$ in the equation for $y(t)$. This gives the parametrization

$$x(t) = t, \quad y(t) = 2t^2 - 3.$$

Since there is no restriction on the domain in the original graph, there is no restriction on the values of $t$.

We have complete freedom in choosing the second parametrization. For example, we can choose $x(t) = 3t - 2$. The only thing we need to check is that there are no restrictions imposed on $x$; that is, the range of $x(t)$ is all real numbers. This is the case for $x(t) = 3t - 2$. Now since $y = 2x^2 - 3$, we can substitute $x(t) = 3t - 2$ for $x$. This gives

$$y(t) = 2(3t - 2)^2 - 2 = 2(9t^2 - 12t + 4) - 2 = 18t^2 - 24t + 8 - 2 = 18t^2 - 24t + 6.$$

Therefore, a second parametrization of the curve can be written as

$$x(t) = 3t - 2 \text{ and } y(t) = 18t^2 - 24t + 6.$$

### Checkpoint 10.2.3

Find two sets of parametric equations to represent the graph of $y = x^2 + 2x$.

**Answer**

One possibility is $x(t) = t, \quad y(t) = t^2 + 2t$. Another possibility is $x(t) = 2t - 3, \quad y(t) = (2t - 3)^2 + 2(2t - 3) = 4t^2 - 8t + 3$. There are, in fact, an infinite number of possibilities.

## Cycloids and Other Parametric Curves

Imagine going on a bicycle ride through the country. The tires stay in contact with the road and rotate in a predictable pattern. Suppose a very determined ant is tired after a long day and wants to get home. So he hangs onto the side of the tire and gets a free ride. The path that this ant travels down a straight road is called a cycloid (Figure 10.2.8). A cycloid generated by a circle (or bicycle wheel) of radius $a$ is given by the parametric equations

$$x(t) = a(t - \sin t), \quad y(t) = a(1 - \cos t).$$

To see why this is true, consider the path that the center of the wheel takes. The center moves along the $x$-axis at a constant height equal to the wheel's radius. If the radius is $a$, then the coordinates of the center can be given by the equations

$$x(t) = at, \quad y(t) = a$$

for any value of $t$. Next, consider the ant, which rotates along a circular path around the center. If the bicycle moves from left to right, the wheels spin clockwise. A possible parametrization of the circular motion of the ant (relative to the center of the wheel) is given by

$$\begin{aligned} x(t) &= -a\sin t \\ y(t) &= -a\cos t. \end{aligned}$$

(The negative sign is needed to reverse the orientation of the curve. If the negative sign were not there, we would have to imagine the wheel rotating counterclockwise.) Adding these equations together gives the equations for the cycloid.

$$\begin{aligned} x(t) &= a(t - \sin t) \\ y(t) &= a(1 - \cos t) \end{aligned}$$

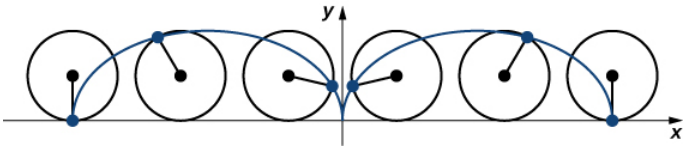


Figure 10.2.8: A wheel traveling along a road without slipping; the point on the edge of the wheel traces out a cycloid.

Now suppose that the bicycle wheel doesn't travel along a straight road but instead moves along the inside of a larger wheel, as in Figure 10.2.9. In this graph, the green circle travels around the blue circle in a counterclockwise direction. A point on the edge of the green circle traces out the red graph, which is called a **hypocycloid**.

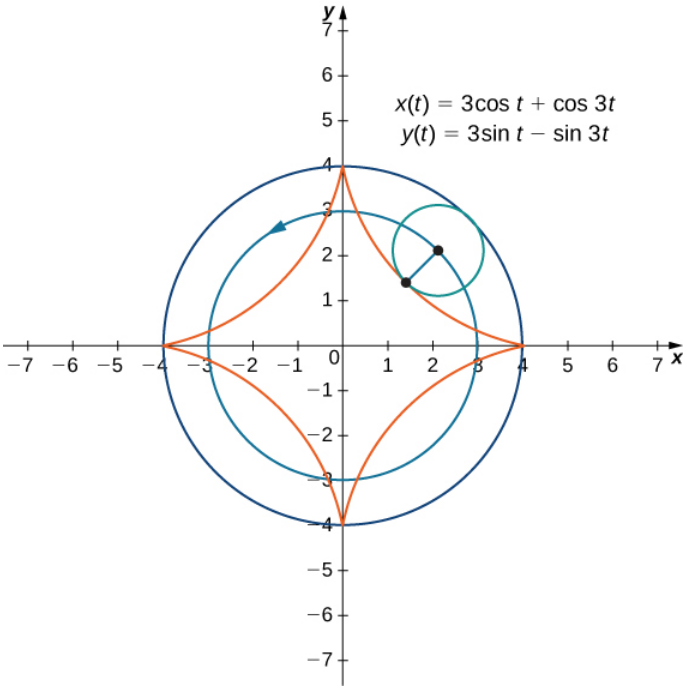

Figure 10.2.9: Graph of the hypocycloid described by the parametric equations shown.

The general parametric equations for a hypocycloid are

$$x(t) = (a-b)\cos t + b\cos\left(\frac{a-b}{b}\right)t$$

$$y(t) = (a-b)\sin t - b\sin\left(\frac{a-b}{b}\right)t.$$

These equations are more complicated. Still, the derivation is somewhat similar to the equations for the cycloid. In this case, we assume the radius of the larger circle is $a$ and the radius of the smaller circle is $b$. Then, the center of the wheel travels along a circle of radius $a-b$. This fact explains the first term in each equation above. The period of the second trigonometric function in both $x(t)$ and $y(t)$ is equal to $\frac{2\pi b}{a-b}$.

The ratio $\frac{a}{b}$ is related to the number of **cusps** on the graph (cusps are the corners or pointed ends of the graph), as illustrated in Figure 10.2.10. This ratio can lead to some fascinating graphs, depending on whether or not the ratio is rational. Figure 10.2.9 corresponds to $a = 4$ and $b = 1$. The result is a hypocycloid with four cusps. Figure 10.2.10 shows other possibilities. The last two hypocycloids have irrational values for $\frac{a}{b}$. In these cases, the hypocycloids have an infinite number of cusps, so they never return to their starting point. These are examples of what are known as **space-filling curves.**

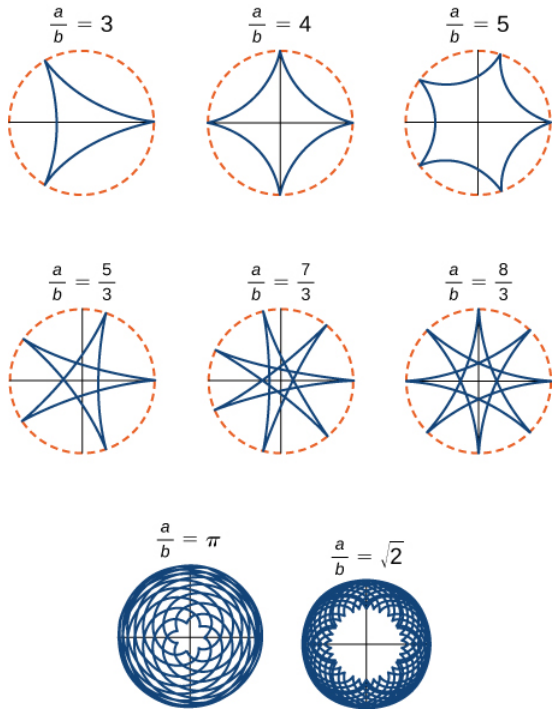

Figure 10.2.10: Graph of various hypocycloids corresponding to different values of $a/b$.

## The Witch of Agnesi

Many plane curves in mathematics are named after the people who first investigated them, like the **Folium of Descartes** or the **Spiral of Archimedes**. However, arguably, the strangest name for a curve is the **Witch of Agnesi.** Why a witch?

Maria Gaetana Agnesi (1718–1799) was one of eighteenth-century Italy's few recognized women mathematicians. She wrote a popular book on Analytic Geometry, published in 1748, which included an interesting curve studied by Fermat in 1630. In 1703, the mathematician Guido Grandi showed how to construct this curve, which he later called the "versoria," a Latin term for a rope used in sailing. Agnesi used the Italian term for this rope, "versiera," but in Latin, this same word means a "female goblin." When Agnesi's book was translated into English in 1801, the translator used "witch" for the curve instead of rope. The name "witch of Agnesi" has stuck ever since.

The witch of Agnesi is a curve defined as follows: Start with a circle of radius $a$ so that the points $(0,0)$ and $(0,2a)$ are points on the circle (Figure 10.2.11). Let $O$ denote the origin. Choose any other point $A$ on the circle, and draw the secant line $OA$. Let $B$ denote the point at which the line $OA$ intersects the horizontal line through $(0,2a)$. The vertical line through $B$ intersects the

horizontal line through $A$ at the point $P$. As the point $A$ varies, the path that the point $P$ travels is the witch of Agnesi curve for the given circle.

Witch of Agnesi curves have applications in physics, including modeling water waves and distributions of spectral lines. In probability theory, the curve describes the probability density function of the **Cauchy distribution**. In this project, you will parametrize these curves.

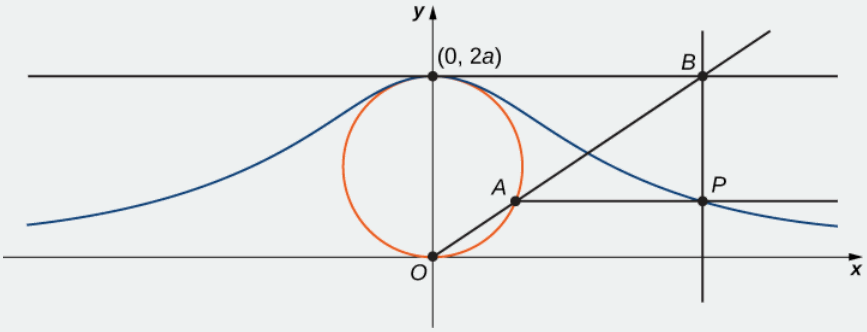

Figure 10.2.11: As the point $A$ moves around the circle, the point $P$ traces out the witch of Agnesi curve for the given circle.

1. On the figure, label the following points, lengths, and angle:
   a. $C$ is the point on the $x$-axis with the same $x$-coordinate as $A$.
   b. $x$ is the $x$-coordinate of $P$, and $y$ is the $y$-coordinate of $P$.
   c. $E$ is the point $(0, a)$.
   d. $F$ is the point on the line segment $OA$ such that the line segment $EF$ is perpendicular to the line segment $OA$.
   e. $b$ is the distance from $O$ to $F$.
   f. $c$ is the distance from $F$ to $A$.
   g. $d$ is the distance from $O$ to $C$.
   h. $\theta$ is the measure of angle $\angle COA$.

This project aims to parametrize the witch using $\theta$ as a parameter. To do this, write equations for $x$ and $y$ in terms of only $\theta$.

2. Show that $d = \frac{2a}{\sin\theta}$.
3. Note that $x = d\cos\theta$. Show that $x = 2a\cot\theta$. When you do this, you will have parametrized the $x$-coordinate of the curve with respect to $\theta$. If you can get a similar equation for $y$, you will have parametrized the curve.
4. In terms of $\theta$, what is the angle $\angle EOA$?
5. Show that $b + c = 2a\cos\left(\frac{\pi}{2} - \theta\right)$.
6. Show that $y = 2a\cos\left(\frac{\pi}{2} - \theta\right)\sin\theta$.
7. Show that $y = 2a\sin^2\theta$. You have now parametrized the $y$-coordinate of the curve with respect to $\theta$.
8. Conclude that a parametrization of the given witch curve is

$$x = 2a\cot\theta, \quad y = 2a\sin^2\theta, \quad \text{for } -\infty < \theta < \infty.$$

9. Use your parametrization to show that the given witch curve is the graph of the function $f(x) = \frac{8a^3}{x^2+4a^2}$.

## Travels with My Ant: The Curtate and Prolate Cycloids

Earlier in this section, we looked at the parametric equations for a cycloid, the path a point on the edge of a wheel traces as the wheel rolls along a straight path. In this project, we look at two different variations of the cycloid, called the **curtate** and **prolate cycloids**.

First, let's revisit the derivation of the parametric equations for a cycloid. Recall that we considered a tenacious ant trying to get home by hanging onto the edge of a bicycle tire. We assumed the ant climbed onto the tire at the very edge, where the tire touched the ground. As the wheel rolls, the ant moves with the edge of the tire (Figure 10.2.12).

As we have discussed, we have a lot of flexibility when parametrizing a curve. In this case, we let our parameter $t$ represent the angle the tire has rotated through. Looking at Figure 10.2.12, we see that after the tire has rotated through an angle of $t$, the

position of the center of the wheel, $C = (x_C, y_C)$, is given by

$$x_C = at \quad \text{and} \quad y_C = a.$$

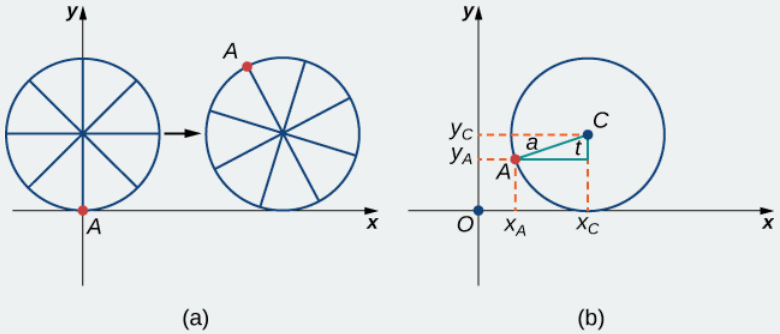
Furthermore, letting $A = (x_A, y_A)$ denote the position of the ant, we note that

$$x_C - x_A = a\sin t \quad \text{and} \quad y_C - y_A = a\cos t.$$

Then

$$x_A = x_C - a\sin t = at - a\sin t = a(t - \sin t)$$

$$y_A = y_C - a\cos t = a - a\cos t = a(1 - \cos t).$$

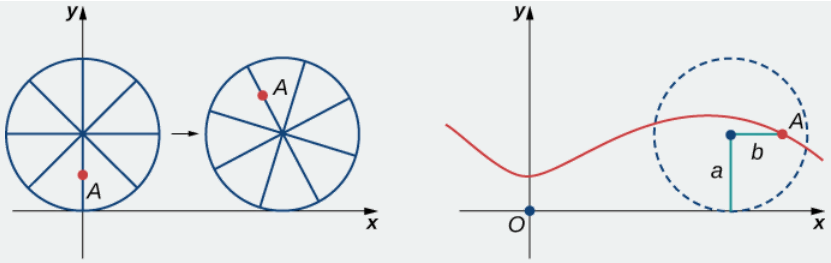


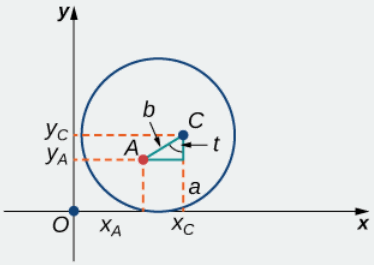
(a) (b)

Figure 10.2.12*a*: The ant clings to the edge of the bicycle tire as the tire rolls along the ground.
Figure 10.2.12*b*: Using Geometry to determine the position of the ant after the tire has rotated through an angle of $t$.

Note that these are the same parametric representations we had before, but we have now assigned a physical meaning to the parametric variable $t$.

After a while, the ant gets dizzy from going round and round on the edge of the tire. So he climbs up one of the spokes toward the center of the wheel. By climbing toward the center of the wheel, the ant has changed his path of motion. The new path has less up-and-down motion and is called a **curtate cycloid** (Figure 10.2.13). As shown in the figure, we let b denote the distance along the spoke from the center of the wheel to the ant. As before, we let $t$ represent the angle the tire has rotated through. Additionally, we let $C = (x_C, y_C)$ represent the position of the center of the wheel and $A = (x_A, y_A)$ represent the position of the ant.





(c)

Figure 10.2.13*a*: The ant climbs up one of the spokes toward the center of the wheel.
Figure 10.2.13*b*: The ant's path of motion after climbing closer to the wheel's center. This is called a curtate cycloid.
Figure 10.2.13*c*: The new setup, now that the ant has moved closer to the center of the wheel.

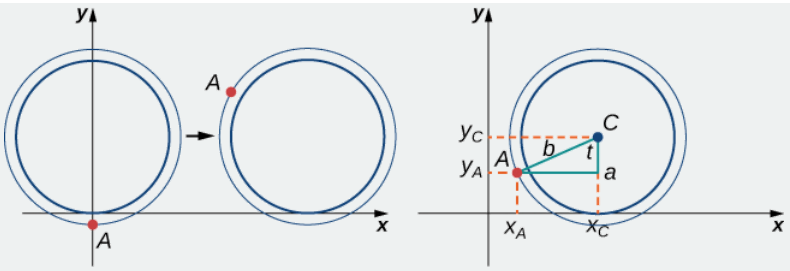
1. What is the position of the center of the wheel after the tire has rotated through an angle of $t$?
2. Use Geometry to find expressions for $x_C - x_A$ and for $y_C - y_A$.
3. Based on your answers to parts 1 and 2, what parametric equations represent the curtate cycloid?

Once the ant's head clears, he realizes that the bicyclist has made a turn and is now traveling away from his home. So he drops off the bicycle tire and looks around. Fortunately, a set of train tracks is nearby, headed back in the right direction. So the ant heads over to the train tracks to wait. After a while, a train goes by, heading in the right direction, and he manages to jump up and catch the edge of the train wheel (without getting squished!).

The ant is still worried about getting dizzy, but the train wheel is slippery and has no spokes to climb, so he decides to hang on to the edge of the wheel and hope for the best. Now, train wheels have a flange to keep the wheel running on the tracks. So, in this case, since the ant is hanging on to the very edge of the flange, the distance from the center of the wheel to the ant is greater than the radius of the wheel (Figure 10.2.14).

The setup here is essentially the same as when the ant climbed up the spoke on the bicycle wheel. We let b denote the distance from the center of the wheel to the ant, and we let t represent the angle the tire has rotated through. Additionally, we let $C = (x_C, y_C)$ represent the position of the center of the wheel and $A = (x_A, y_A)$ represent the position of the ant (Figure 10.2.14).

When the distance from the center of the wheel to the ant is greater than the wheel's radius, his path of motion is called a prolate cycloid. A graph of a **prolate cycloid** is shown in the figure.



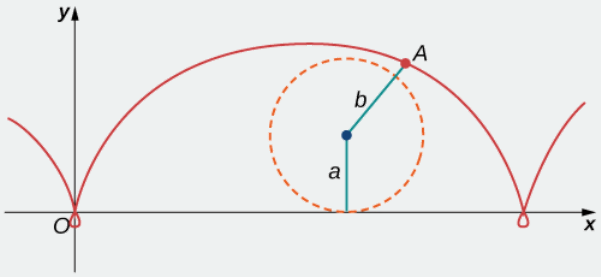


Figure **10.2.14*a***: The ant is hanging onto the flange of the train wheel.
Figure **10.2.14*b***: The new setup, now that the ant has jumped onto the train wheel.
Figure **10.2.14*c***: The ant travels along a prolate cycloid.

4. Using the same approach you used in parts 1– 3, find the parametric equations for the path of motion of the ant.
5. What do you notice about your answer to part 3 and your answer to part 4?

Notice that the ant is traveling backward at times (the "loops" in the graph), even though the train continues to move forward. He is probably going to be dizzy by the time he gets home!

## Key Concepts

- Parametric equations provide a convenient way to describe a curve. A parameter can represent time or some other meaningful quantity.
- It is often possible to eliminate the parameter in a parametrized curve to obtain a function or relation describing that curve.
- There is always more than one way to parametrize a curve.
- Parametric equations can describe complicated curves that are difficult or impossible to describe using rectangular coordinates.

## Glossary

**cycloid**
the curve traced by a point on the rim of a circular wheel as the wheel rolls along a straight line without slippage

**cusp**
a pointed end or part where two curves meet

**orientation**
the direction that a point moves on a graph as the parameter increases

**parameter**
an independent variable that both $x$ and $y$ depend on in a parametric curve; usually represented by the variable $t$

**parametric curve**

the graph of the parametric equations $x(t)$ and $y(t)$ over an interval $a \leq t \leq b$ combined with the equations

**parametric equations**

the equations $x = x(t)$ and $y = y(t)$ that define a parametric curve

**parametrization of a curve**

rewriting the equation of a curve defined by a function $y = f(x)$ as parametric equations

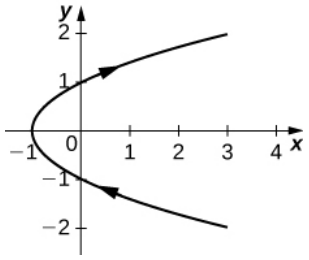
# 10.2E: EXERCISES

**In exercises 1 - 4, sketch the curves below by eliminating the parameter $t$. Give the orientation of the curve.**

1) $x = t^2 + 2t, \quad y = t + 1$

**Answer**

Orientation: bottom to top

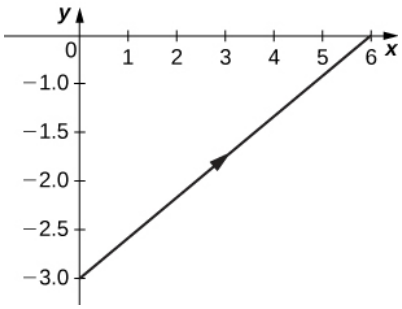


2) $x = \cos(t), \quad y = \sin(t), \quad \text{for } (0, 2\pi]$

3) $x = 2t + 4, \quad y = t - 1$

**Answer**

Orientation: left to right



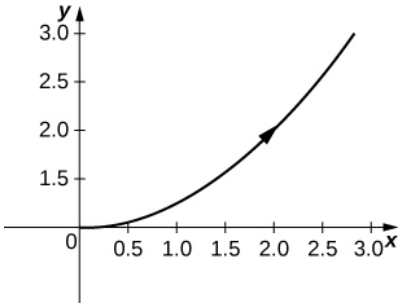
4) $x = 3 - t, \quad y = 2t - 3, \quad \text{for } 1.5 \le t \le 3$

**In exercise 5, eliminate the parameter and sketch the graph.**

5) $x = 2t^2, \quad y = t^4 + 1$

**Answer**

$y = \dfrac{x^2}{4} + 1$

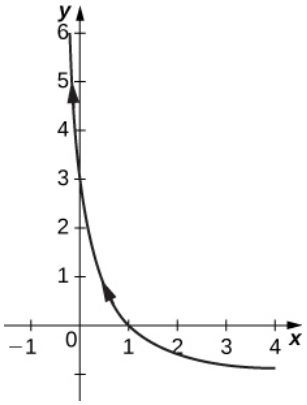


**In exercises 6 - 9, use technology (CAS or calculator) to sketch the parametric equations.**

6) [Technology Required] $x = t^2 + t, \quad y = t^2 - 1$

7) [Technology Required] $x = e^{-t}, \quad y = e^{2t} - 1$

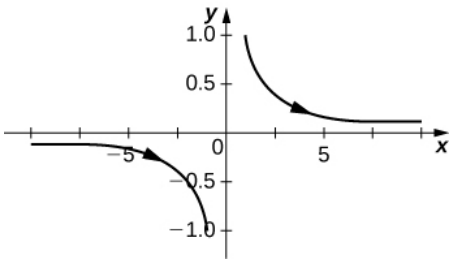
**Answer**



8) [Technology Required] $x = 3\cos t, \quad y = 4\sin t$

9) [Technology Required] $x = \sec t, \quad y = \cos t$

**Answer**

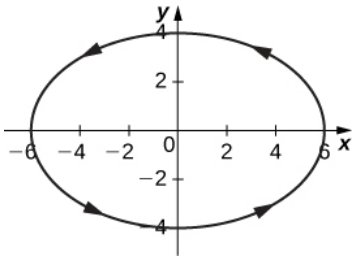


**In exercises 10 - 20, sketch the parametric equations by eliminating the parameter. Indicate any asymptotes of the graph.**

10) $x = e^t, \quad y = e^{2t} + 1$

11) $x = 6\sin(2\theta), \quad y = -4\cos(2\theta)$

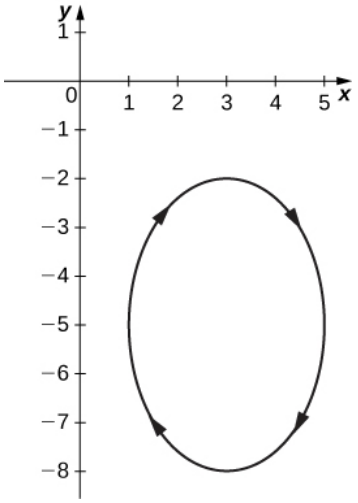
**Answer**



12) $x = \cos\theta, \quad y = 2\sin(2\theta)$

13) $x = 3 - 2\cos\theta, \quad y = -5 + 3\sin\theta$

**Answer**

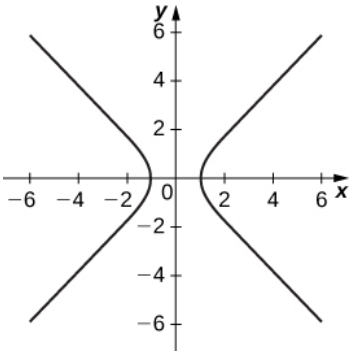


14) $x = 4 + 2\cos\theta, \quad y = -1 + \sin\theta$

15) $x = \sec t, \quad y = \tan t$

**Answer**

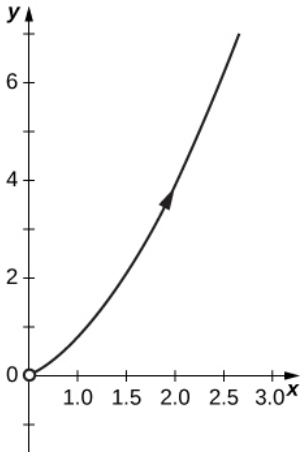
Asymptotes are $y = x$ and $y = -x$



16) $x = \ln(2t), \quad y = t^2$

17) $x = e^t, \quad y = e^{2t}$

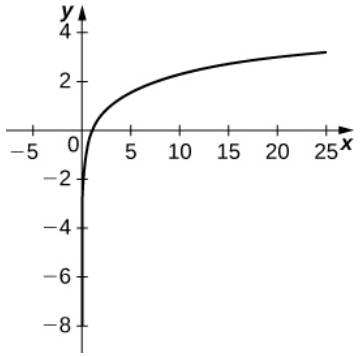
**Answer**



18) $x = e^{-2t}, \quad y = e^{3t}$

19) $x = t^3, \quad y = 3\ln t$

**Answer**



20) $x = 4\sec\theta, \quad y = 3\tan\theta$

**In exercises 21 - 38, convert the parametric equations of a curve into rectangular form. No sketch is necessary. State the domain of the rectangular form.**

21) $x = t^2 - 1, \quad y = \dfrac{t}{2}$

**Answer**

$x = 4y^2 - 1$; domain: $x \in [1, \infty)$.

22) $x = \dfrac{1}{\sqrt{t+1}}, \quad y = \dfrac{t}{1+t}, \quad \text{for } t > -1$

23) $x = 4\cos\theta, \quad y = 3\sin\theta, \quad \text{for } t \in (0, 2\pi]$

**Answer**

$\dfrac{x^2}{16} + \dfrac{y^2}{9} = 1$; domain $x \in [-4, 4]$.

24) $x = \cosh t, \quad y = \sinh t$

25) $x = 2t - 3, \quad y = 6t - 7$

**Answer**

$y = 3x + 2$; domain: all real numbers.

26) $x = t^2, \quad y = t^3$

27) $x = 1 + \cos t, \quad y = 3 - \sin t$

**Answer**

$(x-1)^2 + (y-3)^2 = 1$; domain: $x \in [0, 2]$.

28) $x = \sqrt{t}, \quad y = 2t + 4$

29) $x = \sec t, \quad y = \tan t, \quad \text{for } \pi \le t < \frac{3\pi}{2}$

**Answer**

$y = \sqrt{x^2 - 1}$; domain: $x \in (-\infty, -1]$.

30) $x = 2\cosh t, \quad y = 4\sinh t$

31) $x = \cos(2t), \quad y = \sin t$

**Answer**

$y^2 = \dfrac{1-x}{2}$; domain: $x \in [-1, 1]$.

32) $x = 4t + 3, \quad y = 16t^2 - 9$

33) $x = t^2, \quad y = 2\ln t, \quad \text{for } t \ge 1$

**Answer**

$y = \ln x$; domain: $x \in [1, \infty)$.

34) $x = t^3, \quad y = 3 \ln t, \quad \text{for } t \geq 1$

35) $x = t^n, \quad y = n \ln t, \quad \text{for } t \geq 1$, where $n$ is a natural number

**Answer**

$y = \ln x$; domain: $x \in (0, \infty)$.

36) $x = \ln(5t), \quad y = \ln(t^2)$ where $1 \leq t \leq e$

37) $x = 2 \sin(8t), \quad y = 2 \cos(8t)$

**Answer**

$x^2 + y^2 = 4$; domain: $x \in [-2, 2]$.

38) $x = \tan t, \quad y = \sec^2 t - 1$

**In exercises 39 - 48, the pairs of parametric equations represent lines, parabolas, circles, ellipses, or hyperbolas. Name the type of basic curve that each pair of equations represents.**

39) $x = 3t + 4, \quad y = 5t - 2$

**Answer**

line

40) $x - 4 = 5t, \quad y + 2 = t$

41) $x = 2t + 1, \quad y = t^2 - 3$

**Answer**

parabola

42) $x = 3 \cos t, \quad y = 3 \sin t$

43) $x = 2 \cos(3t), \quad y = 2 \sin(3t)$

**Answer**

circle

44) $x = \cosh t, \quad y = \sinh t$

45) $x = 3 \cos t, \quad y = 4 \sin t$

**Answer**

ellipse

46) $x = 2 \cos(3t), \quad y = 5 \sin(3t)$

47) $x = 3 \cosh(4t) \quad y = 4 \sinh(4t)$

**Answer**

the right branch of a horizontally opening hyperbola

48) $x = 2 \cosh t, \quad y = 2 \sinh t$

49) Show that $x = h + r \cos \theta, \quad y = k + r \sin \theta$ represents the equation of a circle.

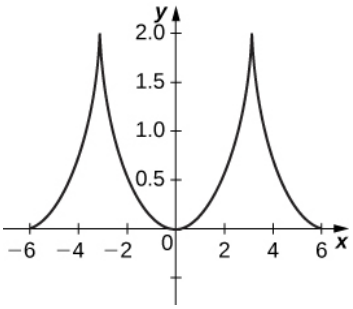
50) Use the equations in the preceding problem to find a set of parametric equations for a circle whose radius is $5$ and whose center is $(-2, 3)$.

**In exercises 51 - 53, use a graphing utility to graph the curve represented by the parametric equations and identify the curve from its equation.**

51) [Technology Required] $x = \theta + \sin \theta, \quad y = 1 - \cos \theta$

**Answer**

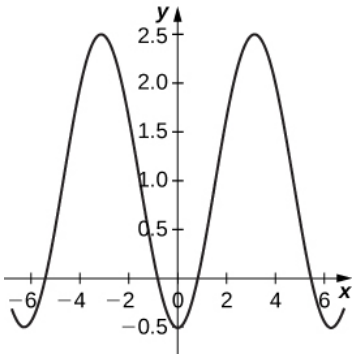
The equations represent a cycloid.



52) [Technology Required] $x = 2t - 2\sin t, \quad y = 2 - 2\cos t$

53) [Technology Required] $x = t - 0.5\sin t, \quad y = 1 - 1.5\cos t$

**Answer**



54) An airplane traveling horizontally at 100 m/s over flat ground at an elevation of 4000 meters must drop an emergency package on a target on the ground. The trajectory of the package is given by $x = 100t, \quad y = -4.9t^2 + 4000, \quad \text{where } t \geq 0$ where the origin is the point on the ground directly beneath the plane at the moment of release. How many horizontal meters before the target should the package be released in order to hit the target?

55) The trajectory of a bullet is given by $x = v_0(\cos\alpha)t, \quad y = v_0(\sin\alpha)t - \frac{1}{2}gt^2$ where $v_0 = 500$ m/s, $g = 9.8 = 9.8\ \text{m/s}^2$, and $\alpha = 30$ degrees. When will the bullet hit the ground? How far from the gun will the bullet hit the ground?

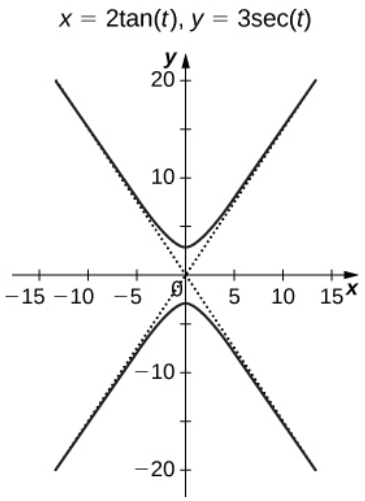
**Answer**

22,092 meters at approximately 51 seconds.

56) [Technology Required] Use technology to sketch the curve represented by $x = \sin(4t), \quad y = \sin(3t), \quad \text{for } 0 \leq t \leq 2\pi$.

57) [Technology Required] Use technology to sketch $x = 2\tan(t), \quad y = 3\sec(t), \quad \text{for } -\pi < t < \pi$.

**Answer**



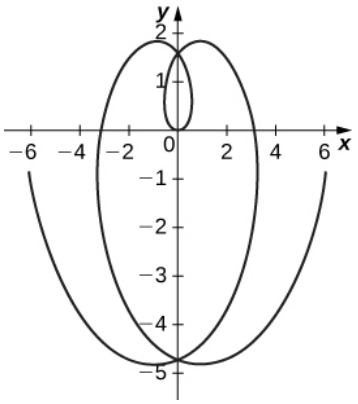
58) Sketch the curve known as an **epitrochoid**, which gives the path of a point on a circle of radius $b$ as it rolls on the outside of a circle of radius $a$. The equations are

$x = (a+b)\cos t - c \cdot \cos\left[\frac{(a+b)t}{b}\right], \quad y = (a+b)\sin t - c \cdot \sin\left[\frac{(a+b)t}{b}\right].$

Let $a = 1,\ b = 2,\ c = 1.$

59) [Technology Required] Use technology to sketch the spiral curve given by $x = t\cos(t), \quad y = t\sin(t)$ for $-2\pi \le t \le 2\pi.$

**Answer**



60) [Technology Required] Use technology to graph the curve given by the parametric equations $x = 2\cot(t), \quad y = 1 - \cos(2t), \quad \text{for } -\pi/2 \le t \le \pi/2.$ This curve is known as the witch of Agnesi.

61) [Technology Required] Sketch the curve given by parametric equations $x = \cosh(t), \quad y = \sinh(t)$, for $-2 \le t \le 2.$

# 10.3: Calculus of Parametric Curves

**Learning Objectives**

- Determine derivatives and equations of tangents for parametric curves.
- Find the area under a parametric curve.
- Use the equation for the arc length of a parametric curve.
- Apply the formula for surface area to a volume generated by a parametric curve.

Now that we have introduced the concept of a parametrized curve, our next step is to learn how to work with this concept in the context of Calculus. For example, if we know a parametrization of a given curve, is it possible to calculate the slope of a tangent line to the curve? How about the arc length of the curve? Or the area under the curve?

Another scenario: Suppose we would like to represent the location of a baseball after the ball leaves a pitcher's hand. If the position of the baseball is represented by the plane curve $(x(t), y(t))$, then we should be able to use Calculus to find the speed of the ball at any given time. Furthermore, we should be able to calculate how far that ball has traveled as a function of time.

## Derivatives of Parametric Equations

We start by asking how to calculate the slope of a line tangent to a parametric curve at a point. Consider the plane curve defined by the parametric equations

$$x(t) = 2t + 3 \tag{10.3.1}$$

$$y(t) = 3t - 4 \tag{10.3.2}$$

within $-2 \leq t \leq 3$.

The graph of this curve appears in Figure 10.3.1. It is a line segment starting at $(-1, -10)$ and ending at $(9, 5)$.

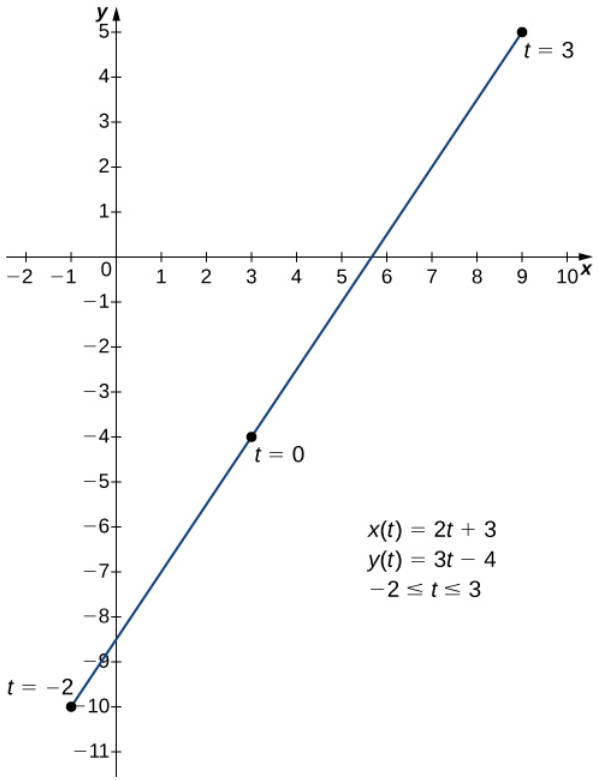

Figure 10.3.1: Graph of the line segment described by the given parametric equations.

We can eliminate the parameter by first solving Equation 10.3.1 for $t$:

$$\begin{aligned} x(t) &= 2t+3 \\ \Rightarrow \quad x-3 &= 2t \\ \Rightarrow \quad t &= \frac{x-3}{2}. \end{aligned}$$

Substituting this into $y(t)$ (Equation 10.3.2), we obtain

$$\begin{aligned} y(t) &= 3t-4 \\ \Rightarrow \quad y &= 3\left(\frac{x-3}{2}\right)-4 \\ \Rightarrow \quad y &= \frac{3x}{2}-\frac{9}{2}-4 \\ \Rightarrow \quad y &= \frac{3x}{2}-\frac{17}{2}. \end{aligned}$$

The slope of this line is given by $\frac{dy}{dx}=\frac{3}{2}$. Next we calculate $x'(t)$ and $y'(t)$. This gives $x'(t)=2$ and $y'(t)=3$. Notice that

$$\frac{dy}{dx}=\frac{dy/dt}{dx/dt}=\frac{3}{2}.$$

This is no coincidence, as outlined in the following theorem.

**Theorem: Derivative of Parametric Equations**

Consider the plane curve defined by the parametric equations $x=x(t)$ and $y=y(t)$. Suppose that $x'(t)$ and $y'(t)$ exist, and assume that $x'(t)\neq 0$. Then the derivative $\frac{dy}{dx}$ is given by

$$\frac{dy}{dx}=\frac{dy/dt}{dx/dt}=\frac{y'(t)}{x'(t)}. \tag{10.3.3}$$

**Proof**

This theorem can be proven using the Chain Rule. In particular, assume that the parameter $t$ can be eliminated, yielding a differentiable function $y=F(x)$. Then $y(t)=F(x(t))$. Differentiating both sides of this equation using the Chain Rule yields

$$y'(t)=F'(x(t))\,x'(t),$$

so

$$F'(x(t))=\frac{y'(t)}{x'(t)}.$$

But $F'(x(t))=\frac{dy}{dx}$, which proves the theorem.

Equation 10.3.3 can be used to calculate derivatives of plane curves, as well as critical points. Recall that a critical point of a differentiable function $y=f(x)$ is any point $x=x_0$ such that either $f'(x_0)=0$ or $f'(x_0)$ does not exist. Equation 10.3.3 gives a formula for the slope of a tangent line to a curve defined parametrically regardless of whether the curve can be described by a function $y=f(x)$ or not.

**Example 10.3.1: Finding the Derivative of a Parametric Curve**

Calculate the derivative $\frac{dy}{dx}$ for each of the following parametrically-defined plane curves, and locate any critical points on their respective graphs.

a. $x(t)=t^2-3, \quad y(t)=2t-1, \quad \text{for } -3\leq t\leq 4$
b. $x(t)=2t+1, \quad y(t)=t^3-3t+4, \quad \text{for } -2\leq t\leq 2$
c. $x(t)=5\cos t, \quad y(t)=5\sin t, \quad \text{for } 0\leq t\leq 2\pi$

**Solutions**

a. To apply Equation 10.3.3, first calculate $x'(t)$ and $y'(t)$:

$$\begin{aligned} x'(t) &= 2t \\ y'(t) &= 2. \end{aligned}$$

Next substitute these into the equation:

$$\begin{aligned} \frac{dy}{dx} &= \frac{dy/dt}{dx/dt} \\ \Rightarrow \quad \frac{dy}{dx} &= \frac{2}{2t} \\ \Rightarrow \quad \frac{dy}{dx} &= \frac{1}{t}. \end{aligned}$$

This derivative is undefined when $t = 0$. Calculating $x(0)$ and $y(0)$ gives $x(0) = (0)^2 - 3 = -3$ and $y(0) = 2(0) - 1 = -1$, which corresponds to the point $(-3, -1)$ on the graph. The graph of this curve is a parabola opening to the right, and the point $(-3, -1)$ is its vertex, as shown.

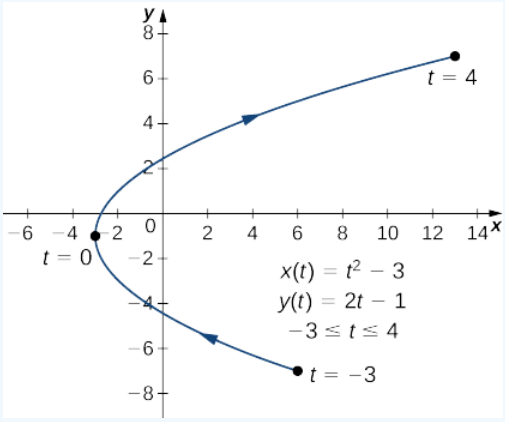

Figure 10.3.2: Graph of the parabola described by parametric equations in part a.

b. To apply Equation 10.3.3, first calculate $x'(t)$ and $y'(t)$:

$$\begin{aligned} x'(t) &= 2 \\ y'(t) &= 3t^2 - 3. \end{aligned}$$

Next substitute these into the equation:

$$\begin{aligned} \frac{dy}{dx} &= \frac{dy/dt}{dx/dt} \\ \frac{dy}{dx} &= \frac{3t^2 - 3}{2}. \end{aligned}$$

This derivative is zero when $t = \pm 1$. When $t = -1$ we have

$$x(-1) = 2(-1) + 1 = -1 \text{ and } y(-1) = (-1)^3 - 3(-1) + 4 = -1 + 3 + 4 = 6,$$

which corresponds to the point $(-1, 6)$ on the graph. When $t = 1$ we have

$$x(1) = 2(1) + 1 = 3 \text{ and } y(1) = (1)^3 - 3(1) + 4 = 1 - 3 + 4 = 2,$$

which corresponds to the point $(3, 2)$ on the graph. The point $(3, 2)$ is a relative minimum, and the point $(-1, 6)$ is a relative maximum, as seen in the following graph.

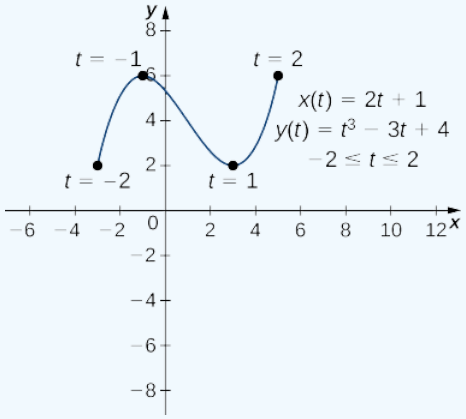

Figure 10.3.3: Graph of the curve described by parametric equations in part b.

c. To apply Equation 10.3.3, first calculate $x'(t)$ and $y'(t)$:

$$\begin{aligned} x'(t) &= -5\sin t \\ y'(t) &= 5\cos t. \end{aligned}$$

Next substitute these into the equation:

$$\begin{aligned} \frac{dy}{dx} &= \frac{dy/dt}{dx/dt} \\ \Rightarrow \quad \frac{dy}{dx} &= \frac{5\cos t}{-5\sin t} \\ \Rightarrow \quad \frac{dy}{dx} &= -\cot t. \end{aligned}$$

This derivative is zero when $\cos t = 0$ and is undefined when $\sin t = 0$. This gives $t = 0, \frac{\pi}{2}, \pi, \frac{3\pi}{2}$, and $2\pi$ as critical points for $t$. Substituting each of these into $x(t)$ and $y(t)$, we obtain

| $t$ | $x(t)$ | $y(t)$ |
|---|---|---|
| 0 | 5 | 0 |
| $\frac{\pi}{2}$ | 0 | 5 |
| $\pi$ | −5 | 0 |
| $\frac{3\pi}{2}$ | 0 | −5 |
| $2\pi$ | 5 | 0 |

These points correspond to the sides, top, and bottom of the circle that is represented by the parametric equations (Figure 10.3.4). The derivative is undefined on the left and right edges of the circle. On the top and bottom, the derivative equals zero.

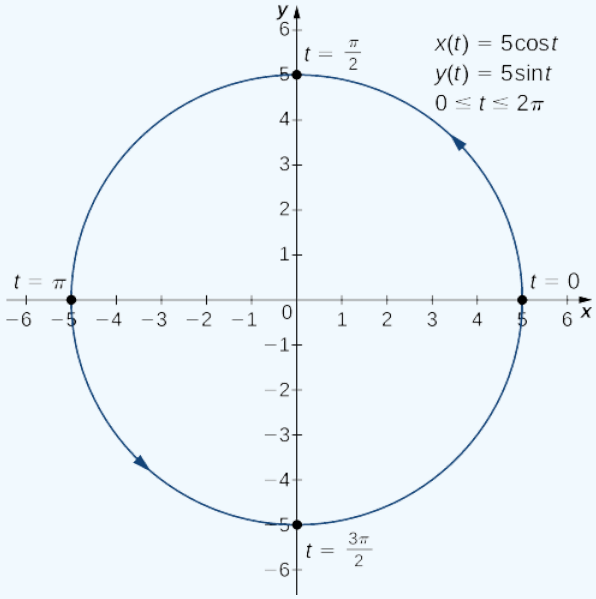

Figure 10.3.4: Graph of the curve described by parametric equations in part c.

## Checkpoint 10.3.1

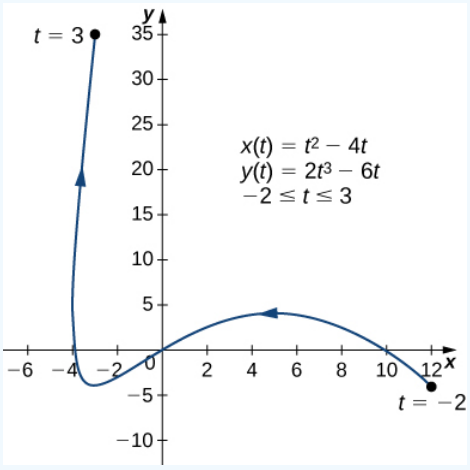
Calculate the derivative $dy/dx$ for the plane curve defined by the equations

$$x(t) = t^2 - 4t, \quad y(t) = 2t^3 - 6t, \quad \text{for } -2 \le t \le 3$$

and locate any critical points on its graph.

**Answer**

$x'(t) = 2t - 4$ and $y'(t) = 6t^2 - 6$, so $\frac{dy}{dx} = \frac{6t^2-6}{2t-4} = \frac{3t^2-3}{t-2}$. This expression is undefined when $t = 2$ and equal to zero when $t = \pm 1$.



## Example 10.3.2: Finding a Tangent Line

Find the equation of the tangent line to the curve defined by the equations

$$x(t) = t^2 - 3, \quad y(t) = 2t - 1, \quad \text{for } -3 \le t \le 4$$

when $t = 2$.

https://math.libretexts.org/@go/page/175633

**Solution**

First find the slope of the tangent line using Equation 10.3.3, which means calculating $x'(t)$ and $y'(t)$:

$$\begin{aligned} x'(t) &= 2t \\ y'(t) &= 2. \end{aligned}$$

Next substitute these into the equation:

$$\begin{aligned} \frac{dy}{dx} &= \frac{dy/dt}{dx/dt} \\ \Rightarrow \quad \frac{dy}{dx} &= \frac{2}{2t} \\ \Rightarrow \quad \frac{dy}{dx} &= \frac{1}{t}. \end{aligned}$$

When $t = 2$, $\frac{dy}{dx} = \frac{1}{2}$, so this is the slope of the tangent line. Calculating $x(2)$ and $y(2)$ gives

$$x(2) = (2)^2 - 3 = 1 \text{ and } y(2) = 2(2) - 1 = 3,$$

which corresponds to the point $(1, 3)$ on the graph (Figure 10.3.5). Now use the point-slope form of the equation of a line to find the equation of the tangent line:

$$\begin{aligned} y - y_0 &= m(x - x_0) \\ \Rightarrow \quad y - 3 &= \frac{1}{2}(x - 1) \\ \Rightarrow \quad y - 3 &= \frac{1}{2}x - \frac{1}{2} \\ \Rightarrow \quad y &= \frac{1}{2}x + \frac{5}{2}. \end{aligned}$$

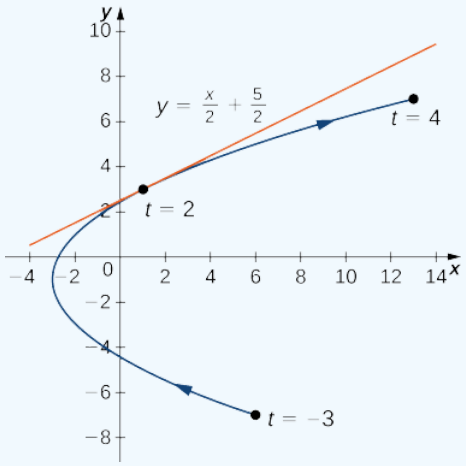


Figure 10.3.5: Tangent line to the parabola described by the given parametric equations when $t = 2$.

**? Checkpoint 10.3.2**

Find the equation of the tangent line to the curve defined by the equations

$$x(t) = t^2 - 4t, \quad y(t) = 2t^3 - 6t, \quad \text{for } -2 \le t \le 6$$

when $t = 5$.

**Answer**

The equation of the tangent line is $y = 24x + 100$.

## Second-Order Derivatives

Our next goal is to see how to take the second derivative of a function defined parametrically. The second derivative of a function $y = f(x)$ is defined to be the derivative of the first derivative; that is,

$$\frac{d^2y}{dx^2} = \frac{d}{dx}\left[\frac{dy}{dx}\right]. \tag{10.3.4}$$

Since

$$\frac{dy}{dx} = \frac{dy/dt}{dx/dt},$$

we can replace the $y$ on both sides of Equation 10.3.4 with $\frac{dy}{dx}$. This gives us

$$\frac{d^2y}{dx^2} = \frac{d}{dx}\left(\frac{dy}{dx}\right) = \frac{(d/dt)(dy/dx)}{dx/dt}. \tag{10.3.5}$$

If we know $dy/dx$ as a function of $t$, then this formula is straightforward to apply

**Example 10.3.3: Finding a Second Derivative**

Calculate the second derivative $d^2y/dx^2$ for the plane curve defined by the parametric equations $x(t) = t^2 - 3, \quad y(t) = 2t - 1,$ for $-3 \le t \le 4$.

**Solution**

From Example 10.3.1 we know that $\frac{dy}{dx} = \frac{2}{2t} = \frac{1}{t}$. Using Equation 10.3.5, we obtain

$$\frac{d^2y}{dx^2} = \frac{(d/dt)(dy/dx)}{dx/dt} = \frac{(d/dt)(1/t)}{2t} = \frac{-t^{-2}}{2t} = -\frac{1}{2t^3}.$$

**Checkpoint 10.3.3**

Calculate the second derivative $d^2y/dx^2$ for the plane curve defined by the equations

$$x(t) = t^2 - 4t, \quad y(t) = 2t^3 - 6t, \quad \text{for } -2 \le t \le 3$$

and locate any critical points on its graph.

**Answer**

$\frac{d^2y}{dx^2} = \frac{3t^2-12t+3}{2(t-2)^3}$. Critical points $(5, 4)$, $(-3, -4)$,and $(-4, 6)$.

## Integrals Involving Parametric Equations

Now that we have seen how to calculate the derivative of a plane curve, we naturally ask ourselves how to find the area under a curve defined parametrically. Recall the cycloid defined by these parametric equations

$$\begin{aligned} x(t) &= t - \sin t \\ y(t) &= 1 - \cos t. \end{aligned} \tag{10.3.6}$$

Suppose we want to find the area of the shaded region in the following graph.

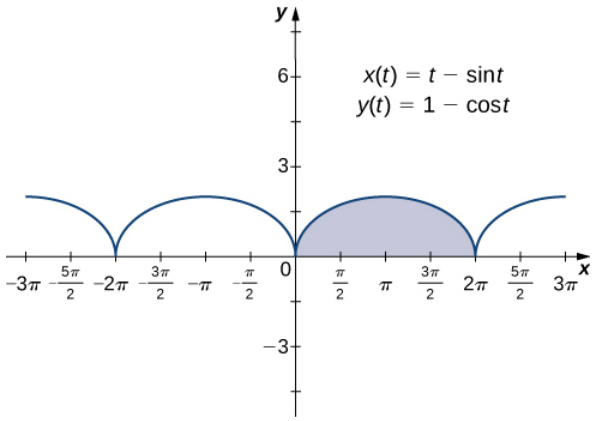

Figure **10.3.6**: Graph of a cycloid with the arch over $[0, 2\pi]$ highlighted.

To derive a formula for the area under the curve defined by the functions

$$\begin{aligned} x &= x(t) \\ y &= y(t) \end{aligned} \tag{10.3.7}$$

where $a \le t \le b$, we assume that $x(t)$ is differentiable and start with an equal partition of the interval $a \le t \le b$. Suppose $t_0 = a < t_1 < t_2 < \cdots < t_n = b$ and consider the following graph.

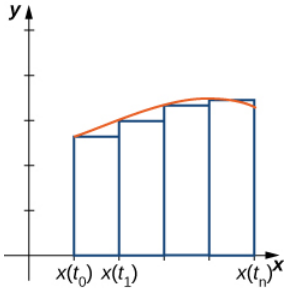

Figure **10.3.7**: Approximating the area under a parametrically defined curve.

We use rectangles to approximate the area under the curve. The height of a typical rectangle in this parametrization is $y(x(\bar{t}_i))$ for some value $\bar{t}_i$ in the $i^{\text{th}}$ subinterval, and the width can be calculated as $x(t_i) - x(t_{i-1})$. Thus the area of the $i^{\text{th}}$ rectangle is given by

$$A_i = y(x(\bar{t}_i))(x(t_i) - x(t_{i-1})).$$

Then a Riemann sum for the area is

$$A_n = \sum_{i=1}^{n} y(x(\bar{t}_i))(x(t_i) - x(t_{i-1})).$$

Multiplying and dividing each area by $t_i - t_{i-1}$ gives

$$\begin{aligned} A_n &= \sum_{i=1}^{n} y(x(\bar{t}_i)) \left( \frac{x(t_i) - x(t_{i-1})}{t_i - t_{i-1}} \right) (t_i - t_{i-1}) \\ &= \sum_{i=1}^{n} y(x(\bar{t}_i)) \left( \frac{x(t_i) - x(t_{i-1})}{\Delta t} \right) \Delta t. \end{aligned}$$

Taking the limit as $n$ approaches infinity gives

$$A = \lim_{n \to \infty} A_n = \int_a^b y(t) x'(t)\, dt.$$

This leads to the following theorem.

**Theorem: Area under a Parametric Curve**

Consider the non-self-intersecting plane curve defined by the parametric equations

$$x = x(t), \quad y = y(t), \quad \text{for } a \le x \le b$$

and assume that $x(t)$ is differentiable. The area under this curve is given by

$$A = \int_{t_a}^{t_b} y(t)x'(t)\,dt, \tag{10.3.8}$$

where $t_a$ is the time-value associated with $x = a$ and $t_b$ is the time-value associated with $x = b$.

If $x(t)$ is invertible, then $t_a = x^{-1}(a)$ and $t_b = x^{-1}(b)$.

As with our previous work, we require $\Delta x$ from our partition of the interval $[a, b]$ to be positive. That is, when building the approximating rectangles from the Riemann sums, we get $x_0 = a$, $x_1 = a + i\Delta x$, ..., $x_n = b$. These values imply the computed width of each rectangle is positive. This creates a need to be careful when computing areas under parametric curves. It is often the case that $a$ is *not* associated with the smallest value of $t$ and $b$ is *not* associated with the largest value of $t$. Therefore, it is best to *initially* think of the area integral for parametric curves as going from $x = a$ to $x = b$.

For example, when finding the area under the parametric curve defined by

$$x(t) = e^{-t}, \quad y(t) = t^2 + 3t + 4,$$

where $0 \le t \le 1$, we start by thinking in terms of how we normally find areas under curves:

$$A = \int f(x)\,dx.$$

Of course, this is an indefinite integral, but it is a placeholder for our thought-process. We know that $f(x)$ is a representation of the $y$-values for the curve and, in this case, $y(t) = t^2 + 3t + 4$. Moreover, $dx = x'(t)\,dt = -e^{-t}\,dt$. Thus, our "placeholder" integral becomes

$$A = \int f(x)\,dx = \int y(t)x'(t)\,dt = \int (t^2 + 3t + 4)(-e^{-t})\,dt = -\int (t^2 + 3t + 4)e^{-t}\,dt.$$

The only thing we have left to consider are the limits of integration.

Assuming the lower limit is $t = 0$ and the upper is $t = 1$ would be incorrect. Why? Since $x(0) = 1 > e^{-1} = x(1)$, our geometric derivation of the Riemann sum (from Calculus I) tells us that the lower limit is the time value corresponding to $x = e^{-1}$ and the upper limit is the time value corresponding to $x = 1$. Thus, the true integral representing the area under the curve from $t = 0$ to $t = 1$ is

$$-\int_{t=1}^{t=0} (t^2 + 3t + 4)e^{-t}\,dt.$$

The following Cautionary statement summarizes our concerns.

**Caution: Areas Are Computed from $x_{\text{low}}$ to $x_{\text{high}}$**

When computing the area under a curve (parametric or not), we integrate from $x = a$ to $x = b$, where $a \le x \le b$. Any other method will result in an incorrect area.

**Example 10.3.4: Finding the Area under a Parametric Curve**

Find the area under the curve of the cycloid defined by the equations

$$x(t) = t - \sin t, \quad y(t) = 1 - \cos t, \quad \text{for } 0 \le t \le 2\pi.$$

**Solution**

We start by making sure we are integrating in the proper direction.

$$x(0) = 0 \quad \text{and} \quad x(2\pi) = 2\pi.$$

This seems convincing that our time-values are "flowing" from a lower $x$-value to a higher one, but just to be sure the parametric curve doesn't "double-back" on itself, let's compute $x'(t)$ to see if it is always increasing (we have to compute $x'$ in any case, so why not get it out of the way right now?).

$$x'(t) = 1 - \cos t,$$

which is non-negative for all $t$. Thus, our $x$-values are *never* decreasing with respect to $t$. Using Equation 10.3.8, we have

$$\begin{aligned} A &= \int_{t_a}^{t_b} y(t)x'(t)\,dt \\ &= \int_0^{2\pi} (1-\cos t)(1-\cos t)\,dt \\ &= \int_0^{2\pi} (1 - 2\cos t + \cos^2 t)\,dt \\ &= \int_0^{2\pi} \left(1 - 2\cos t + \frac{1+\cos(2t)}{2}\right) dt \\ &= \int_0^{2\pi} \left(\frac{3}{2} - 2\cos t + \frac{\cos(2t)}{2}\right) dt \\ &= \frac{3t}{2} - 2\sin t + \frac{\sin(2t)}{4}\Big|_0^{2\pi} \\ &= 3\pi \end{aligned}$$

**? Checkpoint 10.3.4**

Find the area under the curve of the hypocycloid defined by the equations

$$x(t) = 3\cos t + \cos(3t), \quad y(t) = 3\sin t - \sin(3t), \quad \text{for } 0 \le t \le \pi.$$

**Answer**

$A = 3\pi$ (Note that this is one of those cases where the limits of integration go from high time-value to low. This is because $x(t)$ is a decreasing function over the interval $[0, \pi]$; that is, the curve is traced from right to left.)

## Arc Length of a Parametric Curve

Besides finding the area under a parametric curve, we sometimes need to find the arc length of a parametric curve. In the case of a line segment, the arc length is the same as the distance between the endpoints. If a particle travels from point $A$ to point $B$ along a curve, then the distance that particle travels is the arc length. To develop a formula for arc length, we start with an approximation by line segments, as shown in the following graph.

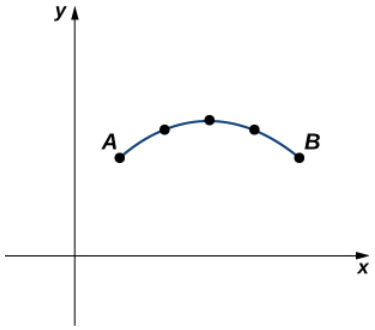

Figure 10.3.7: Approximation of a curve by line segments.

Given a plane curve defined by the functions $x = x(t)$, $y = y(t)$, for $a \le t \le b$, we start by partitioning the interval $[a, b]$ into $n$ equal subintervals: $t_0 = a < t_1 < t_2 < \cdots < t_n = b$. The width of each subinterval is given by $\Delta t = (b-a)/n$. We can calculate the length of each line segment:

$$\begin{aligned} d_1 &= \sqrt{(x(t_1) - x(t_0))^2 + (y(t_1) - y(t_0))^2} \\ d_2 &= \sqrt{(x(t_2) - x(t_1))^2 + (y(t_2) - y(t_1))^2} \\ &\vdots \quad \vdots \quad \vdots \end{aligned}$$

Then add these up. We let $s$ denote the exact arc length and $s_n$ denote the approximation by $n$ line segments:

$$s \approx \sum_{k=1}^{n} s_k = \sum_{k=1}^{n} \sqrt{(x(t_k) - x(t_{k-1}))^2 + (y(t_k) - y(t_{k-1}))^2}. \tag{10.3.9}$$

If we assume that $x(t)$ and $y(t)$ are differentiable functions of $t$, then the Mean Value Theorem applies, so in each subinterval $[t_{k-1}, t_k]$ there exist $\hat{t_k}$ and $\tilde{t_k}$ such that

$$\begin{aligned} x(t_k) - x(t_{k-1}) &= x'(\hat{t_k})(t_k - t_{k-1}) = x'(\hat{t_k})\,\Delta t \\ y(t_k) - y(t_{k-1}) &= y'(\tilde{t_k})(t_k - t_{k-1}) = y'(\tilde{t_k})\,\Delta t. \end{aligned}$$

Therefore Equation 10.3.9 becomes

$$\begin{aligned} s &\approx \sum_{k=1}^{n} s_k \\ &= \sum_{k=1}^{n} \sqrt{(x'(\hat{t_k})\Delta t)^2 + (y'(\tilde{t_k})\Delta t)^2} \\ &= \sum_{k=1}^{n} \sqrt{(x'(\hat{t_k}))^2(\Delta t)^2 + (y'(\tilde{t_k}))^2(\Delta t)^2} \\ &= \sum_{k=1}^{n} \sqrt{(x'(\hat{t_k}))^2 + (y'(\tilde{t_k}))^2}\Delta t. \end{aligned}$$

This is a Riemann sum that approximates the arc length over a partition of the interval $[a, b]$. If we further assume that the derivatives are continuous and let the number of points in the partition increase without bound, the approximation approaches the exact arc length. This gives

$$\begin{aligned} s &= \lim_{n\to\infty} \sum_{k=1}^{n} s_k \\ &= \lim_{n\to\infty} \sum_{k=1}^{n} \sqrt{(x'(\hat{t_k}))^2 + (y'(\tilde{t_k}))^2}\Delta t \\ &= \int_a^b \sqrt{(x'(t))^2 + (y'(t))^2}\, dt. \end{aligned}$$

When taking the limit, the values of $\hat{t_k}$ and $\tilde{t_k}$ are both contained within the same ever-shrinking interval of width $\Delta t$, so they must converge to the same value.

We can summarize this method in the following theorem.

**Theorem: Arc Length of a Parametric Curve**

Consider the plane curve defined by the parametric equations

$$x = x(t), \quad y = y(t), \quad \text{for } t_1 \le t \le t_2$$

and assume that $x(t)$ and $y(t)$ are differentiable functions of $t$. Then the arc length of this curve is given by

$$s = \int_{t_1}^{t_2} \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2}\, dt. \tag{10.3.10}$$

Since the arc length formula involves a square root (which is always non-negative), the value of $dt$ must also be non-negative for the length of an arc to be non-negative. Hence, our integrals for arc length will *always* go from a lower value of $t$ to a higher value of $t$. This is summarized in the following Note.

**Note: Arc Lengths Are Computed from $t_{\text{low}}$ to $t_{\text{high}}$**

Unlike areas under parametric curves, arc lengths of parametric curves are strictly computed from the lowest time value to the highest.

At this point, a side derivation leads to a previous formula for arc length. In particular, suppose the parameter can be eliminated, leading to a function $y = F(x)$. Then $y(t) = F(x(t))$ and the Chain Rule gives

$$y'(t) = F'\left(x(t)\right) x'(t).$$

Substituting this into Equation 10.3.10 gives

$$\begin{aligned} s &= \int_{t_1}^{t_2} \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(F'(x)\frac{dx}{dt}\right)^2}\, dt \\ &= \int_{t_1}^{t_2} \sqrt{\left(\frac{dx}{dt}\right)^2 \left(1 + \left(F'(x)\right)^2\right)}\, dt \\ &= \int_{t_1}^{t_2} x'(t)\sqrt{1 + \left(\frac{dy}{dx}\right)^2}\, dt. \end{aligned}$$

Here we have assumed that $x'(t) > 0$, which is a reasonable assumption. The Chain Rule gives $dx = x'(t)\, dt$, and letting $a = x(t_1)$ and $b = x(t_2)$ we obtain the formula

$$s = \int_a^b \sqrt{1 + \left(\frac{dy}{dx}\right)^2}\, dx,$$

which is the formula for arc length obtained in the Introduction to the Applications of Integration.

**Example 10.3.5: Finding the Arc Length of a Parametric Curve**

Find the arc length of the semicircle defined by the equations

$$x(t) = 3\cos t, \quad y(t) = 3\sin t, \quad \text{for } 0 \le t \le \pi.$$

**Solution**

The values $t = 0$ to $t = \pi$ trace out the blue curve in Figure 10.3.8. To determine its length, use Equation 10.3.10:

$$\begin{aligned} s &= \int_{t_1}^{t_2} \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2}\, dt \\ &= \int_0^{\pi} \sqrt{(-3\sin t)^2 + (3\cos t)^2}\, dt \\ &= \int_0^{\pi} \sqrt{9\sin^2 t + 9\cos^2 t}\, dt \\ &= \int_0^{\pi} \sqrt{9(\sin^2 t + \cos^2 t)}\, dt \\ &= \int_0^{\pi} 3\, dt \\ &= 3t\Big|_0^{\pi} \\ &= 3\pi \text{ units.} \end{aligned}$$

Note that the formula for the arc length of a semicircle is $\pi r$, and the radius of this circle is $3$. This is a great example of using Calculus to derive a known formula for a geometric quantity.

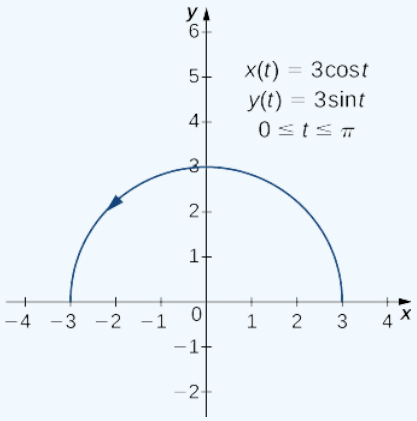

Figure 10.3.8: The arc length of the semicircle is equal to its radius times $\pi$.

**? Checkpoint 10.3.5**

Find the arc length of the curve defined by the equations

$$x(t) = 3t^2, \quad y(t) = 2t^3, \quad \text{for } 1 \le t \le 3.$$

**Answer**

$s = 2(10^{3/2} - 2^{3/2}) \approx 57.589$ units

We now return to the problem at the beginning of the section about a baseball leaving a pitcher's hand. Ignoring the effect of air resistance (unless it is a curve ball!), the ball travels a parabolic path. Assuming the pitcher's hand is at the origin, and the ball travels left to right in the direction of the positive $x$-axis, the parametric equations for this curve can be written as

$$x(t) = 140t, \quad y(t) = -16t^2 + 2t$$

where $t$ represents time. We first calculate the distance the ball travels as a function of time. The arc length represents this distance. We can modify the arc length formula slightly. First, rewrite the functions $x(t)$ and $y(t)$ using $v$ as an independent variable to eliminate any confusion with the parameter $t$:

$$x(v) = 140v, \quad y(v) = -16v^2 + 2v.$$

Then we write the arc length formula as follows:

$$\begin{aligned} s(t) &= \int_0^t \sqrt{(\frac{dx}{dv})^2 + (\frac{dy}{dv})^2}\, dv \\ &= \int_0^t \sqrt{140^2 + (-32v+2)^2}\, dv \end{aligned}$$

The variable $v$ acts as a dummy variable that disappears after integration, leaving the arc length as a function of time $t$. Using our previous integration techniques,

$$\int \sqrt{a^2+u^2}\, du = \frac{u}{2}\sqrt{a^2+u^2} + \frac{a^2}{2}\ln|u+\sqrt{a^2+u^2}| + C.$$

We set $a = 140$ and $u = -32v+2$. This gives $du = -32\, dv$, so $dv = -\frac{1}{32}\, du$. Therefore,

$$\begin{aligned} \int \sqrt{140^2 + (-32v+2)^2}\, dv &= -\frac{1}{32}\int \sqrt{a^2+u^2}\, du \\ &= -\frac{1}{32}\left[\frac{(-32v+2)}{2}\sqrt{140^2+(-32v+2)^2}\right. \\ &\quad \left. + \frac{140^2}{2}\ln|(-32v+2)+\sqrt{140^2+(-32v+2)^2}| + C\right] \end{aligned}$$

and

$$\begin{aligned} s(t) &= -\frac{1}{32}\left[\frac{(-32t+2)}{2}\sqrt{140^2+(-32t+2)^2} + \frac{140^2}{2}\ln\left|(-32t+2)+\sqrt{140^2+(-32t+2)^2}\right|\right] \\ &\quad + \frac{1}{32}\left[\sqrt{140^2+2^2} + \frac{140^2}{2}\ln\left|2+\sqrt{140^2+2^2}\right|\right] \\ &= \left(\frac{t}{2}-\frac{1}{32}\right)\sqrt{1024t^2-128t+19604} - \frac{1225}{4}\ln\left|(-32t+2)+\sqrt{1024t^2-128t+19604}\right| \\ &\quad + \frac{\sqrt{19604}}{32} + \frac{1225}{4}\ln(2+\sqrt{19604}). \end{aligned}$$

This function represents the distance traveled by the ball as a function of time. To calculate the speed, take the derivative of this function with respect to $t$. While this may seem like a daunting task, it is possible to obtain the answer directly from the Fundamental Theorem of Calculus:

$$\frac{d}{dx}\int_a^x f(u)\, du = f(x).$$

Therefore

$$\begin{aligned} s'(t) &= \frac{d}{dt}\left[s(t)\right] \\ &= \frac{d}{dt}\left[\int_0^t \sqrt{140^2+(-32v+2)^2}\, dv\right] \\ &= \sqrt{140^2+(-32t+2)^2} \\ &= \sqrt{1024t^2-128t+19604} \\ &= 2\sqrt{256t^2-32t+4901}. \end{aligned}$$

One-third of a second after the ball leaves the pitcher's hand, the distance it travels is equal to

$$
\begin{aligned}
s\left(\frac{1}{3}\right) &= \left(\frac{1/3}{2}-\frac{1}{32}\right)\sqrt{1024\left(\frac{1}{3}\right)^2-128\left(\frac{1}{3}\right)+19604} \\
&\quad -\frac{1225}{4}\ln\left|\left(-32\left(\frac{1}{3}\right)+2\right)+\sqrt{1024\left(\frac{1}{3}\right)^2-128\left(\frac{1}{3}\right)+19604}\right| \\
&\quad +\frac{\sqrt{19604}}{32}+\frac{1225}{4}\ln(2+\sqrt{19604}) \\
&\approx 46.69 \text{ feet.}
\end{aligned}
$$

This value is just over three-quarters of the way to home plate. The speed of the ball is

$$s'\left(\frac{1}{3}\right)=2\sqrt{256\left(\frac{1}{3}\right)^2-32\left(\frac{1}{3}\right)+4901}\approx 140.27 \text{ ft/s.}$$

This speed translates to approximately 95 mph—a major-league fastball.

## Surface Area Generated by a Parametric Curve

Recall the problem of finding the surface area of a volume of revolution. Earlier in the text, we derived a formula for finding the surface area of a volume generated by a function $y=f(x)$ from $x=a$ to $x=b$, revolved around the $x$-axis:

$$S=2\pi\int_a^b f(x)\sqrt{1+(f'(x))^2}\,dx.$$

We now consider a volume of revolution generated by revolving a parametrically defined curve $x=x(t)$, $y=y(t)$, for $a\le t\le b$ around the $x$-axis as shown in Figure 10.3.9.

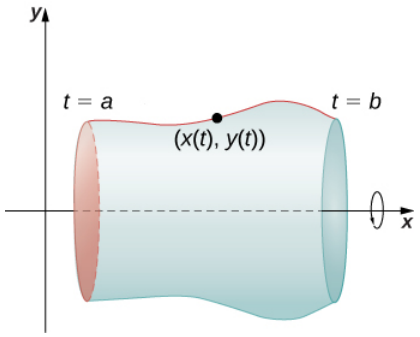

Figure 10.3.9: A surface of revolution generated by a parametrically defined curve.

The analogous formula for a parametrically defined curve is

$$S=2\pi\int_a^b y(t)\sqrt{(x'(t))^2+(y'(t))^2}\,dt \tag{10.3.11}$$

provided that $y(t)$ is not negative on $[a,b]$.

### Example 10.3.6: Finding Surface Area

Find the surface area of a sphere of radius $r$ centered at the origin.

**Solution**

We start with the curve defined by the equations

$$x(t)=r\cos t,\quad y(t)=r\sin t,\quad \text{for } 0\le t\le\pi.$$

This generates an upper semicircle of radius $r$ centered at the origin, as shown in the following graph.

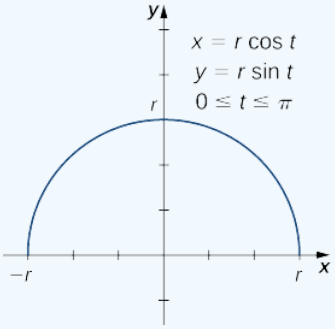

Figure 10.3.10: A semicircle generated by parametric equations.

When this curve is revolved around the $x$-axis, it generates a sphere of radius $r$. To calculate the surface area of the sphere, we use Equation 10.3.11:

$$\begin{aligned} S &= 2\pi \int_a^b y(t)\sqrt{(x'(t))^2 + (y'(t))^2}\, dt \\ &= 2\pi \int_0^\pi r\sin t\sqrt{(-r\sin t)^2 + (r\cos t)^2}\, dt \\ &= 2\pi \int_0^\pi r\sin t\sqrt{r^2\sin^2 t + r^2\cos^2 t}\, dt \\ &= 2\pi \int_0^\pi r\sin t\sqrt{r^2(\sin^2 t + \cos^2 t)}\, dt \\ &= 2\pi \int_0^\pi r^2\sin t\, dt \\ &= 2\pi r^2\left(-\cos t\Big|_0^\pi\right) \\ &= 2\pi r^2(-\cos\pi + \cos 0) \\ &= 4\pi r^2 \text{ units}^2. \end{aligned}$$

This is, in fact, the formula for the surface area of a sphere.

**? Checkpoint 10.3.6**

Find the surface area generated when the plane curve defined by the equations

$$x(t) = t^3, \quad y(t) = t^2, \quad \text{for } 0 \le t \le 1$$

is revolved around the $x$-axis.

**Answer**

$A = \frac{\pi(494\sqrt{13}+128)}{1215}$ units$^2$

## Key Concepts

- The derivative of the parametrically defined curve $x = x(t)$ and $y = y(t)$ can be calculated using the formula $\frac{dy}{dx} = \frac{y'(t)}{x'(t)}$. Using the derivative, we can find the equation of a tangent line to a parametric curve.
- The area between a parametric curve and the $x$-axis can be determined by using the formula $A = \int_{t_1}^{t_2} y(t)x'(t)\, dt$.
- The arc length of a parametric curve can be calculated by using the formula

$$s = \int_{t_1}^{t_2} \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2}\, dt.$$

- The surface area of a volume of revolution revolved around the $x$-axis is given by

$$S = 2\pi \int_a^b y(t)\sqrt{(x'(t))^2 + (y'(t))^2}\, dt.$$

- If the curve is revolved around the $y$-axis, then the formula is

$$S = 2\pi \int_a^b x(t)\sqrt{(x'(t))^2 + (y'(t))^2}\, dt.$$

---

## Key Equations

- **Derivative of parametric equations**

$$\frac{dy}{dx} = \frac{dy/dt}{dx/dt} = \frac{y'(t)}{x'(t)}$$

- **Second-order derivative of parametric equations**

$$\frac{d^2y}{dx^2} = \frac{d}{dx}\left(\frac{dy}{dx}\right) = \frac{(d/dt)(dy/dx)}{dx/dt}$$

- **Area under a parametric curve**

$$A = \int_a^b y(t)x'(t)\, dt$$

- **Arc length of a parametric curve**

$$s = \int_{t_1}^{t_2} \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2}\, dt$$

- **Surface area generated by a parametric curve**

$$S = 2\pi \int_a^b y(t)\sqrt{(x'(t))^2 + (y'(t))^2}\, dt$$

# 10.3E: EXERCISES

**In exercises 1 - 4, each set of parametric equations represents a line. Without eliminating the parameter, find the slope of each line.**

1) $x = 3 + t, \quad y = 1 - t$

2) $x = 8 + 2t, \quad y = 1$

**Answer**

$m = 0$

3) $x = 4 - 3t, \quad y = -2 + 6t$

4) $x = -5t + 7, \quad y = 3t - 1$

**Answer**

$m = -\frac{3}{5}$

**In exercises 5 - 9, determine the slope of the tangent line, then find the equation of the tangent line at the given value of the parameter.**

5) $x = 3\sin t, \quad y = 3\cos t, \quad \text{for } t = \frac{\pi}{4}$

6) $x = \cos t, \quad y = 8\sin t, \quad \text{for } t = \frac{\pi}{2}$

**Answer**

Slope $= 0; y = 8.$

7) $x = 2t, \quad y = t^3, \quad \text{for } t = -1$

8) $x = t + \frac{1}{t}, \quad y = t - \frac{1}{t}, \quad \text{for } t = 1$

**Answer**

Slope is undefined; $x = 2$.

9) $x = \sqrt{t}, \quad y = 2t, \quad \text{for } t = 4$

**In exercises 10 - 13, find all points on the curve that have the given slope.**

10) $x = 4\cos t, \quad y = 4\sin t$, slope = $0.5$

**Solution**

$\frac{dy}{dx} = \frac{dy/dt}{dx/dt} = \frac{4\cos t}{-4\sin t} = -\cot t.$

Setting this derivative equal to $0.5$, we obtain the equation, $\tan t = -2$.

$\tan t = -2 \implies \frac{y}{x} = -2 \implies y = -2x.$

Note also that this pair of parametric equations represents the circle $x^2 + y^2 = 16$.

By substitution, we find that this curve has a slope of $0.5$ at the points:

$\left(\frac{4\sqrt{5}}{5}, \frac{-8\sqrt{5}}{5}\right)$ and $\left(\frac{-4\sqrt{5}}{5}, \frac{8\sqrt{5}}{5}\right)$.

11) $x = 2\cos t, \quad y = 8\sin t$, slope= $-1$

12) $x = t + \frac{1}{t}, \quad y = t - \frac{1}{t}$, slope= $1$

**Answer**

No points possible; undefined expression.

13) $x = 2 + \sqrt{t}, \quad y = 2 - 4t$, slope= $0$

**In exercises 14 - 16, write the equation of the tangent line in Cartesian coordinates for the given parameter $t$.**

14) $x = e^{\sqrt{t}}, \quad y = 1 - \ln t^2, \quad \text{for } t = 1$

**Answer**

$$y = -\left(\frac{4}{e}\right)x + 5$$

15) $x = t \ln t, \quad y = \sin^2 t, \quad \text{for } t = \frac{\pi}{4}$

16) $x = e^t, \quad y = (t-1)^2$, at $(1, 1)$

**Answer**

$$y = -2x + 3$$

17) For $x = \sin(2t), \quad y = 2\sin t$ where $0 \le t < 2\pi$. Find all values of $t$ at which a horizontal tangent line exists.

18) For $x = \sin(2t), \quad y = 2\sin t$ where $0 \le t < 2\pi$. Find all values of $t$ at which a vertical tangent line exists.

**Answer**

A vertical tangent line exists at $t = \frac{\pi}{4}, \frac{5\pi}{4}, \frac{3\pi}{4}, \frac{7\pi}{4}$

19) Find all points on the curve $x = 4\cos(t), \quad y = 4\sin(t)$ that have the slope of $\frac{1}{2}$.

20) Find $\frac{dy}{dx}$ for $x = \sin(t), \quad y = \cos(t)$.

**Answer**

$$\frac{dy}{dx} = -\tan(t)$$

21) Find the equation of the tangent line to $x = \sin(t), \quad y = \cos(t)$ at $t = \frac{\pi}{4}$.

22) For the curve $x = 4t, \quad y = 3t - 2$, find the slope and concavity of the curve at $t = 3$.

**Answer**

$\frac{dy}{dx} = \frac{3}{4}$ and $\frac{d^2y}{dx^2} = 0$, so the curve is neither concave up nor concave down at $t = 3$. Therefore the graph is linear and has a constant slope but no concavity.

23) For the parametric curve whose equation is $x = 4\cos\theta, \quad y = 4\sin\theta$, find the slope and concavity of the curve at $\theta = \frac{\pi}{4}$.

24) Find the slope and concavity for the curve whose equation is $x = 2 + \sec\theta, \quad y = 1 + 2\tan\theta$ at $\theta = \frac{\pi}{6}$.

**Answer**

$\frac{dy}{dx} = 4, \quad \frac{d^2y}{dx^2} = -4\sqrt{3}$; the curve is concave down at $\theta = \frac{\pi}{6}$.

25) Find all points on the curve $x = t + 4, \quad y = t^3 - 3t$ at which there are vertical and horizontal tangents.

26) Find all points on the curve $x = \sec\theta, \quad y = \tan\theta$ at which horizontal and vertical tangents exist.

**Answer**

No horizontal tangents. Vertical tangents at $(1, 0)$ and $(-1, 0)$.

**In exercises 27 - 29, find $d^2y/dx^2$.**

27) $x = t^4 - 1, \quad y = t - t^2$

28) $x = \sin(\pi t), \quad y = \cos(\pi t)$

**Answer**

$$d^2y/dx^2 = -\sec^3(\pi t)$$

29) $x = e^{-t}, \quad y = te^{2t}$

**In exercises 30 - 31, find points on the curve at which tangent line is horizontal or vertical.**

30) $x = t(t^2 - 3), \quad y = 3(t^2 - 3)$

**Answer**

Horizontal $(0, -9)$;
Vertical $(\pm 2, -6)$.

31) $x = \dfrac{3t}{1+t^3}, \quad y = \dfrac{3t^2}{1+t^3}$

**In exercises 32 - 34, find $dy/dx$ at the value of the parameter.**

32) $x = \cos t, y = \sin t, \quad \text{for } t = \frac{3\pi}{4}$

**Answer**

$dy/dx = 1$

33) $x = \sqrt{t}, \quad y = 2t + 4, t = 9$

34) $x = 4\cos(2\pi s), \quad y = 3\sin(2\pi s), \quad \text{for } s = -\frac{1}{4}$

**Answer**

$dy/dx = 0$

**In exercises 35 - 36, find $d^2y/dx^2$ at the given point without eliminating the parameter.**

35) $x = \frac{1}{2}t^2, \quad y = \frac{1}{3}t^3, \quad \text{for } t = 2$

36) $x = \sqrt{t}, \quad y = 2t + 4, \quad \text{for } t = 1$

**Answer**

$d^2y/dx^2 = 4$

37) Find intervals for $t$ on which the curve $x = 3t^2, \quad y = t^3 - t$ is concave up as well as concave down.

38) Determine the concavity of the curve $x = 2t + \ln t, \quad y = 2t - \ln t$.

**Answer**

Concave up on $t > 0$.

39) Sketch and find the area under one arch of the cycloid $x = r(\theta - \sin\theta), \quad y = r(1 - \cos\theta)$.

40) Find the area bounded by the curve $x = \cos t, \quad y = e^t, \quad \text{for } 0 \le t \le \frac{\pi}{2}$ and the lines $y = 1$ and $x = 0$.

**Answer**

$1 \text{ unit}^2$

41) Find the area enclosed by the ellipse $x = a\cos\theta, \quad y = b\sin\theta, \quad \text{for } 0 \le \theta < 2\pi$.

42) Find the area of the region bounded by $x = 2\sin^2\theta, \quad y = 2\sin^2\theta\tan\theta$, for $0 \le \theta \le \frac{\pi}{2}$.

**Answer**

$\frac{3\pi}{2} \text{ units}^2$

**In exercises 43 - 46, find the area of the regions bounded by the parametric curves and the indicated values of the parameter.**

43) $x = 2\cot\theta, \quad y = 2\sin^2\theta, \quad \text{for } 0 \le \theta \le \pi$

44) [Technology Required] $x = 2a\cos t - a\cos(2t), \quad y = 2a\sin t - a\sin(2t), \quad \text{for } 0 \le t < 2\pi$

**Answer**

$6\pi a^2 \text{ units}^2$

45) [Technology Required] $x = a\sin(2t), \quad y = b\sin(t), \quad \text{for } 0 \le t < 2\pi$ (the “hourglass”)

46) [Technology Required] $x = 2a\cos t - a\sin(2t), \quad y = b\sin t, \quad \text{for } 0 \le t < 2\pi$ (the “teardrop”)

**Answer**

$2\pi ab \text{ units}^2$

**In exercises 47 - 52, find the arc length of the curve on the indicated interval of the parameter.**

47) $x = 4t + 3, \quad y = 3t - 2, \quad \text{for } 0 \le t \le 2$

48) $x = \frac{1}{3}t^3, \quad y = \frac{1}{2}t^2, \quad \text{for } 0 \le t \le 1$

**Answer**

$s = \frac{1}{3}(2\sqrt{2} - 1)$ units

49) $x = \cos(2t), \quad y = \sin(2t), \quad \text{for } 0 \le t \le \frac{\pi}{2}$

50) $x = 1 + t^2, \quad y = (1 + t)^3, \quad \text{for } 0 \le t \le 1$

**Answer**

$s = 7.075$ units

51) $x = e^t \cos t, \quad y = e^t \sin t, \quad \text{for } 0 \le t \le \frac{\pi}{2}$ (express answer as a decimal rounded to three places)

52) $x = a\cos^3\theta, \quad y = a\sin^3\theta$ on the interval $[0, 2\pi)$ (the hypocycloid)

**Answer**

$s = 6a$ units

53) Find the length of one arch of the cycloid $x = 4(t - \sin t), \quad y = 4(1 - \cos t)$.

54) Find the distance traveled by a particle with position $(x, y)$ as $t$ varies in the given time interval: $x = \sin^2 t, \quad y = \cos^2 t, \quad \text{for } 0 \le t \le 3\pi$.

**Answer**

$6\sqrt{2}$ units

55) Find the length of one arch of the cycloid $x = \theta - \sin\theta, \quad y = 1 - \cos\theta$.

56) Show that the total length of the ellipse $x = 4\sin\theta, \quad y = 3\cos\theta$ is $L = 16\int_0^{\pi/2} \sqrt{1 - e^2\sin^2\theta}\, d\theta$, where $e = \frac{c}{a}$ and $c = \sqrt{a^2 - b^2}$.

57) Find the length of the curve $x = e^t - t, \quad y = 4e^{t/2}, \quad \text{for } -8 \le t \le 3$.

**In exercises 58 - 59, find the area of the surface obtained by rotating the given curve about the $x$-axis.**

58) $x = t^3, \quad y = t^2, \quad \text{for } 0 \le t \le 1$

**Answer**

$\frac{2\pi(247\sqrt{13} + 64)}{1215}$ $\text{units}^2$

59) $x = a\cos^3\theta, \quad y = a\sin^3\theta, \quad \text{for } 0 \le \theta \le \frac{\pi}{2}$

60) [Technology Required] Use a CAS to find the area of the surface generated by rotating $x = t + t^3, \quad y = t - \frac{1}{t^2}, \quad \text{for } 1 \le t \le 2$ about the $x$ -axis. (Answer to three decimal places.)

**Answer**

$59.101$ $\text{units}^2$

61) Find the surface area obtained by rotating $x = 3t^2, \quad y = 2t^3, \quad \text{for } 0 \le t \le 5$ about the $y$-axis.

62) Find the area of the surface generated by revolving $x = t^2, \quad y = 2t, \quad \text{for } 0 \le t \le 4$ about the $x$-axis.

**Answer**

$\frac{8\pi}{3}(17\sqrt{17} - 1)$ $\text{units}^2$

63) Find the surface area generated by revolving $x = t^2, \quad y = 2t^2, \quad \text{for } 0 \le t \le 1$ about the $y$-axis.

# 10.4: Polar Coordinates

**Learning Objectives**

- Locate points in a plane by using polar coordinates.
- Convert points between rectangular and polar coordinates.
- Sketch polar curves from given equations.
- Convert equations between rectangular and polar coordinates.
- Identify symmetry in polar curves and equations.

The rectangular coordinate system (or Cartesian plane) maps points to ordered pairs and ordered pairs to points. This is called a **one-to-one mapping** from points in the plane to ordered pairs. The polar coordinate system provides an alternative method of mapping points to ordered pairs. This section shows that polar coordinates can be more useful in some circumstances than rectangular coordinates.

## Defining Polar Coordinates

To find the coordinates of a point in the polar coordinate system, consider Figure **10.4.1**. The point $P$ has Cartesian coordinates $(x, y)$. The line segment connecting the origin to the point $P$ measures the distance from the origin to $P$ and has length $r$. The angle between the positive $x$-axis and the line segment has measure $\theta$. This observation suggests a natural correspondence between the coordinate pair $(x, y)$ and the values $r$ and $\theta$. This correspondence is the basis of the **polar coordinate system**. Every point in the Cartesian plane has two values (hence the term ordered pair) associated with it. In the polar coordinate system, each point also has two values associated with it: $r$ and $\theta$.

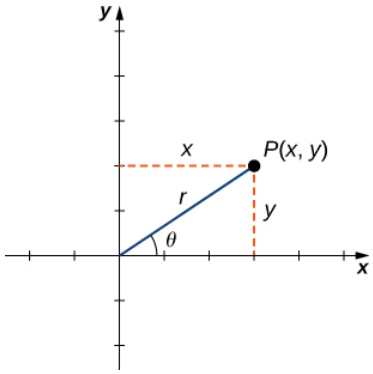

Figure **10.4.1**: An arbitrary point in the Cartesian plane.

Using Right Triangle Trigonometry, the following equations are valid for the point $P$:

$$\cos\theta = \frac{x}{r} \quad \text{so} \quad x = r\cos\theta$$

$$\sin\theta = \frac{y}{r} \quad \text{so} \quad y = r\sin\theta$$

Furthermore,

$$r^2 = x^2 + y^2$$

and

$$\tan\theta = \frac{y}{x}.$$

Each point $(x, y)$ in the Cartesian coordinate system can therefore be represented as an ordered pair $(r, \theta)$ in the polar coordinate system. The first coordinate is called the **radial coordinate** and the second coordinate is called the **angular coordinate**. Every point in the plane can be represented in this form.

The equation $\tan\theta = y/x$ has an infinite number of solutions for any ordered pair $(x, y)$. However, if we restrict the solutions to values between $0$ and $2\pi$, we can assign a unique solution to the quadrant in which the original point $(x, y)$ is located. Then the corresponding value of $r$ is positive, so $r^2 = x^2 + y^2$.

### Theorem: Converting Points between Coordinate Systems

Given a point $P$ in the plane with Cartesian coordinates $(x, y)$ and polar coordinates $(r, \theta)$, the following conversion formulas hold true:

$$x = r\cos\theta \tag{10.4.1}$$

$$y = r\sin\theta \tag{10.4.2}$$

and

$$r^2 = x^2 + y^2 \tag{10.4.3}$$

$$\tan\theta = \frac{y}{x} \tag{10.4.4}$$

These formulas can be used to convert from rectangular to polar or from polar to rectangular coordinates. Notice that Equation 10.4.3 is the Pythagorean Theorem. (Figure 10.4.1).

### Example 10.4.1: Converting between Rectangular and Polar Coordinates

Convert each of the following points into polar coordinates.

a. $(1, 1)$
b. $(-3, 4)$
c. $(0, 3)$
d. $(5\sqrt{3}, -5)$

Convert each of the following points into rectangular coordinates.

e. $(3, \pi/3)$
f. $(2, 3\pi/2)$
g. $(6, -5\pi/6)$

**Solutions**

a. Use $x = 1$ and $y = 1$ in Equation 10.4.3:

$$\begin{aligned} r^2 &= x^2 + y^2 \\ &= 1^2 + 1^2 \\ \Rightarrow \quad r &= \sqrt{2} \end{aligned}$$

and via Equation 10.4.4

$$\begin{aligned} \tan\theta &= \frac{y}{x} \\ &= \frac{1}{1} \\ &= 1 \\ \Rightarrow \quad \theta &= \frac{\pi}{4}. \end{aligned}$$

Therefore this point can be represented as $(\sqrt{2}, \frac{\pi}{4})$ in polar coordinates.

b. Use $x = -3$ and $y = 4$ in Equation 10.4.3:

$$\begin{aligned} r^2 &= x^2 + y^2 \\ &= (-3)^2 + (4)^2 \\ \Longrightarrow \quad r &= 5 \end{aligned}$$

and via Equation 10.4.4

$$\begin{aligned} \tan\theta &= \frac{y}{x} \\ &= -\frac{4}{3} \\ \Longrightarrow \quad \theta &= \arctan\left(-\frac{4}{3}\right) + \pi \\ &\approx 2.21 \end{aligned}$$

Therefore this point can be represented as $(5, 2.21)$ in polar coordinates.

c. Use $x = 0$ and $y = 3$ in Equation 10.4.3:

$$r^2 = x^2 + y^2 = (3)^2 + (0)^2 = 9 + 0 \implies r = 3$$

and via Equation 10.4.4

$$\tan\theta = \frac{y}{x} = \frac{3}{0}.$$

Direct application of the second equation leads to division by zero. Graphing the point $(0, 3)$ on the rectangular coordinate system reveals that the point is located on the positive $y$-axis. The angle between the positive $x$-axis and the positive $y$-axis is $\frac{\pi}{2}$. Therefore this point can be represented as $(3, \frac{\pi}{2})$ in polar coordinates.

d. Use $x = 5\sqrt{3}$ and $y = -5$ in Equation 10.4.3:

$$r^2 = x^2 + y^2 = (5\sqrt{3})^2 + (-5)^2 = 75 + 25 \implies r = 10$$

and via Equation 10.4.4

$$\begin{aligned} \tan\theta &= \frac{y}{x} \\ &= \frac{-5}{5\sqrt{3}} \\ &= -\frac{\sqrt{3}}{3} \\ \Longrightarrow \quad \theta &= -\frac{\pi}{6} \end{aligned}$$

Therefore this point can be represented as $\left(10, -\frac{\pi}{6}\right)$ in polar coordinates.

e. Use $r = 3$ and $\theta = \frac{\pi}{3}$ in Equation 10.4.1:

$$x = r\cos\theta = 3\cos(\frac{\pi}{3}) = 3(\frac{1}{2}) = \frac{3}{2}$$

and

$$y = r\sin\theta = 3\sin\left(\frac{\pi}{3}\right) = 3\left(\frac{\sqrt{3}}{2}\right) = \frac{3\sqrt{3}}{2}.$$

Therefore this point can be represented as $\left(\frac{3}{2}, \frac{3\sqrt{3}}{2}\right)$ in rectangular coordinates.

f. Use $r = 2$ and $\theta = \frac{3\pi}{2}$ in Equation 10.4.1:

$$x = r\cos\theta = 2\cos\left(\frac{3\pi}{2}\right) = 2(0) = 0$$

and

$$y = r\sin\theta = 2\sin\left(\frac{3\pi}{2}\right) = 2(-1) = -2.$$

Therefore this point can be represented as $(0, -2)$ in rectangular coordinates.

g. Use $r = 6$ and $\theta = -\frac{5\pi}{6}$ in Equation 10.4.1:

$$x = r\cos\theta = 6\cos\left(-\frac{5\pi}{6}\right) = 6\left(-\frac{\sqrt{3}}{2}\right) = -3\sqrt{3}$$

and

$$y = r\sin\theta = 6\sin\left(-\frac{5\pi}{6}\right) = 6\left(-\frac{1}{2}\right) = -3.$$

Therefore this point can be represented as $(-3\sqrt{3}, -3)$ in rectangular coordinates.

**? Checkpoint 10.4.1**

Convert $(-8, -8)$ into polar coordinates and $\left(4, \frac{2\pi}{3}\right)$ into rectangular coordinates.

**Answer**

$\left(8\sqrt{2}, \frac{5\pi}{4}\right)$ and $(-2, 2\sqrt{3})$

The polar representation of a point is not unique. For example, the polar coordinates $\left(2, \frac{\pi}{3}\right)$ and $\left(2, \frac{7\pi}{3}\right)$ both represent the point $(1, \sqrt{3})$ in the rectangular system. Also, the value of $r$ can be negative. Therefore, the point with polar coordinates $\left(-2, \frac{4\pi}{3}\right)$ also represents the point $(1, \sqrt{3})$ in the rectangular system, as we can see by using Equation 10.4.1:

$$x = r\cos\theta = -2\cos\left(\frac{4\pi}{3}\right) = -2\left(-\frac{1}{2}\right) = 1$$

and

$$y = r\sin\theta = -2\sin\left(\frac{4\pi}{3}\right) = -2\left(-\frac{\sqrt{3}}{2}\right) = \sqrt{3}.$$

Every point in the plane has infinite representations in polar coordinates. However, each point in the plane has only one representation in the rectangular coordinate system.

Note that the polar representation of a point in the plane also has a visual interpretation. In particular, $r$ is the directed distance that the point lies from the origin, and $\theta$ measures the angle that the line segment from the origin to the point makes with the positive $x$-axis. Positive angles are measured in a counterclockwise direction, and negative angles are measured in a clockwise direction. The polar coordinate system appears in Figure 10.4.2.

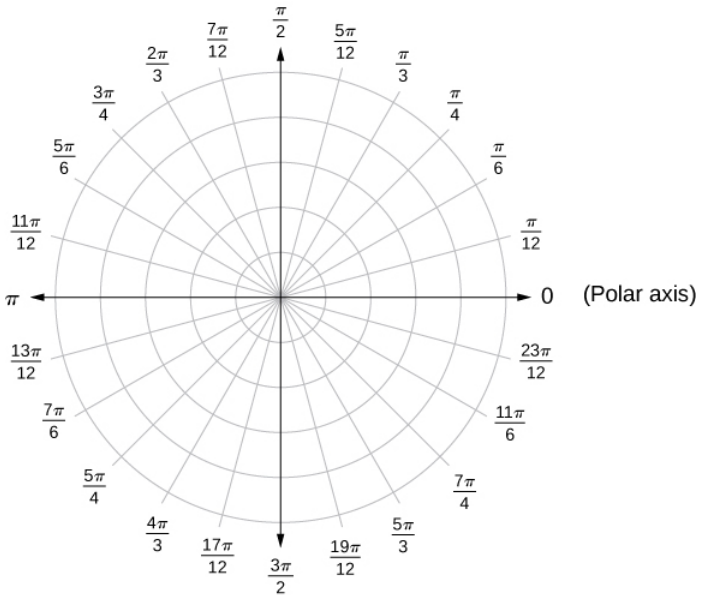

Figure 10.4.2: The polar coordinate system.

The line segment starting from the center of the graph going to the right (called the positive $x$-axis in the Cartesian system) is the **polar axis**. The center point is the **pole**, or **origin**, of the coordinate system, and corresponds to $r = 0$. The innermost circle shown in Figure 10.4.2 contains all points a distance of 1 unit from the pole and is represented by the equation $r = 1$. Then $r = 2$ is the set of points 2 units from the pole, and so on. The line segments emanating from the pole correspond to fixed angles. To plot a point in the polar coordinate system, start with the angle. If the angle is positive, measure the angle from the polar axis in a counterclockwise direction. If it is negative, then measure it clockwise. If the value of $r$ is positive, move that distance along the terminal ray of the angle. If it is negative, move along the ray opposite the given angle's terminal ray.

### Example 10.4.2: Plotting Points in the Polar Plane

Plot each of the following points on the polar plane.

a. $(2, \frac{\pi}{4})$
b. $(-3, \frac{2\pi}{3})$
c. $(4, \frac{5\pi}{4})$

**Solutions**

The three points are plotted in Figure 10.4.3.

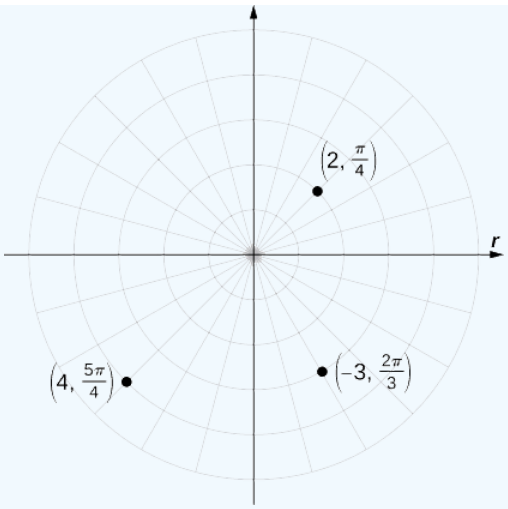

Figure **10.4.3**: Three points plotted in the polar coordinate system.

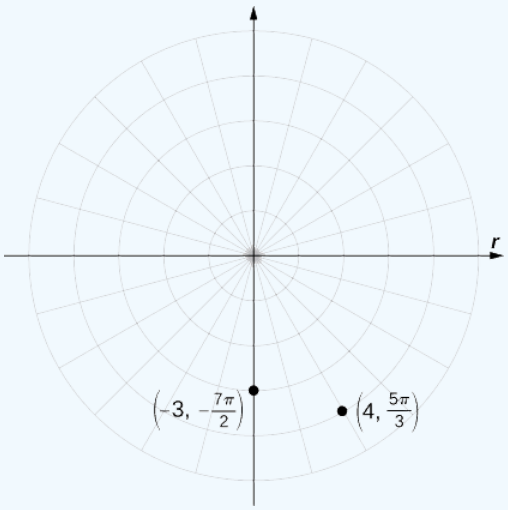
**? Checkpoint 10.4.2**

Plot $\left(4, \frac{5\pi}{3}\right)$ and $\left(-3, -\frac{7\pi}{2}\right)$ on the polar plane.

**Answer**



## Polar Curves

Now that we know how to plot points in the polar coordinate system, we can discuss how to plot curves. In the rectangular coordinate system, we can graph a function $y = f(x)$ and create a curve in the Cartesian plane. Similarly, we can graph a curve that is generated by a function $r = f(\theta)$.

The general idea behind graphing a function in polar coordinates is the same as graphing a function in rectangular coordinates. Start with a list of values for the independent variable ($\theta$ in this case) and calculate the corresponding values of the dependent variable $r$. This process generates a list of ordered pairs, which can be plotted in the polar coordinate system. Finally, connect the points and take advantage of any patterns. The function may be periodic, for example, which indicates that only a limited number of values for the independent variable are needed.

### Problem-Solving Strategy: Plotting a Curve in Polar Coordinates

1. Create a table with two columns. The first column is for $\theta$, and the second is for $r$.
2. Create a list of values for $\theta$.
3. Calculate the corresponding $r$ values for each $\theta$.
4. Plot each ordered pair $(r, \theta)$ on the coordinate axes.
5. Connect the points and look for a pattern.

### Example 10.4.3: Graphing a Function in Polar Coordinates

Graph the curve defined by the function $r = 4\sin\theta$. Identify the curve and rewrite the equation in rectangular coordinates.

**Solution**

Because the function is a multiple of a sine function, it is periodic with period $2\pi$, so use values for $\theta$ between $0$ and $2\pi$. The results of steps 1–3 appear in the following table. Figure 10.4.4 shows the graph based on this table.

| $\theta$ | $r = 4\sin\theta$ | $\theta$ | $r = 4\sin\theta$ |
|---|---|---|---|
| 0 | 0 | $\pi$ | 0 |
| $\frac{\pi}{6}$ | 2 | $\frac{7\pi}{6}$ | $-2$ |
| $\frac{\pi}{4}$ | $2\sqrt{2} \approx 2.8$ | $\frac{5\pi}{4}$ | $-2\sqrt{2} \approx -2.8$ |
| $\frac{\pi}{3}$ | $2\sqrt{3} \approx 3.4$ | $\frac{4\pi}{3}$ | $-2\sqrt{3} \approx -3.4$ |
| $\frac{\pi}{2}$ | 4 | $\frac{3\pi}{2}$ | $-4$ |
| $\frac{2\pi}{3}$ | $2\sqrt{3} \approx 3.4$ | $\frac{5\pi}{3}$ | $-2\sqrt{3} \approx -3.4$ |
| $\frac{3\pi}{4}$ | $2\sqrt{2} \approx 2.8$ | $\frac{7\pi}{4}$ | $-2\sqrt{2} \approx -2.8$ |
| $\frac{5\pi}{6}$ | 2 | $\frac{11\pi}{6}$ | $-2$ |
| | | $2\pi$ | 0 |

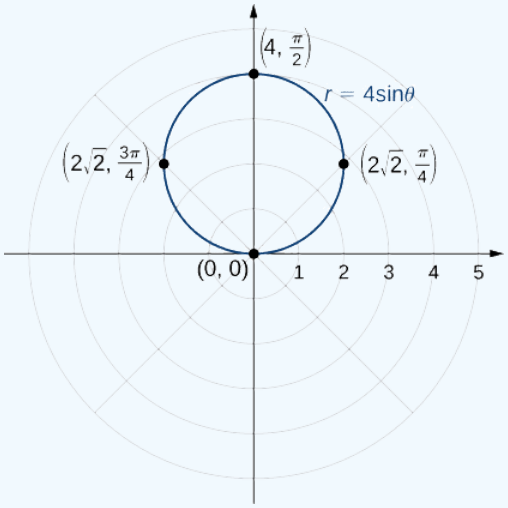


Figure 10.4.4: The graph of the function $r = 4\sin\theta$ is a circle.

This is the graph of a circle. The equation $r = 4\sin\theta$ can be converted into rectangular coordinates by multiplying both sides by $r$. This gives the equation $r^2 = 4r\sin\theta$. Next use the facts that $r^2 = x^2 + y^2$ and $y = r\sin\theta$. This gives $x^2 + y^2 = 4y$. To put this equation into standard form, subtract $4y$ from both sides of the equation and complete the square:

$$\begin{aligned} x^2+y^2-4y &= 0 \\ \Rightarrow \quad x^2+(y^2-4y) &= 0 \\ \Rightarrow \quad x^2+(y^2-4y+4) &= 0+4 \\ \Rightarrow \quad x^2+(y-2)^2 &= 4 \end{aligned}$$

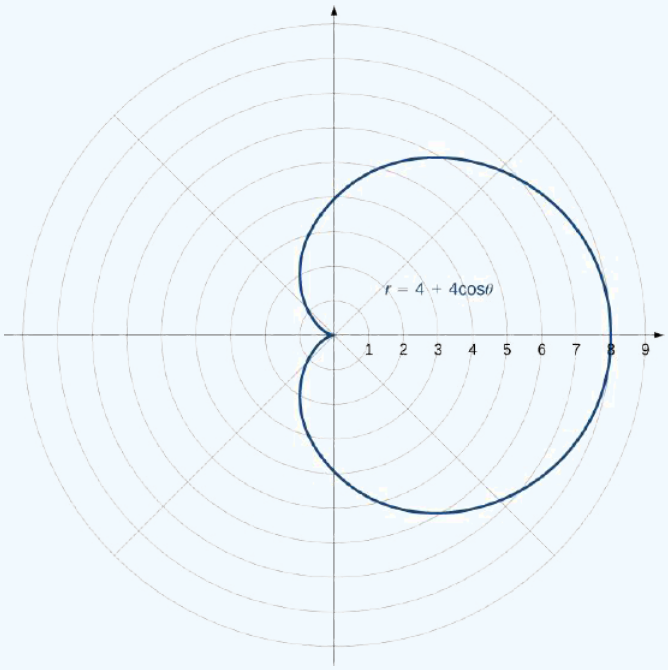
This is the equation of a circle with radius 2 and center $(0,2)$ in the rectangular coordinate system.

**Checkpoint 10.4.3**

Create a graph of the curve defined by the function $r=4+4\cos\theta$.

**Answer**

The name of this shape is a cardioid, which we will study further later in this section.



The graph in Example **10.4.3** was that of a circle. The equation of the circle can be transformed into rectangular coordinates using the coordinate transformation formulas in Equation 10.4.1. Example **10.4.4** gives some more examples of functions for transforming from polar to rectangular coordinates.

**Example 10.4.4: Transforming Polar Equations to Rectangular Coordinates**

Rewrite the following equations in rectangular coordinates and identify the graph.

a. $\theta=\frac{\pi}{3}$
b. $r=3$
c. $r=6\cos\theta-8\sin\theta$

**Solutions**

a. Take the tangent of both sides. This gives $\tan\theta=\tan(\pi/3)=\sqrt{3}$. Since $\tan\theta=y/x$, we can replace the left-hand side of this equation with $y/x$. This gives $y/x=\sqrt{3}$, which can be rewritten as $y=x\sqrt{3}$. This is the equation of a straight line passing through the origin with slope $\sqrt{3}$. In general, any polar equation of the form $\theta=K$ represents a straight line through the pole with slope equal to $\tan K$.

b. First, square both sides of the equation. This gives $r^2 = 9$. Next replace $r^2$ with $x^2 + y^2$. This gives the equation $x^2 + y^2 = 9$, which is the equation of a circle centered at the origin with radius $3$. In general, any polar equation of the form $r = k$ where $k$ is a positive constant represents a circle of radius $k$ centered at the origin. (Note: when squaring both sides of an equation, it is possible to introduce new points unintentionally. This should always be taken into consideration. However, in this case, we do not introduce new points. For example, $\left(-3, \frac{\pi}{3}\right)$ is the same point as $\left(3, \frac{4\pi}{3}\right)$.)

c. Multiply both sides of the equation by $r$. This leads to $r^2 = 6r\cos\theta - 8r\sin\theta$. Next, use the formulas

$$r^2 = x^2 + y^2, x = r\cos\theta, y = r\sin\theta.$$

This gives

$$\begin{aligned} r^2 &= 6(r\cos\theta) - 8(r\sin\theta) \\ \implies x^2 + y^2 &= 6x - 8y \end{aligned}$$

To put this equation into standard form, move the variables from the right-hand side of the equation to the left-hand side, then complete the square.

$$\begin{aligned} x^2 + y^2 &= 6x - 8y \\ \implies x^2 - 6x + y^2 + 8y &= 0 \\ \implies (x^2 - 6x) + (y^2 + 8y) &= 0 \\ \implies (x^2 - 6x + 9) + (y^2 + 8y + 16) &= 9 + 16 \\ \implies (x-3)^2 + (y+4)^2 &= 25. \end{aligned}$$

This is the equation of a circle with center at $(3, -4)$ and radius $5$. Notice that the circle passes through the origin since the center is $5$ units away.

**? Checkpoint 10.4.4**

Rewrite the equation $r = \sec\theta\tan\theta$ in rectangular coordinates and identify its graph.

**Answer**

$y = x^2$, which is the equation of a parabola opening upward.

We have now seen several examples of drawing graphs of curves defined by **polar equations**. A summary of some common curves is given in the tables below. In each equation, $a$ and $b$ are arbitrary constants.

| Name | Equation | Example |
|---|---|---|
| Line passing through the pole with slope tan $K$ | $\theta = K$ |   |
| Circle | $r = a\cos\theta + b\sin\theta$ |   |
| Spiral | $r = a + b\theta$ |   |

Figure 10.4.5

| Name | Equation | Example |
|---|---|---|
| Cardioid | $r = a(1 + \cos\theta)$<br>$r = a(1 - \cos\theta)$<br>$r = a(1 + \sin\theta)$<br>$r = a(1 - \sin\theta)$ |  |
| Limaçon | $r = a\cos\theta + b$<br>$r = a\sin\theta + b$ |  |
| Rose | $r = a\cos(b\theta)$<br>$r = a\sin(b\theta)$ |  |

Figure 10.4.6

A **cardioid** is a special case of a **limaçon** (pronounced “lee-mah-son”), in which $a = b$ or $a = -b$. The **rose** is an interesting curve. Notice that the graph of $r = 3\sin 2\theta$ has four petals. However, the graph of $r = 3\sin 3\theta$ has three petals.

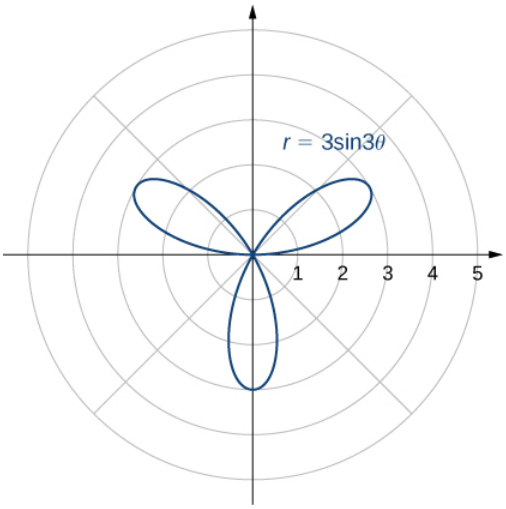


Figure 10.4.7: Graph of $r = 3\sin 3\theta$.

If the coefficient of $\theta$ is even, the graph has twice as many petals as the coefficient. If the coefficient of $\theta$ is odd, then the number of petals equals the coefficient. You are encouraged to explore why this happens. Even more interesting graphs emerge when the coefficient of $\theta$ is not an integer. For example, if it is rational, then the curve is closed; that is, it eventually ends where it started (Figure 10.4.8*a*). However, if the coefficient is irrational, then the curve never closes (Figure 10.4.8*b*). Although it may appear that the curve is closed, a closer examination reveals that the petals just above the positive $x$ axis are slightly thicker. This is because the petal does not quite match up with the starting point.

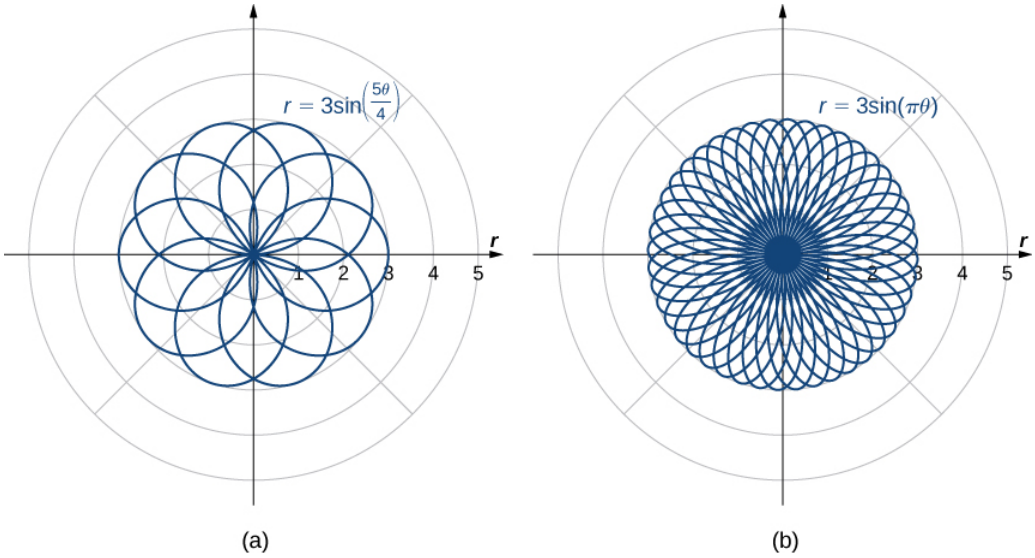

Figure 10.4.8: Polar rose graphs of functions with (a) rational coefficient and (b) irrational coefficient. Note that the rose in part (b) would fill the entire circle if plotted in full.

Since the curve defined by the graph of $r = 3\sin(\pi\theta)$ never closes, the curve depicted in Figure 10.4.8*b* is only a partial depiction. This is an example of a **space-filling curve**. A space-filling curve occupies a two-dimensional subset of the real plane. In this case, the curve occupies the circle of radius 3 centered at the origin.

### Example 10.4.5: Describing a Spiral

The **chambered nautilus** displays a spiral when half the outer shell is cut away. It is possible to describe a spiral using rectangular coordinates. Figure 10.4.9 shows a spiral in rectangular coordinates. How can we describe this curve mathematically?

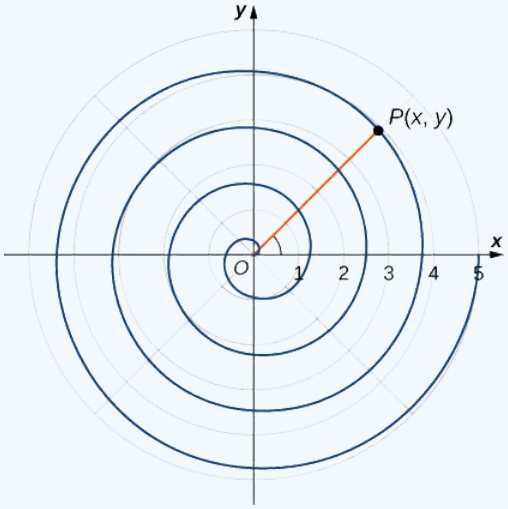

Figure 10.4.9: How can we describe a spiral graph mathematically?

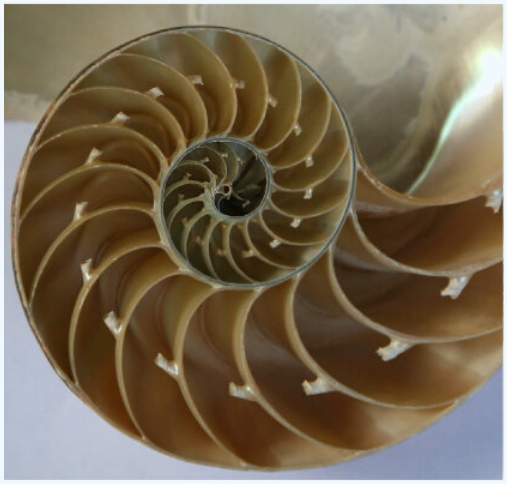
**Solution**

As the point $P$ travels around the spiral in a counterclockwise direction, its distance $d$ from the origin increases. Assume that the distance $d$ is a constant multiple $k$ of the angle $\theta$ that the line segment $OP$ makes with the positive $x$-axis. Therefore $d(P,O) = k\theta$, where $O$ is the origin. Now use the Distance Formula and some Trigonometry:

$$\begin{aligned} & d(P,O) = k\theta \\ \Rightarrow \quad & \sqrt{(x-0)^2+(y-0)^2} = k \arctan\left(\frac{y}{x}\right) \\ \Rightarrow \quad & \sqrt{x^2+y^2} = k \arctan\left(\frac{y}{x}\right) \\ \Rightarrow \quad & \arctan\left(\frac{y}{x}\right) = \frac{\sqrt{x^2+y^2}}{k} \\ \Rightarrow \quad & y = x \tan\left(\frac{\sqrt{x^2+y^2}}{k}\right). \end{aligned}$$

Although this equation describes the spiral, it is not possible to solve it directly for either $x$ or $y$. However, if we use polar coordinates, the equation becomes much simpler. In particular, $d(P,O) = r$, and $\theta$ is the second coordinate. Therefore, the equation for the spiral becomes $r = k\theta$. Note that when $\theta = 0$, we also have $r = 0$, so the spiral emanates from the origin. We can remove this restriction by adding a constant to the equation. Then, the equation for the spiral becomes $r = a + k\theta$ for arbitrary constants $a$ and $k$. This is referred to as an **Archimedean spiral**, after the Greek mathematician Archimedes.

Another type of spiral is the **logarithmic spiral**, described by the function $r = a \cdot b^{\theta}$. A graph of the function $r = 1.2(1.25^{\theta})$ is given in Figure 10.4.10. This spiral describes the shell shape of the chambered nautilus.



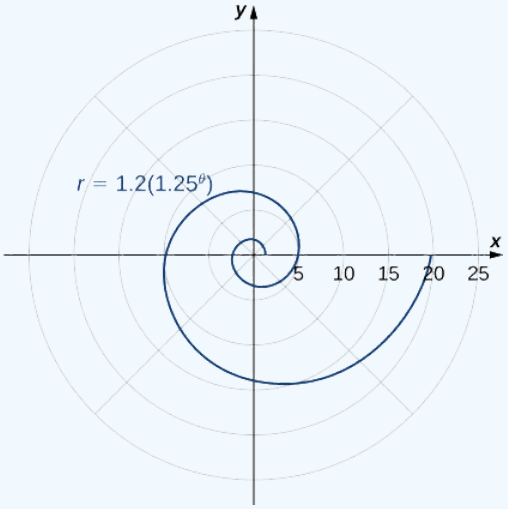


Figure 10.4.10: A logarithmic spiral is similar to the shape of the chambered nautilus shell. (credit: modification of work by Jitze Couperus, Flickr)

Suppose a curve is described in the polar coordinate system via the function $r = f(\theta)$. Since we have conversion formulas from polar to rectangular coordinates given by

$$\begin{aligned} x &= r\cos\theta \\ y &= r\sin\theta \end{aligned}$$

it is possible to rewrite these formulas using the function

$$\begin{aligned} x &= f(\theta)\cos\theta \\ y &= f(\theta)\sin\theta \end{aligned}$$

This step gives a parametrization of the curve in rectangular coordinates using $\theta$ as the parameter. For example, the spiral formula $r = a + b\theta$ from Figure becomes

$$\begin{aligned} x &= (a + b\theta)\cos\theta \\ y &= (a + b\theta)\sin\theta \end{aligned}$$

Letting $\theta$ range from $-\infty$ to $\infty$ generates the entire spiral.

## Symmetry in Polar Coordinates

When studying **symmetry** of functions in rectangular coordinates (i.e., in the form $y = f(x)$), we talk about symmetry with respect to the $y$-axis and symmetry with respect to the origin. In particular, if $f(-x) = f(x)$ for all $x$ in the domain of $f$, then $f$ is an even function and its graph is symmetric with respect to the $y$-axis. If $f(-x) = -f(x)$ for all $x$ in the domain of $f$, then $f$ is an odd function and its graph is symmetric with respect to the origin. By determining which types of symmetry a graph exhibits, we can learn more about the shape and appearance of the graph. Symmetry can also reveal other properties of the function that generates the graph. Symmetry in polar curves works similarly.

### Symmetry in Polar Curves and Equations

Consider a curve generated by the function $r = f(\theta)$ in polar coordinates.

i. The curve is symmetric about the polar axis if for every point $(r, \theta)$ on the graph, the point $(r, -\theta)$ is also on the graph. Similarly, the equation $r = f(\theta)$ is unchanged by replacing $\theta$ with $-\theta$.
ii. The curve is symmetric about the pole if for every point $(r, \theta)$ on the graph, the point $(r, \pi + \theta)$ is as well. Similarly, the equation $r = f(\theta)$ is unchanged when replacing $r$ with $-r$, or $\theta$ with $\pi + \theta$.

iii. The curve is symmetric about the vertical line $\theta = \frac{\pi}{2}$ if for every point $(r, \theta)$ on the graph, the point $(r, \pi - \theta)$ is also on the graph. Similarly, the equation $r = f(\theta)$ is unchanged when $\theta$ is replaced by $\pi - \theta$.

The following table shows examples of each type of symmetry.

| | |
|---|---|
| **Symmetry with respect to the polar axis:** For every point $(r, \theta)$ on the graph, there is also a point reflected directly across the horizontal (polar) axis. |   |
| **Symmetry with respect to the pole:** For every point $(r, \theta)$ on the graph, there is also a point on the graph that is reflected through the pole as well. |   |
| **Symmetry with respect to the vertical line $\theta = \frac{\pi}{2}$:** For every point $(r, \theta)$ on the graph, there is also a point reflected directly across the vertical axis. |   |

## Example 10.4.6: Using Symmetry to Graph a Polar Equation

Find the symmetry of the rose defined by the equation $r = 3\sin(2\theta)$ and create a graph.

**Solution**

Suppose the point $(r, \theta)$ is on the graph of $r = 3\sin(2\theta)$.

i. To test for symmetry about the polar axis, first try replacing $\theta$ with $-\theta$. This gives $r = 3\sin(2(-\theta)) = -3\sin(2\theta)$. Since this changes the original equation, this test is not satisfied. However, returning to the original equation and replacing $r$ with $-r$ and $\theta$ with $\pi - \theta$ yields

$$\begin{aligned} -r &= 3\sin(2(\pi-\theta)) \\ \Rightarrow \quad -r &= 3\sin(2\pi-2\theta) \\ \Rightarrow \quad -r &= 3\sin(-2\theta) \\ \Rightarrow \quad -r &= -3\sin 2\theta. \end{aligned}$$

Multiplying both sides of this equation by $-1$ gives $r = 3\sin 2\theta$, which is the original equation. This demonstrates that the graph is symmetric with respect to the polar axis.

ii. To test for symmetry with respect to the pole, first replace $r$ with $-r$, which yields $-r = 3\sin(2\theta)$. Multiplying both sides by $-1$ gives $r = -3\sin(2\theta)$, which does not agree with the original equation. Therefore, the equation does not pass the test for this symmetry. However, returning to the original equation and replacing $\theta$ with $\theta + \pi$ gives

$$\begin{aligned} r &= 3\sin(2(\theta+\pi)) \\ &= 3\sin(2\theta+2\pi) \\ &= 3(\sin 2\theta\cos 2\pi + \cos 2\theta\sin 2\pi) \\ &= 3\sin 2\theta. \end{aligned}$$

Since this agrees with the original equation, the graph is symmetric about the pole.

iii. To test for symmetry with respect to the vertical line $\theta = \frac{\pi}{2}$, first replace both $r$ with $-r$ and $\theta$ with $-\theta$.

$$\begin{aligned} -r &= 3\sin(2(-\theta)) \\ \Rightarrow \quad -r &= 3\sin(-2\theta) \\ \Rightarrow \quad -r &= -3\sin 2\theta. \end{aligned}$$

Multiplying both sides of this equation by $-1$ gives $r = 3\sin 2\theta$, which is the original equation. Therefore the graph is symmetric about the vertical line $\theta = \frac{\pi}{2}$.

This graph has symmetry with respect to the polar axis, the origin, and the vertical line going through the pole. To graph the function, tabulate values of $\theta$ between $0$ and $\pi/2$ and then reflect the resulting graph.

| | |
|---|---|
| 0 | 0 |
| $\frac{\pi}{6}$ | $\frac{3\sqrt{3}}{2} \approx 2.6$ |
| $\frac{\pi}{4}$ | 3 |
| $\frac{\pi}{3}$ | $\frac{3\sqrt{3}}{2} \approx 2.6$ |
| $\frac{\pi}{2}$ | 0 |

This gives one petal of the rose, as shown in the following graph.

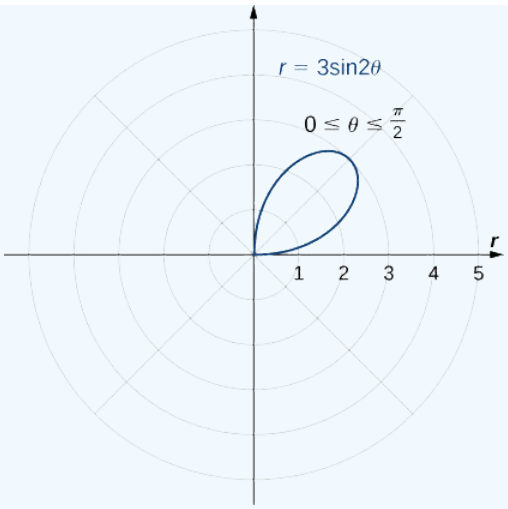

Figure **10.4.11**: The graph of the equation between $\theta = 0$ and $\theta = \pi/2$.

Reflecting this image into the other three quadrants shows the entire graph.

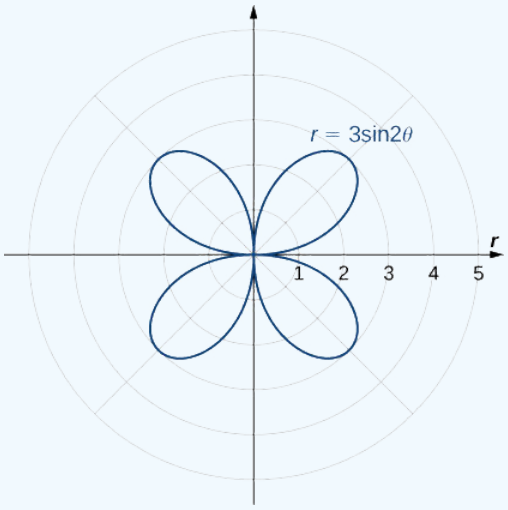

Figure **10.4.12**: The entire graph of the equation is called a four-petaled rose.

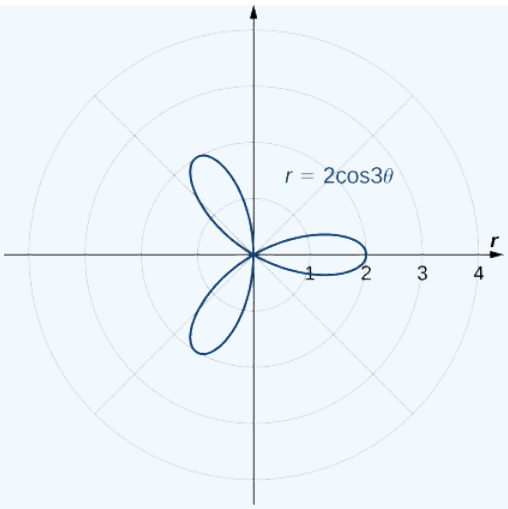
## ? Checkpoint 10.4.6: Symmetry

Determine the symmetry of the graph determined by the equation $r = 2\cos(3\theta)$ and create a graph.

**Answer**

Symmetric with respect to the polar axis.

https://math.libretexts.org/@go/page/175635



## Key Concepts

- The polar coordinate system provides an alternative way to locate points in the plane.
- Convert points between rectangular and polar coordinates using the formulas

$$x = r\cos\theta \text{ and } y = r\sin\theta$$

and

$$r = \sqrt{x^2 + y^2} \text{ and } \tan\theta = \frac{y}{x}.$$

- To sketch a polar curve from a given polar function, make a table of values and take advantage of periodic properties.
- Use the conversion formulas to convert equations between rectangular and polar coordinates.
- Identify symmetry in polar curves, which can occur through the pole, the horizontal axis, or the vertical axis.

## Glossary

**angular coordinate**

$\theta$ the angle formed by a line segment connecting the origin to a point in the polar coordinate system with the positive radial (x) axis, measured counterclockwise

**cardioid**

a plane curve traced by a point on the perimeter of a circle that is rolling around a fixed circle of the same radius; the equation of a cardioid is $r = a(1 + \sin\theta)$ or $r = a(1 + \cos\theta)$

**limaçon**

the graph of the equation $r = a + b\sin\theta$ or $r = a + b\cos\theta$. If $a = b$ then the graph is a cardioid

**polar axis**

the horizontal axis in the polar coordinate system corresponding to $r \geq 0$

**polar coordinate system**

a system for locating points in the plane. The coordinates are $r$, the radial coordinate, and $\theta$, the angular coordinate

**polar equation**

an equation or function relating the radial coordinate to the angular coordinate in the polar coordinate system

**pole**

the central point of the polar coordinate system, equivalent to the origin of a Cartesian system

**radial coordinate**

$r$ the coordinate in the polar coordinate system that measures the distance from a point in the plane to the pole

**rose**

graph of the polar equation $r = a\cos 2\theta$ or $r = a\sin 2\theta$for a positive constant $a$

**space-filling curve**

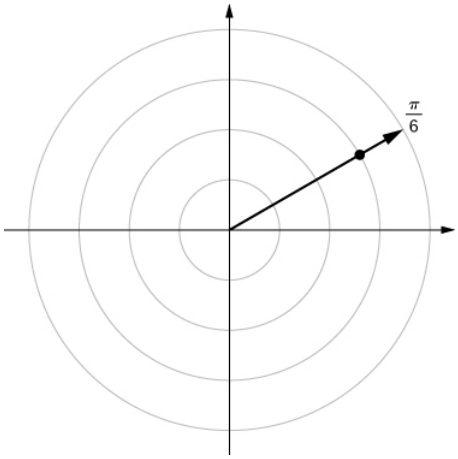
a curve that completely occupies a two-dimensional subset of the real plane

# 10.4E: Exercises

**In exercises 1 - 7, plot the point whose polar coordinates are given by first constructing the angle $\theta$ and then marking off the distance $r$ along the ray.**

1) $(3, \frac{\pi}{6})$

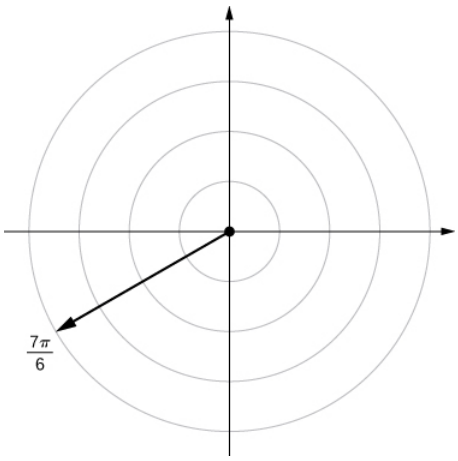
**Answer**



2) $(-2, \frac{5\pi}{3})$

3) $(0, \frac{7\pi}{6})$

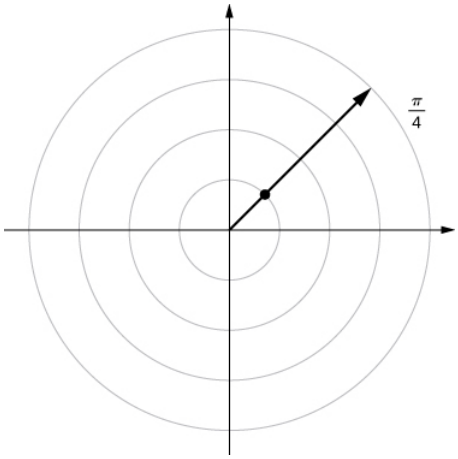
**Answer**



4) $(-4, \frac{3\pi}{4})$

5) $(1, \frac{\pi}{4})$

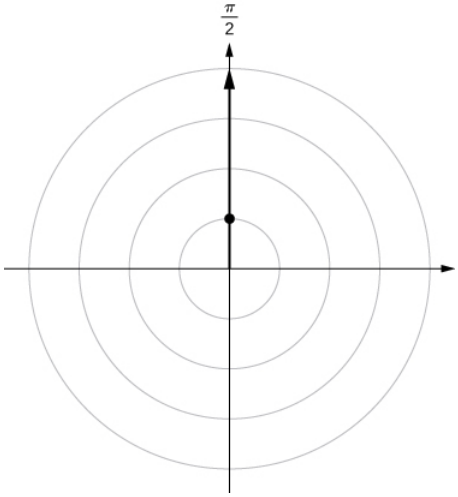
**Answer**



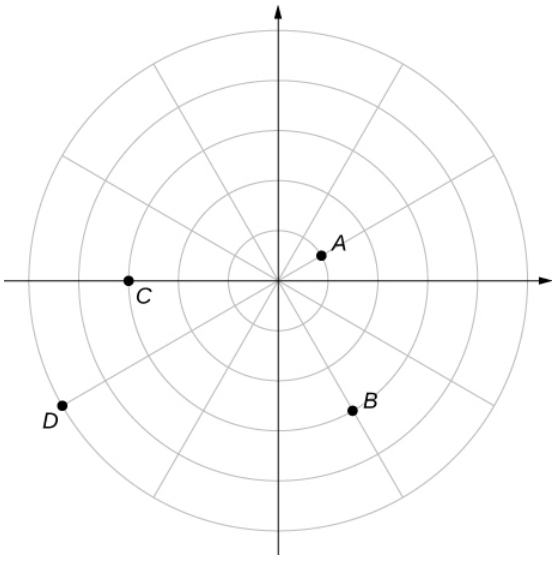
6) $(2, \frac{5\pi}{6})$

7) $(1, \frac{\pi}{2})$

**Answer**



**In exercises 8 - 11, consider the polar graph below. Give two sets of polar coordinates for each point.**



8) Coordinates of point A.

9) Coordinates of point B.

**Answer**

$B\left(3, \frac{-\pi}{3}\right) B\left(-3, \frac{2\pi}{3}\right)$

10) Coordinates of point C.

11) Coordinates of point D.

**Answer**

$D\left(5, \frac{7\pi}{6}\right) D\left(-5, \frac{\pi}{6}\right)$

**In exercises 12 - 17, the rectangular coordinates of a point are given. Find two sets of polar coordinates for the point in $(0, 2\pi]$. Round to three decimal places.**

12) $(2, 2)$

13) $(3, -4)$

**Answer**

$(5, -0.927),\ (-5, -0.927 + \pi)$

14) $(8, 15)$

15) $(-6, 8)$

**Answer**

$(10, -0.927),\ (-10, -0.927 + \pi)$

16) $(4, 3)$

17) $(3, -\sqrt{3})$

**Answer**

$(2\sqrt{3}, -0.524),\ (-2\sqrt{3}, -0.524 + \pi)$

**In exercises 18 - 24, find rectangular coordinates for the given point in polar coordinates.**

18) $\left(2, \frac{5\pi}{4}\right)$

19) $\left(-2, \frac{\pi}{6}\right)$

**Answer**

$(-\sqrt{3}, -1)$

20) $\left(5, \frac{\pi}{3}\right)$

21) $\left(1, \frac{7\pi}{6}\right)$

**Answer**

$\left(-\frac{\sqrt{3}}{2}, \frac{-1}{2}\right)$

22) $\left(-3, \frac{3\pi}{4}\right)$

23) $\left(0, \frac{\pi}{2}\right)$

**Answer**

$(0, 0)$

24) $(-4.5, 6.5)$

**In exercises 25 - 29, determine whether the graphs of the polar equation are symmetric with respect to the $x$-axis, the $y$ -axis, or the origin.**

25) $r = 3\sin(2\theta)$

**Answer**

Symmetry with respect to the *x*-axis, *y*-axis, and origin.

26) $r^2 = 9\cos\theta$

27) $r = \cos\left(\frac{\theta}{5}\right)$

**Answer**

Symmetric with respect to *x*-axis only.

28) $r = 2\sec\theta$

29) $r = 1 + \cos\theta$

**Answer**

Symmetry with respect to *x*-axis only.

**In exercises 30 - 33, describe the graph of each polar equation. Confirm each description by converting into a rectangular equation.**

30) $r = 3$

31) $\theta = \frac{\pi}{4}$

**Answer**

Line $y = x$

32) $r = \sec\theta$

33) $r = \csc\theta$

**Answer**

$y = 1$

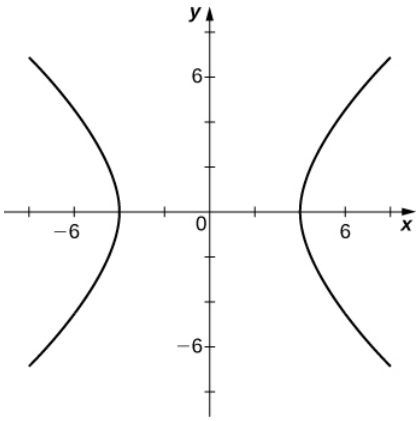
**In exercises 34 - 36, convert the rectangular equation to polar form and sketch its graph.**

34) $x^2 + y^2 = 16$

35) $x^2 - y^2 = 16$

**Answer**

Hyperbola; polar form $r^2\cos(2\theta) = 16$ or $r^2 = 16\sec\theta$.



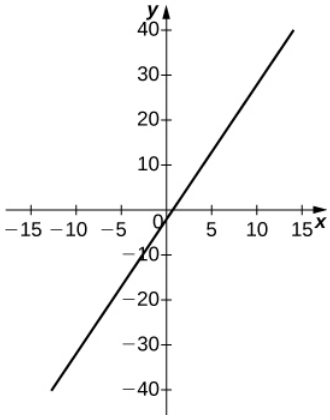
36) $x = 8$

**In exercises 37 - 38, convert the rectangular equation to polar form and sketch its graph.**

37) $3x - y = 2$

**Answer**

$r = \frac{2}{3\cos\theta - \sin\theta}$



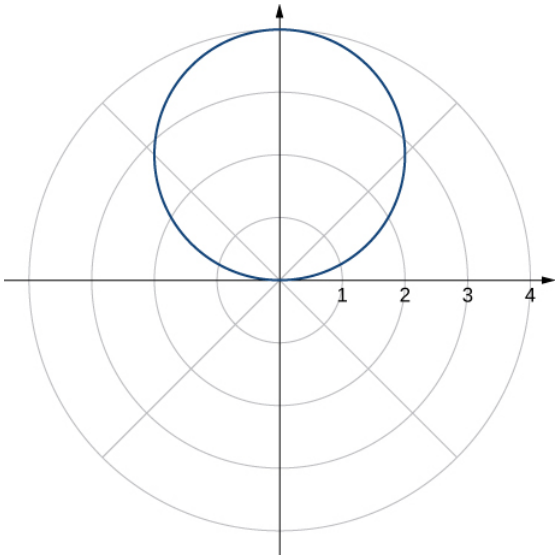
38) $y^2 = 4x$

**In exercises 39 - 43, convert the polar equation to rectangular form and sketch its graph.**

39) $r = 4\sin\theta$

40) $x^2 + y^2 = 4y$

**Answer**

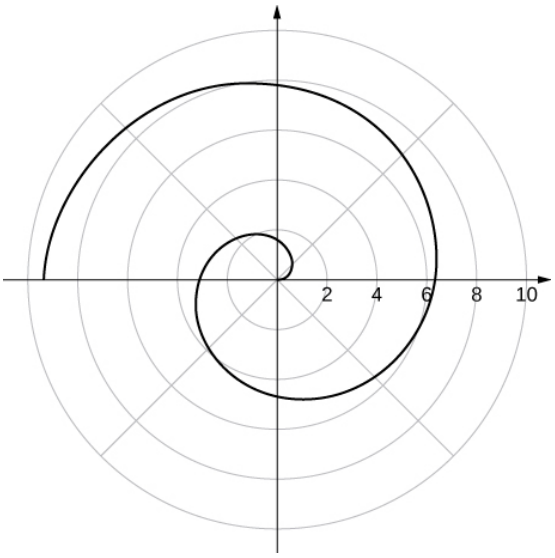


41) $r = 6\cos\theta$

42) $r = \theta$

**Answer**

$x \tan\sqrt{x^2 + y^2} = y$



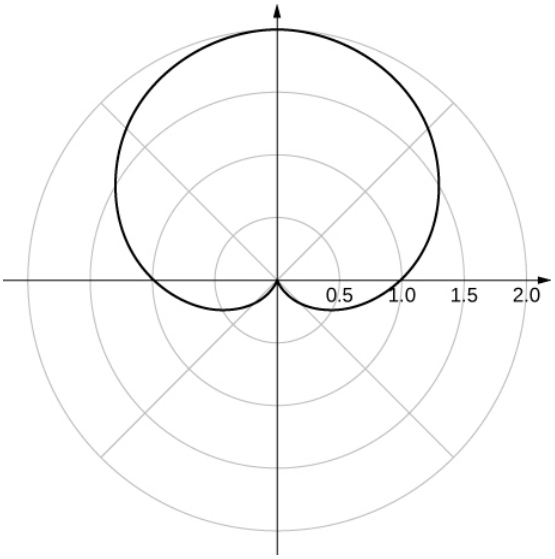
43) $r = \cot\theta \csc\theta$

**In exercises 44 - 54, sketch a graph of the polar equation and identify any symmetry.**

44) $r = 1 + \sin\theta$

**Answer**

$y$-axis symmetry

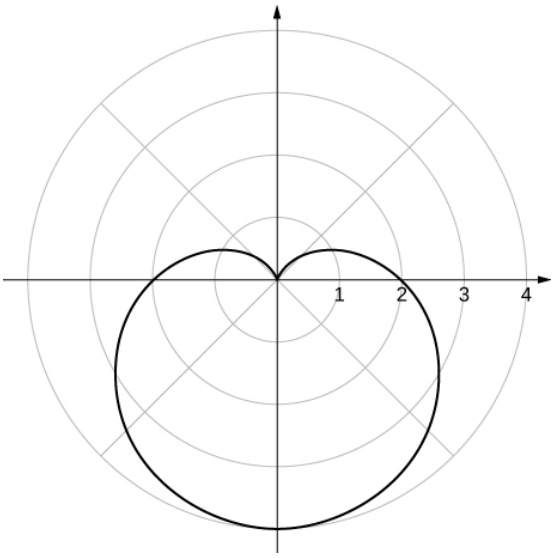


45) $r = 3 - 2\cos\theta$

46) $r = 2 - 2\sin\theta$

**Answer**

$y$-axis symmetry

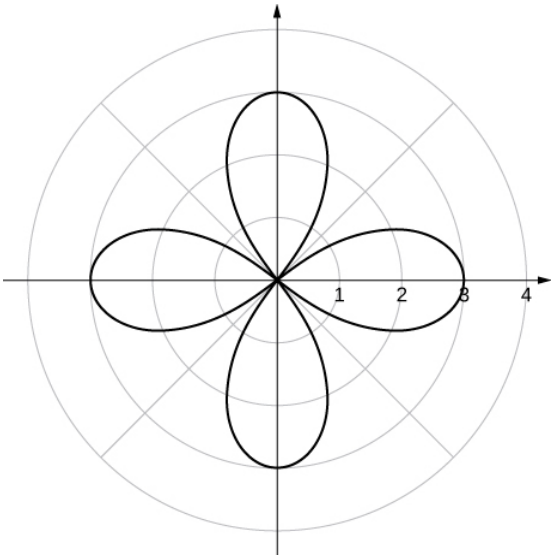


47) $r = 5 - 4\sin\theta$

48) $r = 3\cos(2\theta)$

**Answer**

$x$-and $y$-axis symmetry and symmetry about the pole

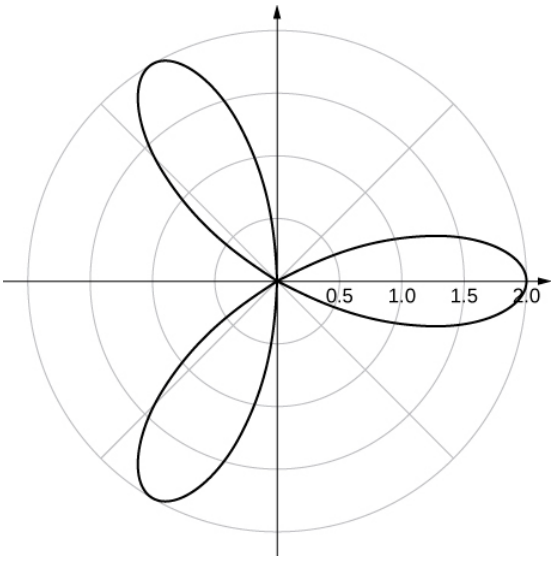


49) $r = 3\sin(2\theta)$

50) $r = 2\cos(3\theta)$

**Answer**

$x$-axis symmetry

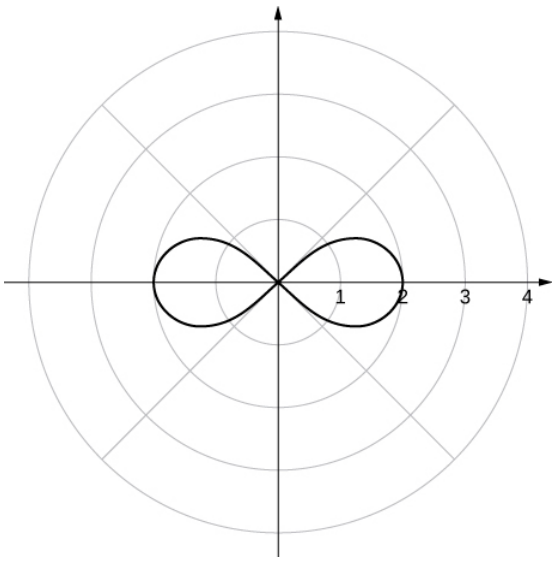


51) $r = 3\cos\left(\frac{\theta}{2}\right)$

52) $r^2 = 4\cos\left(\frac{2}{\theta}\right)$

**Answer**

$x$-and $y$-axis symmetry and symmetry about the pole

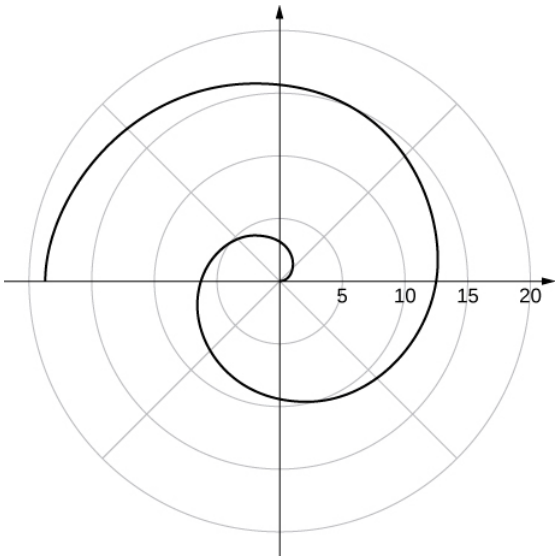


53) $r^2 = 4\sin\theta$

54) $r = 2\theta$

**Answer**

no symmetry

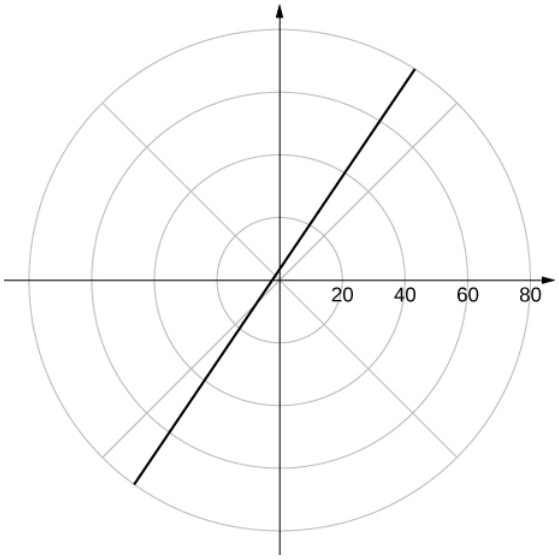


55) [Technology Required] The graph of $r = 2\cos(2\theta)\sec(\theta)$. is called a strophoid. Use a graphing utility to sketch the graph, and, from the graph, determine the asymptote.

56) [Technology Required] Use a graphing utility and sketch the graph of $r = \dfrac{6}{2\sin\theta - 3\cos\theta}$.

**Answer**

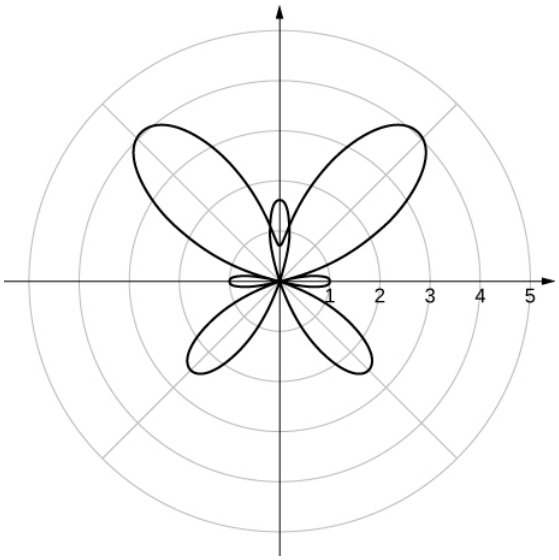
a line



57) [Technology Required] Use a graphing utility to graph $r = \frac{1}{1-\cos\theta}$.

58) [Technology Required] Use technology to graph $r = e^{\sin(\theta)} - 2\cos(4\theta)$.

**Answer**

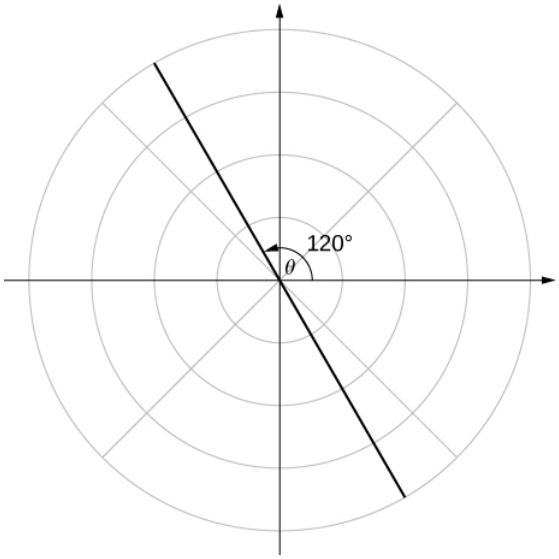


59) [Technology Required] Use technology to plot $r = \sin(\frac{3\theta}{7})$ (use the interval $0 \leq \theta \leq 14\pi$).

60) Without using technology, sketch the polar curve $\theta = \frac{2\pi}{3}$.

**Answer**

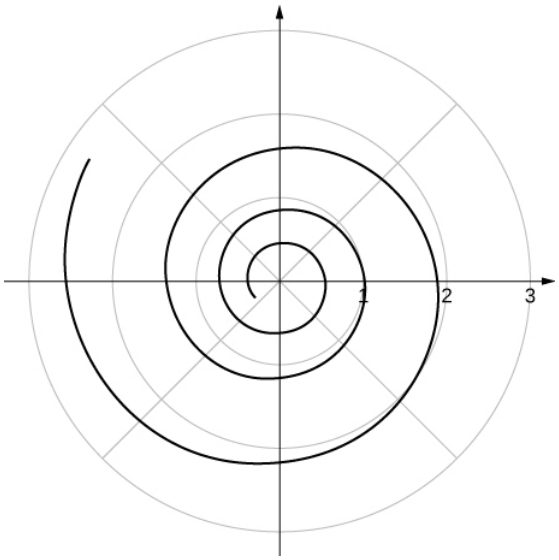
https://math.libretexts.org/@go/page/175636



61) [Technology Required] Use a graphing utility to plot $r = \theta \sin \theta$ for $-\pi \leq \theta \leq \pi$.

62) [Technology Required] Use technology to plot $r = e^{-0.1\theta}$ for $-10 \leq \theta \leq 10$.

**Answer**



63) [Technology Required] There is a curve known as the "Black Hole." Use technology to plot $r = e^{-0.01\theta}$ for $-100 \leq \theta \leq 100$.

64) [Technology Required] Use the results of the preceding two problems to explore the graphs of $r = e^{-0.001\theta}$ and $r = e^{-0.0001\theta}$ for $|\theta| > 100$.

**Answer**

Answers vary. One possibility is the spiral lines become closer together and the total number of spirals increases.

# 10.5: Area and Arc Length in Polar Coordinates

**Learning Objectives**

- Apply the formula for the area of a region in polar coordinates.
- Determine the arc length of a polar curve.

In the rectangular coordinate system, the definite integral provides a way to calculate the area under a curve. In particular, if we have a function $y = f(x)$ defined from $x = a$ to $x = b$ where $f(x) > 0$ on this interval, the area between the curve and the x-axis is given by

$$A = \int_a^b f(x)dx.$$

This fact, along with the formula for evaluating this integral, is summarized in the Fundamental Theorem of Calculus. Similarly, the arc length of this curve is given by

$$L = \int_a^b \sqrt{1 + (f'(x))^2}dx.$$

In this section, we study analogous formulas for area and arc length in the polar coordinate system.

## Areas of Regions Bounded by Polar Curves

We have studied the formulas for the area under a curve defined in rectangular coordinates and parametrically defined curves. Now, we focus on deriving a formula for the area of a region bounded by a polar curve. Recall that the proof of the Fundamental Theorem of Calculus used the concept of a Riemann sum to approximate the area under a curve by using rectangles. For polar curves, we use the Riemann sum again, but sectors of a circle replace the rectangles.

Consider a curve defined by the function $r = f(\theta)$, where $\alpha \leq \theta \leq \beta$. Our first step is to partition the interval $[\alpha, \beta]$ into $n$ equal-width subintervals. The width of each subinterval is given by the formula $\Delta\theta = (\beta - \alpha)/n$, and the $i^{\text{th}}$ partition point $\theta_i$ is given by the formula $\theta_i = \alpha + i\Delta\theta$. Each partition point $\theta = \theta_i$ defines a line with slope $\tan\theta_i$ passing through the pole as shown in the following graph.

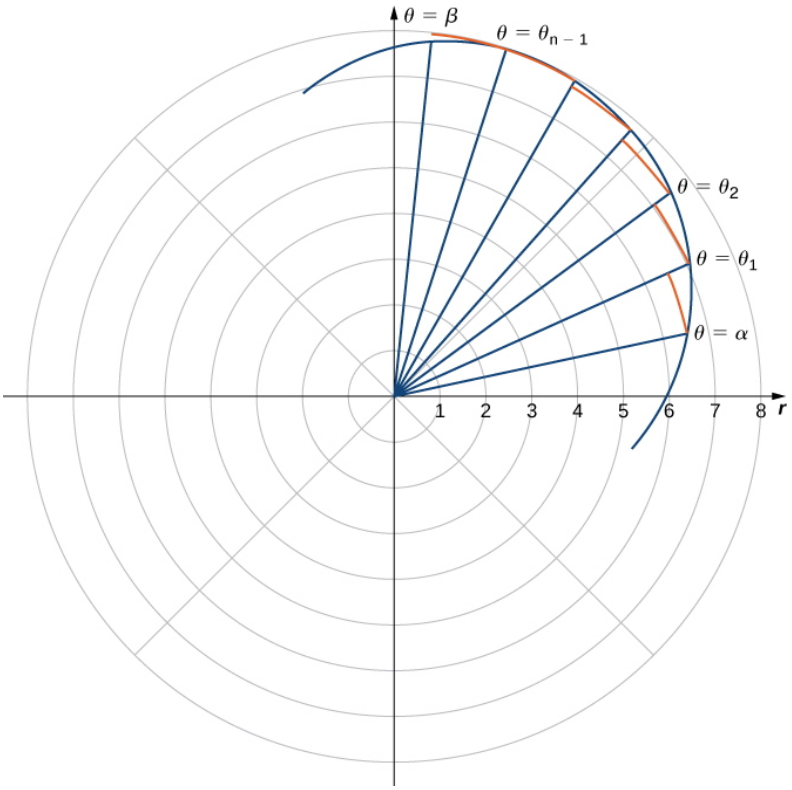

Figure 10.5.1: A partition of a typical curve in polar coordinates.

The line segments are connected by arcs of constant radius. This defines sectors whose areas can be calculated by using a geometric formula. The area of each sector is then used to approximate the area between successive line segments. We then sum the areas of the sectors to approximate the total area. This approach gives a Riemann sum approximation for the total area. The formula for the area of a sector of a circle is illustrated in the following figure.

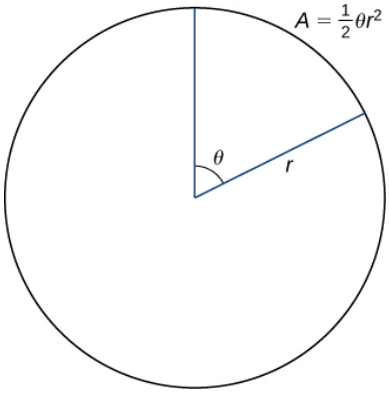

Figure 10.5.2: The area of a sector of a circle is given by $A = \frac{1}{2}\theta r^2$.

Recall that the area of a circle is $A = \pi r^2$. When measuring angles in radians, 360 degrees is equal to $2\pi$ radians. Therefore, a fraction of a circle can be measured by the central angle $\theta$. The fraction of the circle is given by $\frac{\theta}{2\pi}$, so the area of the sector is this fraction multiplied by the total area:

$$A = \left(\frac{\theta}{2\pi}\right)\pi r^2 = \frac{1}{2}\theta r^2.$$

Since the radius of a typical sector in Figure 10.5.1 is given by $r_i = f(\theta_i)$, the area of the $i^{\text{th}}$ sector is given by

$$A_i = \frac{1}{2}(\Delta\theta)(f(\theta_i))^2.$$

Therefore, a Riemann sum that approximates the area is given by

$$A_n = \sum_{i=1}^{n} A_i \approx \sum_{i=1}^{n} \frac{1}{2}(\Delta\theta)(f(\theta_i))^2.$$

We take the limit as $n \to \infty$ to get the exact area:

$$A = \lim_{n\to\infty} A_n = \frac{1}{2}\int_{\alpha}^{\beta} (f(\theta))^2 d\theta.$$

This gives the following theorem.

**Theorem: Area of a Region Bounded by a Polar Curve**

Suppose $f$ is continuous and nonnegative on the interval $\alpha \le \theta \le \beta$ with $0 < \beta - \alpha \le 2\pi$. The area of the region bounded by the graph of $r = f(\theta)$ between the radial lines $\theta = \alpha$ and $\theta = \beta$ is

$$A = \frac{1}{2}\int_{\alpha}^{\beta} [f(\theta)]^2 d\theta \tag{10.5.1}$$

$$= \frac{1}{2}\int_{\alpha}^{\beta} r^2 d\theta. \tag{10.5.2}$$

**Example 10.5.1: Finding an Area of a Polar Region**

Find the area of one petal of the rose defined by the equation $r = 3\sin(2\theta)$.

**Solution**

The graph of $r = 3\sin(2\theta)$ follows.

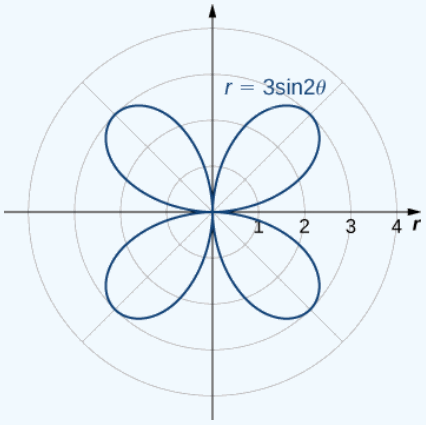

Figure 10.5.3: The graph of $r = 3\sin(2\theta)$.

When $\theta = 0$ we have $r = 3\sin(2(0)) = 0$. The next value for which $r = 0$ is $\theta = \pi/2$. This can be seen by solving the equation $3\sin(2\theta) = 0$ for $\theta$. Therefore the values $\theta = 0$ to $\theta = \pi/2$ trace out the first petal of the rose. To find the area inside this petal, use Equation 10.5.2 with $f(\theta) = 3\sin(2\theta), \alpha = 0$, and $\beta = \pi/2$:

$$\begin{aligned} A &= \frac{1}{2}\int_{\alpha}^{\beta} [f(\theta)]^2\, d\theta \\ &= \frac{1}{2}\int_{0}^{\pi/2} [3\sin(2\theta)]^2\, d\theta \\ &= \frac{1}{2}\int_{0}^{\pi/2} 9\sin^2(2\theta)\, d\theta. \end{aligned}$$

To evaluate this integral, use the formula $\sin^2\alpha = (1 - \cos(2\alpha))/2$ with $\alpha = 2\theta$:

$$\begin{aligned} A &= \frac{1}{2}\int_0^{\pi/2} 9\sin^2(2\theta)\,d\theta \\ &= \frac{9}{2}\int_0^{\pi/2} \frac{(1-\cos(4\theta))}{2}\,d\theta \\ &= \frac{9}{4}\left(\int_0^{\pi/2} 1-\cos(4\theta)\,d\theta\right) \\ &= \frac{9}{4}\left(\theta - \frac{\sin(4\theta)}{4}\right|_0^{\pi/2} \\ &= \frac{9}{4}\left(\frac{\pi}{2} - \frac{\sin 2\pi}{4}\right) - \frac{9}{4}\left(0 - \frac{\sin 4(0)}{4}\right) \\ &= \frac{9\pi}{8} \end{aligned}$$

**? Checkpoint 10.5.1**

Find the area inside the cardioid defined by the equation $r = 1-\cos\theta$.

**Answer**

$A = 3\pi/2$

Example 10.5.1 involved finding the area inside one curve. We can also use Equation 10.5.2 to find the area between two polar curves. However, we often need to find the points of intersection of the curves and determine which function defines the outer or inner curves between these two points.

**✓ Example 10.5.2: Finding the Area between Two Polar Curves**

Find the area outside the cardioid $r = 2+2\sin\theta$ and inside the circle $r = 6\sin\theta$.

**Solution**

First, draw a graph containing both curves as shown.

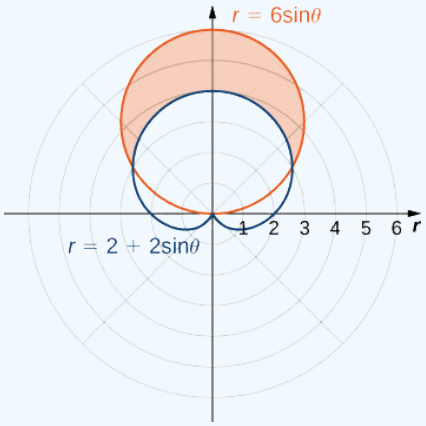

Figure 10.5.4: The region between the curves $r = 2+2\sin\theta$ and $r = 6\sin\theta$.

To determine the limits of integration, first find the points of intersection by setting the two functions equal to each other and solving for $\theta$:

$$\begin{aligned} 6\sin\theta &= 2+2\sin\theta \\ \Rightarrow\quad 4\sin\theta &= 2 \\ \Rightarrow\quad \sin\theta &= \frac{1}{2} \end{aligned}$$

This gives the solutions $\theta = \frac{\pi}{6}$ and $\theta = \frac{5\pi}{6}$, which are the limits of integration. The circle $r = 3\sin\theta$ is the red graph, which is the outer function, and the cardioid $r = 2 + 2\sin\theta$ is the blue graph, which is the inner function. To calculate the area between the curves, start with the area inside the circle between $\theta = \frac{\pi}{6}$ and $\theta = \frac{5\pi}{6}$, then subtract the area inside the cardioid between $\theta = \frac{\pi}{6}$ and $\theta = \frac{5\pi}{6}$:

$$\begin{aligned} A &= \text{circle} - \text{cardioid} \\ &= \frac{1}{2}\int_{\pi/6}^{5\pi/6} [6\sin\theta]^2\, d\theta - \frac{1}{2}\int_{\pi/6}^{5\pi/6} [2+2\sin\theta]^2\, d\theta \\ &= \frac{1}{2}\int_{\pi/6}^{5\pi/6} 36\sin^2\theta\, d\theta - \frac{1}{2}\int_{\pi/6}^{5\pi/6} 4 + 8\sin\theta + 4\sin^2\theta\, d\theta \\ &= 18\int_{\pi/6}^{5\pi/6} \frac{1-\cos(2\theta)}{2}\, d\theta - 2\int_{\pi/6}^{5\pi/6} 1 + 2\sin\theta + \frac{1-\cos(2\theta)}{2}\, d\theta \\ &= 9\left[\theta - \frac{\sin(2\theta)}{2}\right]_{\pi/6}^{5\pi/6} - 2\left[\frac{3\theta}{2} - 2\cos\theta - \frac{\sin(2\theta)}{4}\right]_{\pi/6}^{5\pi/6} \\ &= 9\left(\frac{5\pi}{6} - \frac{\sin(10\pi/6)}{2}\right) - 9\left(\frac{\pi}{6} - \frac{\sin(2\pi/6)}{2}\right) - \left(3\left(\frac{5\pi}{6}\right) - 4\cos\frac{5\pi}{6} - \frac{\sin(10\pi/6)}{2}\right) + \left(3\left(\frac{\pi}{6}\right) - 4\cos\frac{\pi}{6} - \frac{\sin(2\pi/6)}{2}\right) \\ &= 4\pi \end{aligned}$$

**? Checkpoint 10.5.2**

Find the area inside the circle $r = 4\cos\theta$ and outside the circle $r = 2$.

**Answer**

$A = \frac{4\pi}{3} + 2\sqrt{3}$

In Example **10.5.2**, we found the area inside the circle and outside the cardioid by first finding their intersection points. Notice that solving the equation directly for $\theta$ yielded two solutions: $\theta = \frac{\pi}{6}$ and $\theta = \frac{5\pi}{6}$. However, in the graph, there are three intersection points. The third intersection point is the origin. This point did not appear as a solution because the origin is on both graphs but for different values of $\theta$. For example, for the cardioid we get

$$\begin{aligned} 2 + 2\sin\theta &= 0 \\ \Rightarrow \quad \sin\theta &= -1, \end{aligned}$$

so the values for $\theta$ that solve this equation are $\theta = \frac{3\pi}{2} + 2n\pi$, where $n$ is any integer. For the circle, we get

$$6\sin\theta = 0.$$

The solutions to this equation are of the form $\theta = n\pi$ for any integer value of $n$. These two solution sets have no points in common. Regardless of this fact, the curves intersect at the origin. This case must always be taken into consideration.

## Arc Length in Polar Curves

Here, we derive a formula for the arc length of a curve defined in polar coordinates. In rectangular coordinates, the arc length of a parameterized curve $(x(t), y(t))$ for $a \le t \le b$ is given by

$$L = \int_a^b \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2}\, dt.$$

In polar coordinates, we define the curve by the equation $r = f(\theta)$, where $\alpha \le \theta \le \beta$. To adapt the arc length formula for a polar curve, we use the equations

$$x = r\cos\theta = f(\theta)\cos\theta$$

and

$$y = r\sin\theta = f(\theta)\sin\theta,$$

and we replace the parameter $t$ by $\theta$. Then

$$\frac{dx}{d\theta} = f'(\theta)\cos\theta - f(\theta)\sin\theta$$

$$\frac{dy}{d\theta} = f'(\theta)\sin\theta + f(\theta)\cos\theta.$$

We replace $dt$ by $d\theta$, and the lower and upper limits of integration are $\alpha$ and $\beta$, respectively. Then the arc length formula becomes

$$\begin{aligned} L &= \int_a^b \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2}\, dt \\ &= \int_\alpha^\beta \sqrt{\left(\frac{dx}{d\theta}\right)^2 + \left(\frac{dy}{d\theta}\right)^2}\, d\theta \\ &= \int_\alpha^\beta \sqrt{(f'(\theta)\cos\theta - f(\theta)\sin\theta)^2 + (f'(\theta)\sin\theta + f(\theta)\cos\theta)^2}\, d\theta \\ &= \int_\alpha^\beta \sqrt{(f'(\theta))^2(\cos^2\theta + \sin^2\theta) + (f(\theta))^2(\cos^2\theta + \sin^2\theta)}\, d\theta \\ &= \int_\alpha^\beta \sqrt{(f'(\theta))^2 + (f(\theta))^2}\, d\theta \\ &= \int_\alpha^\beta \sqrt{r^2 + \left(\frac{dr}{d\theta}\right)^2}\, d\theta \end{aligned}$$

This gives us the following theorem.

**Theorem: Arc Length of a Curve Defined by a Polar Function**

Let $f$ be a function whose derivative is continuous on an interval $\alpha \le \theta \le \beta$. The length of the graph of $r = f(\theta)$ from $\theta = \alpha$ to $\theta = \beta$ is

$$L = \int_\alpha^\beta \sqrt{[f(\theta)]^2 + [f'(\theta)]^2}\, d\theta \tag{10.5.3}$$

$$= \int_\alpha^\beta \sqrt{r^2 + \left(\frac{dr}{d\theta}\right)^2}\, d\theta. \tag{10.5.4}$$

**Example 10.5.3: Finding the Arc Length of a cardioid**

Find the arc length of the cardioid $r = 2 + 2\cos\theta$.

**Solution**

When $\theta = 0, r = 2 + 2\cos 0 = 4$. Furthermore, as $\theta$ goes from $0$ to $2\pi$, the cardioid is traced out exactly once. Therefore, these are the limits of integration. Using $f(\theta) = 2 + 2\cos\theta, \alpha = 0$, and $\beta = 2\pi$, Equation 10.5.3 becomes

$$\begin{aligned} L &= \int_{\alpha}^{\beta} \sqrt{[f(\theta)]^2 + [f'(\theta)]^2}\, d\theta \\ &= \int_0^{2\pi} \sqrt{[2+2\cos\theta]^2 + [-2\sin\theta]^2}\, d\theta \\ &= \int_0^{2\pi} \sqrt{4 + 8\cos\theta + 4\cos^2\theta + 4\sin^2\theta}\, d\theta \\ &= \int_0^{2\pi} \sqrt{4 + 8\cos\theta + 4(\cos^2\theta + \sin^2\theta)}\, d\theta \\ &= \int_0^{2\pi} \sqrt{8 + 8\cos\theta}\, d\theta \\ &= 2\int_0^{2\pi} \sqrt{2 + 2\cos\theta}\, d\theta. \end{aligned}$$

Next, using the identity $\cos(2\alpha) = 2\cos^2\alpha - 1$, add $1$ to both sides and multiply by $2$. This gives $2 + 2\cos(2\alpha) = 4\cos^2\alpha$. Substituting $\alpha = \theta/2$ gives $2 + 2\cos\theta = 4\cos^2(\theta/2)$, so the integral becomes

$$\begin{aligned} L &= 2\int_0^{2\pi} \sqrt{2 + 2\cos\theta}\, d\theta \\ &= 2\int_0^{2\pi} \sqrt{4\cos^2(\frac{\theta}{2})}\, d\theta \\ &= 4\int_0^{2\pi} \left|\cos(\frac{\theta}{2})\right|\, d\theta. \end{aligned}$$

The absolute value is necessary because the cosine is negative for some values in its domain. To resolve this issue, change the limits from $0$ to $\pi$ and double the answer. This strategy works because cosine is positive between $0$ and $\frac{\pi}{2}$. Thus,

$$\begin{aligned} L &= 4\int_0^{2\pi} \left|\cos(\frac{\theta}{2})\right|\, d\theta \\ &= 8\int_0^{\pi} \cos\left(\frac{\theta}{2}\right)\, d\theta \\ &= 8\left(2\sin\left(\frac{\theta}{2}\right)\right|_0^{\pi} \\ &= 16 \end{aligned}$$

**? Checkpoint 10.5.3**

Find the total arc length of $r = 3\sin\theta$.

**Answer**

$s = 3\pi$

## Key Concepts

- The area of a region in polar coordinates defined by the equation $r = f(\theta)$ with $\alpha \le \theta \le \beta$ is given by the integral $A = \frac{1}{2}\int_{\alpha}^{\beta} [f(\theta)]^2 d\theta$.
- To find the area between two curves in the polar coordinate system, first find the points of intersection, then subtract the corresponding areas.
- The arc length of a polar curve defined by the equation $r = f(\theta)$ with $\alpha \le \theta \le \beta$ is given by the integral $L = \int_{\alpha}^{\beta} \sqrt{[f(\theta)]^2 + [f'(\theta)]^2} d\theta$ $= \int_{\alpha}^{\beta} \sqrt{r^2 + (\frac{dr}{d\theta})^2} d\theta$.

## Key Equations

- **Area of a region bounded by a polar curve**

$$A = \frac{1}{2}\int_{\alpha}^{\beta}[f(\theta)]^2 d\theta = \frac{1}{2}\int_{\alpha}^{\beta} r^2 d\theta$$

- **Arc length of a polar curve**

$$L = \int_{\alpha}^{\beta}\sqrt{[f(\theta)]^2 + [f'(\theta)]^2}d\theta = \int_{\alpha}^{\beta}\sqrt{r^2 + (\frac{dr}{d\theta})^2}d\theta$$

# 10.5E: Exercises

**In exercises 1 -13, determine a definite integral that represents the area.**

1) Region enclosed by $r = 4$

2) Region enclosed by $r = 3\sin\theta$

**Answer**

$$\frac{9}{2}\int_0^{\pi} \sin^2\theta\, d\theta$$

3) Region in the first quadrant within the cardioid $r = 1 + \sin\theta$

4) Region enclosed by one petal of $r = 8\sin(2\theta)$

**Answer**

$$\frac{3}{2}\int_0^{\pi/2} \sin^2(2\theta)\, d\theta$$

5) Region enclosed by one petal of $r = cos(3\theta)$

6) Region below the polar axis and enclosed by $r = 1 - \sin\theta$

**Answer**

$$\frac{1}{2}\int_{\pi}^{2\pi} (1 - \sin\theta)^2\, d\theta$$

7) Region in the first quadrant enclosed by $r = 2 - \cos\theta$

8) Region enclosed by the inner loop of $r = 2 - 3\sin\theta$

**Answer**

$$\int_{\sin^{-1}(2/3)}^{\pi/2} (2 - 3\sin\theta)^2\, d\theta$$

9) Region enclosed by the inner loop of $r = 3 - 4\cos\theta$

10) Region enclosed by $r = 1 - 2\cos\theta$ and outside the inner loop

**Answer**

$$\int_0^{\pi} (1 - 2\cos\theta)^2\, d\theta - \int_0^{\pi/3} (1 - 2\cos\theta)^2\, d\theta$$

11) Region common to $r = 3\sin\theta$ and $r = 2 - \sin\theta$

12) Region common to $r = 2$ and $r = 4\cos\theta$

**Answer**

$$4\int_0^{\pi/3} d\theta + 16\int_{\pi/3}^{\pi/2} (\cos^2\theta)\, d\theta$$

13) Region common to $r = 3\cos\theta$ and $r = 3\sin\theta$

**In exercises 14 -26, find the area of the described region.**

14) Enclosed by $r = 6\sin\theta$

**Answer**

$9\pi$ units$^2$

15) Above the polar axis enclosed by $r = 2 + \sin\theta$

16) Below the polar axis and enclosed by $r = 2 - \cos\theta$

**Answer**

$\frac{9\pi}{4}$ units$^2$

17) Enclosed by one petal of $r = 4\cos(3\theta)$

18) Enclosed by one petal of $r = 3\cos(2\theta)$

**Answer**

$\frac{9\pi}{8}$ units$^2$

19) Enclosed by $r = 1 + \sin\theta$

20) Enclosed by the inner loop of $r = 3 + 6\cos\theta$

**Answer**

$\frac{18\pi - 27\sqrt{3}}{2}$ units$^2$

21) Enclosed by $r = 2 + 4\cos\theta$ and outside the inner loop

22) Common interior of $r = 4\sin(2\theta)$ and $r = 2$

**Answer**

$\frac{4}{3}(4\pi - 3\sqrt{3})$ units$^2$

23) Common interior of $r = 3 - 2\sin\theta$ and $r = -3 + 2\sin\theta$

24) Common interior of $r = 6\sin\theta$ and $r = 3$

**Answer**

$\frac{3}{2}(4\pi - 3\sqrt{3})$ units$^2$

25) Inside $r = 1 + \cos\theta$ and outside $r = \cos\theta$

26) Common interior of $r = 2 + 2\cos\theta$ and $r = 2\sin\theta$

**Answer**

$(2\pi - 4)$ units$^2$

**In exercises 27 - 30, find a definite integral that represents the arc length.**

27) $r = 4\cos\theta$ on the interval $0 \le \theta \le \frac{\pi}{2}$

28) $r = 1 + \sin\theta$ on the interval $0 \le \theta \le 2\pi$

**Answer**

$$\int_0^{2\pi} \sqrt{(1+\sin\theta)^2 + \cos^2\theta}\, d\theta$$

29) $r = 2\sec\theta$ on the interval $0 \le \theta \le \frac{\pi}{3}$

30) $r = e^\theta$ on the interval $0 \le \theta \le 1$

**Answer**

$$\sqrt{2}\int_0^1 e^\theta\, d\theta$$

**In exercises 31 - 35, find the length of the curve over the given interval.**

31) $r = 6$ on the interval $0 \le \theta \le \frac{\pi}{2}$

32) $r = e^{3\theta}$ on the interval $0 \le \theta \le 2$

**Answer**

$\frac{\sqrt{10}}{3}(e^6 - 1)$ units

33) $r = 6\cos\theta$ on the interval $0 \le \theta \le \frac{\pi}{2}$

34) $r = 8 + 8\cos\theta$ on the interval $0 \le \theta \le \pi$

**Answer**

32 units

35) $r = 1 - \sin\theta$ on the interval $0 \le \theta \le 2\pi$

**In exercises 36 - 40, use the integration capabilities of a calculator to approximate the length of the curve.**

36) [Technology Required] $r = 3\theta$ on the interval $0 \le \theta \le \frac{\pi}{2}$

**Answer**

6.238 units

37) [Technology Required] $r = \dfrac{2}{\theta}$ on the interval $\pi \le \theta \le 2\pi$

38) [Technology Required] $r = \sin^2\left(\frac{\theta}{2}\right)$ on the interval $0 \le \theta \le \pi$

**Answer**

2 units

39) [Technology Required] $r = 2\theta^2$ on the interval $0 \le \theta \le \pi$

40) [Technology Required] $r = \sin(3\cos\theta)$ on the interval $0 \le \theta \le \pi$

**Answer**

4.39 units

**In exercises 41 - 43, use the familiar formula from geometry to find the area of the region described and then confirm by using the definite integral.**

41) $r = 3\sin\theta$ on the interval $0 \le \theta \le \pi$

42) $r = \sin\theta + \cos\theta$ on the interval $0 \le \theta \le \pi$

**Answer**

$A = \pi\left(\frac{\sqrt{2}}{2}\right)^2 = \frac{\pi}{2}$ units$^2$ and $\frac{1}{2}\int_0^{\pi}(1 + 2\sin\theta\cos\theta)\,d\theta = \frac{\pi}{2}$ units$^2$

43) $r = 6\sin\theta + 8\cos\theta$ on the interval $0 \le \theta \le \pi$

**In exercises 44 - 46, use the familiar formula from geometry to find the length of the curve and then confirm using the definite integral.**

44) $r = 3\sin\theta$ on the interval $0 \le \theta \le \pi$

**Answer**

$C = 2\pi\left(\frac{3}{2}\right) = 3\pi$ units and $\int_0^{\pi} 3\,d\theta = 3\pi$ units

45) $r = \sin\theta + \cos\theta$ on the interval $0 \le \theta \le \pi$

46) $r = 6\sin\theta + 8\cos\theta$ on the interval $0 \le \theta \le \pi$

**Answer**

$C = 2\pi(5) = 10\pi$ units and $\int_0^{\pi} 10\,d\theta = 10\pi$ units

47) Verify that if $y = r\sin\theta = f(\theta)\sin\theta$ then $\frac{dy}{d\theta} = f'(\theta)\sin\theta + f(\theta)\cos\theta$.

**In exercises 48 - 56, find the slope of a tangent line to a polar curve $r = f(\theta)$. Let $x = r\cos\theta = f(\theta)\cos\theta$ and $y = r\sin\theta = f(\theta)\sin\theta$, so the polar equation $r = f(\theta)$ is now written in parametric form.**

48) Use the definition of the derivative $\frac{dy}{dx} = \frac{dy/d\theta}{dx/d\theta}$ and the Product Rule to derive the derivative of a polar equation.

**Answer**

$$\frac{dy}{dx} = \frac{f'(\theta)\sin\theta + f(\theta)\cos\theta}{f'(\theta)\cos\theta - f(\theta)\sin\theta}$$

49) $r = 1 - \sin\theta;\ \left(\frac{1}{2}, \frac{\pi}{6}\right)$

50) $r = 4\cos\theta;\ \left(2, \frac{\pi}{3}\right)$

**Answer**

The slope is $\frac{1}{\sqrt{3}}$.

51) $r = 8\sin\theta;\ \left(4, \frac{5\pi}{6}\right)$

52) $r = 4 + \sin\theta;\ \left(3, \frac{3\pi}{2}\right)$

**Answer**

The slope is 0.

53) $r = 6 + 3\cos\theta;\ (3, \pi)$

54) $r = 4\cos(2\theta)$; tips of the leaves

**Answer**

At $(4, 0)$, the slope is undefined. At $\left(-4, \frac{\pi}{2}\right)$, the slope is 0.

55) $r = 2\sin(3\theta)$; tips of the leaves

56) $r = 2\theta;\ \left(\frac{\pi}{2}, \frac{\pi}{4}\right)$

**Answer**

The slope is undefined at $\theta = \frac{\pi}{4}$.

57) Find the points on the interval $-\pi \le \theta \le \pi$ at which the cardioid $r = 1 - \cos\theta$ has a vertical or horizontal tangent line.

58) For the cardioid $r = 1 + \sin\theta$, find the slope of the tangent line when $\theta = \frac{\pi}{3}$.

**Answer**

Slope = −1.

**In exercises 59 - 62, find the slope of the tangent line to the given polar curve at the point given by the value of $\theta$.**

59) $r = 3\cos\theta,\ \theta = \frac{\pi}{3}$

60) $r = \theta,\ \theta = \frac{\pi}{2}$

**Answer**

Slope is $\frac{-2}{\pi}$.

61) $r = \ln\theta,\ \theta = e$

62) [Technology Required] Use technology: $r = 2 + 4\cos\theta$ at $\theta = \frac{\pi}{6}$

**Answer**

Calculator answer: $-0.836$.

**In exercises 63 - 66, find the points at which the following polar curves have a horizontal or vertical tangent line.**

63) $r = 4\cos\theta$

64) $r^2 = 4\cos(2\theta)$

**Answer**

Horizontal tangent at $\left(\pm\sqrt{2}, \frac{\pi}{6}\right)$, $\left(\pm\sqrt{2}, -\frac{\pi}{6}\right)$.

65) $r = 2\sin(2\theta)$

66) The cardioid $r = 1 + \sin\theta$

**Answer**

Horizontal tangents at $\frac{\pi}{2}$, $\frac{7\pi}{6}$, $\frac{11\pi}{6}$.
Vertical tangents at $\frac{\pi}{6}$, $\frac{5\pi}{6}$ and also at the pole $(0, 0)$.

67) Show that the curve $r = \sin\theta\tan\theta$ (called a **cissoid of Diocles**) has the line $x = 1$ as a vertical asymptote.

# 10.6: Conic Sections

**Learning Objectives**

- Identify the equation of a parabola in standard form with given focus and directrix.
- Identify the equation of an ellipse in standard form with given foci.
- Identify the equation of a hyperbola in standard form with given foci.
- Recognize a parabola, ellipse, or hyperbola from its eccentricity value.
- Write the polar equation of a conic section with eccentricity $e$.
- Identify when a general equation of degree two is a parabola, ellipse, or hyperbola.

Conic sections have been studied since the time of the ancient Greeks, and were considered to be an important mathematical concept. As early as 320 BCE, such Greek mathematicians as Menaechmus, Appollonius, and Archimedes were fascinated by these curves. Appollonius wrote an entire eight-volume treatise on conic sections in which he was, for example, able to derive a specific method for identifying a conic section through the use of geometry. Since then, important applications of conic sections have arisen (for example, in astronomy), and the properties of conic sections are used in radio telescopes, satellite dish receivers, and even architecture. In this section we discuss the three basic conic sections, some of their properties, and their equations.

Conic sections get their name because they can be generated by intersecting a plane with a cone. A cone has two identically shaped parts called **nappes.** One nappe is what most people mean by "cone," having the shape of a party hat. A right circular cone can be generated by revolving a line passing through the origin around the $y$-axis as shown in Figure **10.6.1**.

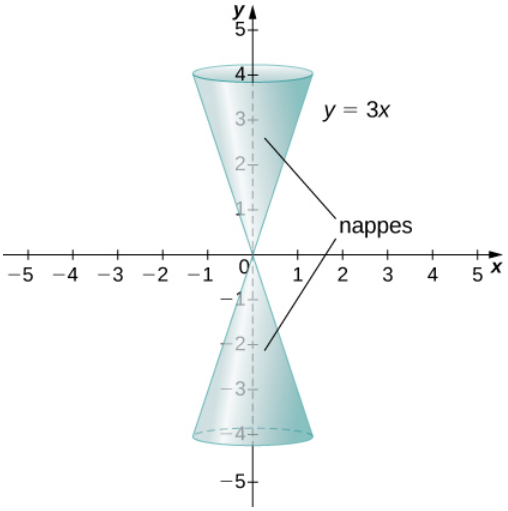

Figure **10.6.1**: A cone generated by revolving the line $y = 3x$ around the $y$-axis.

Conic sections are generated by the intersection of a plane with a cone (Figure **10.6.2**). If the plane is parallel to the axis of revolution (the $y$-axis), then the **conic section** is a hyperbola. If the plane is parallel to the generating line, the conic section is a parabola. If the plane is perpendicular to the axis of revolution, the conic section is a circle. If the plane intersects one nappe at an angle to the axis (other than **90^{\circ}** ), then the conic section is an ellipse.

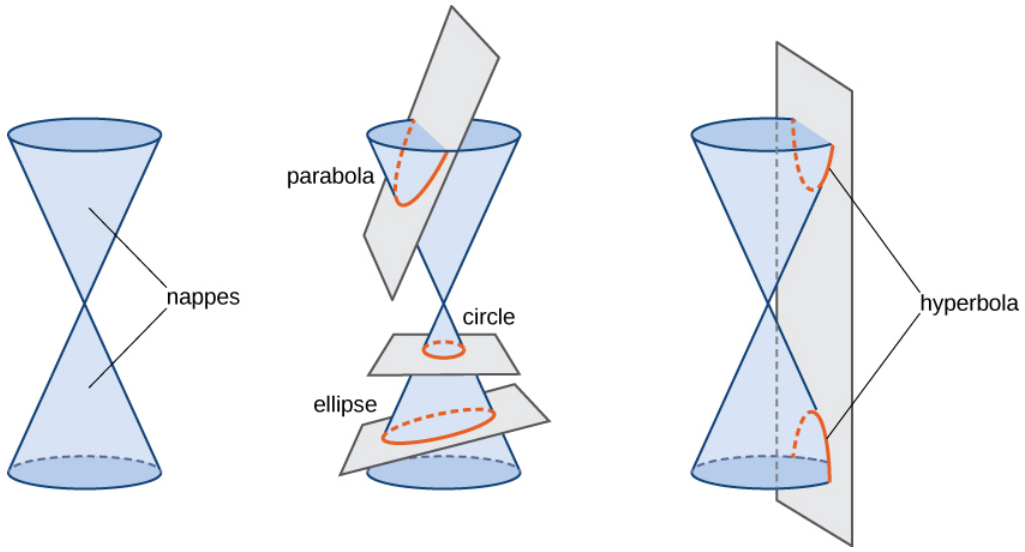

Figure **10.6.2**: The four conic sections. Each conic is determined by the angle the plane makes with the axis of the cone.

## Parabolas

A parabola is generated when a plane intersects a cone parallel to the generating line. In this case, the plane intersects only one of the nappes. A parabola can also be defined in terms of distances.

**Definitions: The Focus, Directrix and Vertex**

A parabola is the set of all points whose distance from a fixed point, called the *focus*, is equal to the distance from a fixed line, called the *directrix*. The point halfway between the focus and the directrix is called the *vertex* of the parabola.

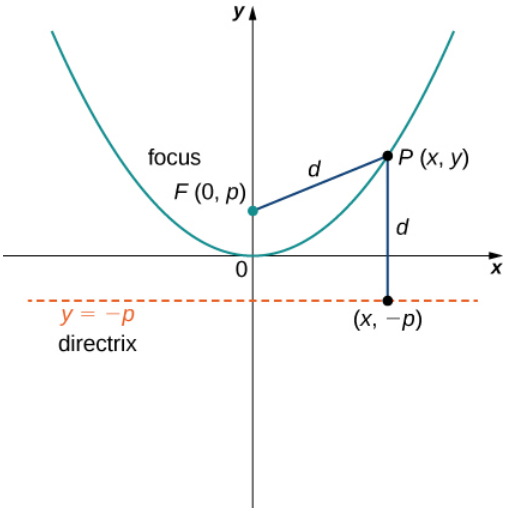

Figure **10.6.3**: A typical parabola in which the distance from the focus to the vertex is represented by the variable $p$.

A graph of a typical parabola appears in Figure **10.6.3**. Using this diagram in conjunction with the distance formula, we can derive an equation for a parabola. Recall the distance formula: Given point P with coordinates $(x_1, y_1)$ and point $Q$ with coordinates $(x_2, y_2)$, the distance between them is given by the formula

$$d(P,Q) = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}.$$

Then from the definition of a parabola and Figure **10.6.3**, we get

$$d(F,P) = d(P,Q)$$

$$\sqrt{(0-x)^2+(p-y)^2}=\sqrt{(x-x)^2+(-p-y)^2}.$$

Squaring both sides and simplifying yields

$$x^2+(p-y)^2=0^2+(-p-y)^2 \tag{10.6.1}$$
$$x^2+p^2-2py+y^2=p^2+2py+y^2 \tag{10.6.2}$$
$$x^2-2py=2py \tag{10.6.3}$$
$$x^2=4py. \tag{10.6.4}$$

Now suppose we want to relocate the vertex. We use the variables $(h,k)$ to denote the coordinates of the vertex. Then if the focus is directly above the vertex, it has coordinates $(h,k+p)$ and the directrix has the equation $y=k-p$. Going through the same derivation yields the formula $(x-h)^2=4p(y-k)$. Solving this equation for $y$ leads to the following theorem.

### Equations for Parabolas: standard form

Given a parabola opening upward with vertex located at $(h,k)$ and focus located at $(h,k+p)$, where $p$ is a constant, the equation for the parabola is given by

$$y=\frac{1}{4p}(x-h)^2+k.$$

This is the *standard form* of a parabola.

We can also study the cases when the parabola opens down or to the left or the right. The equation for each of these cases can also be written in standard form as shown in the following graphs.

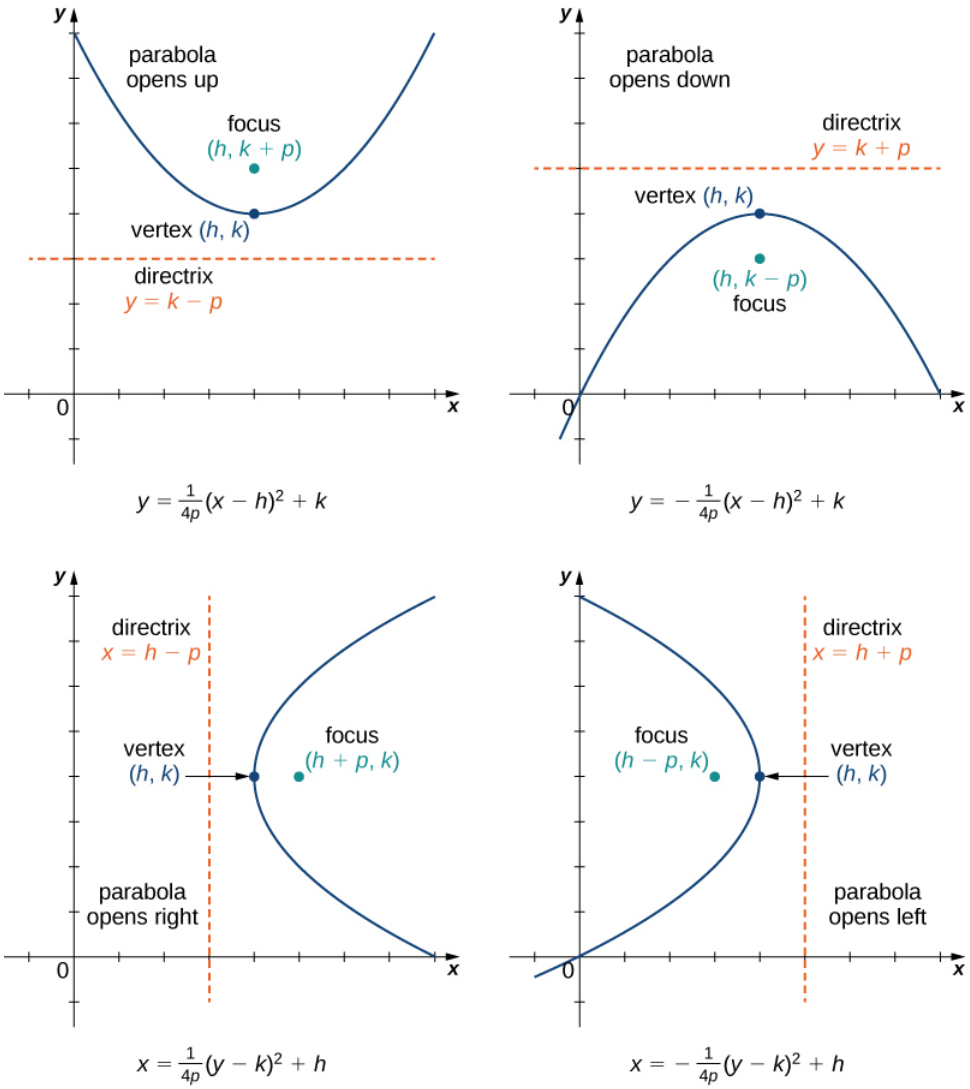

Figure **10.6.4**: Four parabolas, opening in various directions, along with their equations in standard form.

In addition, the equation of a parabola can be written in the **general form**, though in this form the values of $h$, $k$, and $p$ are not immediately recognizable. The general form of a parabola is written as

$$ax^2 + bx + cy + d = 0 \tag{10.6.5}$$

or

$$ay^2 + bx + cy + d = 0. \tag{10.6.6}$$

Equation 10.6.5 represents a parabola that opens either up or down. Equation 10.6.6 represents a parabola that opens either to the left or to the right. To put the equation into standard form, use the method of completing the square.

### Example 10.6.1: Converting the Equation of a Parabola from General into Standard Form

Put the equation

$$x^2 - 4x - 8y + 12 = 0$$

into standard form and graph the resulting parabola.

**Solution**

Since y is not squared in this equation, we know that the parabola opens either upward or downward. Therefore we need to solve this equation for y, which will put the equation into standard form. To do that, first add $8y$ to both sides of the equation:

$$8y = x^2 - 4x + 12.$$

The next step is to complete the square on the right-hand side. Start by grouping the first two terms on the right-hand side using parentheses:

$$8y = (x^2 - 4x) + 12.$$

Next determine the constant that, when added inside the parentheses, makes the quantity inside the parentheses a perfect square trinomial. To do this, take half the coefficient of x and square it. This gives $(\frac{-4}{2})^2 = 4$. Add 4 inside the parentheses and subtract 4 outside the parentheses, so the value of the equation is not changed:

$$8y = (x^2 - 4x + 4) + 12 - 4.$$

Now combine like terms and factor the quantity inside the parentheses:

$$8y = (x - 2)^2 + 8.$$

Finally, divide by 8:

$$y = \frac{1}{8}(x - 2)^2 + 1.$$

This equation is now in standard form. Comparing this to Equation gives $h = 2, k = 1$, and $p = 2$. The parabola opens up, with vertex at $(2, 1)$, focus at $(2, 3)$, and directrix $y = -1$. The graph of this parabola appears as follows.

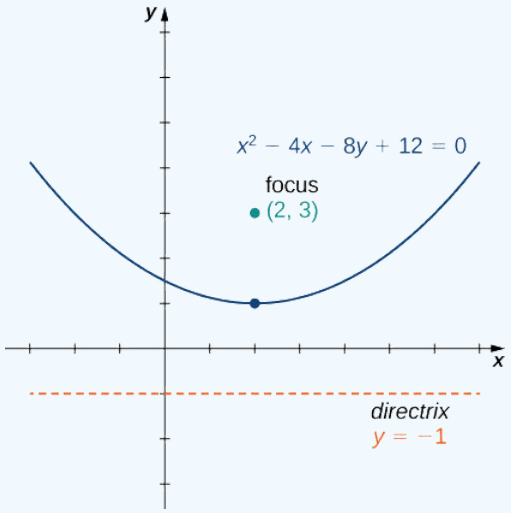

Figure **10.6.5**: The parabola in Example **10.6.1**.

## ? Exercise 10.6.1

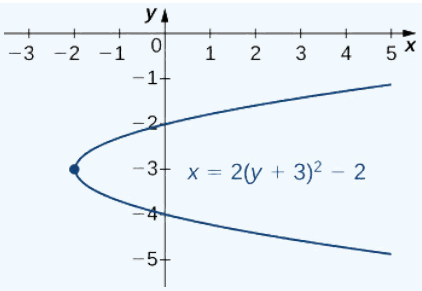
Put the equation $2y^2 - x + 12y + 16 = 0$ into standard form and graph the resulting parabola.

**Hint**

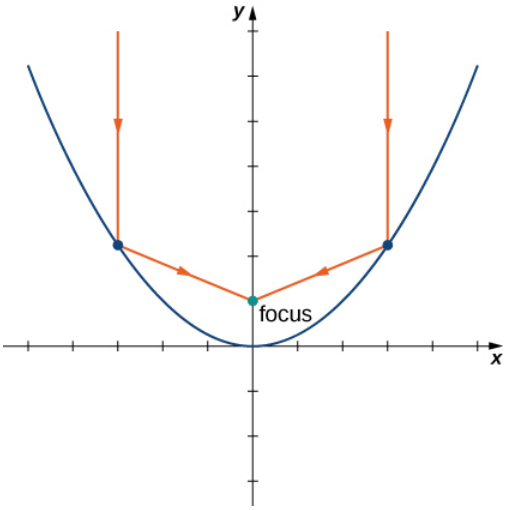
Solve for $x$. Check which direction the parabola opens.

**Answer**

$$x = 2(y + 3)^2 - 2$$



The axis of symmetry of a vertical (opening up or down) parabola is a vertical line passing through the vertex. The parabola has an interesting reflective property. Suppose we have a satellite dish with a parabolic cross section. If a beam of electromagnetic waves, such as light or radio waves, comes into the dish in a straight line from a satellite (parallel to the axis of symmetry), then the waves reflect off the dish and collect at the focus of the parabola as shown.



Consider a parabolic dish designed to collect signals from a satellite in space. The dish is aimed directly at the satellite, and a receiver is located at the focus of the parabola. Radio waves coming in from the satellite are reflected off the surface of the parabola to the receiver, which collects and decodes the digital signals. This allows a small receiver to gather signals from a wide angle of sky. Flashlights and headlights in a car work on the same principle, but in reverse: the source of the light (that is, the light bulb) is located at the focus and the reflecting surface on the parabolic mirror focuses the beam straight ahead. This allows a small light bulb to illuminate a wide angle of space in front of the flashlight or car.

## Ellipses

An ellipse can also be defined in terms of distances. In the case of an ellipse, there are two foci (plural of focus), and two directrices (plural of directrix). We look at the directrices in more detail later in this section.

**Definition: Ellipse**

An ellipse is the set of all points for which the sum of their distances from two fixed points (the foci) is constant.

A graph of a typical ellipse is shown in Figure **10.6.6**. In this figure the foci are labeled as $F$ and $F'$. Both are the same fixed distance from the origin, and this distance is represented by the variable $c$. Therefore the coordinates of $F$ are $(c, 0)$ and the coordinates of $F'$ are $(-c, 0)$. The points $P$ and $P'$ are located at the ends of the **major axis** of the ellipse, and have coordinates $(a, 0)$ and $(-a, 0)$, respectively. The major axis is always the longest distance across the ellipse, and can be horizontal or vertical. Thus, the length of the major axis in this ellipse is $2a$. Furthermore, $P$ and $P'$ are called the vertices of the ellipse. The points $Q$ and $Q'$ are located at the ends of the **minor axis** of the ellipse, and have coordinates $(0, b)$ and $(0, -b)$, respectively. The minor axis is the shortest distance across the ellipse. The minor axis is perpendicular to the major axis.

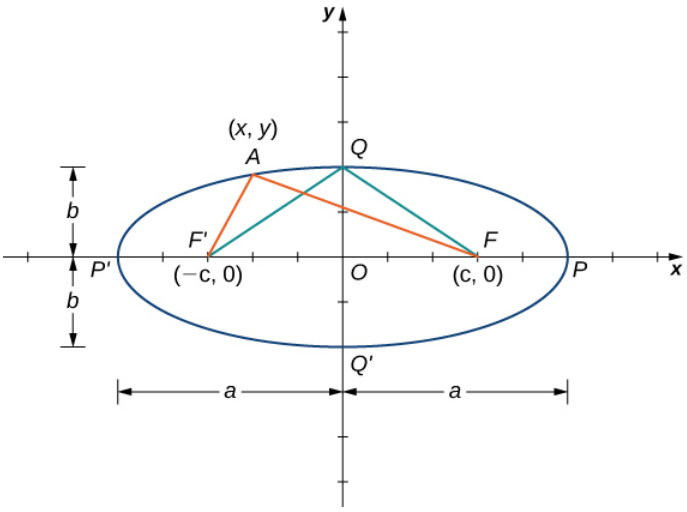


Figure **10.6.6**: A typical ellipse in which the sum of the distances from any point on the ellipse to the foci is constant.

According to the definition of the ellipse, we can choose any point on the ellipse and the sum of the distances from this point to the two foci is constant. Suppose we choose the point $P$. Since the coordinates of point $P$ are $(a, 0)$, the sum of the distances is

$$d(P, F) + d(P, F') = (a - c) + (a + c) = 2a.$$

Therefore the sum of the distances from an arbitrary point A with coordinates $(x, y)$ is also equal to $2a$. Using the distance formula, we get

$$d(A, F) + d(A, F') = 2a.$$

$$\sqrt{(x - c)^2 + y^2} + \sqrt{(x + c)^2 + y^2} = 2a$$

Subtract the second radical from both sides and square both sides:

$$\sqrt{(x - c)^2 + y^2} = 2a - \sqrt{(x + c)^2 + y^2}$$

$$(x - c)^2 + y^2 = 4a^2 - 4a\sqrt{(x + c)^2 + y^2} + (x + c)^2 + y^2$$

$$x^2 - 2cx + c^2 + y^2 = 4a^2 - 4a\sqrt{(x + c)^2 + y^2} + x^2 + 2cx + c^2 + y^2$$

$$-2cx = 4a^2 - 4a\sqrt{(x + c)^2 + y^2} + 2cx.$$

Now isolate the radical on the right-hand side and square again:

$$-2cx = 4a^2 - 4a\sqrt{(x + c)^2 + y^2} + 2cx$$

$$4a\sqrt{(x + c)^2 + y^2} = 4a^2 + 4cx$$

$$\sqrt{(x + c)^2 + y^2} = a + \frac{cx}{a}$$

$$(x + c)^2 + y^2 = a^2 + 2cx + \frac{c^2x^2}{a^2}$$

$$x^2 + 2cx + c^2 + y^2 = a^2 + 2cx + \frac{c^2x^2}{a^2}$$

$$x^2 + c^2 + y^2 = a^2 + \frac{c^2x^2}{a^2}.$$

Isolate the variables on the left-hand side of the equation and the constants on the right-hand side:

$$x^2 - \frac{c^2x^2}{a^2} + y^2 = a^2 - c^2$$

$$\frac{(a^2 - c^2)x^2}{a^2} + y^2 = a^2 - c^2.$$

Divide both sides by $a^2 - c^2$. This gives the equation

$$\frac{x^2}{a^2} + \frac{y^2}{a^2 - c^2} = 1.$$

If we refer back to Figure 10.6.6, then the length of each of the two green line segments is equal to $a$. This is true because the sum of the distances from the point $Q$ to the foci $F$ and $F'$ is equal to $2a$, and the lengths of these two line segments are equal. This line segment forms a right triangle with hypotenuse length $a$ and leg lengths $b$ and $c$. From the Pythagorean Theorem, $b^2 + c^2 = a^2$ and $b^2 = a^2 - c^2$. Therefore the equation of the ellipse becomes

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1.$$

Finally, if the center of the ellipse is moved from the origin to a point $(h, k)$, we have the following standard form of an ellipse.

### Equation of an Ellipse in Standard Form

Consider the ellipse with center $(h, k)$, a horizontal major axis with length $2a$, and a vertical minor axis with length $2b$. Then the equation of this ellipse in standard form is

$$\frac{(x-h)^2}{a^2} + \frac{(y-k)^2}{b^2} = 1 \tag{10.6.7}$$

and the foci are located at $(h \pm c, k)$, where $c^2 = a^2 - b^2$. The equations of the directrices are $x = h \pm \frac{a^2}{c}$.

If the major axis is vertical, then the equation of the ellipse becomes

$$\frac{(x-h)^2}{b^2} + \frac{(y-k)^2}{a^2} = 1 \tag{10.6.8}$$

and the foci are located at $(h, k \pm c)$, where $c^2 = a^2 - b^2$. The equations of the directrices in this case are $y = k \pm \frac{a^2}{c}$.

If the major axis is horizontal, then the ellipse is called horizontal, and if the major axis is vertical, then the ellipse is called vertical. The equation of an ellipse is in general form if it is in the form

$$Ax^2 + By^2 + Cx + Dy + E = 0,$$

where $A$ and $B$ are either both positive or both negative. To convert the equation from general to standard form, use the method of **completing the square**.

### Example 10.6.2: Finding the Standard Form of an Ellipse

Put the equation

$$9x^2 + 4y^2 - 36x + 24y + 36 = 0$$

into standard form and graph the resulting ellipse.

**Solution**

First subtract 36 from both sides of the equation:

$$9x^2 + 4y^2 - 36x + 24y = -36.$$

Next group the $x$ terms together and the $y$ terms together, and factor out the common factor:

$$(9x^2 - 36x) + (4y^2 + 24y) = -36$$

$$9(x^2-4x)+4(y^2+6y)=-36.$$

We need to determine the constant that, when added inside each set of parentheses, results in a perfect square. In the first set of parentheses, take half the coefficient of $x$ and square it. This gives $(\frac{-4}{2})^2=4$. In the second set of parentheses, take half the coefficient of $y$ and square it. This gives $(\frac{6}{2})^2=9$. Add these inside each pair of parentheses. Since the first set of parentheses has a 9 in front, we are actually adding 36 to the left-hand side. Similarly, we are adding 36 to the second set as well. Therefore the equation becomes

$$9(x^2-4x+4)+4(y^2+6y+9)=-36+36+36$$

$$9(x^2-4x+4)+4(y^2+6y+9)=36.$$

Now factor both sets of parentheses and divide by 36:

$$9(x-2)^2+4(y+3)^2=36$$

$$\frac{9(x-2)^2}{36}+\frac{4(y+3)^2}{36}=1$$

$$\frac{(x-2)^2}{4}+\frac{(y+3)^2}{9}=1.$$

The equation is now in standard form. Comparing this to Equation 10.6.8 gives $h=2, k=-3, a=3,$ and $b=2$. This is a vertical ellipse with center at $(2,-3)$, major axis 6, and minor axis 4. The graph of this ellipse appears as follows.

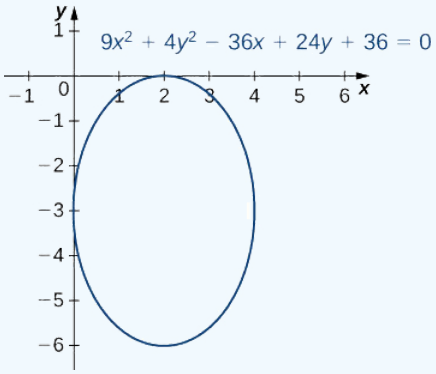

Figure 10.6.7: The ellipse in Example 10.6.2.

## Exercise 10.6.2

Put the equation

$$9x^2+16y^2+18x-64y-71=0$$

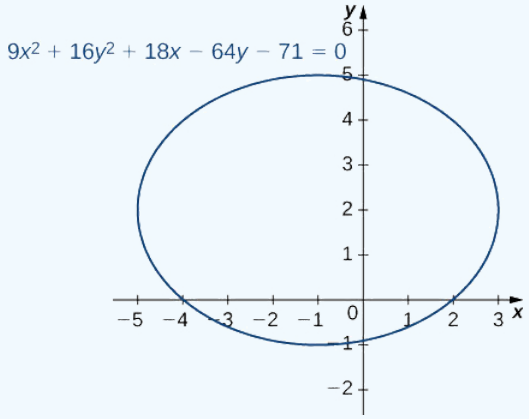
into standard form and graph the resulting ellipse.

**Hint**

Move the constant over and complete the square.

**Answer**

$$\frac{(x+1)^2}{16}+\frac{(y-2)^2}{9}=1$$



According to Kepler's first law of planetary motion, the orbit of a planet around the Sun is an ellipse with the Sun at one of the foci as shown in Figure **10.6.8*A***. Because Earth's orbit is an ellipse, the distance from the Sun varies throughout the year. A commonly held misconception is that Earth is closer to the Sun in the summer. In fact, in summer for the northern hemisphere, Earth is farther from the Sun than during winter. The difference in season is caused by the tilt of Earth's axis in the orbital plane. Comets that orbit the Sun, such as Halley's Comet, also have elliptical orbits, as do moons orbiting the planets and satellites orbiting Earth.

Ellipses also have interesting reflective properties: A light ray emanating from one focus passes through the other focus after mirror reflection in the ellipse. The same thing occurs with a sound wave as well. The National Statuary Hall in the U.S. Capitol in Washington, DC, is a famous room in an elliptical shape as shown in Figure **10.6.8*B***. This hall served as the meeting place for the U.S. House of Representatives for almost fifty years. The location of the two foci of this semi-elliptical room are clearly identified by marks on the floor, and even if the room is full of visitors, when two people stand on these spots and speak to each other, they can hear each other much more clearly than they can hear someone standing close by. Legend has it that John Quincy Adams had his desk located on one of the foci and was able to eavesdrop on everyone else in the House without ever needing to stand. Although this makes a good story, it is unlikely to be true, because the original ceiling produced so many echoes that the entire room had to be hung with carpets to dampen the noise. The ceiling was rebuilt in 1902 and only then did the now-famous whispering effect emerge. Another famous whispering gallery—the site of many marriage proposals—is in Grand Central Station in New York City.

(b)

Figure **10.6.8**: (a) Earth's orbit around the Sun is an ellipse with the Sun at one focus. (b) Statuary Hall in the U.S. Capitol is a whispering gallery with an elliptical cross section.

## Hyperbolas

A hyperbola can also be defined in terms of distances. In the case of a hyperbola, there are two foci and two directrices. Hyperbolas also have two asymptotes.

**Definition: hyperbola**

A hyperbola is the set of all points where the difference between their distances from two fixed points (the foci) is constant.

A graph of a typical hyperbola appears as follows.

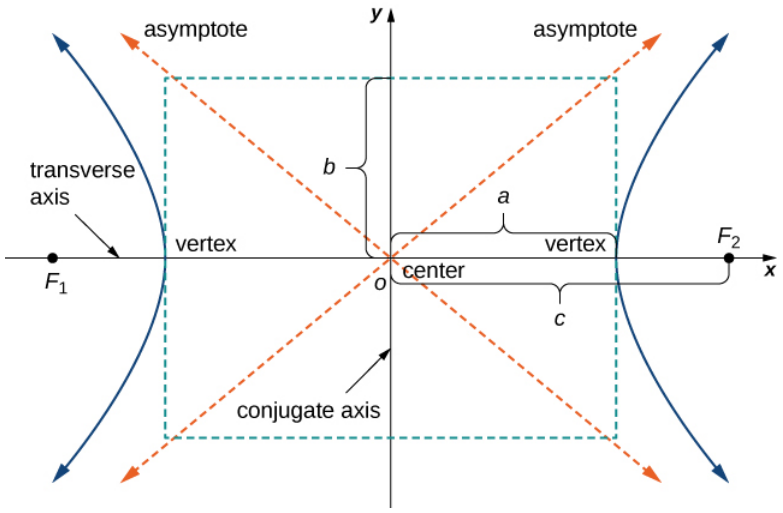

Figure **10.6.9**: A typical hyperbola in which the difference of the distances from any point on the hyperbola to the foci is constant. The transverse axis is also called the major axis, and the conjugate axis is also called the minor axis.

The derivation of the equation of a hyperbola in standard form is virtually identical to that of an ellipse. One slight hitch lies in the definition: The difference between two numbers is always positive. Let $P$ be a point on the hyperbola with coordinates $(x, y)$. Then the definition of the hyperbola gives $|d(P, F_1) - d(P, F_2)| = constant$. To simplify the derivation, assume that $P$ is on the right branch of the hyperbola, so the absolute value bars drop. If it is on the left branch, then the subtraction is reversed. The vertex of the right branch has coordinates $(a, 0)$, so

$$d(P, F_1) - d(P, F_2) = (c + a) - (c - a) = 2a.$$

This equation is therefore true for any point on the hyperbola. Returning to the coordinates $(x, y)$ for $P$:

$$d(P, F_1) - d(P, F_2) = 2a$$

$$\sqrt{(x + c)^2 + y^2} - \sqrt{(x - c)^2 + y^2} = 2a.$$

Isolate the second radical and square both sides:

$$\sqrt{(x - c)^2 + y^2} = -2a + \sqrt{(x + c)^2 + y^2}$$

$$(x - c)^2 + y^2 = 4a^2 - 4a\sqrt{(x + c)^2 + y^2} + (x + c)^2 + y^2$$

$$x^2 - 2cx + c^2 + y^2 = 4a^2 - 4a\sqrt{(x + c)^2 + y^2} + x^2 + 2cx + c^2 + y^2$$

$$-2cx = 4a^2 - 4a\sqrt{(x + c)^2 + y^2} + 2cx.$$

Now isolate the radical on the right-hand side and square again:

$$-2cx = 4a^2 - 4a\sqrt{(x + c)^2 + y^2} + 2cx$$

$$-4a\sqrt{(x + c)^2 + y^2} = -4a^2 - 4cx$$

$$-\sqrt{(x + c)^2 + y^2} = -a - \frac{cx}{a}$$

$$(x + c)^2 + y^2 = a^2 + 2cx + \frac{c^2x^2}{a^2}$$

$$x^2 + 2cx + c^2 + y^2 = a^2 + 2cx + \frac{c^2x^2}{a^2}$$

$$x^2 + c^2 + y^2 = a^2 + \frac{c^2x^2}{a^2}.$$

Isolate the variables on the left-hand side of the equation and the constants on the right-hand side:

$$x^2 - \frac{c^2x^2}{a^2} + y^2 = a^2 - c^2$$

$$\frac{(a^2 - c^2)x^2}{a^2} + y^2 = a^2 - c^2.$$

Finally, divide both sides by $a^2 - c^2$. This gives the equation

$$\frac{x^2}{a^2} + \frac{y^2}{a^2 - c^2} = 1.$$

We now define $b$ so that $b^2 = c^2 - a^2$. This is possible because $c > a$. Therefore the equation of the hyperbola becomes

$$\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1.$$

Finally, if the center of the hyperbola is moved from the origin to the point $(h, k)$, we have the following standard form of a hyperbola.

### Equation of a Hyperbola in Standard Form

Consider the hyperbola with center $(h, k)$, a horizontal major axis, and a vertical minor axis. Then the equation of this hyperbola is

$$\frac{(x-h)^2}{a^2} - \frac{(y-k)^2}{b^2} = 1 \tag{10.6.9}$$

and the foci are located at $(h \pm c, k)$, where $c^2 = a^2 + b^2$. The equations of the asymptotes are given by $y = k \pm \frac{b}{a}(x - h)$. The equations of the directrices are

$$x = h \pm \frac{a^2}{\sqrt{a^2 + b^2}} = h \pm \frac{a^2}{c}$$

If the major axis is vertical, then the equation of the hyperbola becomes

$$\frac{(y-k)^2}{a^2} - \frac{(x-h)^2}{b^2} = 1$$

and the foci are located at $(h, k \pm c)$, where $c^2 = a^2 + b^2$. The equations of the asymptotes are given by $y = k \pm \frac{a}{b}(x - h)$. The equations of the directrices are

$$y = k \pm \frac{a^2}{\sqrt{a^2 + b^2}} = k \pm \frac{a^2}{c}.$$

If the major axis (transverse axis) is horizontal, then the hyperbola is called horizontal, and if the major axis is vertical then the hyperbola is called vertical. The equation of a hyperbola is in general form if it is in the form

$$Ax^2 + By^2 + Cx + Dy + E = 0,$$

where A and B have opposite signs. In order to convert the equation from general to standard form, use the method of completing the square.

### Example 10.6.3: Finding the Standard Form of a Hyperbola

Put the equation $9x^2 - 16y^2 + 36x + 32y - 124 = 0$ into standard form and graph the resulting hyperbola. What are the equations of the asymptotes?

**Solution**

First add 124 to both sides of the equation:

$$9x^2 - 16y^2 + 36x + 32y = 124.$$

Next group the $x$ terms together and the $y$ terms together, then factor out the common factors:

$$(9x^2 + 36x) - (16y^2 - 32y) = 124$$

$$9(x^2 + 4x) - 16(y^2 - 2y) = 124.$$

We need to determine the constant that, when added inside each set of parentheses, results in a perfect square. In the first set of parentheses, take half the coefficient of x and square it. This gives $(\frac{4}{2})^2 = 4$. In the second set of parentheses, take half the coefficient of y and square it. This gives $(\frac{-2}{2})^2 = 1$. Add these inside each pair of parentheses. Since the first set of parentheses has a 9 in front, we are actually adding 36 to the left-hand side. Similarly, we are subtracting 16 from the second set of parentheses. Therefore the equation becomes

$$9(x^2 + 4x + 4) - 16(y^2 - 2y + 1) = 124 + 36 - 16$$

$$9(x^2 + 4x + 4) - 16(y^2 - 2y + 1) = 144.$$

Next factor both sets of parentheses and divide by 144:

$$9(x + 2)^2 - 16(y - 1)^2 = 144$$

$$\frac{9(x + 2)^2}{144} - \frac{16(y - 1)^2}{144} = 1$$

$$\frac{(x + 2)^2}{16} - \frac{(y - 1)^2}{9} = 1.$$

The equation is now in standard form. Comparing this to Equation 10.6.9 gives $h = -2, k = 1, a = 4$, and $b = 3$. This is a horizontal hyperbola with center at $(-2, 1)$ and asymptotes given by the equations $y = 1 \pm \frac{3}{4}(x + 2)$. The graph of this hyperbola appears in Figure 10.6.10.

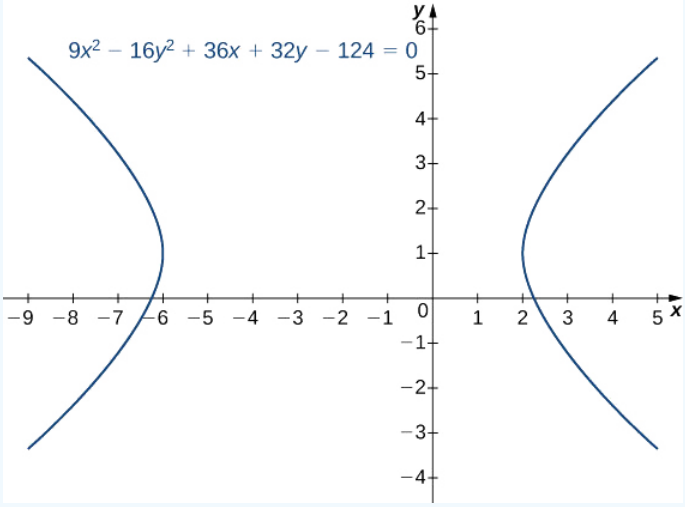

Figure 10.6.10: Graph of the hyperbola in Example 10.6.3.

## ? Exercise 10.6.3

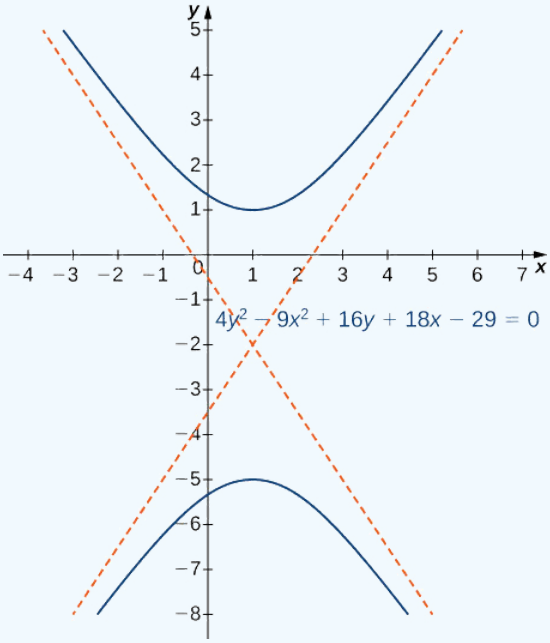
Put the equation $4y^2 - 9x^2 + 16y + 18x - 29 = 0$ into standard form and graph the resulting hyperbola. What are the equations of the asymptotes?

**Hint**

Move the constant over and complete the square. Check which direction the hyperbola opens

**Answer**

$\frac{(y + 2)^2}{9} - \frac{(x - 1)^2}{4} = 1$. This is a vertical hyperbola. Asymptotes $y = -2 \pm \frac{3}{2}(x - 1)$.



Hyperbolas also have interesting reflective properties. A ray directed toward one focus of a hyperbola is reflected by a hyperbolic mirror toward the other focus. This concept is illustrated in Figure 10.6.11.

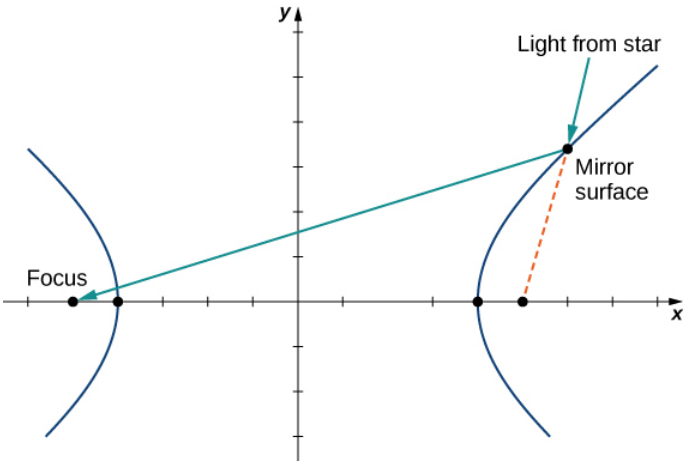


Figure **10.6.11**: A hyperbolic mirror used to collect light from distant stars.

This property of the hyperbola has important applications. It is used in radio direction finding (since the difference in signals from two towers is constant along hyperbolas), and in the construction of mirrors inside telescopes (to reflect light coming from the parabolic mirror to the eyepiece). Another interesting fact about hyperbolas is that for a comet entering the solar system, if the speed is great enough to escape the Sun's gravitational pull, then the path that the comet takes as it passes through the solar system is hyperbolic.

## Eccentricity and Directrix

An alternative way to describe a conic section involves the directrices, the foci, and a new property called eccentricity. We will see that the value of the eccentricity of a conic section can uniquely define that conic.

**Definition: Eccentricity and Directrices**

The *eccentricity* $e$ of a conic section is defined to be the distance from any point on the conic section to its focus, divided by the perpendicular distance from that point to the nearest directrix. This value is constant for any conic section, and can define

the conic section as well:

1. If $e = 1$, the conic is a parabola.
2. If $e < 1$, it is an ellipse.
3. If $e > 1$, it is a hyperbola.

The eccentricity of a circle is zero. The *directrix* of a conic section is the line that, together with the point known as the focus, serves to define a conic section. Hyperbolas and noncircular ellipses have two foci and two associated directrices. Parabolas have one focus and one directrix.

The three conic sections with their directrices appear in Figure 10.6.12.

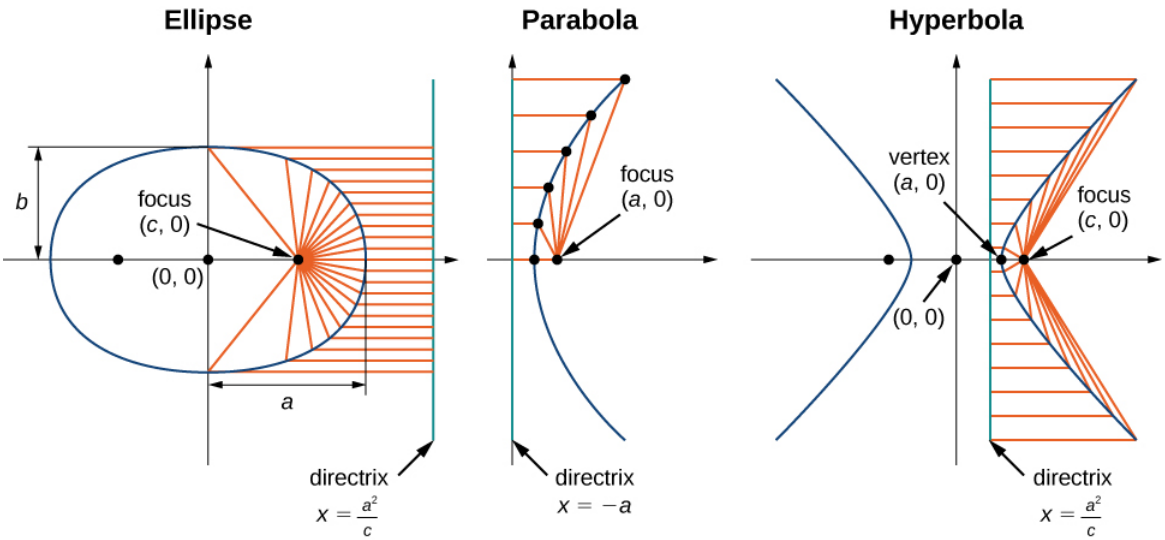

Figure 10.6.12: The three conic sections with their foci and directrices.

Recall from the definition of a parabola that the distance from any point on the parabola to the focus is equal to the distance from that same point to the directrix. Therefore, by definition, the eccentricity of a parabola must be 1. The equations of the directrices of a horizontal ellipse are $x = \pm\frac{a^2}{c}$. The right vertex of the ellipse is located at $(a, 0)$ and the right focus is $(c, 0)$. Therefore the distance from the vertex to the focus is $a - c$ and the distance from the vertex to the right directrix is $\frac{a^2}{c} - c$. This gives the eccentricity as

$$e = \frac{a-c}{\frac{a^2}{c} - a} = \frac{c(a-c)}{a^2 - ac} = \frac{c(a-c)}{a(a-c)} = \frac{c}{a}.$$

Since $c < a$, this step proves that the eccentricity of an ellipse is less than 1. The directrices of a horizontal hyperbola are also located at $x = \pm\frac{a^2}{c}$, and a similar calculation shows that the eccentricity of a hyperbola is also $e = \frac{c}{a}$. However in this case we have $c > a$, so the eccentricity of a hyperbola is greater than 1.

### Example 10.6.4: Determining Eccentricity of a Conic Section

Determine the eccentricity of the ellipse described by the equation

$$\frac{(x-3)^2}{16} + \frac{(y+2)^2}{25} = 1.$$

**Solution**

From the equation we see that $a = 5$ and $b = 4$. The value of $c$ can be calculated using the equation $a^2 = b^2 + c^2$ for an ellipse. Substituting the values of $a$ and $b$ and solving for $c$ gives $c = 3$. Therefore the eccentricity of the ellipse is $e = \frac{c}{a} = \frac{3}{5} = 0.6$.

**Exercise 10.6.4**

Determine the eccentricity of the hyperbola described by the equation

$$\frac{(y-3)^2}{49} - \frac{(x+2)^2}{25} = 1.$$

**Hint**

First find the values of a and b, then determine c using the equation $c^2 = a^2 + b^2$.

**Answer**

$$e = \frac{c}{a} = \frac{\sqrt{74}}{7} \approx 1.229$$

## Polar Equations of Conic Sections

Sometimes it is useful to write or identify the equation of a conic section in polar form. To do this, we need the concept of the focal parameter. The **focal parameter** of a conic section $p$ is defined as the distance from a focus to the nearest directrix. The following table gives the focal parameters for the different types of conics, where $a$ is the length of the semi-major axis (i.e., half the length of the major axis), $c$ is the distance from the origin to the focus, and $e$ is the eccentricity. In the case of a parabola, a represents the distance from the vertex to the focus.

Table **10.6.1**: Eccentricities and Focal Parameters of the Conic Sections

| Conic | $e$ | $p$ |
|---|---|---|
| Ellipse | $0 < e < 1$ | $\frac{a^2 - c^2}{c} = \frac{a(1-e^2)}{c}$ |
| Parabola | $e = 1$ | $2a$ |
| Hyperbola | $e > 1$ | $\frac{c^2 - a^2}{c} = \frac{a(e^2-1)}{c}$ |

Using the definitions of the focal parameter and eccentricity of the conic section, we can derive an equation for any conic section in polar coordinates. In particular, we assume that one of the foci of a given conic section lies at the pole. Then using the definition of the various conic sections in terms of distances, it is possible to prove the following theorem.

**Polar Equation of Conic Sections**

The polar equation of a conic section with focal parameter $p$ is given by

$$r = \frac{ep}{1 \pm e\cos\theta} \text{ or } r = \frac{ep}{1 \pm e\sin\theta}.$$

In the equation on the left, the major axis of the conic section is horizontal, and in the equation on the right, the major axis is vertical. To work with a conic section written in polar form, first make the constant term in the denominator equal to 1. This can be done by dividing both the numerator and the denominator of the fraction by the constant that appears in front of the plus or minus in the denominator. Then the coefficient of the sine or cosine in the denominator is the eccentricity. This value identifies the conic. If cosine appears in the denominator, then the conic is horizontal. If sine appears, then the conic is vertical. If both appear then the axes are rotated. The center of the conic is not necessarily at the origin. The center is at the origin only if the conic is a circle (i.e., $e = 0$).

**Example 10.6.5**: Graphing a Conic Section in Polar Coordinates

Identify and create a graph of the conic section described by the equation

$$r = \frac{3}{1 + 2\cos\theta}.$$

**Solution**

The constant term in the denominator is 1, so the eccentricity of the conic is 2. This is a hyperbola. The focal parameter p can be calculated by using the equation $ep = 3$. Since $e = 2$, this gives $p = \frac{3}{2}$. The cosine function appears in the denominator, so the hyperbola is horizontal. Pick a few values for $\theta$ and create a table of values. Then we can graph the hyperbola (Figure 10.6.13).

| $\theta$ | $r$ | $\theta$ | $r$ |
|---|---|---|---|
| 0 | 1 | $\pi$ | $-3$ |
| $\frac{\pi}{4}$ | $\frac{3}{1+\sqrt{2}} \approx 1.2426$ | $\frac{5\pi}{4}$ | $\frac{3}{1-\sqrt{2}} \approx -7.2426$ |
| $\frac{\pi}{2}$ | 3 | $\frac{3\pi}{2}$ | 3 |
| $\frac{3\pi}{4}$ | $\frac{3}{1-\sqrt{2}} \approx -7.2426$ | $\frac{7\pi}{4}$ | $\frac{3}{1+\sqrt{2}} \approx 1.2426$ |

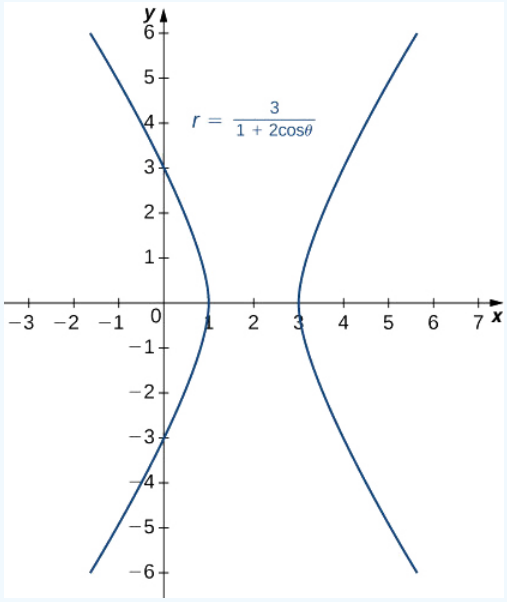

Figure 10.6.13: Graph of the hyperbola described in Example 10.6.5.

## Exercise 10.6.5

Identify and create a graph of the conic section described by the equation

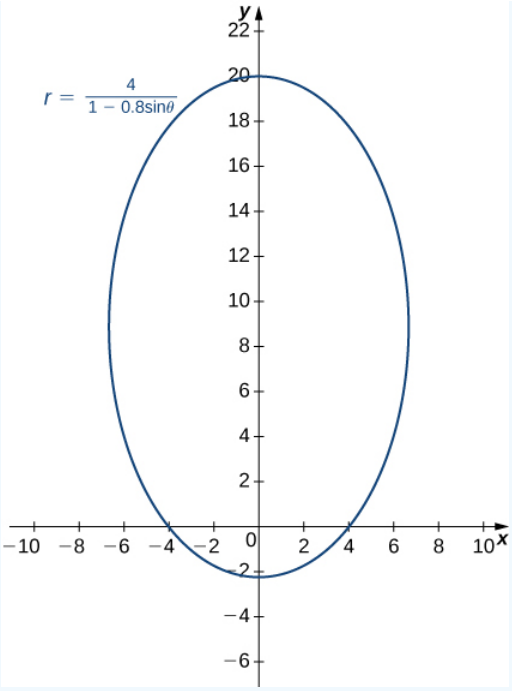
$$r = \frac{4}{1 - 0.8\sin\theta}.$$

**Hint**

First find the values of $e$ and $p$, and then create a table of values.

**Answer**

Here $e = 0.8$ and $p = 5$. This conic section is an ellipse.



## General Equations of Degree Two

A general equation of degree two can be written in the form

$$Ax^2 + Bxy + Cy^2 + Dx + Ey + F = 0.$$

The graph of an equation of this form is a conic section. If $B \neq 0$ then the coordinate axes are rotated. To identify the conic section, we use the discriminant of the conic section $4AC - B^2$.

### Identifying the Conic Section

One of the following cases must be true:

1. $4AC - B^2 > 0$. If so, the graph is an ellipse.
2. $4AC - B^2 = 0$. If so, the graph is a parabola.
3. $4AC - B^2 < 0$. If so, the graph is a hyperbola.

The simplest example of a second-degree equation involving a cross term is $xy = 1$. This equation can be solved for $y$ to obtain $y = \frac{1}{x}$. The graph of this function is called a rectangular hyperbola as shown.

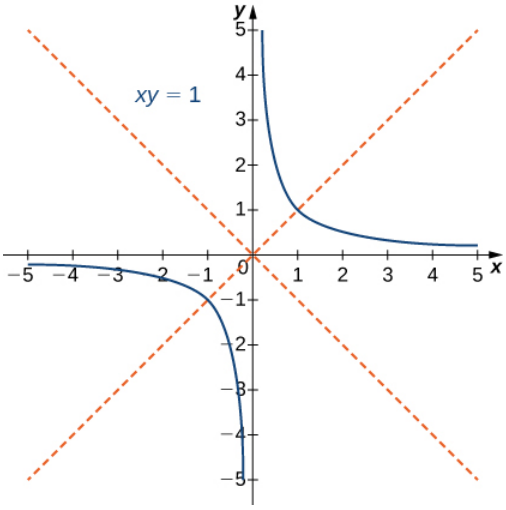


Figure 10.6.14: Graph of the equation $xy = 1$; The red lines indicate the rotated axes.

The asymptotes of this hyperbola are the $x$ and $y$ coordinate axes. To determine the angle \theta of rotation of the conic section, we use the formula $\cot 2\theta = \frac{A-C}{B}$. In this case $A = C = 0$ and $B = 1$, so $\cot 2\theta = (0-0)/1 = 0$ and $\theta = 45°$. The method for graphing a conic section with rotated axes involves determining the coefficients of the conic in the rotated coordinate system. The new coefficients are labeled $A', B', C', D', E'$, and $F'$, and are given by the formulas

$$A' = A\cos^2\theta + B\cos\theta\sin\theta + C\sin^2\theta \tag{10.6.10}$$
$$B' = 0 \tag{10.6.11}$$
$$C' = A\sin^2\theta - B\sin\theta\cos\theta + C\cos^2\theta \tag{10.6.12}$$
$$D' = D\cos\theta + E\sin\theta \tag{10.6.13}$$
$$E' = -D\sin\theta + E\cos\theta \tag{10.6.14}$$
$$F' = F. \tag{10.6.15}$$

### Procedure: graphing a rotated conic

The procedure for graphing a rotated conic is the following:

1. Identify the conic section using the discriminant $4AC - B^2$.
2. Determine $\theta$ using the formula

$$\cot 2\theta = \frac{A-C}{B}. \tag{10.6.16}$$

3. Calculate $A', B', C', D', E'$,and $F'$.
4. Rewrite the original equation using $A', B', C', D', E'$,and $F'$.
5. Draw a graph using the rotated equation.

### Example 10.6.6: Identifying a Rotated Conic

Identify the conic and calculate the angle of rotation of axes for the curve described by the equation

$$13x^2 - 6\sqrt{3}xy + 7y^2 - 256 = 0.$$

**Solution**

In this equation, $A = 13, B = -6\sqrt{3}, C = 7, D = 0, E = 0$, and $F = -256$. The discriminant of this equation is

$$4AC - B^2 = 4(13)(7) - (-6\sqrt{3})^2 = 364 - 108 = 256.$$

Therefore this conic is an ellipse.

To calculate the angle of rotation of the axes, use Equation 10.6.16

$$\cot 2\theta = \frac{A-C}{B}.$$

This gives

$$\cot 2\theta = \frac{A-C}{B} = \frac{13-7}{-6\sqrt{3}} = -\frac{\sqrt{3}}{3}.$$

Therefore $2\theta = 120^o$ and $\theta = 60^o$, which is the angle of the rotation of the axes.

To determine the rotated coefficients, use the formulas given above:

$$\begin{aligned} A' &= A\cos^2\theta + B\cos\theta\sin\theta + C\sin^2\theta \\ &= 13\cos^2 60 + (-6\sqrt{3})\cos 60\sin 60 + 7\sin^2 60 \\ &= 13(\tfrac{1}{2})^2 - 6\sqrt{3}(\tfrac{1}{2})(\tfrac{\sqrt{3}}{2}) + 7(\tfrac{\sqrt{3}}{2})^2 \\ &= 4, \\ B' &= 0 \\ C' &= A\sin^2\theta - B\sin\theta\cos\theta + C\cos^2\theta \\ &= 13\sin^2 60 + (6\sqrt{3})\sin 60\cos 60 + 7\cos^2 60 \\ &= 13(\tfrac{\sqrt{3}}{2})^2 + 6\sqrt{3}(\tfrac{\sqrt{3}}{2})(\tfrac{1}{2}) + 7(\tfrac{1}{2})^2 \\ &= 16, \\ D' &= D\cos\theta + E\sin\theta \\ &= (0)\cos 60 + (0)\sin 60 \\ &= 0, \\ E' &= -D\sin\theta + E\cos\theta \\ &= -(0)\sin 60 + (0)\cos 60 \\ &= 0 \\ F' &= F \\ &= -256. \end{aligned}$$

The equation of the conic in the rotated coordinate system becomes

$$4(x')^2 + 16(y')^2 = 256$$

$$\frac{(x')^2}{64} + \frac{(y')^2}{16} = 1.$$

A graph of this conic section appears as follows.

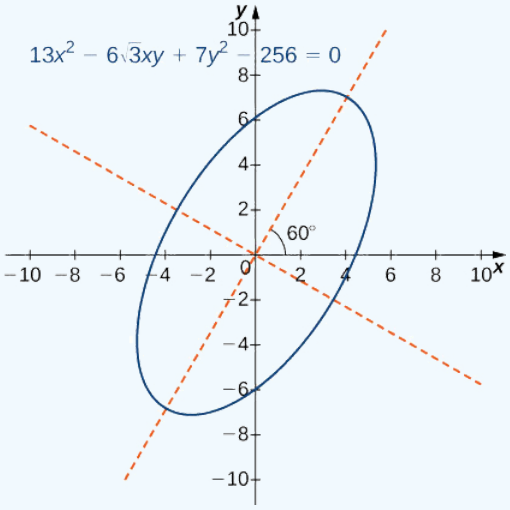

Figure 10.6.15: Graph of the ellipse described by the equation $13x^2 - 6\sqrt{3}xy + 7y^2 - 256 = 0$. The axes are rotated 60°. The red dashed lines indicate the rotated axes.

**? Exercise 10.6.6**

Identify the conic and calculate the angle of rotation of axes for the curve described by the equation

$$3x^2 + 5xy - 2y^2 - 125 = 0.$$

**Hint**

Follow steps 1 and 2 of the five-step method outlined above

**Answer**

The conic is a hyperbola and the angle of rotation of the axes is $\theta = 22.5°$.

## Key Concepts

- The equation of a vertical parabola in standard form with given focus and directrix is $y = \frac{1}{4p}(x-h)^2 + k$ where $p$ is the distance from the vertex to the focus and $(h, k)$ are the coordinates of the vertex.
- The equation of a horizontal ellipse in standard form is $\frac{(x-h)^2}{a^2} + \frac{(y-k)^2}{b^2} = 1$ where the center has coordinates $(h, k)$, the major axis has length $2a$, the minor axis has length $2b$, and the coordinates of the foci are $(h \pm c, k)$, where $c^2 = a^2 - b^2$.
- The equation of a horizontal hyperbola in standard form is $\frac{(x-h)^2}{a^2} - \frac{(y-k)^2}{b^2} = 1$ where the center has coordinates $(h, k)$, the vertices are located at $(h \pm a, k)$, and the coordinates of the foci are $(h \pm c, k)$, where $c^2 = a^2 + b^2$.
- The eccentricity of an ellipse is less than 1, the eccentricity of a parabola is equal to 1, and the eccentricity of a hyperbola is greater than 1. The eccentricity of a circle is 0.
- The polar equation of a conic section with eccentricity $e$ is $r = \frac{ep}{1 \pm e\cos\theta}$ or $r = \frac{ep}{1 \pm e\sin\theta}$, where $p$ represents the focal parameter.
- To identify a conic generated by the equation $Ax^2 + Bxy + Cy^2 + Dx + Ey + F = 0$,first calculate the discriminant $D = 4AC - B^2$. If $D > 0$ then the conic is an ellipse, if $D = 0$ then the conic is a parabola, and if $D < 0$ then the conic is a hyperbola.

## Glossary

**conic section**

a conic section is any curve formed by the intersection of a plane with a cone of two nappes

**directrix**

a directrix (plural: directrices) is a line used to construct and define a conic section; a parabola has one directrix; ellipses and hyperbolas have two

**discriminant**

the value $4AC - B^2$, which is used to identify a conic when the equation contains a term involving $xy$, is called a discriminant

**focus**

a focus (plural: foci) is a point used to construct and define a conic section; a parabola has one focus; an ellipse and a hyperbola have two

**eccentricity**

the eccentricity is defined as the distance from any point on the conic section to its focus divided by the perpendicular distance from that point to the nearest directrix

**focal parameter**

the focal parameter is the distance from a focus of a conic section to the nearest directrix

**general form**

an equation of a conic section written as a general second-degree equation

**major axis**

the major axis of a conic section passes through the vertex in the case of a parabola or through the two vertices in the case of an ellipse or hyperbola; it is also an axis of symmetry of the conic; also called the transverse axis

**minor axis**

the minor axis is perpendicular to the major axis and intersects the major axis at the center of the conic, or at the vertex in the case of the parabola; also called the conjugate axis

**nappe**

a nappe is one half of a double cone

**standard form**

an equation of a conic section showing its properties, such as location of the vertex or lengths of major and minor axes

**vertex**

a vertex is an extreme point on a conic section; a parabola has one vertex at its turning point. An ellipse has two vertices, one at each end of the major axis; a hyperbola has two vertices, one at the turning point of each branch

# 10.6E: Exercises

**In exercises 1 - 8, determine the equation of the parabola using the information given.**

1) Focus $(4,0)$ and directrix $x=-4$

**Answer**

$y^2=16x$

2) Focus $(0,-3)$ and directrix $y=3$

3) Focus $(0,0.5)$ and directrix $y=-0.5$

**Answer**

$x^2=2y$

4) Focus $(2,3)$ and directrix $x=-2$

5) Focus $(0,2)$ and directrix $y=4$

**Answer**

$x^2=-4(y-3)$

6) Focus $(-1,4)$ and directrix $x=5$

7) Focus $(-3,5)$ and directrix $y=1$

**Answer**

$(x+3)^2=8(y-3)$

8) Focus $\left(\frac{5}{2},-4\right)$ and directrix $x=\frac{7}{2}$

**In exercises 9 - 16, determine the equation of the ellipse using the information given.**

9) Endpoints of major axis at $(4,0),\ (-4,0)$ and foci located at $(2,0),\ (-2,0)$

**Answer**

$\frac{x^2}{16}+\frac{y^2}{12}=1$

10) Endpoints of major axis at $(0,5),\ (0,-5)$ and foci located at $(0,3),\ (0,-3)$

11) Endpoints of major axis at $(0,2),\ (0,-2)$ and foci located at $(3,0),\ (-3,0)$

**Answer**

$\frac{x^2}{13}+\frac{y^2}{4}=1$

12) Endpoints of major axis at $(-3,3),\ (7,3)$ and foci located at $(-2,3),\ (6,3)$

13) Endpoints of major axis at $(-3,5),\ (-3,-3)$ and foci located at $(-3,3),\ (-3,-1)$

**Answer**

$\frac{(y-1)^2}{16}+\frac{(x+3)^2}{12}=1$

14) Endpoints of major axis at $(0,0),\ (0,4)$ and foci located at $(5,2),\ (-5,2)$

15) Foci located at $(2,0),\ (-2,0)$ and eccentricity of $\frac{1}{2}$

**Answer**

$$\frac{x^2}{16}+\frac{y^2}{12}=1$$

16) Foci located at $(0,-3),\ (0,3)$ and eccentricity of $\frac{3}{4}$

**In exercises 17 - 24, determine the equation of the hyperbola using the information given.**

17) Vertices located at $(5,0),\ (-5,0)$ and foci located at $(6,0),\ (-6,0)$

**Answer**

$\frac{x^2}{25}-\frac{y^2}{11}=1$

18) Vertices located at $(0,2),\ (0,-2)$ and foci located at $(0,3),\ (0,-3)$

19) Endpoints of the conjugate axis located at $(0,3),\ (0,-3)$ and foci located $(4,0),\ (-4,0)$

**Answer**

$$\frac{x^2}{7}-\frac{y^2}{9}=1$$

20) Vertices located at $(0,1),\ (6,1)$ and focus located at $(8,1)$

21) Vertices located at $(-2,0),\ (-2,-4)$ and focus located at $(-2,-8)$

**Answer**

$$\frac{(y+2)^2}{4}-\frac{(x+2)^2}{32}=1$$

22) Endpoints of the conjugate axis located at $(3,2),\ (3,4)$ and focus located at $(3,7)$

23) Foci located at $(6,-0),\ (6,0)$ and eccentricity of $3$

**Answer**

$$\frac{x^2}{4}-\frac{y^2}{32}=1$$

24) $(0,10),\ (0,-10)$ and eccentricity of 2.5

**In exercises 25 - 30, consider the following polar equations of conics. Determine the eccentricity and identify the conic.**

25) $r=\frac{-1}{1+\cos\theta}$

**Answer**

$e=1$, parabola

26) $r=\frac{8}{2-\sin\theta}$

27) $r=\frac{5}{2+\sin\theta}$

**Answer**

$e=\frac{1}{2}$, ellipse

28) $r=\frac{5}{-1+2\sin\theta}$

29) $r=\frac{3}{2-6\sin\theta}$

**Answer**

$e=3$, hyperbola

30) $r=\frac{3}{-4+3\sin\theta}$

**In exercises 31 - 34, find a polar equation of the conic with focus at the origin and eccentricity and directrix as given.**

31) Directrix: $x = 4;\ e = \frac{1}{5}$

**Answer**

$$r = \frac{4}{5 + \cos\theta}$$

32) Directrix: $x = -4;\ e = 5$

33) Directrix: $y = 2;\ e = 2$

**Answer**

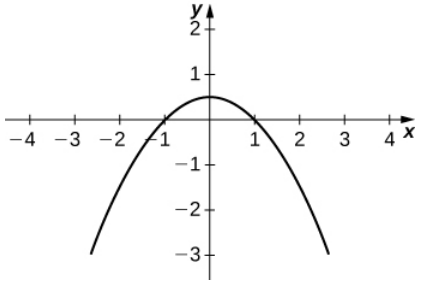
$$r = \frac{4}{1 + 2\sin\theta}$$

34) Directrix: $y = -2;\ e = \frac{1}{2}$

**In exercises 35 - 51, sketch the graph of each conic.**

35) $r = \frac{1}{1 + \sin\theta}$

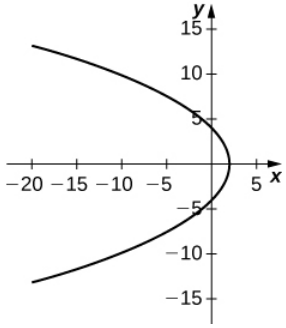
**Answer**



36) $r = \frac{1}{1 - \cos\theta}$

37) $r = \frac{4}{1 + \cos\theta}$

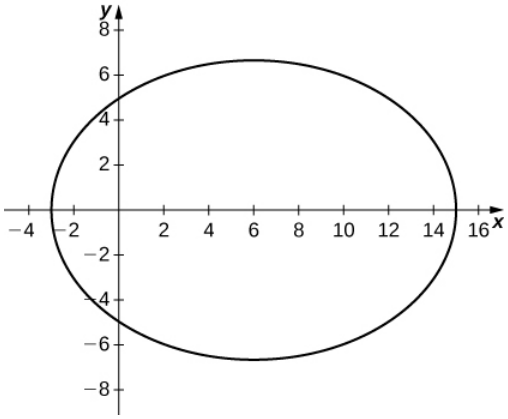
**Answer**



38) $r = \frac{10}{5 + 4\sin\theta}$

39) $r = \frac{15}{3 - 2\cos\theta}$

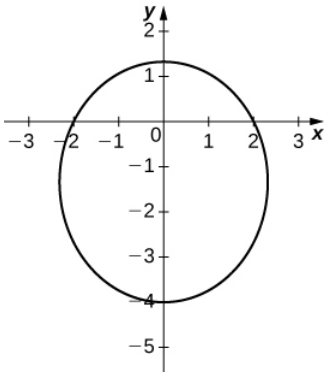
**Answer**



40) $r = \dfrac{32}{3 + 5\sin\theta}$

41) $r(2 + \sin\theta) = 4$

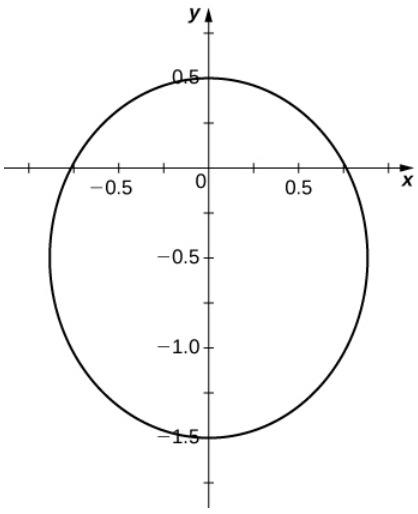
**Answer**



42) $r = \dfrac{3}{2 + 6\sin\theta}$

43) $r = \dfrac{3}{-4 + 2\sin\theta}$

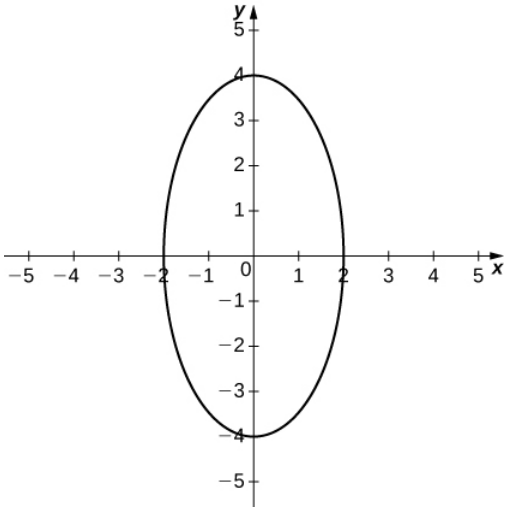
**Answer**



44) $\dfrac{x^2}{9} + \dfrac{y^2}{4} = 1$

45) $\frac{x^2}{4}+\frac{y^2}{16}=1$

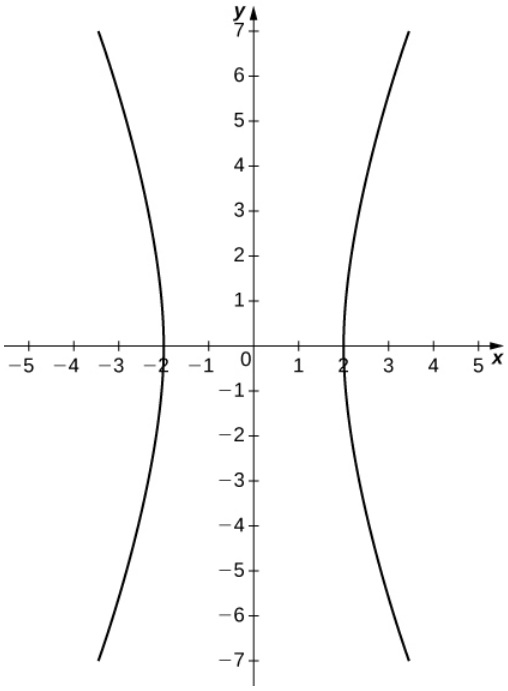
**Answer**



46) $4x^2+9y^2=36$

47) $25x^2-4y^2=100$

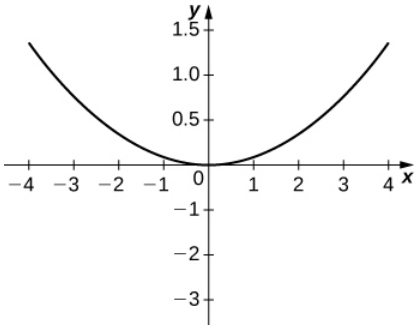
**Answer**



48) $\frac{x^2}{16}-\frac{y^2}{9}=1$

49) $x^2=12y$

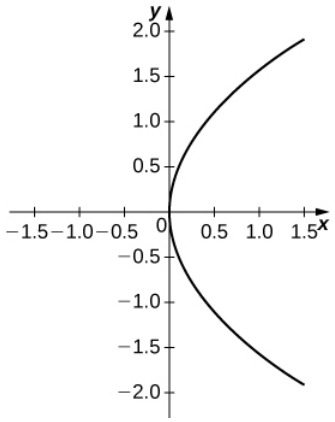
**Answer**



50) $y^2 = 20x$

51) $12x = 5y^2$

**Answer**



**For the equations in exercises 52 - 57, determine which of the conic sections is described.**

52) $xy = 4$

53) $x^2 + 4xy - 2y^2 - 6 = 0$

**Answer**

Hyperbola

54) $x^2 + 2\sqrt{3}xy + 3y^2 - 6 = 0$

55) $x^2 - xy + y^2 - 2 = 0$

**Answer**

Ellipse

56) $34x^2 - 24xy + 41y^2 - 25 = 0$

57) $52x^2 - 72xy + 73y^2 + 40x + 30y - 75 = 0$

**Answer**

Ellipse

58) The mirror in an automobile headlight has a parabolic cross section, with the lightbulb at the focus. On a schematic, the equation of the parabola is given as $x^2 = 4y$. At what coordinates should you place the lightbulb?

59) A satellite dish is shaped like a paraboloid of revolution. The receiver is to be located at the focus. If the dish is 12 feet across at its opening and 4 feet deep at its center, where should the receiver be placed?

**Answer**

At the point 2.25 feet above the vertex.

60) Consider the satellite dish of the preceding problem. If the dish is 8 feet across at the opening and 2 feet deep, where should we place the receiver?

61) A searchlight is shaped like a paraboloid of revolution. A light source is located 1 foot from the base along the axis of symmetry. If the opening of the searchlight is 3 feet across, find the depth.

**Answer**

$0.5625$ feet

62) Whispering galleries are rooms designed with elliptical ceilings. A person standing at one focus can whisper and be heard by a person standing at the other focus because all the sound waves that reach the ceiling are reflected to the other person. If a whispering gallery has a length of 120 feet and the foci are located 30 feet from the center, find the height of the ceiling at the center.

63) A person is standing 8 feet from the nearest wall in a whispering gallery. If that person is at one focus and the other focus is 80 feet away, what is the length and the height at the center of the gallery?

**Answer**

Length is 96 feet and height is approximately 26.53 feet.

**In exercises 64 - 67, determine the polar equation form of the orbit given the length of the major axis and eccentricity for the orbits of the comets or planets. Distance is given in astronomical units (AU).**

64) Halley's Comet: length of major axis = $35.88$, eccentricity = $0.967$

65) Hale-Bopp Comet: length of major axis = $525.91$, eccentricity = $0.995$

**Answer**

$$r = \frac{2.616}{1 + 0.995 \cos \theta}$$

66) Mars: length of major axis = $3.049$, eccentricity = $0.0934$

67) Jupiter: length of major axis = $10.408$, eccentricity = $0.0484$

**Answer**

$$r = \frac{5.192}{1 + 0.0484 \cos \theta}$$

# CHAPTER OVERVIEW

## 11: Introduction to Differential Equations

Many real-world phenomena can be modeled mathematically by using differential equations. Population growth, radioactive decay, predator-prey models, and spring-mass systems are four examples of such phenomena. In this chapter we study some of these applications. A goal of this chapter is to develop solution techniques for different types of differential equations. As the equations become more complicated, the solution techniques also become more complicated, and in fact an entire course could be dedicated to the study of these equations. In this chapter we study several types of differential equations and their corresponding methods of solution.

# 11.1: Chapter 6 Review Exercises

**True or False? Justify your answer with a proof or a counterexample.**

1) The differential equation $y' = 3x^2y - \cos(x)y''$ is linear.

2) The differential equation $y' = x - y$ is separable.

**Answer**

$F$

3) You can explicitly solve all first-order differential equations by separation or by the method of integrating factors.

4) You can determine the behavior of all first-order differential equations using directional fields or Euler's method.

**Answer**

$T$

**For the following problems, find the general solution to the differential equations.**

5) $y' = x^2 + 3e^x - 2x$

6) $y' = 2^x + \cos^{-1} x$

**Answer**

$y(x) = \frac{2^x}{ln(2)} + xcos^{-1}x - \sqrt{1-x^2} + C$

7) $y' = y(x^2 + 1)$

8) $y' = e^{-y} \sin x$

**Answer**

$y(x) = \ln(C - \cos x)$

9) $y' = 3x - 2y$

10) $y' = y \ln y$

**Answer**

$y(x) = e^{e^{C+x}}$

**For the following problems, find the solution to the initial value problem.**

11) $y' = 8x - \ln x - 3x^4, \quad y(1) = 5$

12) $y' = 3x - \cos x + 2, \quad y(0) = 4$

**Answer**

$y(x) = 4 + \frac{3}{2}x^2 + 2x - \sin x$

13) $xy' = y(x - 2), \quad y(1) = 3$

14) $y' = 3y^2(x + \cos x), \quad y(0) = -2$

**Answer**

$$y(x) = -\frac{2}{1 + 3(x^2 + 2\sin x)}$$

15) $(x - 1)y' = y - 2, \quad y(0) = 0$

16) $y' = 3y - x + 6x^2, \quad y(0) = -1$

**Answer**

$y(x) = -2x^2 - 2x - \frac{1}{3} - \frac{2}{3}e^{3x}$

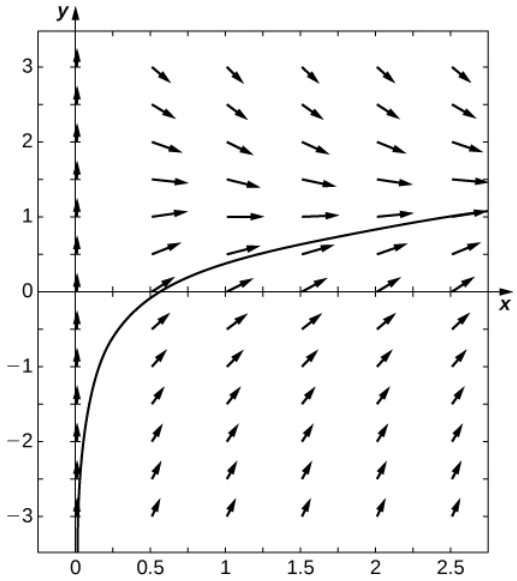
**For the following problems, draw the directional field associated with the differential equation, then solve the differential equation. Draw a sample solution on the directional field.**

17) $y' = 2y - y^2$

18) $y' = \dfrac{1}{x} + \ln x - y$, for $x > 0$

**Answer**

$y(x) = Ce^{-x} + \ln x$



**For the following problems, use Euler's Method with $n = 5$ steps over the interval $t = [0, 1]$. Then solve the initial-value problem exactly. How close is your Euler's Method estimate?**

19) $y' = -4yx, \quad y(0) = 1$

20) $y' = 3^x - 2y, \quad y(0) = 0$

**Answer**

Euler: $0.6939$,

Exact solution: $y(x) = \dfrac{3^x - e^{-2x}}{2 + \ln(3)}$

**For the following problems, set up and solve the differential equations.**

21) A car drives along a freeway, accelerating according to $a = 5\sin(\pi t)$, where $t$ represents time in minutes. Find the velocity at any time $t$, assuming the car starts with an initial speed of $60$ mph.

22) You throw a ball of mass $2$ kilograms into the air with an upward velocity of $8$ m/s. Find exactly the time the ball will remain in the air, assuming that gravity is given by $g = 9.8\,\text{m/s}^2$.

**Answer**

$\frac{40}{49}$ second

23) You drop a ball with a mass of $5$ kilograms out an airplane window at a height of $5000$ m. How long does it take for the ball to reach the ground?

24) You drop the same ball of mass $5$ kilograms out of the same airplane window at the same height, except this time you assume a drag force proportional to the ball's velocity, using a proportionality constant of $3$ and the ball reaches terminal velocity. Solve for the distance fallen as a function of time. How long does it take the ball to reach the ground?

**Answer**

$x(t) = 5000 + \frac{245}{9} - \frac{49}{3}t - \frac{245}{9}e^{-5/3t}, \quad t = 307.8$ seconds

25) A drug is administered to a patient every $24$ hours and is cleared at a rate proportional to the amount of drug left in the body, with proportionality constant $0.2$. If the patient needs a baseline level of $5$ mg to be in the bloodstream at all times, how large should the dose be?

26) A $1000$-liter tank contains pure water and a solution of $0.2$ kg salt/L is pumped into the tank at a rate of $1$ L/min and is drained at the same rate. Solve for total amount of salt in the tank at time $t$.

**Answer**

$T(t) = 200\left(1 - e^{-t/1000}\right)$

27) You boil water to make tea. When you pour the water into your teapot, the temperature is $100°C$. After $5$ minutes in your $15°C$ room, the temperature of the tea is $85°C$. Solve the equation to determine the temperatures of the tea at time $t$. How long must you wait until the tea is at a drinkable temperature ($72°C$)?

28) The human population (in thousands) of Nevada in $1950$ was roughly $160$. If the carrying capacity is estimated at $10$ million individuals, and assuming a growth rate of $2\%$ per year, develop a logistic growth model and solve for the population in Nevada at any time (use $1950$ as time = 0). What population does your model predict for $2000$? How close is your prediction to the true value of $1,998,257$?

**Answer**

$P(t) = \frac{1600000e^{0.02t}}{9840 + 160e^{0.02t}}$

29) Repeat the previous problem but use Gompertz growth model. Which is more accurate?

# 11.2: Basics of Differential Equations

**Learning Objectives**

- Identify the order of a differential equation.
- Explain what is meant by a solution to a differential equation.
- Distinguish between the general solution and a particular solution of a differential equation.
- Identify an initial-value problem.
- Identify whether a given function is a solution to a differential equation or an initial-value problem.

Calculus is the mathematics of change, and rates of change are expressed by derivatives. Thus, one of the most common ways to use calculus is to set up an equation containing an unknown function $y = f(x)$ and its derivative, known as a differential equation. Solving such equations often provides information about how quantities change and frequently provides insight into how and why the changes occur.

Techniques for solving differential equations can take many different forms, including direct solution, use of graphs, or computer calculations. We introduce the main ideas in this chapter and describe them in a little more detail later in the course. In this section we study what differential equations are, how to verify their solutions, some methods that are used for solving them, and some examples of common and useful equations.

## General Differential Equations

Consider the equation $y' = 3x^2$, which is an example of a differential equation because it includes a derivative. There is a relationship between the variables $x$ and $y$ : $y$ is an unknown function of $x$. Furthermore, the left-hand side of the equation is the derivative of $y$. Therefore we can interpret this equation as follows: Start with some function $y = f(x)$ and take its derivative. The answer must be equal to $3x^2$. What function has a derivative that is equal to $3x^2$? One such function is $y = x^3$, so this function is considered a *solution* to a differential equation.

**Definition: differential equation**

A *differential equation* is an equation involving an unknown function $y = f(x)$ and one or more of its derivatives. A solution to a differential equation is a function $y = f(x)$ that satisfies the differential equation when $f$ and its derivatives are substituted into the equation.

Go to this website to explore more on this topic.

Some examples of differential equations and their solutions appear in Table **11.2.1**.

Table **11.2.1**: Examples of Differential Equations and Their Solutions

| Equation | Solution |
|---|---|
| $y' = 2x$ | $y = x^2$ |
| $y' + 3y = 6x + 11$ | $y = e^{-3x} + 2x + 3$ |
| $y'' - 3y' + 2y = 24e^{-2x}$ | $y = 3e^x - 4e^{2x} + 2e^{-2x}$ |

Note that a solution to a differential equation is not necessarily unique, primarily because the derivative of a constant is zero. For example, $y = x^2 + 4$ is also a solution to the first differential equation in Table **11.2.1**. We will return to this idea a little bit later in this section. For now, let's focus on what it means for a function to be a solution to a differential equation.

### Example 11.2.1: Verifying Solutions of Differential Equations

Verify that the function $y = e^{-3x} + 2x + 3$ is a solution to the differential equation $y' + 3y = 6x + 11$.

**Solution**

To verify the solution, we first calculate $y'$ using the chain rule for derivatives. This gives $y' = -3e^{-3x} + 2$. Next we substitute $y$ and $y'$ into the left-hand side of the differential equation:

$$(-3e^{-2x} + 2) + 3(e^{-2x} + 2x + 3).$$

The resulting expression can be simplified by first distributing to eliminate the parentheses, giving

$$-3e^{-2x} + 2 + 3e^{-2x} + 6x + 9.$$

Combining like terms leads to the expression $6x + 11$, which is equal to the right-hand side of the differential equation. This result verifies that $y = e^{-3x} + 2x + 3$ is a solution of the differential equation.

### Exercise 11.2.1

Verify that $y = 2e^{3x} - 2x - 2$ is a solution to the differential equation $y' - 3y = 6x + 4$.

**Hint**

First calculate $y'$ then substitute both $y'$ and $y$ into the left-hand side.

It is convenient to define characteristics of differential equations that make it easier to talk about them and categorize them. The most basic characteristic of a differential equation is its order.

### Definition: order of a differential equation

The *order of a differential equation* is the highest order of any derivative of the unknown function that appears in the equation.

### Example 11.2.2: Identifying the Order of a Differential Equation

The highest derivative in the equation is $y'$,

What is the order of each of the following differential equations?

a. $y' - 4y = x^2 - 3x + 4$
b. $x^2y''' - 3xy'' + xy' - 3y = \sin x$
c. $\frac{4}{x}y^{(4)} - \frac{6}{x^2}y'' + \frac{12}{x^4}y = x^3 - 3x^2 + 4x - 12$

**Solution**

a. The highest derivative in the equation is $y'$,so the order is $1$.
b. The highest derivative in the equation is $y'''$, so the order is $3$.
c. The highest derivative in the equation is $y^{(4)}$, so the order is $4$.

### Exercise 11.2.2

What is the order of the following differential equation?

$$(x^4 - 3x)y^{(5)} - (3x^2 + 1)y' + 3y = \sin x \cos x$$

**Hint**

What is the highest derivative in the equation?

**Answer**

5

## General and Particular Solutions

We already noted that the differential equation $y' = 2x$ has at least two solutions: $y = x^2$ and $y = x^2 + 4$. The only difference between these two solutions is the last term, which is a constant. What if the last term is a different constant? Will this expression still be a solution to the differential equation? In fact, any function of the form $y = x^2 + C$, where $C$ represents any constant, is a solution as well. The reason is that the derivative of $x^2 + C$ is $2x$, regardless of the value of $C$. It can be shown that any solution of this differential equation must be of the form $y = x^2 + C$. This is an example of a **general solution** to a differential equation. A graph of some of these solutions is given in Figure 11.2.1. (Note: in this graph we used even integer values for C ranging between $-4$ and $4$. In fact, there is no restriction on the value of $C$; it can be an integer or not.)

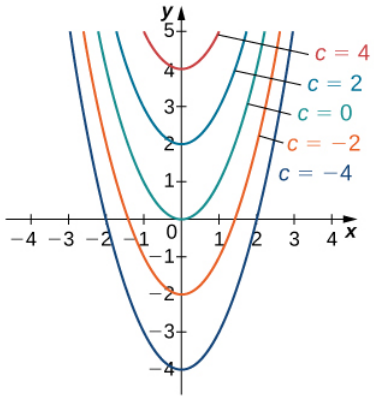

Figure 11.2.1: Family of solutions to the differential equation $y' = 2x$.

In this example, we are free to choose any solution we wish; for example, $y = x^2 - 3$ is a member of the family of solutions to this differential equation. This is called a particular solution to the differential equation. A particular solution can often be uniquely identified if we are given additional information about the problem.

### Example 11.2.3: Finding a Particular Solution

Find the particular solution to the differential equation $y' = 2x$ passing through the point $(2, 7)$.

**Solution**

Any function of the form $y = x^2 + C$ is a solution to this differential equation. To determine the value of $C$, we substitute the values $x = 2$ and $y = 7$ into this equation and solve for $C$:

$$\begin{aligned} y &= x^2 + C \\ 7 &= 2^2 + C \\ &= 4 + C \\ C &= 3. \end{aligned}$$

Therefore the particular solution passing through the point $(2, 7)$ is $y = x^2 + 3$.

### Exercise 11.2.3

Find the particular solution to the differential equation

$$y' = 4x + 3$$

passing through the point $(1, 7)$, given that $y = 2x^2 + 3x + C$ is a general solution to the differential equation.

**Hint**

First substitute $x = 1$ and $y = 7$ into the equation, then solve for $C$.

**Answer**

$$y = 2x^2 + 3x + 2$$

## Initial-Value Problems

Usually a given differential equation has an infinite number of solutions, so it is natural to ask which one we want to use. To choose one solution, more information is needed. Some specific information that can be useful is an *initial value*, which is an ordered pair that is used to find a particular solution.

A differential equation together with one or more initial values is called an *initial-value problem*. The general rule is that the number of initial values needed for an initial-value problem is equal to the order of the differential equation. For example, if we have the differential equation $y' = 2x$, then $y(3) = 7$ is an initial value, and when taken together, these equations form an initial-value problem. The differential equation $y'' - 3y' + 2y = 4e^x$ is second order, so we need two initial values. With initial-value problems of order greater than one, the same value should be used for the independent variable. An example of initial values for this second-order equation would be $y(0) = 2$ and $y'(0) = -1$. These two initial values together with the differential equation form an initial-value problem. These problems are so named because often the independent variable in the unknown function is $t$, which represents time. Thus, a value of $t = 0$ represents the beginning of the problem.

### Example 11.2.4: Verifying a Solution to an Initial-Value Problem

Verify that the function $y = 2e^{-2t} + e^t$ is a solution to the initial-value problem

$$y' - y = -6e^{-2t}, \quad y(0) = 3.$$

**Solution**

For a function to satisfy an initial-value problem, it must satisfy both the differential equation and the initial condition. To show that $y$ satisfies the differential equation, we start by calculating $y'$. This gives $y' = -4e^{-2t} + e^t$. Next we substitute both $y$ and $y'$ into the left-hand side of the differential equation and simplify:

$$\begin{aligned} y' - y &= (-4e^{-2t} + e^t) - (2e^{-2t} + e^t) \\ &= -4e^{-2t} + e^t - 2e^{-2t} - e^t = -6e^{-2t}. \end{aligned}$$

This is equal to the right-hand side of the differential equation, so $y = 2e^{-2t} + e^t$ solves the differential equation. Next we calculate $y(0)$:

$$y(0) = 2e^{-2(0)} + e^0 = 2 + 1 = 3.$$

This result verifies the initial value. Therefore the given function satisfies the initial-value problem.

### Exercise 11.2.4

Verify that $y = 3e^{2t} + 4\sin t$ is a solution to the initial-value problem

$$y' - 2y = 4\cos t - 8\sin t, y(0) = 3.$$

**Hint**

First verify that $y$ solves the differential equation. Then check the initial value.

In Example 11.2.4, the initial-value problem consisted of two parts. The first part was the differential equation $y' - y = -6e^{-2t}$, and the second part was the initial value $y(0) = 3$. These two equations together formed the initial-value problem.

The same is true in general. An initial-value problem will consists of two parts: the differential equation and the initial condition. The differential equation has a family of solutions, and the initial condition determines the value of $C$. The family of solutions to the differential equation in Example 11.2.4 is given by $y = 2e^{-2t} + Ce^t$. This family of solutions is shown in Figure 11.2.2, with the particular solution $y = 2e^{-2t} + e^t$ labeled.

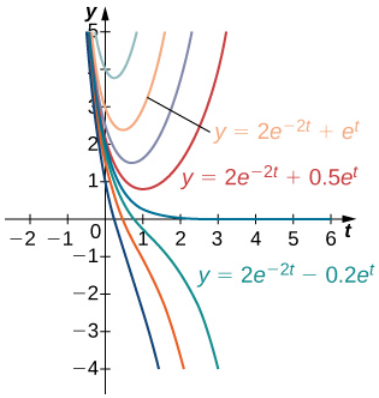

Figure 11.2.2: A family of solutions to the differential equation $y' - y = -6e^{-2t}$. The particular solution $y = 2e^{-2t} + e^t$ is labeled.

### Example 11.2.5: Solving an Initial-value Problem

Solve the following initial-value problem:

$$y' = 3e^x + x^2 - 4, y(0) = 5.$$

#### Solution

The first step in solving this initial-value problem is to find a general family of solutions. To do this, we find an antiderivative of both sides of the differential equation

$$\int y' \, dx = \int (3e^x + x^2 - 4) \, dx,$$

namely,

$$y + C_1 = 3e^x + \tfrac{1}{3}x^3 - 4x + C_2.$$

We are able to integrate both sides because the y term appears by itself. Notice that there are two integration constants: $C_1$ and $C_2$. Solving this equation for $y$ gives

$$y = 3e^x + \tfrac{1}{3}x^3 - 4x + C_2 - C_1.$$

Because $C_1$ and $C_2$ are both constants, $C_2 - C_1$ is also a constant. We can therefore define $C = C_2 - C_1$, which leads to the equation

$$y = 3e^x + \tfrac{1}{3}x^3 - 4x + C.$$

Next we determine the value of $C$. To do this, we substitute $x = 0$ and $y = 5$ into this equation and solve for $C$:

$$\begin{aligned} 5 &= 3e^0 + \frac{1}{3}0^3 - 4(0) + C \\ 5 &= 3 + C \\ C &= 2 \end{aligned}$$

Now we substitute the value $C = 2$ into the general equation. The solution to the initial-value problem is $y = 3e^x + \tfrac{1}{3}x^3 - 4x + 2$.

#### Analysis

The difference between a general solution and a particular solution is that a general solution involves a family of functions, either explicitly or implicitly defined, of the independent variable. The initial value or values determine which particular solution in the family of solutions satisfies the desired conditions.

**? Exercise 11.2.5**

Solve the initial-value problem

$$y' = x^2 - 4x + 3 - 6e^x, y(0) = 8.$$

**Hint**

First take the antiderivative of both sides of the differential equation. Then substitute $x = 0$ and $y = 8$ into the resulting equation and solve for $C$.

**Answer**

$y = \frac{1}{3}x^3 - 2x^2 + 3x - 6e^x + 14$

## Applications

In physics and engineering applications, we often consider the forces acting upon an object, and use this information to understand the resulting motion that may occur. For example, if we start with an object at Earth's surface, the primary force acting upon that object is gravity. Physicists and engineers can use this information, along with Newton's **second law of motion** (in equation form $F = ma$, where $F$ represents force, $m$ represents mass, and $a$ represents acceleration), to derive an equation that can be solved.

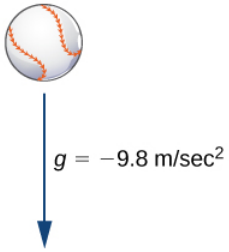

Figure **11.2.3**: For a baseball falling in air, the only force acting on it is gravity (neglecting air resistance).

In Figure **11.2.3** we assume that the only force acting on a baseball is the force of gravity. This assumption ignores air resistance. (The force due to air resistance is considered in a later discussion.) The acceleration due to gravity at Earth's surface, g, is approximately $9.8\ \text{m/s}^2$. We introduce a frame of reference, where Earth's surface is at a height of 0 meters. Let $v(t)$ represent the velocity of the object in meters per second. If $v(t) > 0$, the ball is rising, and if $v(t) < 0$, the ball is falling (Figure).

Figure **11.2.4**: Possible velocities for the rising/falling baseball.

Our goal is to solve for the velocity $v(t)$ at any time $t$. To do this, we set up an initial-value problem. Suppose the mass of the ball is $m$, where $m$ is measured in kilograms. We use Newton's second law, which states that the force acting on an object is equal to its mass times its acceleration ($F = ma$). Acceleration is the derivative of velocity, so $a(t) = v'(t)$. Therefore the force acting on the baseball is given by $F = mv'(t)$. However, this force must be equal to the force of gravity acting on the object, which (again using Newton's second law) is given by $F_g = -mg$, since this force acts in a downward direction. Therefore we obtain the equation $F = F_g$, which becomes $mv'(t) = -mg$. Dividing both sides of the equation by $m$ gives the equation

$$v'(t) = -g.$$

Notice that this differential equation remains the same regardless of the mass of the object.

We now need an initial value. Because we are solving for velocity, it makes sense in the context of the problem to assume that we know the **initial velocity**, or the velocity at time $t = 0$. This is denoted by $v(0) = v_0$.

### Example 11.2.6: Velocity of a Moving Baseball

A baseball is thrown upward from a height of $3$ meters above Earth's surface with an initial velocity of $10$ m/s, and the only force acting on it is gravity. The ball has a mass of $0.15$ kg at Earth's surface.

a. Find the velocity $v(t)$ of the basevall at time $t$.
b. What is its velocity after $2$ seconds?

#### Solution

a. From the preceding discussion, the differential equation that applies in this situation is

$$v'(t) = -g,$$

where $g = 9.8\ \text{m/s}^2$. The initial condition is $v(0) = v_0$, where $v_0 = 10$ m/s. Therefore the initial-value problem is $v'(t) = -9.8\ \text{m/s}^2$, $v(0) = 10$ m/s.

The first step in solving this initial-value problem is to take the antiderivative of both sides of the differential equation. This gives

$$\int v'(t)\,dt = \int -9.8\,dt$$

$$v(t) = -9.8t + C.$$

The next step is to solve for $C$. To do this, substitute $t = 0$ and $v(0) = 10$:

$$\begin{aligned} v(t) &= -9.8t + C \\ v(0) &= -9.8(0) + C \\ 10 &= C. \end{aligned}$$

Therefore $C = 10$ and the velocity function is given by $v(t) = -9.8t + 10$.

b. To find the velocity after $2$ seconds, substitute $t = 2$ into $v(t)$.

$$\begin{aligned} v(t) &= -9.8t + 10 \\ v(2) &= -9.8(2) + 10 \\ v(2) &= -9.6 \end{aligned}$$

The units of velocity are meters per second. Since the answer is negative, the object is falling at a speed of $9.6$ m/s.

### Exercise 11.2.6

Suppose a rock falls from rest from a height of $100$ meters and the only force acting on it is gravity. Find an equation for the velocity $v(t)$ as a function of time, measured in meters per second.

**Hint**

What is the initial velocity of the rock? Use this with the differential equation in Example $11.2.6$ to form an initial-value problem, then solve for $v(t)$.

**Answer**

$v(t) = -9.8t$

A natural question to ask after solving this type of problem is how high the object will be above Earth's surface at a given point in time. Let $s(t)$ denote the height above Earth's surface of the object, measured in meters. Because velocity is the derivative of position (in this case height), this assumption gives the equation $s'(t) = v(t)$. An initial value is necessary; in this case the initial height of the object works well. Let the initial height be given by the equation $s(0) = s_0$. Together these assumptions give the initial-value problem

$$s'(t) = v(t), s(0) = s_0.$$

If the velocity function is known, then it is possible to solve for the position function as well.

### Example 11.2.7: Height of a Moving Baseball

A baseball is thrown upward from a height of $3$ meters above Earth's surface with an initial velocity of $10m/s$, and the only force acting on it is gravity. The ball has a mass of $0.15$ kilogram at Earth's surface.

a. Find the position $s(t)$ of the baseball at time $t$.
b. What is its height after $2$ seconds?

#### Solution

We already know the velocity function for this problem is $v(t) = -9.8t + 10$. The initial height of the baseball is $3$ meters, so $s_0 = 3$. Therefore the initial-value problem for this example is

To solve the initial-value problem, we first find the antiderivatives:

$$\int s'(t)\,dt = \int (-9.8t + 10)\,dt$$

$$s(t) = -4.9t^2 + 10t + C.$$

Next we substitute $t = 0$ and solve for $C$:

$$s(t) = -4.9t^2 + 10t + C$$

$$s(0) = -4.9(0)^2 + 10(0) + C$$

$$3 = C.$$

Therefore the position function is $s(t) = -4.9t^2 + 10t + 3$.

b. The height of the baseball after $2$ sec is given by $s(2)$ :

$$s(2) = -4.9(2)^2 + 10(2) + 3 = -4.9(4) + 23 = 3.4.$$

Therefore the baseball is $3.4$ meters above Earth's surface after $2$ seconds. It is worth noting that the mass of the ball cancelled out completely in the process of solving the problem.

## Key Concepts

- A differential equation is an equation involving a function $y = f(x)$ and one or more of its derivatives. A solution is a function $y = f(x)$ that satisfies the differential equation when $f$ and its derivatives are substituted into the equation.
- The order of a differential equation is the highest order of any derivative of the unknown function that appears in the equation.
- A differential equation coupled with an initial value is called an initial-value problem. To solve an initial-value problem, first find the general solution to the differential equation, then determine the value of the constant. Initial-value problems have many applications in science and engineering.

## Glossary

**differential equation**
an equation involving a function $y = y(x)$ and one or more of its derivatives

**general solution (or family of solutions)**

the entire set of solutions to a given differential equation

**initial value(s)**
a value or set of values that a solution of a differential equation satisfies for a fixed value of the independent variable

**initial velocity**
the velocity at time $t = 0$

**initial-value problem**
a differential equation together with an initial value or values

**order of a differential equation**
the highest order of any derivative of the unknown function that appears in the equation

**particular solution**
member of a family of solutions to a differential equation that satisfies a particular initial condition

**solution to a differential equation**
a function $y = f(x)$ that satisfies a given differential equation

# 11.2E: Exercises for Section 8.1

**In exercises 1 - 7, determine the order of each differential equation.**

1) $y'+y=3y^2$

**Answer**

1st-order

2) $(y')^2=y'+2y$

3) $y'''+y''y'=3x^2$

**Answer**

3rd-order

4) $y'=y''+3t^2$

5) $\frac{dy}{dt}=t$

**Answer**

1st-order

6) $\frac{dy}{dx}+\frac{d^2y}{dx^2}=3x^4$

7) $\left(\frac{dy}{dt}\right)^2+8\frac{dy}{dt}+3y=4t$

**Answer**

1st-order

**In exercises 8 - 17, verify that the given function is a solution to the given differential equation.**

8) $y=\frac{x^3}{3}$ solves $y'=x^2$

9) $y=2e^{-x}+x-1$ solves $y'=x-y$

10) $y=e^{3x}-\frac{e^x}{2}$ solves $y'=3y+e^x$

11) $y=\frac{1}{1-x}$ solves $y'=y^2$

12) $y=\frac{e^{x^2}}{2}$ solves $y'=2xy$

13) $y=4+\ln x$ solves $xy'=1$

14) $y=3-x+x\ln x$ solves $y'=\ln x$

15) $y=2e^x-x-1$ solves $y'=y+x$

16) $y=e^x+\frac{\sin x}{2}-\frac{\cos x}{2}$ solves $y'=\cos x+y$

17) $y=\pi e^{-\cos x}$ solves $y'=y\sin x$

**In exercises 18 - 27, verify the given general solution and find the particular solution.**

18) Find the particular solution to the differential equation $y'=4x^2$ that passes through $(-3,-30)$, given that $y=C+\frac{4x^3}{3}$ is a general solution.

19) Find the particular solution to the differential equation $y'=3x^3$ that passes through $(1,4.75)$, given that $y=C+\frac{3x^4}{4}$ is a general solution.

**Answer**

$y = 4 + \frac{3x^4}{4}$

20) Find the particular solution to the differential equation $y' = 3x^2y$ that passes through $(0, 12)$, given that $y = Ce^{x^3}$ is a general solution.

21) Find the particular solution to the differential equation $y' = 2xy$ that passes through $\left(0, \frac{1}{2}\right)$, given that $y = Ce^{x^2}$ is a general solution.

**Answer**

$y = \frac{1}{2}e^{x^2}$

22) Find the particular solution to the differential equation $y' = \left(2xy\right)^2$ that passes through $\left(1, -\frac{1}{2}\right)$, given that $y = -\frac{3}{C + 4x^3}$ is a general solution.

23) Find the particular solution to the differential equation $y'x^2 = y$ that passes through $\left(1, \frac{2}{e}\right)$, given that $y = Ce^{-1/x}$ is a general solution.

**Answer**

$y = 2e^{-1/x}$

24) Find the particular solution to the differential equation $8\frac{dx}{dt} = -2\cos(2t) - \cos(4t)$ that passes through $(\pi, \pi)$, given that $x = C - \frac{1}{8}\sin(2t) - \frac{1}{32}\sin(4t)$ is a general solution.

25) Find the particular solution to the differential equation $\frac{du}{dt} = \tan u$ that passes through $\left(1, \frac{\pi}{2}\right)$, given that $u = \sin^{-1}\left(e^{C+t}\right)$ is a general solution.

**Answer**

$u = \sin^{-1}\left(e^{-1+t}\right)$

26) Find the particular solution to the differential equation $\frac{dy}{dt} = e^{t+y}$ that passes through $(1, 0)$, given that $y = -\ln(C - e^t)$ is a general solution.

27) Find the particular solution to the differential equation $y'(1 - x^2) = 1 + y$ that passes through $(0, -2)$, given that $y = C\frac{\sqrt{x+1}}{\sqrt{1-x}} - 1$ is a general solution.

**Answer**

$y = -\frac{\sqrt{x+1}}{\sqrt{1-x}} - 1$

**In exercises 28 - 37, find the general solution to the differential equation.**

28) $y' = 3x + e^x$

29) $y' = \ln x + \tan x$

**Answer**

$y = C - x + x\ln x - \ln(\cos x)$

30) $y' = \sin x e^{\cos x}$

31) $y' = 4^x$

**Answer**

$y = C + \frac{4^x}{\ln 4}$

32) $y' = \sin^{-1}(2x)$

33) $y' = 2t\sqrt{t^2+16}$

**Answer**

$y = \frac{2}{3}\sqrt{t^2+16}\left(t^2+16\right) + C$

34) $x' = \coth t + \ln t + 3t^2$

35) $x' = t\sqrt{4+t}$

**Answer**

$x = \frac{2}{15}\sqrt{4+t}\left(3t^2+4t-32\right) + C$

36) $y' = y$

37) $y' = \frac{y}{x}$

**Answer**

$y = Cx$

**In exercises 38 - 42, solve the initial-value problems starting from $y(t=0) = 1$ and $y(t=0) = -1$. Draw both solutions on the same graph.**

38) $\frac{dy}{dt} = 2t$

39) $\frac{dy}{dt} = -t$

**Answer**

$y = 1 - \frac{t^2}{2}$, and $y = -\frac{t^2}{2} - 1$

40) $\frac{dy}{dt} = 2y$

41) $\frac{dy}{dt} = -y$

**Answer**

$y = e^{-t}$ and $y = -e^{-t}$

42) $\frac{dy}{dt} = 2$

**In exercises 43 - 47, solve the initial-value problems starting from $y_0 = 10$. At what time does $y$ increase to 100 or drop to 1?**

43) $\frac{dy}{dt} = 4t$

**Answer**

$y = 2(t^2+5)$, When $t = 3\sqrt{5}$, $y$ will increase to $100$.

44) $\frac{dy}{dt} = 4y$

45) $\frac{dy}{dt} = -2y$

**Answer**

$y = 10e^{-2t}$, When $t = -\frac{1}{2}\ln\left(\frac{1}{10}\right)$, $y$ will decrease to $1$.

46) $\frac{dy}{dt} = e^{4t}$

47) $\frac{dy}{dt} = e^{-4t}$

**Answer**

$y = \frac{1}{4}(41 - e^{-4t})$, Neither condition will ever happen.

**Recall that a family of solutions includes solutions to a differential equation that differ by a constant. For exercises 48 - 52, use your calculator to graph a family of solutions to the given differential equation. Use initial conditions from $y(t = 0) = -10$ to $y(t = 0) = 10$ increasing by 2. Is there some critical point where the behavior of the solution begins to change?**

48) [T] $y' = y(x)$

49) [T] $xy' = y$

**Answer**

Solution changes from increasing to decreasing at $y(0) = 0$.

50) [T] $y' = t^3$

51) [T] $y' = x + y$ (Hint: $y = Ce^x - x - 1$ is the general solution)

**Answer**

Solution changes from increasing to decreasing at $y(0) = 0$.

52) [T] $y' = x \ln x + \sin x$

53) Find the general solution to describe the velocity of a ball of mass $1$ lb that is thrown upward at a rate of $a$ ft/sec.

**Answer**

$v(t) = -32t + a$

54) In the preceding problem, if the initial velocity of the ball thrown into the air is $a = 25$ ft/s, write the particular solution to the velocity of the ball. Solve to find the time when the ball hits the ground.

55) You throw two objects with differing masses $m_1$ and $m_2$ upward into the air with the same initial velocity of $a$ ft/s. What is the difference in their velocity after $1$ second?

**Answer**

$0$ ft/s

56) [T] You throw a ball of mass $1$ kilogram upward with a velocity of $a = 25$ m/s on Mars, where the force of gravity is $g = -3.711$ m/s$^2$. Use your calculator to approximate how much longer the ball is in the air on Mars.

57) [T] For the previous problem, use your calculator to approximate how much higher the ball went on Mars.

**Answer**

$4.86$ meters

58) [T] A car on the freeway accelerates according to $a = 15\cos(\pi t)$, where $t$ is measured in hours. Set up and solve the differential equation to determine the velocity of the car if it has an initial speed of $51$ mph. After $40$ minutes of driving, what is the driver's velocity?

59) [T] For the car in the preceding problem, find the expression for the distance the car has traveled in time $t$, assuming an initial distance of $0$. How long does it take the car to travel $100$ miles? Round your answer to hours and minutes.

**Answer**

$x = 50t - \frac{15}{\pi^2}\cos(\pi t) + \frac{3}{\pi^2}$, $2$ hours $1$ minute

60) [T] For the previous problem, find the total distance traveled in the first hour.

61) Substitute $y = Be^{3t}$ into $y' - y = 8e^{3t}$ to find a particular solution.

**Answer**

$y = 4e^{3t}$

62) Substitute $y = a\cos(2t) + b\sin(2t)$ into $y' + y = 4\sin(2t)$ to find a particular solution.

63) Substitute $y = a + bt + ct^2$ into $y' + y = 1 + t^2$ to find a particular solution.

**Answer**

$y = 1 - 2t + t^2$

64) Substitute $y = ae^t \cos t + be^t \sin t$ into $y' = 2e^t \cos t$ to find a particular solution.

65) Solve $y' = e^{kt}$ with the initial condition $y(0) = 0$ and solve $y' = 1$ with the same initial condition. As $k$ approaches $0$, what do you notice?

**Answer**

$y = \frac{1}{k}(e^{kt} - 1)$ and $y = t$

# 11.3: Direction Fields and Numerical Methods

**Learning Objectives**

- Draw the direction field for a given first-order differential equation.
- Use a direction field to draw a solution curve of a first-order differential equation.
- Use Euler's Method to approximate the solution to a first-order differential equation.

For the rest of this chapter we will focus on various methods for solving differential equations and analyzing the behavior of the solutions. In some cases it is possible to predict properties of a solution to a differential equation without knowing the actual solution. We will also study numerical methods for solving differential equations, which can be programmed by using various computer languages or even by using a spreadsheet program, such as Microsoft Excel.

## Creating Direction Fields

Direction fields (also called slope fields) are useful for investigating first-order differential equations. In particular, we consider a first-order differential equation of the form

$$y' = f(x, y).$$

An applied example of this type of differential equation appears in Newton's law of cooling, which we will solve explicitly later in this chapter. First, though, let us create a direction field for the differential equation

$$T'(t) = -0.4(T - 72).$$

Here $T(t)$ represents the temperature (in degrees Fahrenheit) of an object at time $t$, and the ambient temperature is $72°F$. Figure 11.3.1 shows the direction field for this equation.

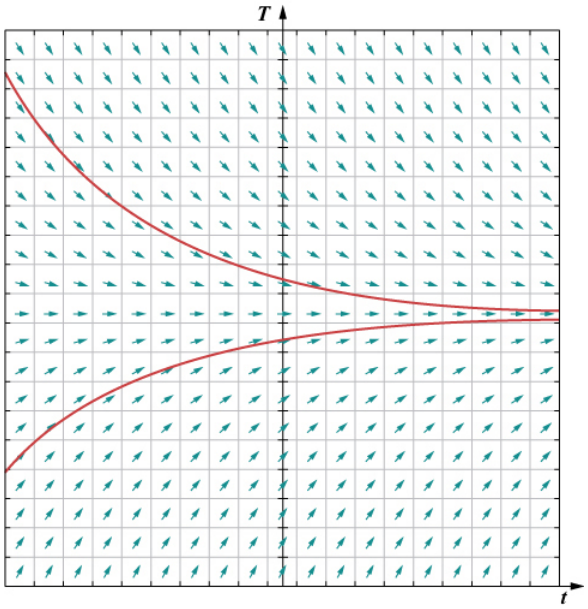

Figure 11.3.1: Direction field for the differential equation $T'(t) = -0.4(T - 72)$. Two solutions are plotted: one with initial temperature less than $72°F$ and the other with initial temperature greater than $72°F$.

The idea behind a direction field is the fact that the derivative of a function evaluated at a given point is the slope of the tangent line to the graph of that function at the same point. Other examples of differential equations for which we can create a direction field include

$$y' = 3x + 2y - 4$$

$$y' = x^2 - y^2$$

$$y' = \frac{2x+4}{y-2}.$$

To create a direction field, we start with the first equation: $y' = 3x + 2y - 4$. We let $(x_0, y_0)$ be any ordered pair, and we substitute these numbers into the right-hand side of the differential equation. For example, if we choose $x = 1$ and $y = 2$, substituting into the right-hand side of the differential equation yields

$$y' = 3x + 2y - 4 = 3(1) + 2(2) - 4 = 3.$$

This tells us that if a solution to the differential equation $y' = 3x + 2y - 4$ passes through the point $(1, 2)$, then the slope of the solution at that point must equal 3. To start creating the direction field, we put a short line segment at the point $(1, 2)$ having slope $3$. We can do this for any point in the domain of the function $f(x, y) = 3x + 2y - 4$, which consists of all ordered pairs $(x, y)$ in $R^2$. Therefore any point in the Cartesian plane has a slope associated with it, assuming that a solution to the differential equation passes through that point. The direction field for the differential equation $y' = 3x + 2y - 4$ is shown in Figure 11.3.2.

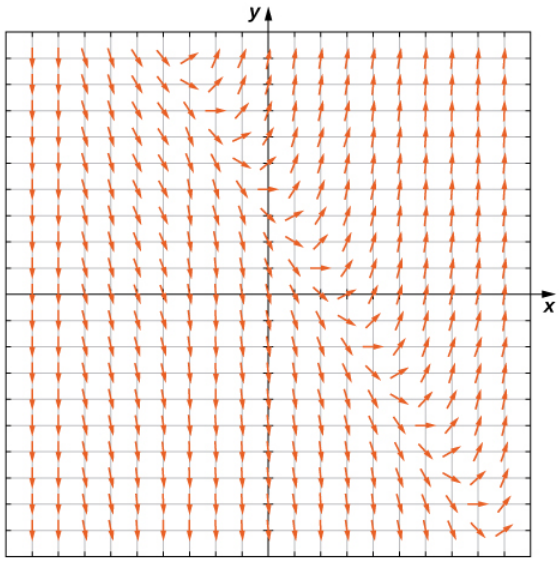

Figure 11.3.2: Direction field for the differential equation $y' = 3x + 2y - 4$.

We can generate a direction field of this type for any differential equation of the form $y' = f(x, y)$.

**Definition: Direction Field (Slope Field)**

A direction field (slope field) is a mathematical object used to graphically represent solutions to a first-order differential equation. At each point in a direction field, a line segment appears whose slope is equal to the slope of a solution to the differential equation passing through that point.

## Using Direction Fields

We can use a direction field to predict the behavior of solutions to a differential equation without knowing the actual solution. For example, the direction field in Figure 11.3.3 serves as a guide to the behavior of solutions to the differential equation $y' = 3x + 2y - 4$.

To use a direction field, we start by choosing any point in the field. The line segment at that point serves as a signpost telling us what direction to go from there. For example, if a solution to the differential equation passes through the point $(0, 1)$, then the slope of the solution passing through that point is given by $y' = 3(0) + 2(1) - 4 = -2$. Now let $x$ increase slightly, say to $x = 0.1$. Using the method of linear approximations gives a formula for the approximate value of $y$ for $x = 0.1$. In particular,

$$L(x) = y_0 + f'(x_0)(x - x_0) = 1 - 2(x_0 - 0) = 1 - 2x_0.$$

Substituting $x_0 = 0.1$ into $L(x)$ gives an approximate $y$ value of $0.8$.

At this point the slope of the solution changes (again according to the differential equation). We can keep progressing, recalculating the slope of the solution as we take small steps to the right, and watching the behavior of the solution. Figure 11.3.3 shows a graph of the solution passing through the point $(0,1)$.

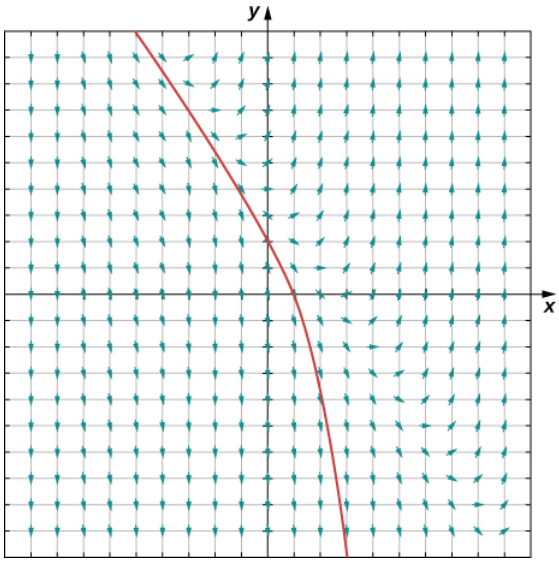

Figure 11.3.3: Direction field for the differential equation $y' = 3x + 2y - 4$ with the solution passing through the point $(0,1)$.

The curve is the graph of the solution to the initial-value problem

$$y' = 3x + 2y - 4,\ y(0) = 1.$$

This curve is called a solution curve passing through the point $(0,1)$. The exact solution to this initial-value problem is

$$y = -\frac{3}{2}x + \frac{5}{4} - \frac{1}{4}e^{2x},$$

and the graph of this solution is identical to the curve in Figure 11.3.3.

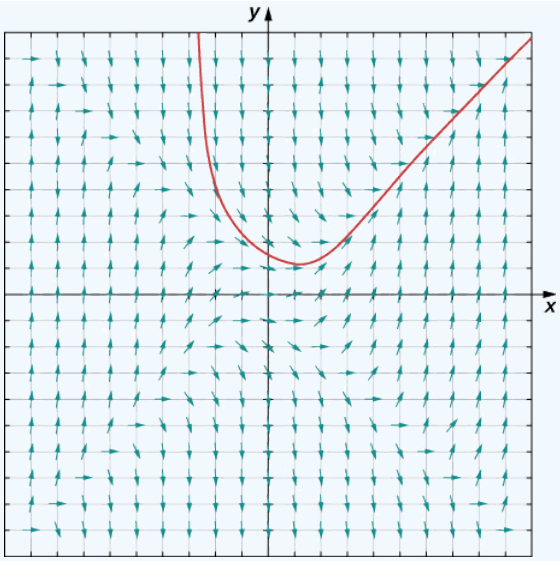
## ? Exercise 11.3.1

Create a direction field for the differential equation $y' = x^2 - y^2$ and sketch a solution curve passing through the point $(-1,2)$.

**Hint**

Use $x$ and $y$ values ranging from $-5$ to $5$. For each coordinate pair, calculate $y'$ using the right-hand side of the differential equation.

**Answer**



Now consider the direction field for the differential equation $y' = (x-3)(y^2-4)$, shown in Figure 11.3.4. This direction field has several interesting properties. First of all, at $y = -2$ and $y = 2$, horizontal dashes appear all the way across the graph. This means that if $y = -2$, then $y' = 0$. Substituting this expression into the right-hand side of the differential equation gives

$$\begin{aligned}(x-3)(y^2-4) &= (x-3)((-2)^2-4)\\ &= (x-3)(0)\\ &= 0\\ &= y'.\end{aligned}$$

Therefore $y = -2$ is a solution to the differential equation. Similarly, $y = 2$ is a solution to the differential equation. These are the only constant-valued solutions to the differential equation, as we can see from the following argument. Suppose $y = k$ is a constant solution to the differential equation. Then $y' = 0$. Substituting this expression into the differential equation yields $0 = (x-3)(k^2-4)$. This equation must be true for all values of $x$, so the second factor must equal zero. This result yields the equation $k^2 - 4 = 0$. The solutions to this equation are $k = -2$ and $k = 2$, which are the constant solutions already mentioned. These are called the equilibrium solutions to the differential equation.

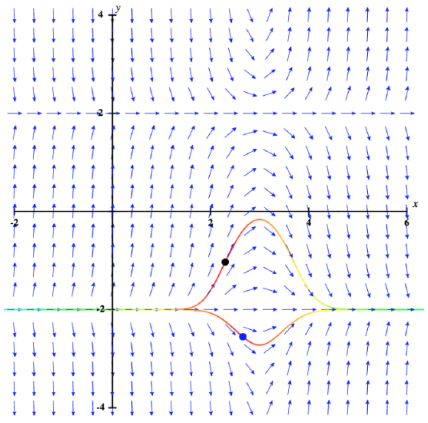


Figure 11.3.4: Direction field for the differential equation $y' = (x-3)(y^2-4)$ showing two solutions. These solutions are very close together, but one is barely above the equilibrium solution $y = -2$ and the other is barely below the same equilibrium solution.

**Definition: Equilibrium Solutions**

Consider the differential equation $y' = f(x, y)$. An *equilibrium solution* is any solution to the differential equation of the form $y = c$, where $c$ is a constant.

To determine the equilibrium solutions to the differential equation $y' = f(x, y)$, set the right-hand side equal to zero. An equilibrium solution of the differential equation is any function of the form $y = k$ such that $f(x, k) = 0$ for all values of $x$ in the domain of $f$.

An important characteristic of equilibrium solutions concerns whether or not they approach the line $y = k$ as an asymptote for large values of $x$.

**Definition: asymptotically Stable, Unstable and Semi-Stable Solutions**

Consider the differential equation $y' = f(x, y)$, and assume that all solutions to this differential equation are defined for $x \geq x_0$. Let $y = k$ be an equilibrium solution to the differential equation.

1. $y = k$ is an *asymptotically stable solution* to the differential equation if there exists $\varepsilon > 0$ such that for any value $c \in (k - \varepsilon, k + \varepsilon)$ the solution to the initial-value problem $y' = f(x, y)$, $y(x_0) = c$ approaches $k$ as $x$ approaches infinity.
2. $y = k$ is an *asymptotically unstable solution* to the differential equation if there exists $\varepsilon > 0$ such that for any value $c \in (k - \varepsilon, k + \varepsilon)$ the solution to the initial-value problem $y' = f(x, y)$, $y(x_0) = c$ never approaches $k$ as $x$ approaches infinity.
3. $y = k$ is an *asymptotically semi-stable solution* to the differential equation if it is neither asymptotically stable nor asymptotically unstable.

Now we return to the differential equation $y' = (x - 3)(y^2 - 4)$, with the initial condition $y(0) = 0.5$. The direction field for this initial-value problem, along with the corresponding solution, is shown in Figure 11.3.5.

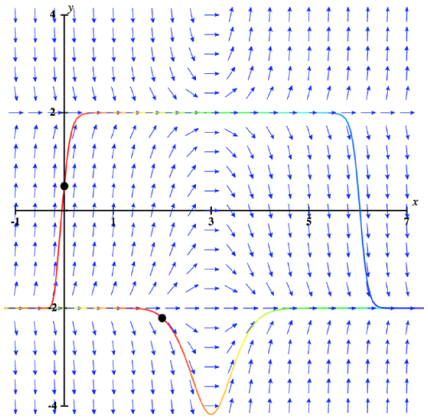

Figure 11.3.5: Direction field for the initial-value problem $y' = (x - 3)(y^2 - 4)$, $y(0) = 0.5$. A second solution curve is graphed with initial condition $(2, -2.2)$.

The values of the solution to this initial-value problem stay between $y = -2$ and $y = 2$, which are the equilibrium solutions to the differential equation. Furthermore, as $x$ approaches infinity, although they initially appear to approach the line y = 2, the $y$-coordinates clearly approach $-2$. The behavior of solutions is similar if the initial value is below $-2$, for example, $y(2) = -2.2$. In this case, the solutions increase and approach $y = -2$ as $x$ approaches infinity. Therefore $y = -2$ is an asymptotically stable solution to this differential equation.

What happens when the initial value is above $y = 2$? This scenario is illustrated in Figure 11.3.6, with the initial value $y(0) = 3$.

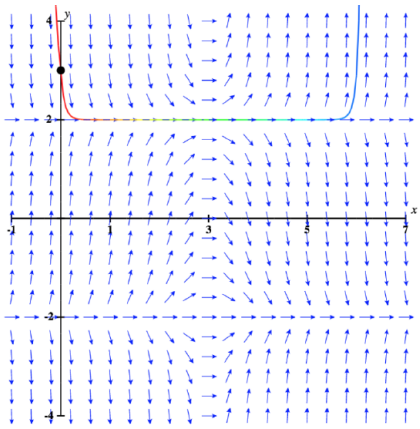

Figure 11.3.6: Direction field for the initial-value problem $y' = (x-3)(y^2-4),\ y(0)=3$.

The solution increases rapidly toward positive infinity as $x$ approaches infinity. Furthermore, if the initial value is slightly below 2, then the solution approaches $-2$, which is the other equilibrium solution. Therefore in neither case does the solution approach $y=2$, so $y=2$ is called an asymptotically unstable, or unstable, equilibrium solution.

### Example 11.3.1: Stability of an Equilibrium Solution

Create a direction field for the differential equation $y' = (y-3)^2(y^2+y-2)$ and identify any equilibrium solutions. Classify each of the equilibrium solutions as stable, unstable, or semi-stable.

#### Solution

The direction field is shown in Figure 11.3.7.

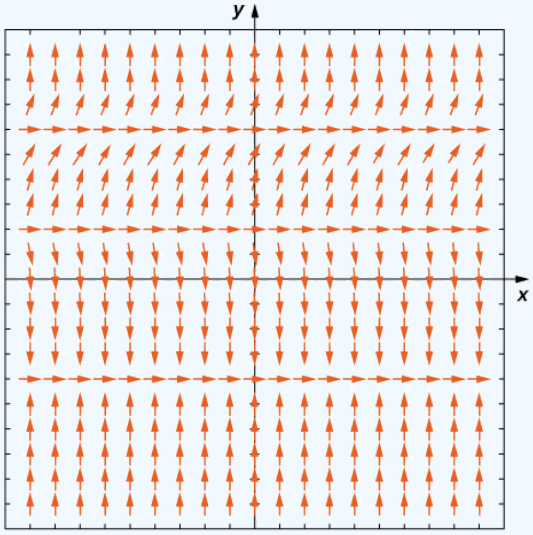

Figure 11.3.7: Direction field for the differential equation $y' = (y-3)^2(y^2+y-2)$.

The equilibrium solutions are $y=-2$, $y=1$, and $y=3$. To classify each of the solutions, look at an arrow directly above or below each of these values. For example, at $y=-2$ the arrows directly below this solution point up, and the arrows directly above the solution point down. Therefore all initial conditions close to $y=-2$ approach $y=-2$, and the solution is stable. For the solution $y=1$, all initial conditions above and below $y=1$ are repelled (pushed away) from $y=1$, so this solution is unstable. The solution $y=3$ is semi-stable, because for initial conditions slightly greater than 3, the solution approaches infinity, and for initial conditions slightly less than 3, the solution approaches $y=1$.

#### Analysis

It is possible to find the equilibrium solutions to the differential equation by setting the right-hand side equal to zero and solving for $y$. This approach gives the same equilibrium solutions as those we saw in the direction field.

**Exercise 11.3.2**

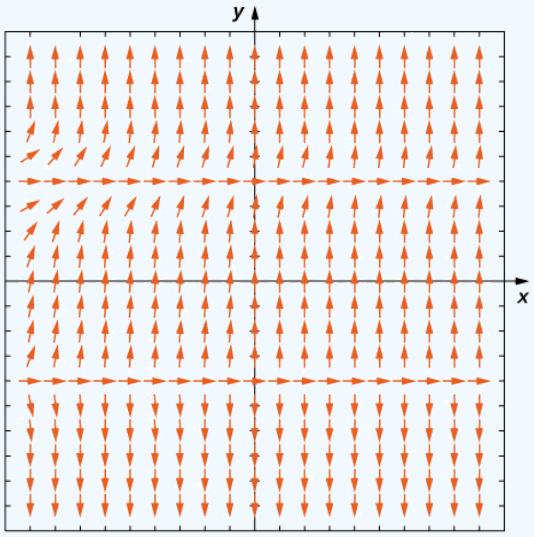
Create a direction field for the differential equation $y' = (x+5)(y+2)(y^2-4y+4)$ and identify any equilibrium solutions. Classify each of the equilibrium solutions as stable, unstable, or semi-stable.

**Hint**

First create the direction field and look for horizontal dashes that go all the way across. Then examine the slope lines directly above and below the equilibrium solutions.

**Answer**

The equilibrium solutions are $y = -2$ and $y = 2$. For this equation, $y = -2$ is an unstable equilibrium solution, and $y = 2$ is a semi-stable equilibrium solution.



## Euler's Method

Consider the initial-value problem

$$y' = 2x - 3,\ y(0) = 3.$$

Integrating both sides of the differential equation gives $y = x^2 - 3x + C$, and solving for $C$ yields the particular solution $y = x^2 - 3x + 3$. The solution for this initial-value problem appears as the parabola in Figure 11.3.8.

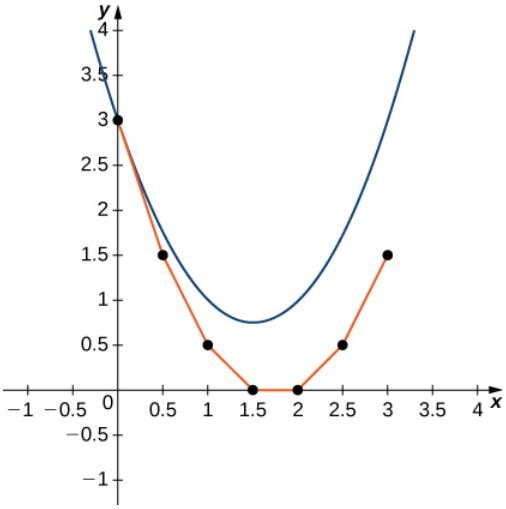


Figure 11.3.8: Euler's Method for the initial-value problem $y' = 2x - 3, y(0) = 3$.

The red graph consists of line segments that approximate the solution to the initial-value problem. The graph starts at the same initial value of $(0, 3)$. Then the slope of the solution at any point is determined by the right-hand side of the differential equation, and the length of the line segment is determined by increasing the $x$ value by $0.5$ each time (the step size). This approach is the basis of Euler's Method.

Before we state Euler's Method as a theorem, let's consider another initial-value problem:

$$y' = x^2 - y^2,\ y(-1) = 2.$$

The idea behind direction fields can also be applied to this problem to study the behavior of its solution. For example, at the point $(-1, 2)$, the slope of the solution is given by $y' = (-1)^2 - 2^2 = -3$, so the slope of the tangent line to the solution at that point is also equal to $-3$. Now we define $x_0 = -1$ and $y_0 = 2$. Since the slope of the solution at this point is equal to $-3$, we can use the method of linear approximation to approximate y near $(-1, 2)$.

$$L(x) = y_0 + f'(x_0)(x - x_0).$$

Here $x_0 = -1, y_0 = 2$, and $f'(x_0) = -3$, so the linear approximation becomes

$$L(x) = 2 - 3(x - (-1)) = 2 - 3x - 3 = -3x - 1.$$

Now we choose a **step size**. The step size is a small value, typically $0.1$ or less, that serves as an increment for $x$; it is represented by the variable $h$. In our example, let $h = 0.1$. Incrementing $x_0$ by $h$ gives our next $x$ value:

$$x_1 = x_0 + h = -1 + 0.1 = -0.9.$$

We can substitute $x_1 = -0.9$ into the linear approximation to calculate $y_1$.

$$y_1 = L(x_1) = -3(-0.9) - 1 = 1.7.$$

Therefore the approximate $y$ value for the solution when $x = -0.9$ is $y = 1.7$. We can then repeat the process, using $x_1 = -0.9$ and $y_1 = 1.7$ to calculate $x_2$ and $y_2$. The new slope is given by $y' = (-0.9)^2 - (1.7)^2 = -2.08$. First, $x_2 = x_1 + h = -0.9 + 0.1 = -0.8$. Using linear approximation gives

$$\begin{aligned} L(x) &= y_1 + f'(x_1)(x - x_1) \\ &= 1.7 - 2.08(x - (-0.9)) \\ &= 1.7 - 2.08x - 1.872 \\ &= -2.08x - 0.172. \end{aligned}$$

Finally, we substitute $x_2 = -0.8$ into the linear approximation to calculate $y_2$.

$$\begin{aligned} y_2 &= L(x_2) \\ &= -2.08x_2 - 0.172 \\ &= -2.08(-0.8) - 0.172 \\ &= 1.492. \end{aligned}$$

Therefore the approximate value of the solution to the differential equation is $y = 1.492$ when $x = -0.8$.

What we have just shown is the idea behind **Euler's Method**. Repeating these steps gives a list of values for the solution. These values are shown in the table, rounded off to four decimal places.

Table **11.3.1**: Using Euler's Method to Approximate Solutions to a Differential Equation

| $n$ | 0 | 1 | 2 | 3 | 4 | 5 |
|---|---|---|---|---|---|---|
| $x_n$ | −1 | −0.9 | −0.8 | −0.7 | −0.6 | −0.5 |
| $y_n$ | 2 | 1.7 | 1.492 | 1.3334 | 1.2046 | 1.0955 |
| $n$ | 6 | 7 | 8 | 9 | 10 | |
| $x_n$ | −0.4 | −0.3 | −0.2 | −0.1 | 0 | |
| $y_n$ | 1.0004 | 1.9164 | 1.8414 | 1.7746 | 1.7156 | |

### Euler's method

Consider the initial-value problem

$$y' = f(x, y),\ y(x_0) = y_0.$$

To approximate a solution to this problem using Euler's method, define

$$x_n = x_0 + nh$$

$$y_n = y_{n-1} + hf(x_{n-1}, y_{n-1}).$$

Here $h > 0$ represents the step size and $n$ is an integer, starting with $1$. The number of steps taken is counted by the variable $n$.

Typically $h$ is a small value, say $0.1$ or $0.05$. The smaller the value of $h$, the more calculations are needed. The higher the value of $h$, the fewer calculations are needed. However, the tradeoff results in a lower degree of accuracy for larger step size, as illustrated in Figure **11.3.9**.

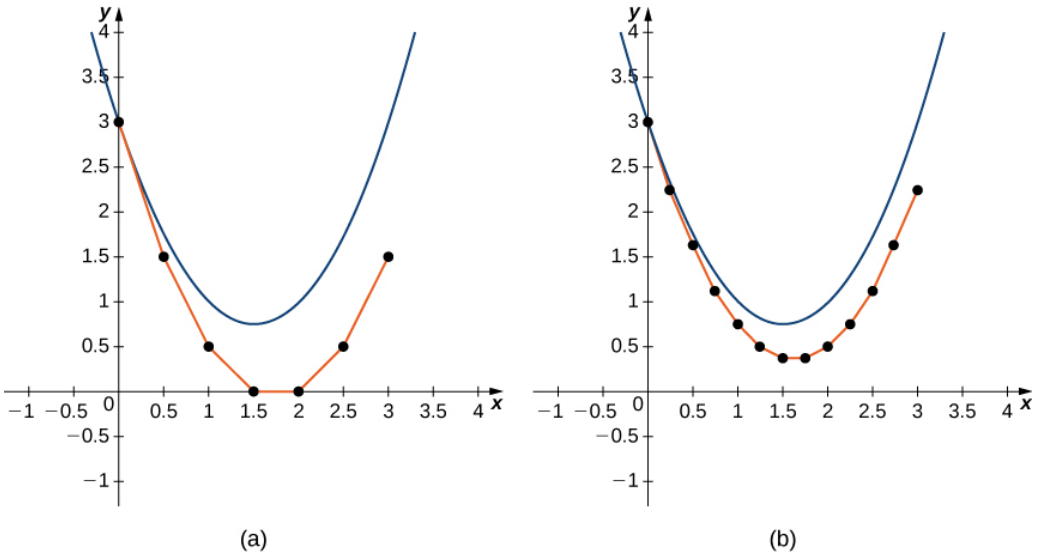

Figure **11.3.9**: Euler's method for the initial-value problem $y' = 2x - 3,\ y(0) = 3$ with (a) a step size of $h = 0.5$; and (b) a step size of $h = 0.25$.

## Example 11.3.2: Using Euler's Method

Consider the initial-value problem

$$y' = 3x^2 - y^2 + 1,\ y(0) = 2.$$

Use Euler's method with a step size of $0.1$ to generate a table of values for the solution for values of $x$ between $0$ and $1$.

### Solution

We are given $h = 0.1$ and $f(x, y) = 3x^2 - y^2 + 1$. Furthermore, the initial condition $y(0) = 2$ gives $x_0 = 0$ and $y_0 = 2$. Using Equation with $n = 0$, we can generate this table.

Table 11.3.2: Using Euler's Method to Approximate Solutions to a Differential Equation

| $n$ | $x_n$ | $y_n = y_{n-1} + hf(x_{n-1}, y_{n-1})$ |
|---|---|---|
| 0 | 0 | 2 |
| 1 | 0.1 | $y_1 = y_0 + hf(x_0, y_0) = 1.7$ |
| 2 | 0.2 | $y_2 = y_1 + hf(x_1, y_1) = 1.514$ |
| 3 | 0.3 | $y_3 = y_2 + hf(x_2, y_2) = 1.3968$ |
| 4 | 0.4 | $y_4 = y_3 + hf(x_3, y_3) = 1.3287$ |
| 5 | 0.5 | $y_5 = y_4 + hf(x_4, y_4) = 1.3001$ |
| 6 | 0.6 | $y_6 = y_5 + hf(x_5, y_5) = 1.3061$ |
| 7 | 0.7 | $y_7 = y_6 + hf(x_6, y_6) = 1.3435$ |
| 8 | 0.8 | $y_8 = y_7 + hf(x_7, y_7) = 1.4100$ |
| 9 | 0.9 | $y_9 = y_8 + hf(x_8, y_8) = 1.5032$ |
| 10 | 1.0 | $y_{10} = y_9 + hf(x_9, y_9) = 1.6202$ |

With ten calculations, we are able to approximate the values of the solution to the initial-value problem for values of $x$ between $0$ and $1$.

Go to this website for a chance to visually explore Euler's method.

## Exercise 11.3.3

Consider the initial-value problem

$$y' = x^3 + y^2,\ y(1) = -2.$$

Using a step size of $0.1$, generate a table with approximate values for the solution to the initial-value problem for values of $x$ between $1$ and $2$.

**Hint**

Start by identifying the value of $h$, then figure out what $f(x, y)$ is. Then use the formula for Euler's Method to calculate $y_1, y_2$, and so on.

**Answer**

Table **11.3.3**: Using Euler's Method to approximate solutions to the differential equation in Exercise **11.3.3**.

| $n$ | \( x_n) | $y_n = y_{n-1} + hf(x_{n-1}, y_{n-1})$ |
|---|---|---|
| 0 | 1 | $-2$ |
| 1 | 1.1 | $y_1 = y_0 + hf(x_0, y_0) = -1.5$ |
| 2 | 1.2 | $y_2 = y_1 + hf(x_1, y_1) = -1.1419$ |
| 3 | 1.3 | $y_3 = y_2 + hf(x_2, y_2) = -0.8387$ |
| 4 | 1.4 | $y_4 = y_3 + hf(x_3, y_3) = -0.5487$ |
| 5 | 1.5 | $y_5 = y_4 + hf(x_4, y_4) = -0.2442$ |
| 6 | 1.6 | $y_6 = y_5 + hf(x_5, y_5) = 0.0993$ |
| 7 | 1.7 | $y_7 = y_6 + hf(x_6, y_6) = 0.5099$ |
| 8 | 1.8 | $y_8 = y_7 + hf(x_7, y_7) = 1.0272$ |
| 9 | 1.9 | $y_9 = y_8 + hf(x_8, y_8) = 1.7159$ |
| 10 | 2 | $y_{10} = y_9 + hf(x_9, y_9) = 2.6962$ |

## Key Concepts

- A direction field is a mathematical object used to graphically represent solutions to a first-order differential equation.
- Euler's Method is a numerical technique that can be used to approximate solutions to a differential equation.

## Key Equations

- **Euler's Method**

  $x_n = x_0 + nh$

  $y_n = y_{n-1} + hf(x_{n-1}, y_{n-1})$, where $h$ is the step size

## Glossary

**asymptotically semi-stable solution**

$y = k$ if it is neither asymptotically stable nor asymptotically unstable

**asymptotically stable solution**

$y = k$ if there exists $\varepsilon > 0$ such that for any value $c \in (k - \varepsilon,\ k + \varepsilon)$ the solution to the initial-value problem $y' = f(x, y),\ y(x_0) = c$ approaches $k$ as $x$ approaches infinity

**asymptotically unstable solution**

$y = k$ if there exists $\varepsilon > 0$ such that for any value $c \in (k - \varepsilon,\ k + \varepsilon)$ the solution to the initial-value problem $y' = f(x, y),\ y(x_0) = c$ never approaches $k$ as $x$approaches infinity

**direction field (slope field)**

a mathematical object used to graphically represent solutions to a first-order differential equation; at each point in a direction field, a line segment appears whose slope is equal to the slope of a solution to the differential equation passing through that point

**equilibrium solution**

any solution to the differential equation of the form $y = c$, where $c$ is a constant

**Euler's Method**

a numerical technique used to approximate solutions to an initial-value problem

**solution curve**

a curve graphed in a direction field that corresponds to the solution to the initial-value problem passing through a given point in the direction field

**step size**

the increment hh that is added to the xx value at each step in Euler's Method

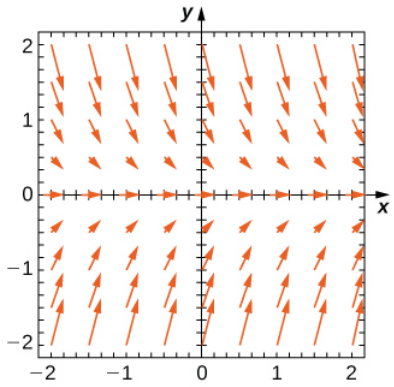
# 11.3E: Exercises for Section 8.2

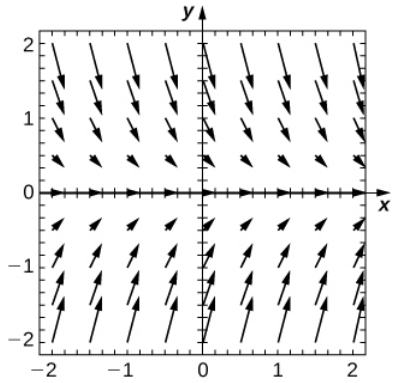
**For exercises 1 - 3, use the direction field below from the differential equation $y' = -2y$. Sketch the graph of the solution for the given initial conditions.**



1) $y(0) = 1$

2) $y(0) = 0$

**Answer**



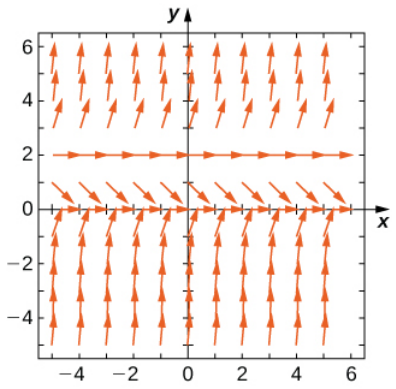
3) $y(0) = -1$

4) Are there any equilibria among the solutions of the differential equation from exercises 1 - 3? List any equilibria along with their stabilities.

**Answer**

$y = 0$ is a stable equilibrium

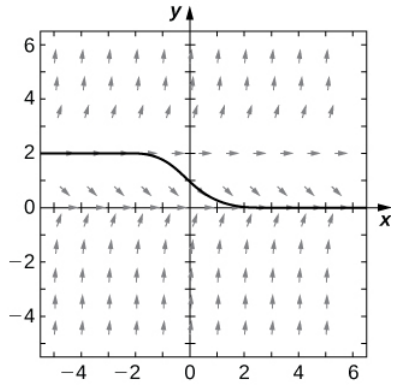
**For exercises 5 - 7, use the direction field below from the differential equation $y' = y^2 - 2y$. Sketch the graph of the solution for the given initial conditions.**



5) $y(0) = 3$

6) $y(0) = 1$

**Answer**



7) $y(0) = -1$

8) Are there any equilibria among the solutions of the differential equation from exercises 5 - 7? List any equilibria along with their stabilities.

**Answer**

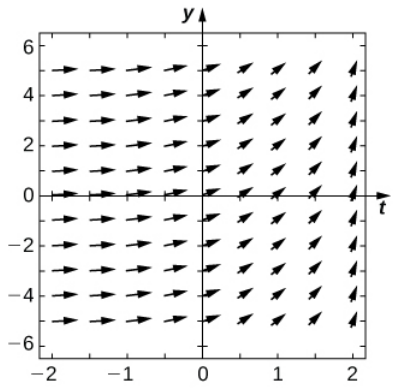
$y = 0$ is a stable equilibrium and $y = 2$ is unstable

**In exercises 9 - 13, draw the direction field for the following differential equations, then solve the differential equation. Draw your solution on top of the direction field. Does your solution follow along the arrows on your direction field?**

9) $y' = t^3$

10) $y' = e^t$

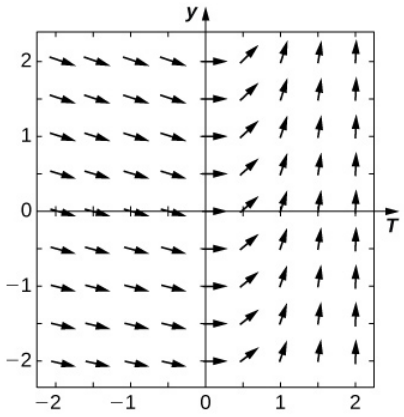
**Answer**



11) $\frac{dy}{dx} = x^2 \cos x$

12) $\frac{dy}{dt} = te^t$

**Answer**



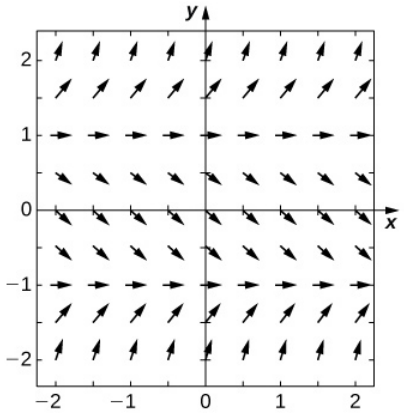
13) $\frac{dx}{dt} = \cosh(t)$

**In exercises 14 - 18, draw the directional field for the following differential equations. What can you say about the behavior of the solution? Are there equilibria? What stability do these equilibria have?**

14) $y' = y^2 - 1$

**Answer**

There appear to be equlibria at $y = -1$ (stable) and $y = 1$ (unstable).

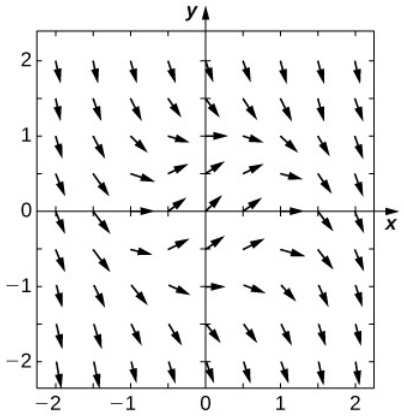


15) $y' = y - x$

16) $y' = 1 - y^2 - x^2$

**Answer**

There do not appear to be any equilibria.

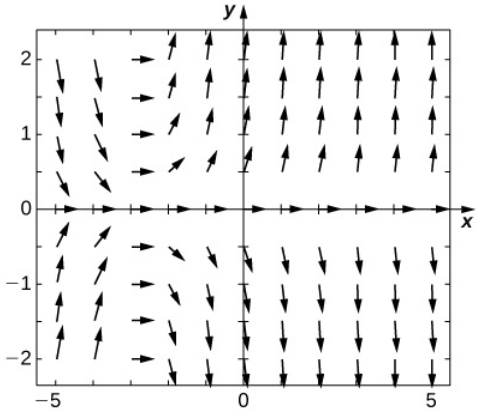


17) $y' = t^2 \sin y$

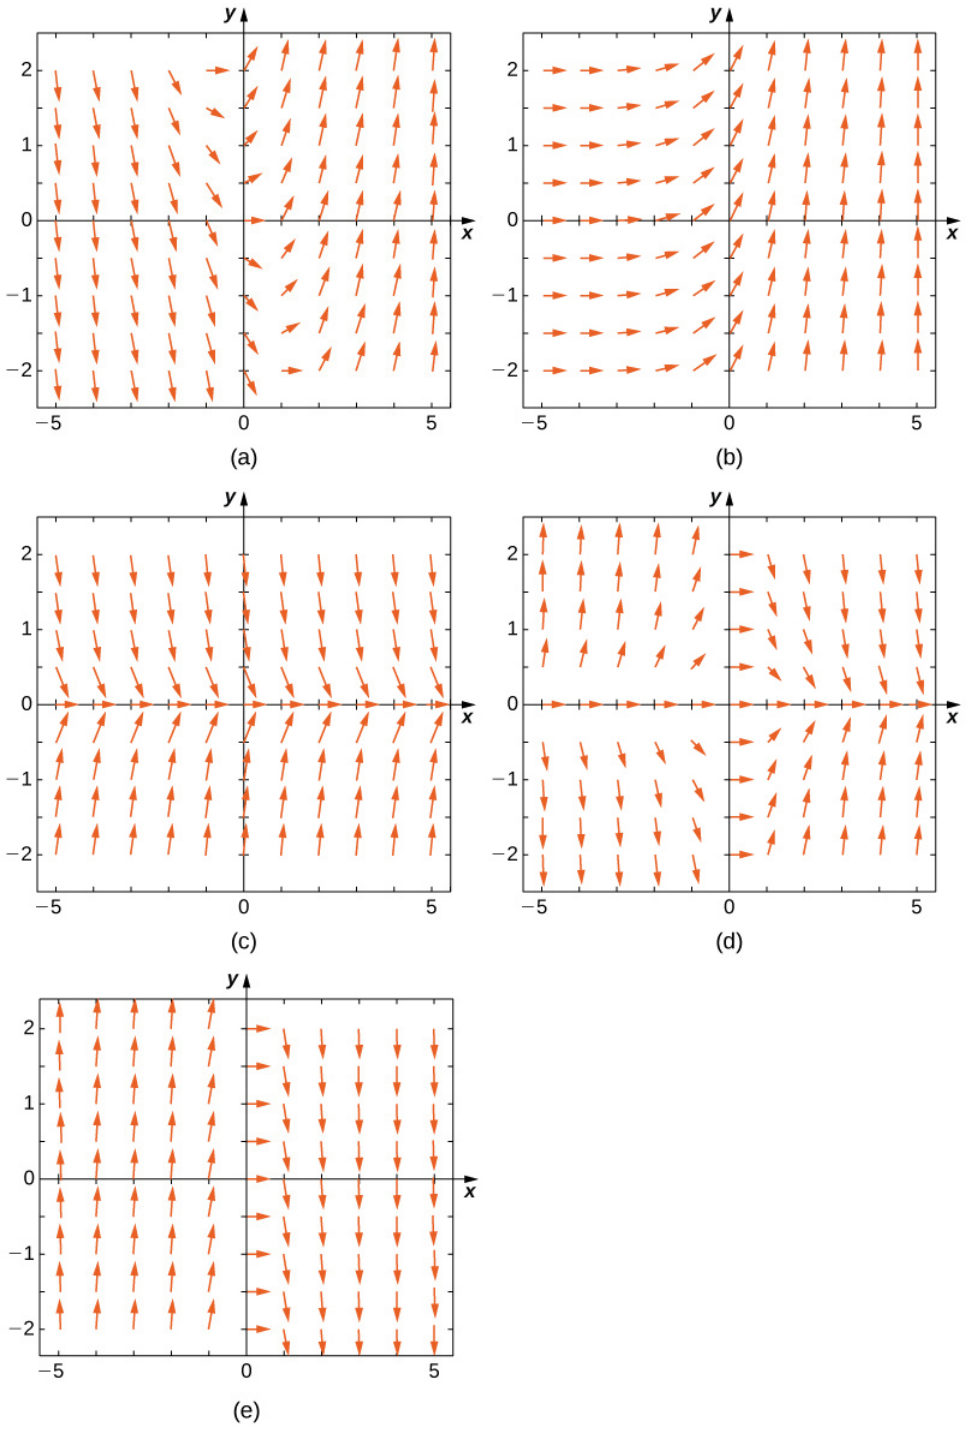
18) $y' = 3y + xy$

**Answer**

There appears to be an unstable equilibrium at $y = 0$.



**Match the direction field with the given differential equations. Explain your selections.**



19) $y' = -3y$

20) $y' = -3t$

**Answer**

$E$

21) $y' = e^t$

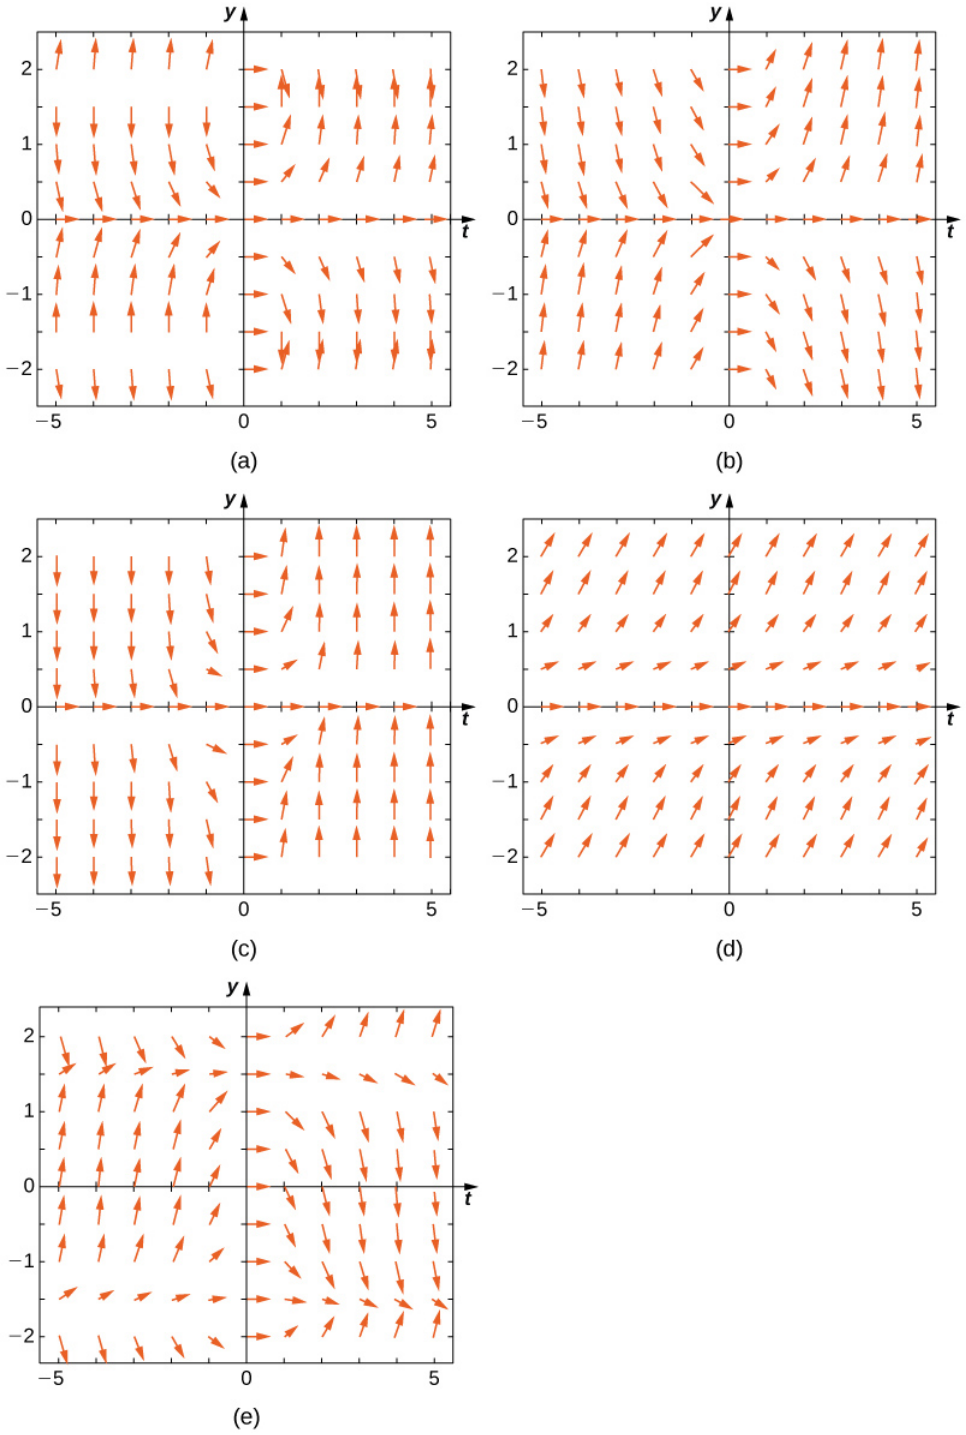
22) $y' = \frac{1}{2}y + t$

**Answer**

$A$

23) $y' = -ty$

**Match the direction field with the given differential equations. Explain your selections.**



24) $y' = t \sin y$

**Answer**

$B$

25) $y' = -t\cos y$

26) $y' = t\tan y$

**Answer**

$A$

27) $y' = \sin^2 y$

28) $y' = y^2 t^3$

**Answer**

$C$

**Estimate the following solutions using Euler's method with $n = 5$ steps over the interval $t = [0, 1]$. If you are able to solve the initial-value problem exactly, compare your solution with the exact solution. If you are unable to solve the initial-value problem, the exact solution will be provided for you to compare with Euler's method. How accurate is Euler's method?**

29) $y' = -3y, \quad y(0) = 1$

30) $y' = t^2, \quad y(0) = 1$

**Answer**

$1.24$, exact: $\frac{4}{3} \approx 1.33$

Solution:

31) $y' = 3t - y, \quad y(0) = 1$. Exact solution is $y = 3t + 4e^{-t} - 3$

32) $y' = y + t^2, \quad y(0) = 3$. Exact solution is $y = 5e^t - 2 - t^2 - 2t$

**Answer**

$7.739364$, exact: $5(e - 1)$

33) $y' = 2t, \quad y(0) = 0$

34) [T] $y' = e^{x+y}, y(0) = -1$. Exact solution is $y = -\ln(e + 1 - e^x)$

**Answer**

$-0.2535$, exact: $0$

35) $y' = y^2 \ln(x + 1), \quad y(0) = 1$. Exact solution is $y = -\dfrac{1}{(x + 1)(\ln(x + 1) - 1)}$

36) $y' = 2^x, \quad y(0) = 0$. Exact solution is $y = \dfrac{2^x - 1}{\ln 2}$

**Answer**

$1.345$, exact: $\frac{1}{\ln(2)}$

37) $y' = y, \quad y(0) = -1$. Exact solution is $y = -e^x$.

38) $y' = -5t, \quad y(0) = -2$. Exact solution is $y = -\frac{5}{2}t^2 - 2$

**Answer**

$-4$, exact: $-9/2 = -4.5$

Differential equations can be used to model **disease epidemics.** In the next set of problems, we examine the change of size of two sub-populations of people living in a city: individuals who are infected and individuals who are susceptible to infection. $S$ represents the size of the susceptible population, and $I$ represents the size of the infected population. We assume that if a

susceptible person interacts with an infected person, there is a probability $c$ that the susceptible person will become infected. Each infected person recovers from the infection at a rate $r$ and becomes susceptible again. We consider the case of influenza, where we assume that no one dies from the disease, so we assume that the total population size of the two sub-populations is a constant number, $N$. The differential equations that model these population sizes are

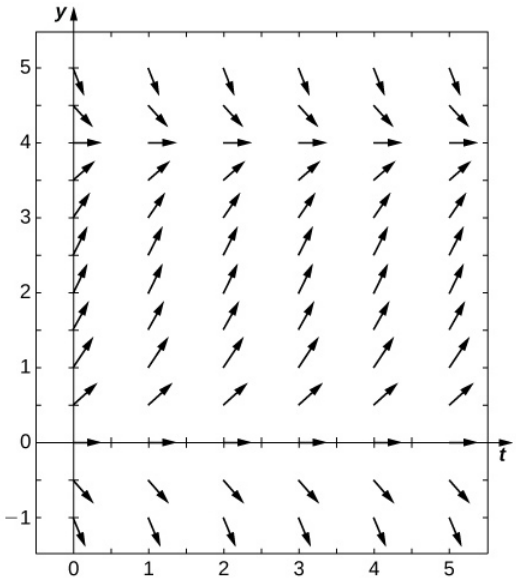
$$S' = rI - cSI \text{ and } I' = cSI - rI.$$

Here $c$ represents the contact rate and $r$ is the recovery rate.

39) Show that, by our assumption that the total population size is constant $(S + I = N)$, you can reduce the system to a single differential equation in $I$ : $I' = c(N - I)I - rI$.

40) Assuming the parameters are $c = 0.5, N = 5$, and $r = 0.5$, draw the resulting directional field.

**Answer**



41) [T] Use computational software or a calculator to compute the solution to the initial-value problem $y' = ty, y(0) = 2$ using Euler's Method with the given step size $h$. Find the solution at $t = 1$. For a hint, here is "pseudo-code" for how to write a computer program to perform Euler's Method for $y' = f(t, y), y(0) = 2$ :

Create function $f(t, y)$

Define parameters $y(1) = y_0, t(0) = 0$, step size $h$, and total number of steps, $N$

Write a for-loop:

for $k = 1$ to $N$

$fn = f(t(k), y(k))$

$y(k + 1) = y(k) + h * fn$

$t(k + 1) = t(k) + h$

42) Solve the initial-value problem for the exact solution.

**Answer**

$y' = 2e^{t^2/2}$

43) Draw the directional field

44) $h = 1$

**Answer**

$2$

45) [T] $h = 10$

46) [T] $h = 100$

**Answer**

$3.2756$

47) [T] $h = 1000$

48) [T] Evaluate the exact solution at $t = 1$. Make a table of errors for the relative error between the Euler's method solution and the exact solution. How much does the error change? Can you explain?

**Answer**

Exact solution: y =$2\sqrt{e}$.

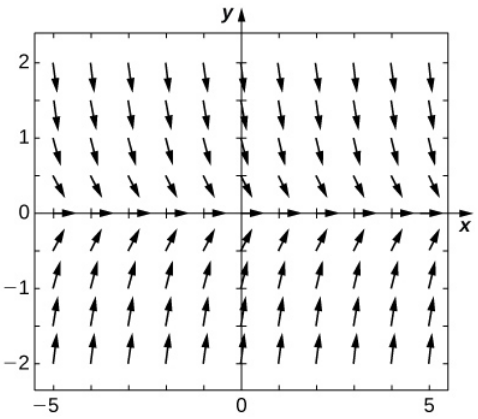
| Step Size | Error |
|---|---|
| $h = 1$ | 0.3935 |
| $h = 10$ | 0.06163 |
| $h = 100$ | 0.006612 |
| $h = 10000$ | 0.0006661 |

**For exercises 49 - 53, consider the initial-value problem $y' = -2y$, with $y(0) = 2$.**

49) Show that $y = 2e^{-2x}$ solves this initial-value problem.

50) Draw the directional field of this differential equation.

**Answer**



51) [T] By hand or by calculator or computer, approximate the solution using Euler's Method at $t = 10$ using $h = 5$.

52) [T] By calculator or computer, approximate the solution using Euler's Method at $t = 10$ using $h = 100$.

**Answer**

$4.0741e^{-10}$

53) [T] Plot exact answer and each Euler approximation (for $h = 5$ and $h = 100$) at each h on the directional field. What do you notice?

This page titled 11.3E: Exercises for Section 8.2 is shared under a CC BY-NC-SA 4.0 license and was authored, remixed, and/or curated by Gilbert Strang & Edwin “Jed” Herman (OpenStax) via source content that was edited to the style and standards of the LibreTexts platform.

# 11.4: Separable Equations

**Learning Objectives**

- Use separation of variables to solve a differential equation.
- Solve applications using separation of variables.

We now examine a solution technique for finding exact solutions to a class of differential equations known as separable differential equations. These equations are common in a wide variety of disciplines, including physics, chemistry, and engineering. We illustrate a few applications at the end of the section.

## Separation of Variables

We start with a definition and some examples.

**Definition: Separable Differential Equations**

A *separable differential equation* is any equation that can be written in the form

$$y' = f(x)g(y). \tag{11.4.1}$$

The term 'separable' refers to the fact that the right-hand side of Equation 11.4.1 can be separated into a function of $x$ times a function of $y$. Examples of separable differential equations include

$$y' = (x^2 - 4)(3y + 2) \tag{11.4.2}$$
$$y' = 6x^2 + 4x \tag{11.4.3}$$
$$y' = \sec y + \tan y \tag{11.4.4}$$
$$y' = xy + 3x - 2y - 6. \tag{11.4.5}$$

Equation 11.4.3 is separable with $f(x) = 6x^2 + 4x$ and $g(y) = 1$, Equation 11.4.4 is separable with $f(x) = 1$ and $g(y) = \sec y + \tan y$, and the right-hand side of Equation 11.4.5 can be factored as $(x + 3)(y - 2)$, so it is separable as well. Equation 11.4.4 is also called an *autonomous differential equation* because the right-hand side of the equation is a function of $y$ alone. If a differential equation is separable, then it is possible to solve the equation using the method of *separation of variables*.

**Problem-Solving Strategy: Separation of Variables**

1. Check for any values of $y$ that make $g(y) = 0$. These correspond to constant solutions.
2. Rewrite the differential equation in the form
$$\frac{dy}{g(y)} = f(x)dx.$$
3. Integrate both sides of the equation.
4. Solve the resulting equation for $y$ if possible.
5. If an initial condition exists, substitute the appropriate values for $x$ and $y$ into the equation and solve for the constant.

Note that Step 4 states "Solve the resulting equation for $y$ if possible." It is not always possible to obtain $y$ as an explicit function of $x$. Quite often we have to be satisfied with finding y as an implicit function of $x$.

**Example 11.4.1: Using Separation of Variables**

Find a general solution to the differential equation $y' = (x^2 - 4)(3y + 2)$ using the method of separation of variables.

**Solution**

Follow the five-step method of separation of variables.

1. In this example, $f(x) = x^2 - 4$ and $g(y) = 3y + 2$. Setting $g(y) = 0$ gives $y = -\frac{2}{3}$ as a constant solution.

2. Rewrite the differential equation in the form

$$\frac{dy}{3y+2} = (x^2 - 4)\,dx.$$

3. Integrate both sides of the equation:

$$\int \frac{dy}{3y+2} = \int (x^2 - 4)\,dx.$$

Let $u = 3y + 2$. Then $du = 3\frac{dy}{dx}\,dx$, so the equation becomes

$$\frac{1}{3}\int \frac{1}{u}\,du = \frac{1}{3}x^3 - 4x + C$$

$$\frac{1}{3}\ln|u| = \frac{1}{3}x^3 - 4x + C$$

$$\frac{1}{3}\ln|3y+2| = \frac{1}{3}x^3 - 4x + C.$$

4. To solve this equation for $y$, first multiply both sides of the equation by $3$.

$$\ln|3y+2| = x^3 - 12x + 3C$$

Now we use some logic in dealing with the constant $C$. Since $C$ represents an arbitrary constant, $3C$ also represents an arbitrary constant. If we call the second arbitrary constant $C_1$, where $C_1 = 3C$, the equation becomes

$$\ln|3y+2| = x^3 - 12x + C_1.$$

Now exponentiate both sides of the equation (i.e., make each side of the equation the exponent for the base $e$).

$$e^{\ln|3y+2|} = e^{x^3 - 12x + C_1}$$
$$|3y+2| = e^{C_1}e^{x^3 - 12x}$$

Again define a new constant $C_2 = e^{C_1}$ (note that $C_2 > 0$):

$$|3y+2| = C_2 e^{x^3 - 12x}.$$

Because of the absolute value on the left side of the equation, this corresponds to two separate equations:

$$3y + 2 = C_2 e^{x^3 - 12x}$$

and

$$3y + 2 = -C_2 e^{x^3 - 12x}.$$

The solution to either equation can be written in the form

$$y = \frac{-2 \pm C_2 e^{x^3 - 12x}}{3}.$$

Since $C_2 > 0$, it does not matter whether we use plus or minus, so the constant can actually have either sign. Furthermore, the subscript on the constant $C$ is entirely arbitrary, and can be dropped. Therefore the solution can be written as

$$y = \frac{-2 + Ce^{x^3 - 12x}}{3}, \text{ where } C = \pm C_2 \text{ or } C = 0.$$

Note that in writing a single general solution in this way, we are also allowing $C$ to equal $0$. This gives us the singular solution, $y = -\frac{2}{3}$, for the given differential equation. Check that this is indeed a solution of this differential equation!

5. No initial condition is imposed, so we are finished.

**? Exercise 11.4.1**

Use the method of separation of variables to find a general solution to the differential equation

$$y' = 2xy + 3y - 4x - 6.$$

**Hint**

First factor the right-hand side of the equation by grouping, then use the five-step strategy of separation of variables.

**Answer**

$$y = 2 + Ce^{x^2+3x}$$

**✓ Example 11.4.2: Solving an Initial-Value Problem**

Using the method of separation of variables, solve the initial-value problem

$$y' = (2x+3)(y^2-4), \quad y(0) = -1.$$

**Solution**

Follow the five-step method of separation of variables.

1. In this example, $f(x) = 2x + 3$ and $g(y) = y^2 - 4$. Setting $g(y) = 0$ gives $y = \pm 2$ as constant solutions.

2. Divide both sides of the equation by $y^2 - 4$ and multiply by $dx$. This gives the equation

$$\frac{dy}{y^2-4} = (2x+3)\,dx.$$

3. Next integrate both sides:

$$\int \frac{1}{y^2-4}dy = \int (2x+3)\,dx. \tag{11.4.6}$$

To evaluate the left-hand side, use the method of partial fraction decomposition. This leads to the identity

$$\frac{1}{y^2-4} = \frac{1}{4}\left(\frac{1}{y-2} - \frac{1}{y+2}\right).$$

Then Equation 11.4.6 becomes

$$\frac{1}{4}\int \left(\frac{1}{y-2} - \frac{1}{y+2}\right)dy = \int (2x+3)\,dx$$

$$\frac{1}{4}\left(\ln|y-2| - \ln|y+2|\right) = x^2 + 3x + C.$$

Multiplying both sides of this equation by $4$ and replacing $4C$ with $C_1$ gives

$$\ln|y-2| - \ln|y+2| = 4x^2 + 12x + C_1$$

$$\ln\left|\frac{y-2}{y+2}\right| = 4x^2 + 12x + C_1.$$

4. It is possible to solve this equation for $y$. First exponentiate both sides of the equation and define $C_2 = e^{C_1}$:

$$\left|\frac{y-2}{y+2}\right| = C_2 e^{4x^2+12x}.$$

Next we can remove the absolute value and let a new constant $C_3$ be positive, negative, or zero, i.e., $C_3 = \pm C_2$ or $C_3 = 0$.

Then multiply both sides by $y+2$.

$$y - 2 = C_3(y+2)e^{4x^2+12x}$$

$$y - 2 = C_3 y e^{4x^2+12x} + 2C_3 e^{4x^2+12x}.$$

Now collect all terms involving $y$ on one side of the equation, and solve for $y$:

$$y - C_3 y e^{4x^2+12x} = 2 + 2C_3 e^{4x^2+12x}$$

$$y\left(1 - C_3 e^{4x^2+12x}\right) = 2 + 2C_3 e^{4x^2+12x}$$

$$y = \frac{2 + 2C_3 e^{4x^2+12x}}{1 - C_3 e^{4x^2+12x}}.$$

5. To determine the value of $C_3$, substitute $x = 0$ and $y = -1$ into the general solution. Alternatively, we can put the same values into an earlier equation, namely the equation $\frac{y-2}{y+2} = C_3 e^{4x^2+12}$. This is much easier to solve for $C_3$:

$$\frac{y-2}{y+2} = C_3 e^{4x^2+12x}$$

$$\frac{-1-2}{-1+2} = C_3 e^{4(0)^2+12(0)}$$

$$C_3 = -3.$$

Therefore the solution to the initial-value problem is

$$y = \frac{2 - 6e^{4x^2+12x}}{1 + 3e^{4x^2+12x}}.$$

A graph of this solution appears in Figure 11.4.1.

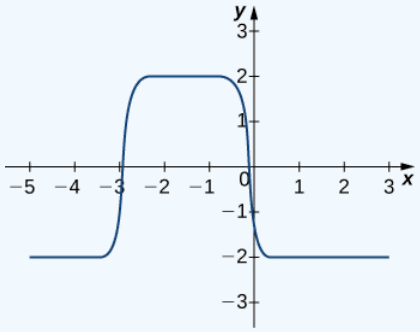


Figure 11.4.1: Graph of the solution to the initial-value problem $y' = (2x+3)(y^2-4), y(0) = -1$.

## ? Exercise 11.4.2

Find the solution to the initial-value problem

$$6y' = (2x+1)(y^2 - 2y - 8)$$

with $y(0) = -3$ using the method of separation of variables.

**Hint**

Follow the steps for separation of variables to solve the initial-value problem.

**Answer**

$$y = \frac{4 + 14e^{x^2+x}}{1 - 7e^{x^2+x}}$$

## Applications of Separation of Variables

Many interesting problems can be described by separable equations. We illustrate two types of problems: solution concentrations and Newton's law of cooling.

## Solution concentrations

Consider a tank being filled with a salt solution. We would like to determine the amount of salt present in the tank as a function of time. We can apply the process of separation of variables to solve this problem and similar problems involving *solution concentrations*.

### Example 11.4.3: Determining Salt Concentration over Time

A tank containing 100 L of a brine solution initially has 4 kg of salt dissolved in the solution. At time $t = 0$, another brine solution flows into the tank at a rate of 2 L/min. This brine solution contains a concentration of 0.5 kg/L of salt. At the same time, a stopcock is opened at the bottom of the tank, allowing the combined solution to flow out at a rate of 2 L/min, so that the level of liquid in the tank remains constant (Figure 11.4.2). Find the amount of salt in the tank as a function of time (measured in minutes), and find the limiting amount of salt in the tank, assuming that the solution in the tank is well mixed at all times.

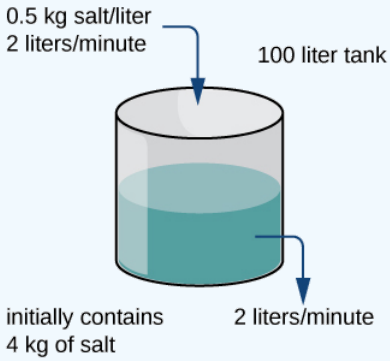

Figure 11.4.2: A brine tank with an initial amount of salt solution accepts an input flow and delivers an output flow. How does the amount of salt change with time?

**Solution**

First we define a function $u(t)$ that represents the amount of salt in kilograms in the tank as a function of time. Then $\frac{du}{dt}$ represents the rate at which the amount of salt in the tank changes as a function of time. Also, $u(0)$ represents the amount of salt in the tank at time $t = 0$, which is 4 kilograms.

The general setup for the differential equation we will solve is of the form

$$\frac{du}{dt} = \text{INFLOW RATE} - \text{OUTFLOW RATE}.$$

INFLOW RATE represents the rate at which salt enters the tank, and OUTFLOW RATE represents the rate at which salt leaves the tank. Because solution enters the tank at a rate of 2 L/min, and each liter of solution contains 0.5 kilogram of salt, every minute $2(0.5) = 1$ kilogram of salt enters the tank. Therefore INFLOW RATE = 1.

To calculate the rate at which salt leaves the tank, we need the concentration of salt in the tank at any point in time. Since the actual amount of salt varies over time, so does the concentration of salt. However, the volume of the solution remains fixed at 100 liters. The number of kilograms of salt in the tank at time $t$ is equal to $u(t)$. Thus, the concentration of salt is $\frac{u(t)}{100}$ kg/L, and the solution leaves the tank at a rate of 2 L/min. Therefore salt leaves the tank at a rate of $\frac{u(t)}{100} \cdot 2 = \frac{u(t)}{50}$ kg/min, and OUTFLOW RATE is equal to $\frac{u(t)}{50}$. Therefore the differential equation becomes $\frac{du}{dt} = 1 - \frac{u}{50}$, and the initial condition is $u(0) = 4$. The initial-value problem to be solved is

$$\frac{du}{dt} = 1 - \frac{u}{50}, u(0) = 4.$$

The differential equation is a separable equation, so we can apply the five-step strategy for solution.

Step 1. Setting $1 - \frac{u}{50} = 0$ gives $u = 50$ as a constant solution. Since the initial amount of salt in the tank is 4 kilograms, this solution does not apply.

Step 2. Rewrite the equation as

$$\frac{du}{dt} = \frac{50-u}{50}.$$

Then multiply both sides by $dt$ and divide both sides by $50-u$:

$$\frac{du}{50-u} = \frac{dt}{50}.$$

Step 3. Integrate both sides:

$$\int \frac{du}{50-u} = \int \frac{dt}{50}$$
$$-\ln|50-u| = \frac{t}{50} + C.$$

Step 4. Solve for $u(t)$:

$$\ln|50-u| = -\frac{t}{50} - C$$

$$e^{\ln|50-u|} = e^{-(t/50)-C}$$

$$|50-u| = C_1 e^{-t/50}, \text{ where } C_1 = e^{-C}.$$

Eliminate the absolute value by allowing the constant to be positive, negative, or zero, i.e., $C_1 = \pm e^{-C}$ or $C_1 = 0$:

$$50-u = C_1 e^{-t/50}.$$

Finally, solve for $u(t)$:

$$u(t) = 50 - C_1 e^{-t/50}.$$

Step 5. Solve for $C_1$:

$$u(0) = 50 - C_1 e^{-0/50}$$
$$4 = 50 - C_1$$
$$C_1 = 46.$$

The solution to the initial value problem is $u(t) = 50 - 46e^{-t/50}$. To find the limiting amount of salt in the tank, take the limit as $t$ approaches infinity:

$$\lim_{t\to\infty} u(t) = 50 - 46e^{-t/50}$$
$$= 50 - 46(0) = 50.$$

Note that this was the constant solution to the differential equation. If the initial amount of salt in the tank is $50$ kilograms, then it remains constant. If it starts at less than $50$ kilograms, then it approaches $50$ kilograms over time.

## ? Exercise 11.4.3

A tank contains $3$ kilograms of salt dissolved in $75$ liters of water. A salt solution of $0.4$ kg salt/L is pumped into the tank at a rate of $6$ L/min and is drained at the same rate. Solve for the salt concentration at time $t$. Assume the tank is well mixed at all times.

**Hint**

Follow the steps in Example $11.4.3$ and determine an expression for INFLOW and OUTFLOW. Formulate an initial-value problem, and then solve it.

*Initial value problem:*

$$\frac{du}{dt} = 2.4 - \frac{2u}{25},\ u(0) = 3$$

**Answer**

$$u(t) = 30 - 27e^{-t/50}$$

## Newton's Law of Cooling

*Newton's law of cooling* states that the rate of change of an object's temperature is proportional to the difference between its own temperature and the ambient temperature (i.e., the temperature of its surroundings). If we let $T(t)$ represent the temperature of an object as a function of time, then $\frac{dT}{dt}$ represents the rate at which that temperature changes. The temperature of the object's surroundings can be represented by $T_s$. Then Newton's law of cooling can be written in the form

$$\frac{dT}{dt} = k(T(t) - T_s)$$

or simply

$$\frac{dT}{dt} = k(T - T_s).$$

The temperature of the object at the beginning of any experiment is the initial value for the initial-value problem. We call this temperature $T_0$. Therefore the initial-value problem that needs to be solved takes the form

$$\frac{dT}{dt} = k(T - T_s) \tag{11.4.7}$$

with $T(0) = T_0$, where $k$ is a constant that needs to be either given or determined in the context of the problem. We use these equations in Example 11.4.4.

### Example 11.4.4: Waiting for a Pizza to Cool

A pizza is removed from the oven after baking thoroughly, and the temperature of the oven is $350°F$. The temperature of the kitchen is $75°F$, and after $5$ minutes the temperature of the pizza is $340°F$. We would like to wait until the temperature of the pizza reaches $300°F$ before cutting and serving it (Figure 11.4.3). How much longer will we have to wait?

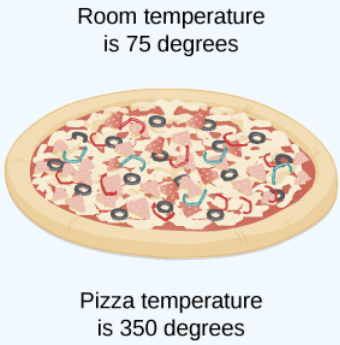

Figure 11.4.3: From Newton's law of cooling, if the pizza cools $10°F$ in $5$ minutes, how long before it cools to $300°F$?

**Solution**

The ambient temperature (surrounding temperature) is $75°F$, so $T_s = 75$. The temperature of the pizza when it comes out of the oven is $350°F$, which is the initial temperature (i.e., initial value), so $T_0 = 350$. Therefore Equation 11.4.7 becomes

$$\frac{dT}{dt} = k(T - 75)$$

with $T(0) = 350$.

To solve the differential equation, we use the five-step technique for solving separable equations.

1. Setting the right-hand side equal to zero gives $T = 75$ as a constant solution. Since the pizza starts at $350°F$, this is not the solution we are seeking.

2. Rewrite the differential equation by multiplying both sides by $dt$ and dividing both sides by $T - 75$:

$$\frac{dT}{T-75} = k\,dt.$$

3. Integrate both sides:

$$\int \frac{dT}{T-75} = \int k\,dt$$
$$\ln|T-75| = kt + C.$$

4. Solve for $T$ by first exponentiating both sides:

$$\begin{aligned} e^{\ln|T-75|} &= e^{kt+C} \\ |T-75| &= C_1 e^{kt}, && \text{where } C_1 = e^C. \\ T-75 &= \pm C_1 e^{kt} \\ T-75 &= Ce^{kt}, && \text{where } C = \pm C_1 \text{ or } C = 0. \\ T(t) &= 75 + Ce^{kt}. \end{aligned}$$

5. Solve for $C$ by using the initial condition $T(0) = 350$ :

$$\begin{aligned} T(t) &= 75 + Ce^{kt} \\ T(0) &= 75 + Ce^{k(0)} \\ 350 &= 75 + C \\ C &= 275. \end{aligned}$$

Therefore the solution to the initial-value problem is

$$T(t) = 75 + 275e^{kt}.$$

To determine the value of $k$, we need to use the fact that after $5$ minutes the temperature of the pizza is $340°F$. Therefore $T(5) = 340$. Substituting this information into the solution to the initial-value problem, we have

$$T(t) = 75 + 275e^{kt}$$

$$T(5) = 340 = 75 + 275e^{5k}$$

$$265 = 275e^{5k}$$

$$e^{5k} = \frac{53}{55}$$

$$\ln e^{5k} = \ln\left(\frac{53}{55}\right)$$

$$5k = \ln\left(\frac{53}{55}\right)$$

$$k = \frac{1}{5}\ln\left(\frac{53}{55}\right) \approx -0.007408.$$

So now we have $T(t) = 75 + 275e^{-0.007048t}$. When is the temperature $300°F$? Solving for $t$, we find

$$T(t) = 75 + 275e^{-0.007048t}$$

$$300 = 75 + 275e^{-0.007048t}$$

$$225 = 275e^{-0.007048t}$$

$$e^{-0.007048t} = \frac{9}{11}$$

$$\ln e^{-0.007048t} = \ln\frac{9}{11}$$

$$-0.007048t = \ln\frac{9}{11}$$

$$t = -\frac{1}{0.007048}\ln\frac{9}{11} \approx 28.5.$$

Therefore we need to wait an additional $23.5$ minutes (after the temperature of the pizza reached $340°F$). That should be just enough time to finish this calculation.

**? Exercise 11.4.4**

A cake is removed from the oven after baking thoroughly, and the temperature of the oven is $450°F$. The temperature of the kitchen is $70°F$, and after $10$ minutes the temperature of the cake is $430°F$.

a. Write the appropriate initial-value problem to describe this situation.
b. Solve the initial-value problem for $T(t)$.
c. How long will it take until the temperature of the cake is within $5°F$ of room temperature?

**Hint**

Determine the values of $T_s$ and $T_0$ then use Equation 11.4.7.

**Answer a**

Initial-value problem

$$\frac{dT}{dt} = k(T - 70), \quad T(0) = 450$$

**Answer b**

$$T(t) = 70 + 380e^{kt}$$

**Answer c**

Approximately $114$ minutes.

## Key Concepts

- A separable differential equation is any equation that can be written in the form $y' = f(x)g(y)$.
- The method of separation of variables is used to find the general solution to a separable differential equation.

## Key Equations

- **Separable differential equation**

  $y' = f(x)g(y)$

- **Solution concentration**

  $\frac{du}{dt} = \text{INFLOW RATE} - \text{OUTFLOW RATE}$

- **Newton's law of cooling**

  $\frac{dT}{dt} = k(T - T_s)$

## Glossary

**autonomous differential equation**
an equation in which the right-hand side is a function of $y$ alone

**separable differential equation**
any equation that can be written in the form $y' = f(x)g(y)$

**separation of variables**
a method used to solve a separable differential equation

# 11.4E: Exercises for Section 8.3

**In exercises 1 - 4, solve the following initial-value problems with the initial condition $y_0 = 0$ and graph the solution.**

1) $\frac{dy}{dt} = y + 1$

**Answer**

$y = e^t - 1$

2) $\frac{dy}{dt} = y - 1$

3) $\frac{dy}{dt} = -y + 1$

**Answer**

$y = 1 - e^{-t}$

4) $\frac{dy}{dt} = -y - 1$

**In exercises 5 - 14, find the general solution to the differential equation.**

5) $x^2y' = (x + 1)y$

**Answer**

$y = Cxe^{-1/x}$

6) $y' = \tan(y)x$

7) $y' = 2xy^2$

**Answer**

$y = \frac{1}{C - x^2}$

8) $\frac{dy}{dt} = y\cos(3t + 2)$

9) $2x\frac{dy}{dx} = y^2$

**Answer**

$y = -\frac{2}{C + \ln|x|}$

10) $y' = e^y x^2$

11) $(1 + x)y' = (x + 2)(y - 1)$

**Answer**

$y = Ce^x(x + 1) + 1$

12) $\frac{dx}{dt} = 3t^2(x^2 + 4)$

13) $t\frac{dy}{dt} = \sqrt{1 - y^2}$

**Answer**

$y = \sin(\ln|t| + C)$

14) $y' = e^x e^y$

**In exercises 15 - 24, find the solution to the initial-value problem.**

15) $y' = e^{y-x}, \quad y(0) = 0$

**Answer**

$y = -\ln(e^{-x})$ which simplifies to $y = x$

16) $y' = y^2(x+1), \quad y(0) = 2$

17) $\frac{dy}{dx} = y^3 x e^{x^2}, \quad y(0) = 1$

**Answer**

$$y = \frac{1}{\sqrt{2 - e^{x^2}}}$$

18) $\frac{dy}{dt} = y^2 e^x \sin(3x), \quad y(0) = 1$

19) $y' = \frac{x}{\operatorname{sech}^2 y}, \quad y(0) = 0$

**Answer**

$$y = \tanh^{-1}\left(\frac{x^2}{2}\right)$$

20) $y' = 2xy(1+2y), \quad y(0) = -1$

21) $\frac{dx}{dt} = \ln(t)\sqrt{1-x^2}, \quad x(1) = 0$

**Answer**

$x = \sin(1 - t + t\ln t)$

22) $y' = 3x^2(y^2+4), \quad y(0) = 0$

23) $y' = e^y 5^x, \quad y(0) = \ln(\ln(5))$

**Answer**

$y = \ln(\ln(5)) - \ln(2 - 5^x)$

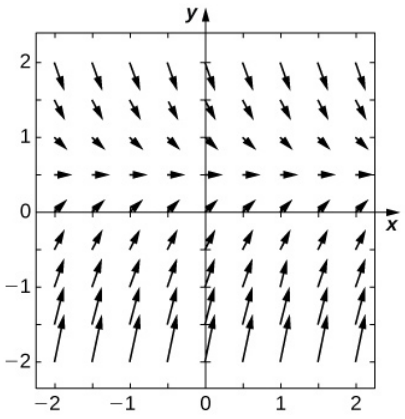
24) $y' = -2x\tan(y), \quad y(0) = \frac{\pi}{2}$

**For problems 25 - 29, use a software program or your calculator to generate the directional fields. Solve explicitly and draw solution curves for several initial conditions. Are there some critical initial conditions that change the behavior of the solution?**

25) [T] $y' = 1 - 2y$

**Answer**

$$y = Ce^{-2x} + \frac{1}{2}$$

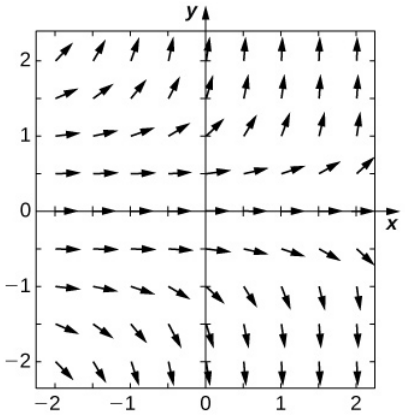


26) [T] $y' = y^2x^3$

27) [T] $y' = y^3e^x$

**Answer**

$$y = \frac{1}{\sqrt{2}\sqrt{C - e^x}}$$

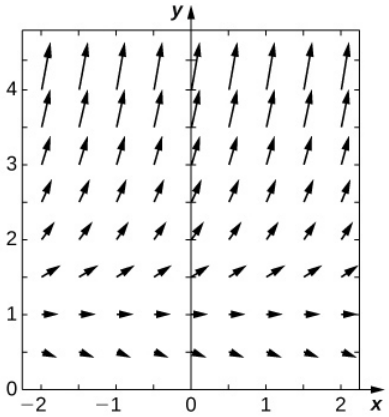


28) [T] $y' = e^y$

29) [T] $y' = y\ln(x)$

**Answer**

$$y = Ce^{-x}x^x$$



30) Most **drugs in the bloodstream** decay according to the equation $y' = cy$, where $y$ is the concentration of the drug in the bloodstream. If the half-life of a drug is $2$ hours, what fraction of the initial dose remains after $6$ hours?

31) A drug is administered intravenously to a patient at a rate $r$ mg/h and is cleared from the body at a rate proportional to the amount of drug still present in the body, $d$. Set up and solve the differential equation, assuming there is no drug initially present in the body.

**Answer**

$y = \frac{r}{d}(1 - e^{-dt})$

32) [T] How often should a drug be taken if its dose is $3$ mg, it is cleared at a rate $c = 0.1$ mg/h, and $1$ mg is required to be in the bloodstream at all times?

33) A tank contains $1$ kilogram of salt dissolved in $100$ liters of water. A salt solution of $0.1$ kg salt/L is pumped into the tank at a rate of $2$ L/min and is drained at the same rate. Solve for the salt concentration at time $t$. Assume the tank is well mixed.

**Answer**

Since the amount of salt at time $t$ is given by the equation $A(t) = 10 - 9e^{-t/50}$, and the tank volume stays constant at $100$ liters, the concentration at time $t$ would be $c(t) = \frac{1}{100}\left(10 - 9e^{-t/50}\right)$.

34) A tank containing $10$ kilograms of salt dissolved in $1000$ liters of water has two salt solutions pumped in. The first solution of $0.2$ kg salt/L is pumped in at a rate of $20$ L/min and the second solution of $0.05$ kg salt/L is pumped in at a rate of $5$ L/min. The tank drains at $25$ L/min. Assume the tank is well mixed. Solve for the salt concentration at time $t$.

35) [T] For the preceding problem, find how much salt is in the tank $1$ hour after the process begins.

**Answer**

$134.3$ kilograms

36) Torricelli's law states that for a water tank with a hole in the bottom that has a cross-section of $A$ and with a height of water $h$ above the bottom of the tank, the rate of change of volume of water flowing from the tank is proportional to the square root of the height of water, according to $\frac{dV}{dt} = -A\sqrt{2gh}$, where $g$ is the acceleration due to gravity. Note that $\frac{dV}{dt} = A\frac{dh}{dt}$. Solve the resulting initial-value problem for the height of the water, assuming a tank with a hole of radius $2$ ft. The initial height of water is $100$ ft.

37) For the preceding problem, determine how long it takes the tank to drain.

**Answer**

$720$ seconds

**For problems 38 - 44, use Newton's law of cooling.**

38) The liquid base of an ice cream has an initial temperature of $200°F$ before it is placed in a freezer with a constant temperature of $0°F$. After $1$ hour, the temperature of the ice-cream base has decreased to $140°F$. Formulate and solve the initial-value problem to determine the temperature of the ice cream.

39) [T] The liquid base of an ice cream has an initial temperature of $210°F$ before it is placed in a freezer with a constant temperature of $20°F$. After $2$ hours, the temperature of the ice-cream base has decreased to $170°F$. At what time will the ice cream be ready to eat? (Assume $30°F$ is the optimal eating temperature.)

**Answer**

$24$ hours $55$ minutes

40) [T] You are organizing an ice cream social. The outside temperature is $80°F$ and the ice cream is at $10°F$. After $10$ minutes, the ice cream temperature has risen by $10°F$. How much longer can you wait before the ice cream melts at $40°F$?

41) You have a cup of coffee at temperature $70°C$ and the ambient temperature in the room is $20°C$. Assuming a cooling rate $k$ of $0.125$, write and solve the differential equation to describe the temperature of the coffee with respect to time.

**Answer**

$T(t) = 20 + 50e^{-0.125t}$

42) [T] You have a cup of coffee at temperature $70°C$ that you put outside, where the ambient temperature is $0°C$. After $5$ minutes, how much colder is the coffee?

43) You have a cup of coffee at temperature $70°C$ and you immediately pour in $1$ part milk to $5$ parts coffee. The milk is initially at temperature $1°C$. Write and solve the differential equation that governs the temperature of this coffee.

**Answer**

$T(t) = 20 + 38.5e^{-0.125t}$

44) You have a cup of coffee at temperature $70°C$, which you let cool $10$ minutes before you pour in the same amount of milk at $1°C$ as in the preceding problem. How does the temperature compare to the previous cup after $10$ minutes?

45) Solve the generic problem $y' = ay + b$ with initial condition $y(0) = c$.

**Answer**

$y = (c + ba)e^{ax} - \frac{b}{a}$

46) Prove the basic continual compounded interest equation. Assuming an initial deposit of $P_0$ and an interest rate of $r$, set up and solve an equation for continually compounded interest.

47) Assume an initial nutrient amount of $I$ kilograms in a tank with $L$ liters. Assume a concentration of $c$ kg/L being pumped in at a rate of $r$ L/min. The tank is well mixed and is drained at a rate of $r$ L/min. Find the equation describing the amount of nutrient in the tank.

**Answer**

$y(t) = cL + (I - cL)e^{-rt/L}$

48) Leaves accumulate on the forest floor at a rate of $2$ g/cm$^2$/yr and also decompose at a rate of $90\%$ per year. Write a differential equation governing the number of grams of leaf litter per square centimeter of forest floor, assuming at time $0$ there is no leaf litter on the ground. Does this amount approach a steady value? What is that value?

49) Leaves accumulate on the forest floor at a rate of $4$ g/cm$^2$/yr. These leaves decompose at a rate of $10\%$ per year. Write a differential equation governing the number of grams of leaf litter per square centimeter of forest floor. Does this amount approach a steady value? What is that value?

**Answer**

Differential Equation: $\frac{dy}{dt} = 4 - 0.1y$
Solution, the model for this situation: $y = 40(1 - e^{-0.1t})$,
Amount approaches a steady value of 40 g/cm$^2$

# 11.5: The Logistic Equation

**Learning Objectives**

- Describe the concept of environmental carrying capacity in the logistic model of population growth.
- Draw a direction field for a logistic equation and interpret the solution curves.
- Solve a logistic equation and interpret the results.

Differential equations can be used to represent the size of a population as it varies over time. We saw this in an earlier chapter in the section on exponential growth and decay, which is the simplest model. A more realistic model includes other factors that affect the growth of the population. In this section, we study the logistic differential equation and see how it applies to the study of population dynamics in the context of biology.

## Population Growth and Carrying Capacity

To model population growth using a differential equation, we first need to introduce some variables and relevant terms. The variable $t$. will represent time. The units of time can be hours, days, weeks, months, or even years. Any given problem must specify the units used in that particular problem. The variable $P$ will represent population. Since the population varies over time, it is understood to be a function of time. Therefore we use the notation $P(t)$ for the population as a function of time. If $P(t)$ is a differentiable function, then the first derivative $\frac{dP}{dt}$ represents the instantaneous rate of change of the population as a function of time.

In Exponential Growth and Decay, we studied the exponential growth and decay of populations and radioactive substances. An example of an exponential growth function is $P(t) = P_0e^{rt}$. In this function, $P(t)$ represents the population at time $t$, $P_0$ represents the **initial population** (population at time $t = 0$), and the constant $r > 0$ is called the **growth rate**. Figure 11.5.1 shows a graph of $P(t) = 100e^{0.03t}$. Here $P_0 = 100$ and $r = 0.03$.

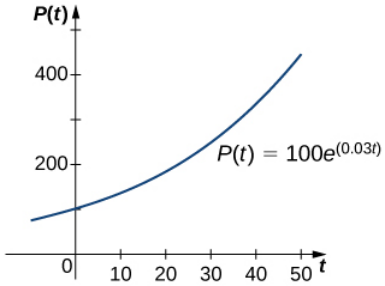

Figure 11.5.1: An exponential growth model of population.

We can verify that the function $P(t) = P_0e^{rt}$ satisfies the initial-value problem

$$\frac{dP}{dt} = rP$$

with $P(0) = P_0$.

This differential equation has an interesting interpretation. The left-hand side represents the rate at which the population increases (or decreases). The right-hand side is equal to a positive constant multiplied by the current population. Therefore the differential equation states that the rate at which the population increases is proportional to the population at that point in time. Furthermore, it states that the constant of proportionality never changes.

One problem with this function is its prediction that as time goes on, the population grows without bound. This is unrealistic in a real-world setting. Various factors limit the rate of growth of a particular population, including birth rate, death rate, food supply, predators, and so on. The growth constant $r$ usually takes into consideration the birth and death rates but none of the other factors, and it can be interpreted as a net (birth minus death) percent growth rate per unit time. A natural question to ask is whether the population growth rate stays constant, or whether it changes over time. Biologists have found that in many biological systems, the population grows until a certain steady-state population is reached. This possibility is not taken into account with exponential

growth. However, the concept of carrying capacity allows for the possibility that in a given area, only a certain number of a given organism or animal can thrive without running into resource issues.

**Definition: Carrying Capacity**

The *carrying capacity* of an organism in a given environment is defined to be the maximum population of that organism that the environment can sustain indefinitely.

We use the variable $K$ to denote the carrying capacity. The growth rate is represented by the variable $r$. Using these variables, we can define the logistic differential equation.

**Definition: Logistic Differential Equation**

Let $K$ represent the carrying capacity for a particular organism in a given environment, and let $r$ be a real number that represents the growth rate. The function $P(t)$ represents the population of this organism as a function of time $t$, and the constant $P_0$ represents the initial population (population of the organism at time $t = 0$). Then the *logistic differential equation* is

$$\frac{dP}{dt} = rP\left(1 - \frac{P}{K}\right). \tag{11.5.1}$$

The logistic equation was first published by Pierre Verhulst in 1845. This differential equation can be coupled with the initial condition $P(0) = P_0$ to form an initial-value problem for $P(t)$.

Suppose that the initial population is small relative to the carrying capacity. Then $\frac{P}{K}$ is small, possibly close to zero. Thus, the quantity in parentheses on the right-hand side of Equation 11.5.1 is close to 1, and the right-hand side of this equation is close to $rP$. If $r > 0$, then the population grows rapidly, resembling exponential growth.

However, as the population grows, the ratio $\frac{P}{K}$ also grows, because $K$ is constant. If the population remains below the carrying capacity, then $\frac{P}{K}$ is less than 1, so $1 - \frac{P}{K} > 0$. Therefore the right-hand side of Equation 11.5.1 is still positive, but the quantity in parentheses gets smaller, and the growth rate decreases as a result. If $P = K$ then the right-hand side is equal to zero, and the population does not change.

Now suppose that the population starts at a value higher than the carrying capacity. Then $\frac{P}{K} > 1$, and $1 - \frac{P}{K} < 0$. Then the right-hand side of Equation 11.5.1 is negative, and the population decreases. As long as $P > K$, the population decreases. It never actually reaches K because $\frac{dP}{dt}$ will get smaller and smaller, but the population approaches the carrying capacity as $t$ approaches infinity. This analysis can be represented visually by way of a phase line. A **phase line** describes the general behavior of a solution to an autonomous differential equation, depending on the initial condition. For the case of a carrying capacity in the logistic equation, the phase line is as shown in Figure 11.5.2.

Figure 11.5.2: A phase line for the differential equation $\frac{dP}{dt} = rP(1 - \frac{P}{K})$.

This phase line shows that when $P$ is less than zero or greater than $K$, the population decreases over time. When $P$ is between 0 and $K$, the population increases over time.

## Example 11.5.1: Examining the Carrying Capacity of a Deer Population

Let's consider the population of white-tailed deer (*Odocoileus virginianus*) in the state of Kentucky. The Kentucky Department of Fish and Wildlife Resources (KDFWR) sets guidelines for hunting and fishing in the state. Before the hunting season of 2004, it estimated a population of 900,000 deer. Johnson notes: "A deer population that has plenty to eat and is not hunted by humans or other predators will double every three years." (George Johnson, "The Problem of Exploding Deer Populations Has No Attractive Solutions," January 12,2001, accessed April 9, 2015)

Figure **11.5.3**: (credit: modification of work by Rachel Kramer, Flickr)

This observation corresponds to a rate of increase $r = \frac{\ln(2)}{3} = 0.2311$, so the approximate growth rate is 23.11% per year. (This assumes that the population grows exponentially, which is reasonable—at least in the short term—with plentiful food supply and no predators.) The KDFWR also reports deer population densities for 32 counties in Kentucky, the average of which is approximately 27 deer per square mile. Suppose this is the deer density for the whole state (39,732 square miles). The carrying capacity $K$ is 39,732 square miles times 27 deer per square mile, or 1,072,764 deer.

a. For this application, we have $P_0 = 900,000, K = 1,072,764$, and $r = 0.2311$. Substitute these values into Equation 11.5.1 and form the initial-value problem.
b. Solve the initial-value problem from part a.
c. According to this model, what will be the population in 3 years? Recall that the doubling time predicted by Johnson for the deer population was 3 years. How do these values compare?

Suppose the population managed to reach **1,200,000** What does the logistic equation predict will happen to the population in this scenario?

### Solution

a. The initial value problem is

$$\frac{dP}{dt} = 0.2311P\left(1 - \frac{P}{1,072,764}\right), \; P(0) = 900,000.$$

b. The logistic equation is an autonomous differential equation, so we can use the method of separation of variables.

Step 1: Setting the right-hand side equal to zero gives $P = 0$ and $P = 1,072,764$. This means that if the population starts at zero it will never change, and if it starts at the carrying capacity, it will never change.

Step 2: Rewrite the differential equation and multiply both sides by:

$$\frac{dP}{dt} = 0.2311P\left(\frac{1,072,764 - P}{1,072,764}\right)$$

$$dP = 0.2311P\left(\frac{1,072,764 - P}{1,072,764}\right)dt$$

$$\frac{dP}{P(1,072,764 - P)} = \frac{0.2311}{1,072,764}dt.$$

Step 3: Integrate both sides of the equation using partial fraction decomposition:

$$\int \frac{dP}{P(1,072,764-P)} = \int \frac{0.2311}{1,072,764}dt$$
$$\frac{1}{1,072,764}\int \left(\frac{1}{P}+\frac{1}{1,072,764-P}\right)dP = \frac{0.2311t}{1,072,764}+C$$
$$\frac{1}{1,072,764}\left(\ln|P|-\ln|1,072,764-P|\right) = \frac{0.2311t}{1,072,764}+C.$$

Step 4: Multiply both sides by 1,072,764 and use the quotient rule for logarithms:

$$\ln\left|\frac{P}{1,072,764-P}\right| = 0.2311t + C_1.$$

Here $C_1 = 1,072,764C$. Next exponentiate both sides and eliminate the absolute value:

$$e^{\ln\left|\frac{P}{1,072,764-P}\right|} = e^{0.2311t+C_1}$$
$$\left|\frac{P}{1,072,764-P}\right| = C_2e^{0.2311t}$$
$$\frac{P}{1,072,764-P} = C_2e^{0.2311t}.$$

Here $C_2 = e^{C_1}$ but after eliminating the absolute value, it can be negative as well. Now solve for:

$$P = C_2e^{0.2311t}(1,072,764-P)$$
$$P = 1,072,764C_2e^{0.2311t} - C_2Pe^{0.2311t}$$
$$P + C_2Pe^{0.2311t} = 1,072,764C_2e^{0.2311t}$$
$$P(1+C_2e^{0.2311t} = 1,072,764C_2e^{0.2311t}$$
$$P(t) = \frac{1,072,764C_2e^{0.2311t}}{1+C_2e^{0.2311t}}.$$

Step 5: To determine the value of $C_2$, it is actually easier to go back a couple of steps to where $C_2$ was defined. In particular, use the equation

$$\frac{P}{1,072,764-P} = C_2e^{0.2311t}.$$

The initial condition is $P(0) = 900,000$. Replace $P$ with $900,000$ and $t$ with zero:

$$\frac{P}{1,072,764-P} = C_2e^{0.2311t}$$
$$\frac{900,000}{1,072,764-900,000} = C_2e^{0.2311(0)}$$
$$\frac{900,000}{172,764} = C_2$$
$$C_2 = \frac{25,000}{4,799}$$
$$\approx 5.209.$$

Therefore

$$P(t) = \frac{1,072,764\left(\frac{25000}{4799}\right)e^{0.2311t}}{1+\left(\frac{25000}{4799}\right)e^{0.2311t}}$$
$$= \frac{1,072,764(25000)e^{0.2311t}}{4799+25000e^{0.2311t}.}$$

Dividing the numerator and denominator by **25,000** gives

$$P(t) = \frac{1,072,764e^{0.2311t}}{0.19196 + e^{0.2311t}}.$$

Figure **11.5.4** is a graph of this equation.

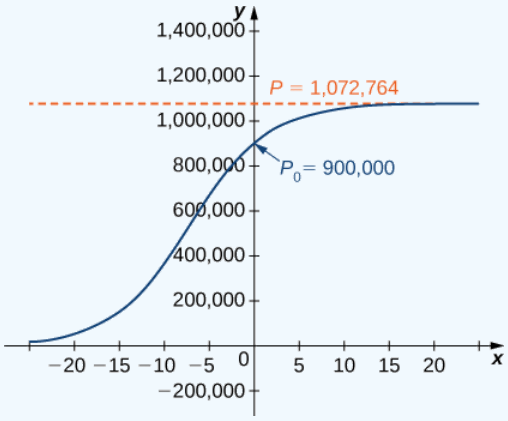

Figure **11.5.4**: Logistic curve for the deer population with an initial population of **900,000** deer.

c. Using this model we can predict the population in **3** years.

$$P(3) = \frac{1,072,764e^{0.2311(3)}}{0.19196 + e^{0.2311(3)}} \approx 978,830\, deer$$

This is far short of twice the initial population of $900,000$. Remember that the doubling time is based on the assumption that the growth rate never changes, but the logistic model takes this possibility into account.

d. If the population reached **1,200,000** deer, then the new initial-value problem would be

$$\frac{dP}{dt} = 0.2311P\left(1 - \frac{P}{1,072,764}\right),\ P(0) = 1,200,000.$$

The general solution to the differential equation would remain the same.

$$P(t) = \frac{1,072,764C_2e^{0.2311t}}{1 + C_2e^{0.2311t}}$$

To determine the value of the constant, return to the equation

$$\frac{P}{1,072,764 - P} = C_2e^{0.2311t}.$$

Substituting the values $t = 0$ and $P = 1,200,000$, you get

$$C_2e^{0.2311(0)} = \frac{1,200,000}{1,072,764 - 1,200,000}$$

$$C_2 = -\frac{100,000}{10,603} \approx -9.431.$$

Therefore

$$P(t) = \frac{1,072,764C_2e^{0.2311t}}{1 + C_2e^{0.2311t}}$$

$$= \frac{1,072,764\left(-\frac{100,000}{10,603}\right)e^{0.2311t}}{1 + \left(-\frac{100,000}{10,603}\right)e^{0.2311t}}$$

$$= -\frac{107,276,400,000e^{0.2311t}}{100,000e^{0.2311t} - 10,603}$$

$$\approx \frac{10,117,551e^{0.2311t}}{9.43129e^{0.2311t} - 1}$$

This equation is graphed in Figure 11.5.5.

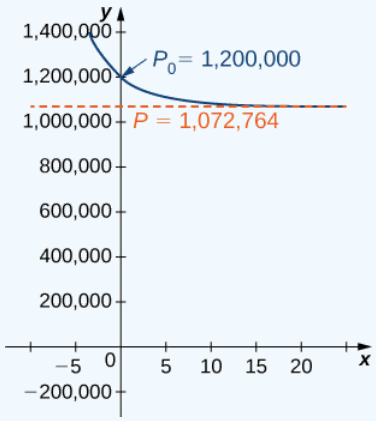

Figure 11.5.5: Logistic curve for the deer population with an initial population of **1,200,000** deer.

## Solving the Logistic Differential Equation

The logistic differential equation is an autonomous differential equation, so we can use separation of variables to find the general solution, as we just did in Example 11.5.1.

Step 1: Setting the right-hand side equal to zero leads to $P = 0$ and $P = K$ as constant solutions. The first solution indicates that when there are no organisms present, the population will never grow. The second solution indicates that when the population starts at the carrying capacity, it will never change.

Step 2: Rewrite the differential equation in the form

$$\frac{dP}{dt} = \frac{rP(K-P)}{K}.$$

Then multiply both sides by $dt$ and divide both sides by $P(K-P)$. This leads to

$$\frac{dP}{P(K-P)} = \frac{r}{K}dt.$$

Multiply both sides of the equation by $K$ and integrate:

$$\int \frac{K}{P(K-P)}dP = \int r dt. \tag{11.5.2}$$

The left-hand side of this equation can be integrated using partial fraction decomposition. We leave it to you to verify that

$$\frac{K}{P(K-P)} = \frac{1}{P} + \frac{1}{K-P}.$$

Then the Equation 11.5.2 becomes

$$\int \frac{1}{P} + \frac{1}{K-P}dP = \int r dt$$

$$\ln|P| - \ln|K-P| = rt + C$$

$$\ln\left|\frac{P}{K-P}\right| = rt + C.$$

Now exponentiate both sides of the equation to eliminate the natural logarithm:

$$e^{\ln\left|\frac{P}{K-P}\right|} = e^{rt+C}$$

$$\left|\frac{P}{K-P}\right| = e^C e^{rt}.$$

We define $C_1 = e^c$ so that the equation becomes

$$\frac{P}{K-P} = C_1 e^{rt}. \tag{11.5.3}$$

To solve this equation for $P(t)$, first multiply both sides by $K-P$ and collect the terms containing $P$ on the left-hand side of the equation:

$$\begin{aligned} P &= C_1 e^{rt}(K-P) \\ &= C_1 K e^{rt} - C_1 P e^{rt} \\ P + C_1 P e^{rt} &= C_1 K e^{rt}. \end{aligned}$$

Next, factor $P$ from the left-hand side and divide both sides by the other factor:

$$\begin{aligned} P(1 + C_1 e^{rt}) &= C_1 K e^{rt} \\ P(t) &= \frac{C_1 K e^{rt}}{1 + C_1 e^{rt}}. \end{aligned}$$

The last step is to determine the value of $C_1$. The easiest way to do this is to substitute $t = 0$ and $P_0$ in place of $P$ in Equation and solve for $C_1$:

$$\begin{aligned} \frac{P}{K-P} &= C_1 e^{rt} \\ \frac{P_0}{K-P_0} &= C_1 e^{r(0)} \\ C_1 &= \frac{P_0}{K-P_0}. \end{aligned}$$

Finally, substitute the expression for $C_1$ into Equation 11.5.3:

$$P(t) = \frac{C_1 K e^{rt}}{1 + C_1 e^{rt}} = \frac{\frac{P_0}{K-P_0} K e^{rt}}{1 + \frac{P_0}{K-P_0} e^{rt}}$$

Now multiply the numerator and denominator of the right-hand side by $(K-P_0)$ and simplify:

$$\begin{aligned} P(t) &= \frac{\frac{P_0}{K-P_0} K e^{rt}}{1 + \frac{P_0}{K-P_0} e^{rt}} \\ &= \frac{\frac{P_0}{K-P_0} K e^{rt}}{1 + \frac{P_0}{K-P_0} e^{rt}} \cdot \frac{K-P_0}{K-P_0} \\ &= \frac{P_0 K e^{rt}}{(K-P_0) + P_0 e^{rt}}. \end{aligned}$$

We state this result as a theorem.

**Solution of the Logistic Differential Equation**

Consider the logistic differential equation subject to an initial population of $P_0$ with carrying capacity $K$ and growth rate $r$. The solution to the corresponding initial-value problem is given by

$$P(t) = \frac{P_0 K e^{rt}}{(K-P_0) + P_0 e^{rt}}$$

.

Now that we have the solution to the initial-value problem, we can choose values for $P_0, r$, and $K$ and study the solution curve. For example, in Example we used the values $r = 0.2311, K = 1,072,764,$ and an initial population of $900,000$ deer. This leads to the

solution

$$P(t) = \frac{P_0 K e^{rt}}{(K - P_0) + P_0 e^{rt}}$$
$$= \frac{900,000(1,072,764)e^{0.2311t}}{(1,072,764 - 900,000) + 900,000e^{0.2311t}}$$
$$= \frac{900,000(1,072,764)e^{0.2311t}}{172,764 + 900,000e^{0.2311t}}.$$

Dividing top and bottom by $900,000$ gives

$$P(t) = \frac{1,072,764e^{0.2311t}}{0.19196 + e^{0.2311t}}.$$

This is the same as the original solution. The graph of this solution is shown again in blue in Figure 11.5.6, superimposed over the graph of the exponential growth model with initial population $900,000$ and growth rate $0.2311$ (appearing in green). The red dashed line represents the carrying capacity, and is a horizontal asymptote for the solution to the logistic equation.

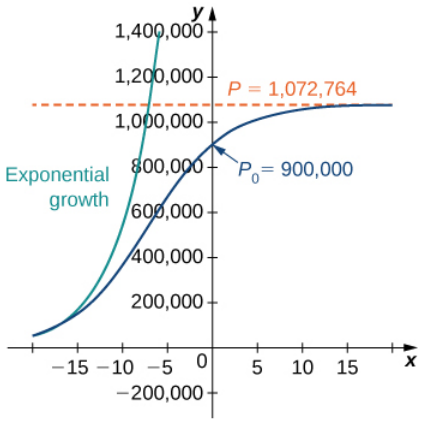

Figure 11.5.6: A comparison of exponential versus logistic growth for the same initial population of $900,000$ organisms and growth rate of $23.11$

Working under the assumption that the population grows according to the logistic differential equation, this graph predicts that approximately $20$ years earlier $(1984)$, the growth of the population was very close to exponential. The net growth rate at that time would have been around $23.1$ per year. As time goes on, the two graphs separate. This happens because the population increases, and the logistic differential equation states that the growth rate decreases as the population increases. At the time the population was measured $(2004)$, it was close to carrying capacity, and the population was starting to level off.

The solution to the logistic differential equation has a point of inflection. To find this point, set the second derivative equal to zero:

$$P(t) = \frac{P_0 K e^{rt}}{(K - P_0) + P_0 e^{rt}}$$
$$P'(t) = \frac{rP_0 K(K - P_0)e^{rt}}{((K - P_0) + P_0 e^{rt})^2}$$
$$P''(t) = \frac{r^2 P_0 K(K - P_0)^2 e^{rt} - r^2 P_0^2 K(K - P_0)e^{2rt}}{((K - P_0) + P_0 e^{rt})^3}$$
$$= \frac{r^2 P_0 K(K - P_0)e^{rt}((K - P_0) - P_0 e^{rt})}{((K - P_0) + P_0 e^{rt})^3}.$$

Setting the numerator equal to zero,

$$r^2 P_0 K(K - P_0)e^{rt}((K - P_0) - P_0 e^{rt}) = 0.$$

As long as $P_0 \neq K$, the entire quantity before and including $e^{rt}$is nonzero, so we can divide it out:

$$(K - P_0) - P_0 e^{rt} = 0.$$

Solving for $t$,

$$P_0 e^{rt} = K - P_0$$

$$e^{rt} = \frac{K - P_0}{P_0}$$

$$\ln e^{rt} = \ln \frac{K - P_0}{P_0}$$

$$rt = \ln \frac{K - P_0}{P_0}$$

$$t = \frac{1}{r} \ln \frac{K - P_0}{P_0}.$$

Notice that if $P_0 > K$, then this quantity is undefined, and the graph does not have a point of inflection. In the logistic graph, the point of inflection can be seen as the point where the graph changes from concave up to concave down. This is where the "leveling off" starts to occur, because the net growth rate becomes slower as the population starts to approach the carrying capacity.

## Exercise 11.5.1

A population of rabbits in a meadow is observed to be $200$ rabbits at time $t = 0$. After a month, the rabbit population is observed to have increased by $4$. Using an initial population of $200$ and a growth rate of $0.04$, with a carrying capacity of $750$ rabbits,

a. Write the logistic differential equation and initial condition for this model.
b. Draw a slope field for this logistic differential equation, and sketch the solution corresponding to an initial population of $200$ rabbits.
c. Solve the initial-value problem for $P(t)$.
d. Use the solution to predict the population after $1$ year.

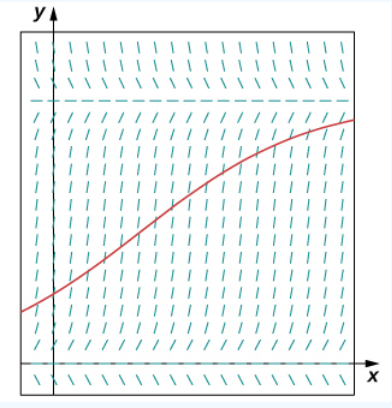
**Hint**

First determine the values of $r, K$, and $P_0$. Then create the initial-value problem, draw the direction field, and solve the problem.

**Answer**

a. $\frac{dP}{dt} = 0.04(1 - \frac{P}{750}), P(0) = 200$

b.



c. $P(t) = \frac{3000e^{.04t}}{11 + 4e^{.04t}}$

d. After $12$ months, the population will be $P(12) \approx 278$ rabbits.

## Student Project: Logistic Equation with a Threshold Population

An improvement to the logistic model includes a **threshold population.** The threshold population is defined to be the minimum population that is necessary for the species to survive. We use the variable $T$ to represent the threshold population. A differential equation that incorporates both the threshold population $T$ and carrying capacity $K$ is

$$\frac{dP}{dt} = -rP\left(1 - \frac{P}{K}\right)\left(1 - \frac{P}{T}\right)$$

where $r$ represents the growth rate, as before.

1. The threshold population is useful to biologists and can be utilized to determine whether a given species should be placed on the endangered list. A group of Australian researchers say they have determined the threshold population for any species to survive: $5000$ adults. (Catherine Clabby, "A Magic Number," American Scientist 98(1): 24, doi:10.1511/2010.82.24. accessed April 9, 2015, www.americanscientist.org/iss...a-magic-number). Therefore we use $T = 5000$ as the threshold population in this project. Suppose that the environmental carrying capacity in Montana for elk is $25,000$. Set up Equation using the carrying capacity of $25,000$ and threshold population of $5000$. Assume an annual net growth rate of 18%.
2. Draw the direction field for the differential equation from step $1$, along with several solutions for different initial populations. What are the constant solutions of the differential equation? What do these solutions correspond to in the original population model (i.e., in a biological context)?
3. What is the limiting population for each initial population you chose in step $2$? (Hint: use the slope field to see what happens for various initial populations, i.e., look for the horizontal asymptotes of your solutions.)
4. This equation can be solved using the method of separation of variables. However, it is very difficult to get the solution as an explicit function of $t$. Using an initial population of $18,000$ elk, solve the initial-value problem and express the solution as an implicit function of t, or solve the general initial-value problem, finding a solution in terms of $r, K, T$, and $P_0$.

## Key Concepts

- When studying population functions, different assumptions—such as exponential growth, logistic growth, or threshold population—lead to different rates of growth.
- The logistic differential equation incorporates the concept of a carrying capacity. This value is a limiting value on the population for any given environment.
- The logistic differential equation can be solved for any positive growth rate, initial population, and carrying capacity.

## Key Equations

- **Logistic differential equation and initial-value problem**

  $$\frac{dP}{dt} = rP\left(1 - \frac{P}{K}\right), \quad P(0) = P_0$$

- **Solution to the logistic differential equation/initial-value problem**

  $$P(t) = \frac{P_0 K e^{rt}}{(K - P_0) + P_0 e^{rt}}$$

- **Threshold population model**

  $$\frac{dP}{dt} = -rP\left(1 - \frac{P}{K}\right)\left(1 - \frac{P}{T}\right)$$

## Glossary

**carrying capacity**
the maximum population of an organism that the environment can sustain indefinitely

**growth rate**
the constant $r > 0$ in the exponential growth function $P(t) = P_0 e^{rt}$

**initial population**

the population at time $t = 0$

**logistic differential equation**

a differential equation that incorporates the carrying capacity $K$ and growth rate rr into a population model

**phase line**

a visual representation of the behavior of solutions to an autonomous differential equation subject to various initial conditions

**threshold population**

the minimum population that is necessary for a species to survive

# 11.5E: Exercises for Section 8.4

## Basic Logistic Model

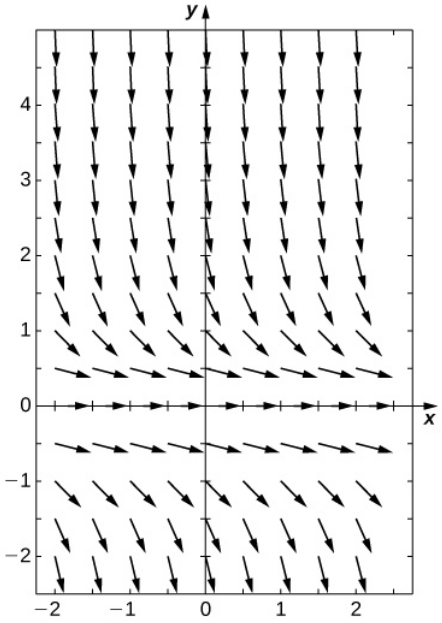
**For problems 1 - 11, consider the logistic equation in the form $P' = CP - P^2$. Draw the directional field and find the stability of the equilibria.**

1) $C = 3$

2) $C = 0$

**Answer**

$P = 0$ semi-stable



3) $C = -3$

4) Solve the logistic equation for $C = 10$ and an initial condition of $P(0) = 2$.

**Answer**

$$P = \frac{10e^{10x}}{e^{10x} + 4}$$

5) Solve the logistic equation for $C = -10$ and an initial condition of $P(0) = 2$.

6) A population of deer inside a park has a carrying capacity of $200$ and a growth rate of $2$. If the initial population is $50$ deer, what is the population of deer at any given time?

**Answer**

$$P(t) = \frac{10000e^{0.02t}}{150 + 50e^{0.02t}}$$

7) A population of frogs in a pond has a growth rate of $5$ If the initial population is $1000$ frogs and the carrying capacity is $6000$, what is the population of frogs at any given time?

8) [T] Bacteria grow at a rate of $20$ per hour in a petri dish. If there is initially one bacterium and a carrying capacity of $1$ million cells, how long does it take to reach $500,000$ cells?

**Answer**

69 hours 5 minutes

9) [T] Rabbits in a park have an initial population of 10 and grow at a rate of 4 per year. If the carrying capacity is 500, at what time does the population reach 100 rabbits?

10) [T] Two monkeys are placed on an island. After 5 years, there are 8 monkeys, and the estimated carrying capacity is 25 monkeys. When does the population of monkeys reach 16 monkeys?

**Answer**

8 years 11 months

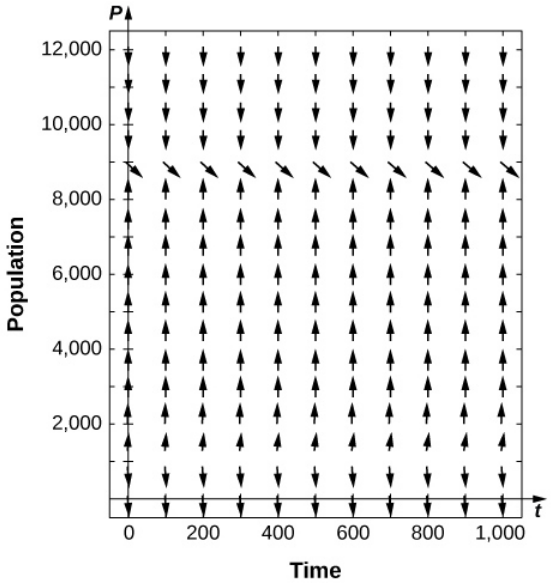
11) [T] A butterfly sanctuary is built that can hold 2000 butterflies, and 400 butterflies are initially moved in. If after 2 months there are now 800 butterflies, when does the population get to 1500 butterflies?

## Logistic Population Model with Depletion

**The following problems consider the logistic equation with an added term for depletion, either through death or emigration.**

12) [T] The population of trout in a pond is given by $P' = 0.4P\left(1 - \frac{P}{10000}\right) - 400$, where 400 trout are caught per year. Use your calculator or computer software to draw a directional field and draw a few sample solutions. What do you expect for the behavior?

**Answer**

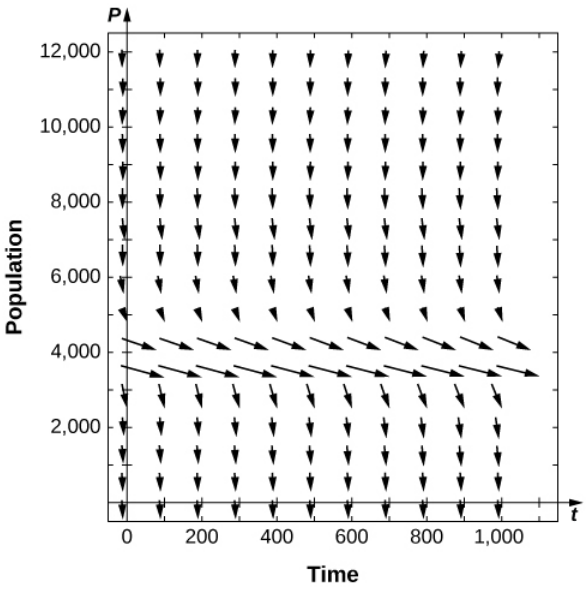


13) In the preceding problem, what are the stabilities of the equilibria $0 < P_1 < P_2$?

14) [T] For the preceding problem, use software to generate a directional field for the value $f = 400$. What are the stabilities of the equilibria?

**Answer**

$P_1$ semi-stable

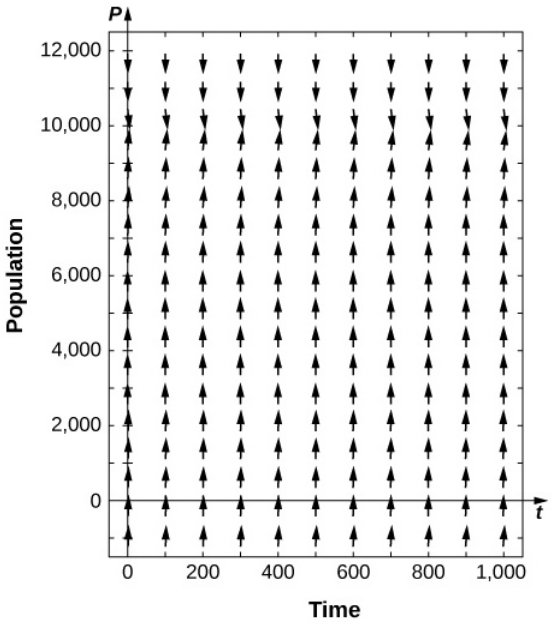


15) [T] For the preceding problems, use software to generate a directional field for the value $f = 600$. What are the stabilities of the equilibria?

16) [T] For the preceding problems, consider the case where a certain number of fish are added to the pond, or $f = -200$. What are the nonnegative equilibria and their stabilities?

**Answer**

$P_2 > 0$ stable



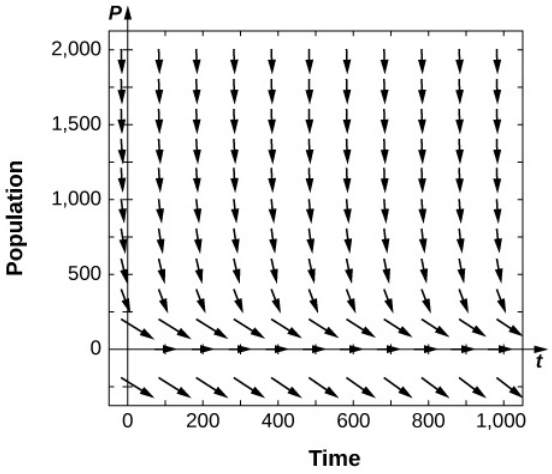
It is more likely that the amount of fishing is governed by the current number of fish present, so instead of a constant number of fish being caught, the rate is proportional to the current number of fish present, with proportionality constant $k$, as $P' = 0.4P\left(1 - \frac{P}{10000}\right) - kP$.

17) [T] For the previous fishing problem, draw a directional field assuming $k = 0.1$. Draw some solutions that exhibit this behavior. What are the equilibria and what are their stabilities?

18) [T] Use software or a calculator to draw directional fields for $k = 0.4$. What are the nonnegative equilibria and their stabilities?

**Answer**

$P_1 = 0$ is semi-stable



19) [T] Use software or a calculator to draw directional fields for $k = 0.6$. What are the equilibria and their stabilities?

20) Solve this equation, assuming a value of $k = 0.05$ and an initial condition of $2000$ fish.

**Answer**

$$y = \frac{-20}{4 \times 10^{-6} - 0.002e^{0.01t}}$$

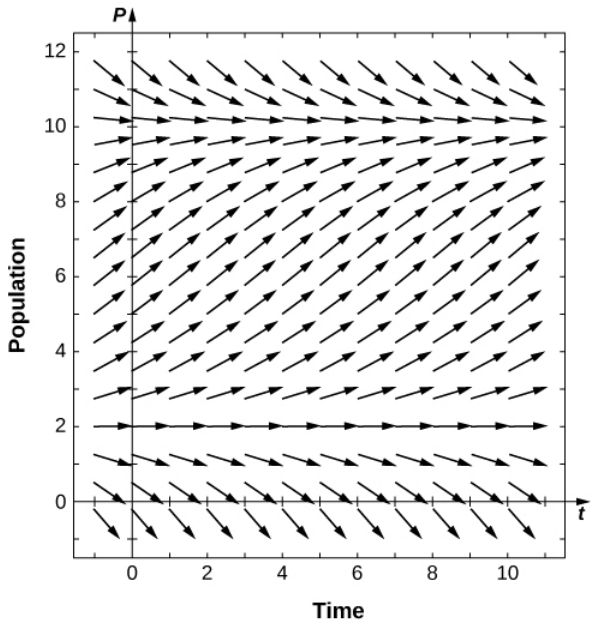
21) Solve this equation, assuming a value of $k = 0.05$ and an initial condition of $5000$ fish.

## Minimal Sustainable Population Thresholds

**The following problems add in a minimal threshold value for the species to survive, $T$, which changes the differential equation to $P'(t) = rP\left(1 - \frac{P}{K}\right)\left(1 - \frac{T}{P}\right)$.**

22) Draw the directional field of the threshold logistic equation, assuming $K = 10, r = 0.1, T = 2$. When does the population survive? When does it go extinct?

**Answer**



23) For the preceding problem, solve the logistic threshold equation, assuming the initial condition $P(0) = P_0$.

24) Bengal tigers in a conservation park have a carrying capacity of $100$ and need a minimum of $10$ to survive. If they grow in population at a rate of $1$ per year, with an initial population of $15$ tigers, solve for the number of tigers present.

**Answer**

$$P(t) = \frac{850 + 500e^{0.009t}}{85 + 5e^{0.009t}}$$

25) A forest containing ring-tailed lemurs in Madagascar has the potential to support $5000$ individuals, and the lemur population grows at a rate of $5$ per year. A minimum of 500 individuals is needed for the lemurs to survive. Given an initial population of $600$ lemurs, solve for the population of lemurs.

26) The population of mountain lions in Northern Arizona has an estimated carrying capacity of $250$ and grows at a rate of $0.25$ per year and there must be $25$ for the population to survive. With an initial population of $30$ mountain lions, how many years will it take to get the mountain lions off the endangered species list (at least $100$)?

**Answer**

$13$ years months

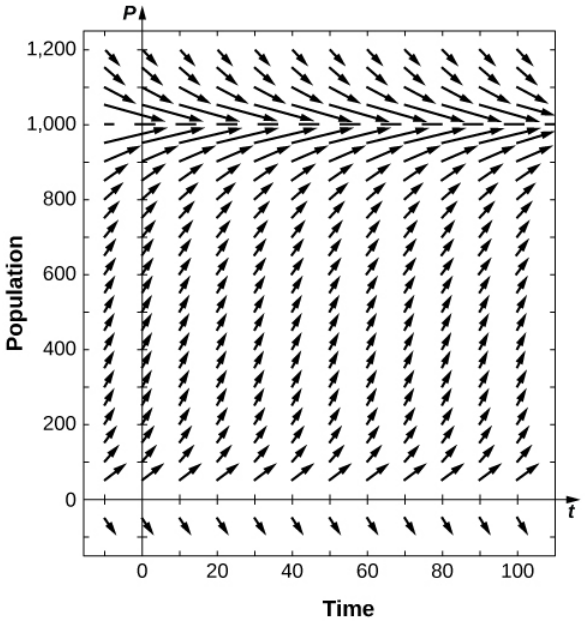
## The Gompertz Equation

**The following questions consider the Gompertz equation, a modification for logistic growth, which is often used for modeling cancer growth, specifically the number of tumor cells.**

27) The Gompertz equation is given by $P(t)' = \alpha \ln\left(\frac{K}{P(t)}\right) P(t)$. Draw the directional fields for this equation assuming all parameters are positive, and given that $K = 1$.

28) Assume that for a population, $K = 1000$ and $\alpha = 0.05$. Draw the directional field associated with this differential equation and draw a few solutions. What is the behavior of the population?

**Answer**



29) Solve the Gompertz equation for generic $\alpha$ and $K$ and $P(0) = P_0$.

30) [T] The Gompertz equation has been used to model tumor growth in the human body. Starting from one tumor cell on day $1$ and assuming $\alpha = 0.1$ and a carrying capacity of $10$ million cells, how long does it take to reach "detection" stage at $5$ million cells?

**Answer**

$31.465$ days

31) [T] It is estimated that the world human population reached $3$ billion people in $1959$ and $6$ billion in $1999$. Assuming a carrying capacity of $16$ billion humans, write and solve the differential equation for logistic growth, and determine what year the population reached $7$ billion.

32) [T] It is estimated that the world human population reached $3$ billion people in $1959$ and $6$ billion in $1999$. Assuming a carrying capacity of $16$ billion humans, write and solve the differential equation for Gompertz growth, and determine what year the population reached $7$ billion. Was logistic growth or Gompertz growth more accurate, considering world population reached $7$ billion on October $31, 2011$?

**Answer**

September $2008$

33) Show that the population grows fastest when it reaches half the carrying capacity for the logistic equation $P' = rP\left(1 - \frac{P}{K}\right)$.

34) When does population increase the fastest in the threshold logistic equation $P'(t) = rP\left(1 - \frac{P}{K}\right)\left(1 - \frac{T}{P}\right)$?

**Answer**

$\frac{K+T}{2}$

35) When does population increase the fastest for the Gompertz equation $P(t)' = \alpha \ln\left(\frac{K}{P(t)}\right) P(t)$?

Below is a table of the populations of whooping cranes in the wild from $1940$ to $2000$. The population rebounded from near extinction after conservation efforts began. The following problems consider applying population models to fit the data. Assume a carrying capacity of $10,000$ cranes. Fit the data assuming years since $1940$ (so your initial population at time $0$ would be $22$ cranes).

| Year (years since conservation began) | Whooping Crane Population |
|---|---|
| 1940(0) | 22 |
| 1950(10) | 31 |
| 1960(20) | 36 |
| 1970(30) | 57 |
| 1980(40) | 91 |
| 1990(50) | 159 |
| 2000(60) | 256 |

Source: www.savingcranes.org/images/...wc_numbers.pdf

36) Find the equation and parameter $r$ that best fit the data for the logistic equation.

**Answer**

$r = 0.0405$

37) Find the equation and parameters $r$ and $T$ that best fit the data for the threshold logistic equation.

38) Find the equation and parameter $\alpha$ that best fit the data for the Gompertz equation.

**Answer**

$\alpha = 0.0081$

39) Graph all three solutions and the data on the same graph. Which model appears to be most accurate?

40) Using the three equations found in the previous problems, estimate the population in $2010$ (year $70$ after conservation). The real population measured at that time was $437$. Which model is most accurate?

**Answer**

Logistic: $361$, Threshold: $436$, Gompertz: $309$.

# 11.6: First-order Linear Equations

**Learning Objectives**

- Write a first-order linear differential equation in standard form.
- Find an integrating factor and use it to solve a first-order linear differential equation.
- Solve applied problems involving first-order linear differential equations.

Earlier, we studied an application of a first-order differential equation that involved solving for the velocity of an object. In particular, if a ball is thrown upward with an initial velocity of $v_0$ ft/s, then an initial-value problem that describes the velocity of the ball after $t$ seconds is given by

$$\frac{dv}{dt} = -32$$

with $v(0) = v_0$.

This model assumes that the only force acting on the ball is gravity. Now we add to the problem by allowing for the possibility of **air resistance** acting on the ball.

Air resistance always acts in the direction opposite to motion. Therefore if an object is rising, air resistance acts in a downward direction. If the object is falling, air resistance acts in an upward direction (Figure 11.6.1). There is no exact relationship between the velocity of an object and the air resistance acting on it. For very small objects, air resistance is proportional to velocity; that is, the force due to air resistance is numerically equal to some constant $k$ times $v$. For larger (e.g., baseball-sized) objects, depending on the shape, air resistance can be approximately proportional to the square of the velocity. In fact, air resistance may be proportional to $v^{1.5}$, or $v^{0.9}$, or some other power of $v$.

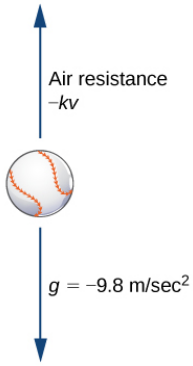

Figure 11.6.1: Forces acting on a moving baseball: gravity acts in a downward direction and air resistance acts in a direction opposite to the direction of motion.

We will work with the linear approximation for air resistance. If we assume $k > 0$, then the expression for the force $F_A$ due to air resistance is given by $F_A = -kv$. Therefore the sum of the forces acting on the object is equal to the sum of the gravitational force and the force due to air resistance. This, in turn, is equal to the mass of the object multiplied by its acceleration at time $t$(Newton's second law). This gives us the differential equation

$$m\frac{dv}{dt} = -kv - mg.$$

Finally, we impose an initial condition $v(0) = v_0$, where $v_0$ is the initial velocity measured in meters per second. This makes $g = 9.8m/s^2$. The initial-value problem becomes

$$m\frac{dv}{dt} = -kv - mg$$

with $v(0) = v_0$.

The differential equation in this initial-value problem is an example of a first-order linear differential equation. (Recall that a differential equation is first-order if the highest-order derivative that appears in the equation is 1.) In this section, we study first-order linear equations and examine a method for finding a general solution to these types of equations, as well as solving initial-value problems involving them.

**Definition: Linear first-order differential equation**

A first-order differential equation is *linear* if it can be written in the form

$$a(x)y'+b(x)y=c(x), \tag{11.6.1}$$

where $a(x), b(x)$, and $c(x)$ are arbitrary functions of $x$.

Remember that the unknown function $y$ depends on the variable $x$; that is, $x$ is the independent variable and $y$ is the dependent variable. Some examples of first-order linear differential equations are

$$\begin{aligned}(3x^2-4)y'+(x-3)y&=\sin x\\ (\sin x)y'-(\cos x)y&=\cot x\\ 4xy'+(3\ln x)y&=x^3-4x.\end{aligned}$$

Examples of first-order nonlinear differential equations include

$$\begin{aligned}(y')^4-(y')^3&=(3x-2)(y+4)\\ 4y'+3y^3&=4x-5\\ (y')^2&=\sin y+\cos x.\end{aligned}$$

These equations are nonlinear because of terms like $(y')^4, y^3$, etc. Due to these terms, it is impossible to put these equations into the same form as Equation 11.6.1.

## Standard Form

Consider the differential equation

$$(3x^2-4)y'+(x-3)y=\sin x.$$

Our main goal in this section is to derive a solution method for equations of this form. It is useful to have the coefficient of $y'$ be equal to 1. To make this happen, we divide both sides by $3x^2-4$.

$$y'+\left(\frac{x-3}{3x^2-4}\right)y=\frac{\sin x}{3x^2-4}$$

This is called the **standard form** of the differential equation. We will use it later when finding the solution to a general first-order linear differential equation. Returning to Equation 11.6.1, we can divide both sides of the equation by $a(x)$. This leads to the equation

$$y'+\frac{b(x)}{a(x)}y=\frac{c(x)}{a(x)}. \tag{11.6.2}$$

Now define

$$p(x)=\frac{b(x)}{a(x)}$$

and

$$q(x)=\frac{c(x)}{a(x)}$$

Then Equation 11.6.2 becomes

$$y'+p(x)y=q(x).$$

We can write any first-order linear differential equation in this form, and this is referred to as the standard form for a first-order linear differential equation.

### Example 11.6.1: Writing First-Order Linear Equations in Standard Form

Put each of the following first-order linear differential equations into standard form. Identify $p(x)$ and $q(x)$ for each equation.

a. $y' = 3x - 4y$

b. $\dfrac{3xy'}{4y-3} = 2$ (here $x > 0$)

c. $y = 3y' - 4x^2 + 5$

**Solution**

a. Add $4y$ to both sides:

$$y' + 4y = 3x.$$

In this equation, $p(x) = 4$ and $q(x) = 3x$.

b. Multiply both sides by $4y - 3$, then subtract $8y$ from each side:

$$\begin{aligned} \frac{3xy'}{4y-3} &= 2 \\ 3xy' &= 2(4y-3) \\ 3xy' &= 8y - 6 \\ 3xy' - 8y &= -6. \end{aligned}$$

Finally, divide both sides by $3x$ to make the coefficient of $y'$ equal to $1$:

$$y' - \frac{8}{3x}y = -\frac{2}{3x}.$$

This is allowable because in the original statement of this problem we assumed that $x > 0$. (If $x = 0$ then the original equation becomes $0 = 2$, which is clearly a false statement.)

In this equation, $p(x) = -\dfrac{8}{3x}$ and $q(x) = -\dfrac{2}{3x}$.

c. Subtract $y$ from each side and add $4x^2 - 5$:

$$3y' - y = 4x^2 - 5.$$

Next divide both sides by $3$:

$$y' - \frac{1}{3}y = \frac{4}{3}x^2 - \frac{5}{3}.$$

In this equation, $p(x) = -\dfrac{1}{3}$ and $q(x) = \dfrac{4}{3}x^2 - \dfrac{5}{3}$.

### Exercise 11.6.1

Put the equation $\dfrac{(x+3)y'}{2x - 3y - 4} = 5$ into standard form and identify $p(x)$ and $q(x)$.

**Hint**

Multiply both sides by the common denominator, then collect all terms involving $y$ on one side.

**Answer**

$$y' + \frac{15}{x+3}y = \frac{10x - 20}{x+3}$$

$$p(x) = \frac{15}{x+3}$$

and

$$q(x) = \frac{10x - 20}{x+3}$$

## Integrating Factors

We now develop a solution technique for any first-order linear differential equation. We start with the standard form of a first-order linear differential equation:

$$y' + p(x)y = q(x). \tag{11.6.3}$$

The first term on the left-hand side of Equation 11.6.3 is the derivative of the unknown function, and the second term is the product of a known function with the unknown function. This is somewhat reminiscent of the power rule. If we multiply Equation 11.6.3 by a yet-to-be-determined function $\mu(x)$, then the equation becomes

$$\mu(x)y' + \mu(x)p(x)y = \mu(x)q(x). \tag{11.6.4}$$

The left-hand side Equation 11.6.4 can be matched perfectly to the product rule:

$$\frac{d}{dx}[f(x)g(x)] = f'(x)g(x) + f(x)g'(x).$$

Matching term by term gives $y = f(x), g(x) = \mu(x)$, and $g'(x) = \mu(x)p(x)$. Taking the derivative of $g(x) = \mu(x)$ and setting it equal to the right-hand side of $g'(x) = \mu(x)p(x)$ leads to

$$\mu'(x) = \mu(x)p(x).$$

This is a first-order, separable differential equation for $\mu(x)$. We know $p(x)$ because it appears in the differential equation we are solving. Separating variables and integrating yields

$$\begin{aligned}
\frac{\mu'(x)}{\mu(x)} &= p(x) \\
\int \frac{\mu'(x)}{\mu(x)}dx &= \int p(x)dx \\
\ln|\mu(x)| &= \int p(x)dx + C \\
e^{\ln|\mu(x)|} &= e^{\int p(x)dx + C} \\
|\mu(x)| &= C_1 e^{\int p(x)dx} \\
\mu(x) &= C_2 e^{\int p(x)dx}.
\end{aligned}$$

Here $C_2$ can be an arbitrary (positive or negative) constant. This leads to a general method for solving a first-order linear differential equation. We first multiply both sides of Equation 11.6.3 by this integrating factor by **integrating factor** $\mu(x)$. This gives

$$\mu(x)y' + \mu(x)p(x)y = \mu(x)q(x). \tag{11.6.5}$$

Note that, since the non-zero constant $C_2$ can be divided out of this equation (as it will appear in every term on both sides), we do not need to use it in this process. That is, we can simply use

$$\mu(x) = e^{\int p(x)dx}.$$

The left-hand side of Equation 11.6.5 can be rewritten as $\frac{d}{dx}(\mu(x)y)$.

$$\frac{d}{dx}(\mu(x)y) = \mu(x)q(x). \tag{11.6.6}$$

Next integrate both sides of Equation 11.6.6 with respect to $x$.

$$\int \frac{d}{dx}(\mu(x)y)dx = \int \mu(x)q(x)dx$$
$$\mu(x)y = \int \mu(x)q(x)dx$$

Divide both sides of Equation 11.6.6 by $\mu(x)$:

$$y = \frac{1}{\mu(x)}\left[\int \mu(x)q(x)dx + C\right]. \tag{11.6.7}$$

Since $\mu(x)$ was previously calculated, we are now finished. An important note about the integrating constant $C$: It may seem that we are inconsistent in the usage of the integrating constant. However, the integral involving $p(x)$ is necessary in order to find an integrating factor for Equation 11.6.3. Only one integrating factor is needed in order to solve the equation; therefore, it is safe to assign a value for $C$ for this integral. We chose $C = 0$. When calculating the integral inside the brackets in Equation 11.6.7, it is necessary to keep our options open for the value of the integrating constant, because our goal is to find a general family of solutions to Equation 11.6.3. This integrating factor guarantees just that.

### Problem-Solving Strategy: Solving a First-order Linear Differential Equation

1. Put the equation into standard form and identify $p(x)$ and $q(x)$.
2. Calculate the integrating factor

$$\mu(x) = e^{\int p(x)dx}. \tag{11.6.8}$$

3. Multiply both sides of the differential equation by $\mu(x)$.
4. Integrate both sides of the equation obtained in step **3**, and divide both sides by $\mu(x)$.
5. If there is an initial condition, determine the value of $C$.

### Example 11.6.2: Solving a First-order Linear Equation

Find a general solution for the differential equation $xy' + 3y = 4x^2 - 3x$. Assume $x > 0$.

**Solution**

1. To put this differential equation into standard form, divide both sides by $x$:

$$y' + \frac{3}{x}y = 4x - 3.$$

Therefore $p(x) = \dfrac{3}{x}$ and $q(x) = 4x - 3$.

2. The integrating factor is $\mu(x) = e^{\int (3/x)dx} = e^{3\ln x} = x^3$.

3. Multiplying both sides of the differential equation by $\mu(x)$ gives us

$$x^3y' + x^3\left(\frac{3}{x}\right)y = x^3(4x - 3)$$
$$x^3y' + 3x^2y = 4x^4 - 3x^3$$
$$\frac{d}{dx}(x^3y) = 4x^4 - 3x^3.$$

4. Integrate both sides of the equation.

$$\int \frac{d}{dx}(x^3y)dx = \int 4x^4 - 3x^3dx$$
$$x^3y = \frac{4x^5}{5} - \frac{3x^4}{4} + C$$
$$y = \frac{4x^2}{5} - \frac{3x}{4} + Cx^{-3}.$$

5. There is no initial value, so the problem is complete.

### Analysis

You may have noticed the condition that was imposed on the differential equation; namely, $x > 0$. For any nonzero value of $C$, the general solution is not defined at $x = 0$. Furthermore, when $x < 0$, the integrating factor changes. The integrating factor is given by Equation 11.6.8 as $\mu(x) = e^{\int p(x)dx}$. For this $p(x)$ we get

$$\begin{aligned} e^{\int p(x)dx} &= e^{\int (3/x)dx} \\ &= e^{3\ln|x|} \\ &= |x|^3 \end{aligned}$$

since $x < 0$. The behavior of the general solution changes at $x = 0$ largely due to the fact that $p(x)$ is not defined there.

## Exercise 11.6.2

Find the general solution to the differential equation $(x-2)y' + y = 3x^2 + 2x$. Assume $x > 2$.

**Hint**

Use the method outlined in the problem-solving strategy for first-order linear differential equations.

**Answer**

$$y = \frac{x^3 + x^2 + C}{x - 2}$$

Now we use the same strategy to find the solution to an initial-value problem.

## Example 11.6.3: A First-order Linear Initial-Value Problem

Solve the initial-value problem

$$y' + 3y = 2x - 1, y(0) = 3.$$

### Solution

1. This differential equation is already in standard form with $p(x) = 3$ and $q(x) = 2x - 1$.

2. The integrating factor is $\mu(x) = e^{\int 3dx} = e^{3x}$.

3. Multiplying both sides of the differential equation by $\mu(x)$ gives

$$\begin{aligned} e^{3x}y' + 3e^{3x}y &= (2x-1)e^{3x} \\ \frac{d}{dx}[ye^{3x}] &= (2x-1)e^{3x}. \end{aligned}$$

Integrate both sides of the equation:

$$\begin{aligned} \int \frac{d}{dx}[ye^{3x}]dx &= \int (2x-1)e^{3x}dx \\ ye^{3x} &= \frac{e^{3x}}{3}(2x-1) - \int \frac{2}{3}e^{3x}dx \\ ye^{3x} &= \frac{e^{3x}(2x-1)}{3} - \frac{2e^{3x}}{9} + C \\ y &= \frac{2x-1}{3} - \frac{2}{9} + Ce^{-3x} \\ y &= \frac{2x}{3} - \frac{5}{9} + Ce^{-3x}. \end{aligned}$$

4. Now substitute $x = 0$ and $y = 3$ into the general solution and solve for $C$:

$$y = \frac{2}{3}x - \frac{5}{9} + Ce^{-3x}$$
$$3 = \frac{2}{3}(0) - \frac{5}{9} + Ce^{-3(0)}$$
$$3 = -\frac{5}{9} + C$$
$$C = \frac{32}{9}.$$

Therefore the solution to the initial-value problem is

$$y = \frac{2}{3}x - \frac{5}{9} + \frac{32}{9}e^{-3x}.$$

**Example 11.6.4:**

Solve the initial-value problem

$$y' - 2y = 4x + 3y(0) = -2.$$

**Solution**

$$y = -2x - 4 + 2e^{2x}$$

## Applications of First-order Linear Differential Equations

We look at two different applications of first-order linear differential equations. The first involves air resistance as it relates to objects that are rising or falling; the second involves an electrical circuit. Other applications are numerous, but most are solved in a similar fashion.

### Free fall with air resistance

We discussed air resistance at the beginning of this section. The next example shows how to apply this concept for a ball in vertical motion. Other factors can affect the force of air resistance, such as the size and shape of the object, but we ignore them here.

**Example 11.6.5: A Ball with Air Resistance**

A racquetball is hit straight upward with an initial velocity of $2\ \mathrm{m/s}$. The mass of a racquetball is approximately $0.0427\ \mathrm{kg}$. Air resistance acts on the ball with a force numerically equal to $0.5v$, where $v$ represents the velocity of the ball at time $t$.

a. Find the velocity of the ball as a function of time.
b. How long does it take for the ball to reach its maximum height?
c. If the ball is hit from an initial height of $1$ meter, how high will it reach?

**Solution**

a. The mass $m = 0.0427\ kg, k = 0.5$, and $g = 9.8\ m/s^2$. The initial velocity is $v_0 = 2\ m/s$. Therefore the initial-value problem is

$$0.0427\frac{dv}{dt} = -0.5v - 0.0427(9.8), v_0 = 2.$$

Dividing the differential equation by $0.0427$ gives

$$\frac{dv}{dt} = -11.7096v - 9.8, v_0 = 2.$$

The differential equation is linear. Using the problem-solving strategy for linear differential equations:

Step 1. Rewrite the differential equation as $\frac{dv}{dt} + 11.7096v = -9.8$. This gives $p(t) = 11.7096$ and $q(t) = -9.8$

Step 2. The integrating factor is $\mu(t) = e^{\int 11.7096dt} = e^{11.7096t}$.

Step 3. Multiply the differential equation by $\mu(t)$:

$$e^{11.7096t}\frac{dv}{dt} + 11.7096ve^{11.7096t} = -9.8e^{11.7096t}$$
$$\frac{d}{dt}[ve^{11.7096t}] = -9.8e^{11.7096t}.$$

Step 4. Integrate both sides:

$$\int \frac{d}{dt}[ve^{11.7096t}]dt = \int -9.8e^{11.7096t}dt$$
$$ve^{11.7096t} = \frac{-9.8}{11.7096}e^{11.7096t} + C$$
$$v(t) = -0.8369 + Ce^{-11.7096t}.$$

Step 5. Solve for $C$ using the initial condition $v_0 = v(0) = 2$:

$$v(t) = -0.8369 + Ce^{-11.7096t}$$
$$v(0) = -0.8369 + Ce^{-11.7096(0)}$$
$$2 = -0.8369 + C$$
$$C = 2.8369.$$

Therefore the solution to the initial-value problem is

$$v(t) = 2.8369e^{-11.7096t} - 0.8369.$$

b. The ball reaches its maximum height when the velocity is equal to zero. The reason is that when the velocity is positive, it is rising, and when it is negative, it is falling. Therefore when it is zero, it is neither rising nor falling, and is at its maximum height:

$$2.8369e^{-11.7096t} - 0.8369 = 0$$
$$2.8369e^{-11.7096t} = 0.8369$$
$$e^{-11.7096t} = \frac{0.8369}{2.8369} \approx 0.295$$
$$\ln e^{-11.7096t} = \ln 0.295 \approx -1.221$$
$$-11.7096t = -1.221$$
$$t \approx 0.104.$$

Therefore it takes approximately $0.104$ second to reach maximum height.

c. To find the height of the ball as a function of time, use the fact that the derivative of position is velocity, i.e., if $h(t)$ represents the height at time $t$, then $h'(t) = v(t)$. Because we know $v(t)$ and the initial height, we can form an initial-value problem:

$$h'(t) = 2.8369e^{-11.7096t} - 0.8369,\ h(0) = 1.$$

Integrating both sides of the differential equation with respect to $t$ gives

$$\int h'(t)dt = \int 2.8369e^{-11.7096t} - 0.8369\ dt$$
$$h(t) = -\frac{2.8369}{11.7096}e^{-11.7096t} - 0.8369t + C$$
$$h(t) = -0.2423e^{-11.7096t} - 0.8369t + C.$$

Solve for $C$ by using the initial condition:

$$h(t) = -0.2423e^{-11.7096t} - 0.8369t + C$$
$$h(0) = -0.2423e^{-11.7096(0)} - 0.8369(0) + C$$
$$1 = -0.2423 + C$$
$$C = 1.2423.$$

Therefore

$$h(t) = -0.2423e^{-11.7096t} - 0.8369t + 1.2423.$$

After $0.104$ second, the height is given by

$$\begin{aligned} h(0.2) &= -0.2423e^{-11.7096t} - 0.8369t + 1.2423 \\ &\approx 1.0836 \text{ meter.} \end{aligned}$$

**? Exercise 11.6.3**

The weight of a penny is $2.5$ grams (United States Mint, "Coin Specifications," accessed April 9, 2015, www.usmint.gov/about_the_mint...specifications), and the upper observation deck of the Empire State Building is $369$ meters above the street. Since the penny is a small and relatively smooth object, air resistance acting on the penny is actually quite small. We assume the air resistance is numerically equal to $0.0025v$. Furthermore, the penny is dropped with no initial velocity imparted to it.

a. Set up an initial-value problem that represents the falling penny.
b. Solve the problem for $v(t)$.
c. What is the terminal velocity of the penny (i.e., calculate the limit of the velocity as $t$ approaches infinity)?

**Hint**

Set up the differential equation the same way as Example **?** $11.6.5$. Remember to convert from grams to kilograms.

**Answer**

a. $\frac{dv}{dt} = -v - 9.8\ v(0) = 0$

b. $v(t) = 9.8(e^{-t} - 1)$

c. $\lim_{t\to\infty} v(t) = \lim_{t\to\infty} (9.8(e^{-t} - 1)) = -9.8 \text{ m/s} \approx -21.922$ mph

## Electrical Circuits

A source of electromotive force (e.g., a battery or generator) produces a flow of current in a closed circuit, and this current produces a voltage drop across each resistor, inductor, and capacitor in the circuit. Kirchhoff's Loop Rule states that the sum of the voltage drops across resistors, inductors, and capacitors is equal to the total electromotive force in a closed circuit. We have the following three results:

1. The voltage drop across a resistor is given by

$$E_R = Ri,$$

where $R$ is a constant of proportionality called the resistance, and $i$ is the current.

2. The voltage drop across an inductor is given by

$$E_L = Li',$$

where $L$ is a constant of proportionality called the inductance, and $i$ again denotes the current.

3. The voltage drop across a capacitor is given by

$$E_C = \frac{1}{C}q,$$

where $C$ is a constant of proportionality called the capacitance, and $q$ is the instantaneous charge on the capacitor. The relationship between $i$ and $q$ is $i = q'$.

We use units of volts $(V)$ to measure voltage $E$, amperes $(A)$ to measure current $i$, coulombs $(C)$ to measure charge $q$, ohms $(\Omega)$ to measure resistance $R$, henrys $(H)$ to measure inductance $L$, and farads $(F)$ to measure capacitance $C$. Consider the circuit in Figure $11.6.2$.

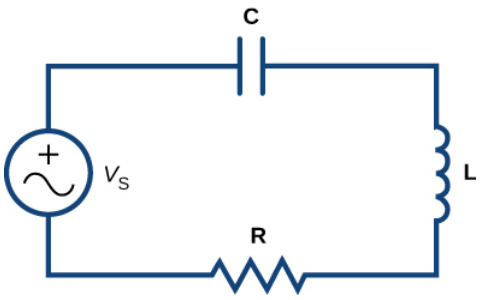

Figure 11.6.2: A typical electric circuit, containing a voltage generator ($V_S$), capacitor ($C$), inductor ($L$), and resistor ($R$).

Applying Kirchhoff's Loop Rule to this circuit, we let $E$ denote the electromotive force supplied by the voltage generator. Then

$$E_L + E_R + E_C = E.$$

Substituting the expressions for $E_L, E_R$, and $E_C$ into this equation, we obtain

$$Li' + Ri + \frac{1}{C}q = E. \tag{11.6.9}$$

If there is no capacitor in the circuit, then the equation becomes

$$Li' + Ri = E. \tag{11.6.10}$$

This is a first-order differential equation in $i$. The circuit is referred to as an **LR circuit**.

Next, suppose there is no inductor in the circuit, but there is a capacitor and a resistor, so $L = 0$, $R \neq 0$, and $C \neq 0$. Then, since $q' = i$, Equation 11.6.9 can be rewritten as

$$Rq' + \frac{1}{C}q = E, \tag{11.6.11}$$

which is a first-order linear differential equation in $q$. This is referred to as an **RC circuit**. In either case, we can set up and solve an initial-value problem.

### Electric Circuit

A circuit has in series an electromotive force given by $E = 50 \sin 20t V$, a resistor of $5\Omega$, and an inductor of $0.4H$. If the initial current is $0$, find the current at time $t > 0$.

#### Solution

We have a resistor and an inductor in the circuit, so we have an LR circuit and can use Equation 11.6.10. The voltage drop across the resistor is given by $E_R = Ri = 5i$. The voltage drop across the inductor is given by $E_L = Li' = 0.4i'$. The electromotive force becomes the right-hand side of Equation 11.6.10. Therefore Equation 11.6.10 becomes

$$0.4i' + 5i = 50 \sin 20t.$$

Dividing both sides by $0.4$ gives the equation

$$i' + 12.5i = 125 \sin 20t.$$

Since the initial current is 0, this result gives an initial condition of $i(0) = 0$. We can solve this initial-value problem using the five-step strategy for solving first-order differential equations.

Step 1. Rewrite the differential equation as $i' + 12.5i = 125 \sin 20t$. This gives $p(t) = 12.5$ and $q(t) = 125 \sin 20t$.

Step 2. The integrating factor is $\mu(t) = e^{\int 12.5 dt} = e^{12.5t}$.

Step 3. Multiply the differential equation by $\mu(t)$:

$$e^{12.5t} i' + 12.5 e^{12.5t} i = 125 e^{12.5t} \sin 20t$$

$$\frac{d}{dt}[ie^{12.5t}] = 125 e^{12.5t} \sin 20t.$$

Step 4. Integrate both sides:

$$\int \frac{d}{dt}[ie^{12.5t}]dt = \int 125e^{12.5t}\sin 20t\ dt$$
$$ie^{12.5t} = \left(\frac{250\sin 20t - 400\cos 20t}{89}\right)e^{12.5t} + C$$
$$i(t) = \frac{250\sin 20t - 400\cos 20t}{89} + Ce^{-12.5t}.$$

Step 5. Solve for $C$ using the initial condition $i(0) = 0$:

$$i(t) = \frac{250\sin 20t - 400\cos 20t}{89} + Ce^{-12.5t}$$
$$i(0) = \frac{250\sin 20(0) - 400\cos 20(0)}{89} + Ce^{-12.5(0)}$$
$$0 = -\frac{400}{89} + C$$
$$C = \frac{400}{89}.$$

Therefore the solution to the initial-value problem is

$$i(t) = \frac{250\sin 20t - 400\cos 20t + 400e^{-12.5t}}{89} = \frac{250\sin 20t - 400\cos 20t}{89} + \frac{400e^{-12.5t}}{89}.$$

The first term can be rewritten as a single cosine function. First, multiply and divide by $\sqrt{250^2 + 400^2} = 50\sqrt{89}$:

$$\frac{250\sin 20t - 400\cos 20t}{89} = \frac{50\sqrt{89}}{89}\left(\frac{250\sin 20t - 400\cos 20t}{50\sqrt{89}}\right) = -\frac{50\sqrt{89}}{89}\left(\frac{8\cos 20t}{\sqrt{89}} - \frac{5\sin 20t}{\sqrt{89}}\right).$$

Next, define $\varphi$ to be an acute angle such that $\cos\varphi = \frac{8}{\sqrt{89}}$. Then $\sin\varphi = \frac{5}{\sqrt{89}}$ and

$$-\frac{50\sqrt{89}}{89}\left(\frac{8\cos 20t}{\sqrt{89}} - \frac{5\sin 20t}{\sqrt{89}}\right) = -\frac{50\sqrt{89}}{89}(\cos\varphi\cos 20t - \sin\varphi\sin 20t) = -\frac{50\sqrt{89}}{89}\cos(20t + \varphi).$$

Therefore the solution can be written as

$$i(t) = -\frac{50\sqrt{89}}{89}cos(20t + \varphi) + \frac{400e^{-12.5t}}{89}.$$

The second term is called the attenuation term, because it disappears rapidly as $t$ grows larger. The phase shift is given by $\varphi$, and the amplitude of the steady-state current is given by $\frac{50\sqrt{89}}{89}$. The graph of this solution appears in Figure **11.6.3**:

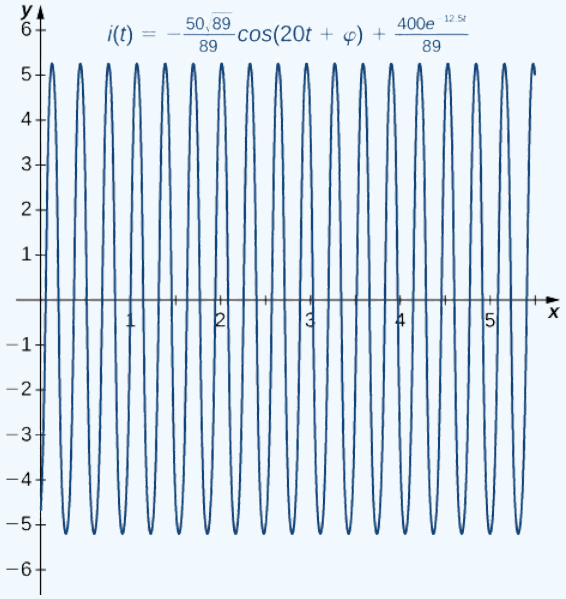

Figure **11.6.3**.

## ? Exercise 11.6.4

A circuit has in series an electromotive force given by $E = 20\sin 5t$ V, a capacitor with capacitance $0.02F$, and a resistor of $8\Omega$. If the initial charge is $4C$, find the charge at time $t > 0$.

**Hint**

Use Equation 11.6.11 for an RC circuit to set up an initial-value problem.

**Answer**

Initial-value problem:

$$8q' + \frac{1}{0.02}q = 20\sin 5t, q(0) = 4$$

$$q(t) = \frac{10\sin 5t - 8\cos 5t + 172e^{-6.25t}}{41}$$

## Key Concepts

- Any first-order linear differential equation can be written in the form $y' + p(x)y = q(x)$.
- We can use a five-step problem-solving strategy for solving a first-order linear differential equation that may or may not include an initial value.
- Applications of first-order linear differential equations include determining motion of a rising or falling object with air resistance and finding current in an electrical circuit.

## Key Equations

- **standard form**

  $y' + p(x)y = q(x)$

- **integrating factor**

  $\mu(x) = e^{\int p(x)dx}$

## Glossary

**integrating factor**

any function $f(x)$ that is multiplied on both sides of a differential equation to make the side involving the unknown function equal to the derivative of a product of two functions

**linear**

description of a first-order differential equation that can be written in the form $a(x)y'+b(x)y=c(x)$

**standard form**

the form of a first-order linear differential equation obtained by writing the differential equation in the form $y'+p(x)y=q(x)$

# 11.6E: Exercises for Section 8.5

**In exercises 1 - 5, state if each of the following differential equations is linear? Explain your reasoning.**

1) $\frac{dy}{dx} = x^2y + \sin x$

2) $\frac{dy}{dt} = ty$

**Answer**

$Yes$

3) $\frac{dy}{dt} + y^2 = x$

4) $y' = x^3 + e^x$

**Answer**

$Yes$

5) $y' = y + e^y$

**In exercises 6 - 10, write the following first-order differential equations in standard form.**

6) $y' = x^3y + \sin x$

**Answer**

$y' - x^3y = \sin x$

7) $y' + 3y - \ln x = 0$

8) $-xy' = (3x + 2)y + xe^x$

**Answer**

$y' + \frac{(3x+2)}{x}y = -e^x$

9) $\frac{dy}{dt} = 4y + ty + \tan t$

10) $\frac{dy}{dt} = yx(x + 1)$

**Answer**

$\frac{dy}{dt} - yx(x + 1) = 0$

**In exercises 11 - 15, state the integrating factors for each of the following differential equations.**

11) $y' = xy + 3$

12) $y' + e^xy = \sin x$

**Answer**

$e^x$

13) $y' = x\ln(x)y + 3x$

14) $\frac{dy}{dx} = \tanh(x)y + 1$

**Answer**

$-\ln(\cosh x)$

15) $\frac{dy}{dt} + 3ty = e^t y$

**In exercises 16 - 25, solve each differential equation by using integrating factors.**

16) $y' = 3y + 2$

**Answer**

$y = Ce^{3x} - \frac{2}{3}$

17) $y' = 2y - x^2$

18) $xy' = 3y - 6x^2$

**Answer**

$y = Cx^3 + 6x^2$

19) $(x + 2)y' = 3x + y$

20) $y' = 3x + xy$

**Answer**

$y = Ce^{x^2/2} - 3$

21) $xy' = x + y$

22) $\sin(x)y' = y + 2x$

**Answer**

$y = C\tan\left(\frac{x}{2}\right) - 2x + 4\tan\left(\frac{x}{2}\right)\ln\left(\sin(\frac{x}{2})\right)$

23) $y' = y + e^x$

24) $xy' = 3y + x^2$

**Answer**

$y = Cx^3 - x^2$

25) $y' + \ln x = \frac{y}{x}$

**In exercises 26 - 33, solve the given differential equation. Use your calculator to draw a family of solutions. Are there certain initial conditions that change the behavior of the solution?**

26) [T] $(x + 2)y' = 2y - 1$

**Answer**

$y = C(x + 2)^2 + \frac{1}{2}$

27) [T] $y' = 3e^{t/3} - 2y$

28) [T] $xy' + \frac{y}{2} = \sin(3t)$

**Answer**

$y = \frac{C}{\sqrt{x}} + 2\sin(3t)$

29) [T] $xy' = 2\frac{\cos x}{x} - 3y$

30) [T] $(x + 1)y' = 3y + x^2 + 2x + 1$

**Answer**

$$y = C(x+1)^3 - x^2 - 2x - 1$$

31) [T] $\sin(x)y' + \cos(x)y = 2x$

32) [T] $\sqrt{x^2+1}y' = y + 2$

**Answer**

$$y = Ce^{\sinh^{-1}x} - 2$$

33) [T] $x^3y' + 2x^2y = x + 1$

**In exercises 34 - 43, solve each initial-value problem by using integrating factors.**

34) $y' + y = x, \quad y(0) = 3$

**Answer**

$$y = x + 4e^x - 1$$

35) $y' = y + 2x^2, \quad y(0) = 0$

36) $xy' = y - 3x^3, \quad y(1) = 0$

**Answer**

$$y = -\frac{3x}{2}(x^2 - 1)$$

37) $x^2y' = xy - \ln x, \quad y(1) = 1$

38) $(1+x^2)y' = y - 1, \quad y(0) = 0$

**Answer**

$$y = 1 - e^{\tan^{-1}x}$$

39) $xy' = y + 2x\ln x, \quad y(1) = 5$

40) $(2+x)y' = y + 2 + x, \quad y(0) = 0$

**Answer**

$$y = (x+2)\ln\left(\frac{x+2}{2}\right)$$

41) $y' = xy + 2xe^x, \quad y(0) = 2$

42) $\sqrt{x}y' = y + 2x, \quad y(0) = 1$

**Answer**

$$y = 2e^{2\sqrt{x}} - 2x - 2\sqrt{x} - 1$$

43) $y' = 2y + xe^x, \quad y(0) = -1$

44) A falling object of mass $m$ can reach terminal velocity when the drag force is proportional to its velocity, with proportionality constant $k$. Set up the differential equation and solve for the velocity given an initial velocity of $0$.

**Answer**

$$v(t) = \frac{gm}{k}\left(1 - e^{-kt/m}\right)$$

45) Using your expression from the preceding problem, what is the terminal velocity? (Hint: Examine the limiting behavior; does the velocity approach a value?)

46) [T] Using your equation for terminal velocity, solve for the distance fallen. How long does it take to fall $5000$ meters if the mass is $100$ kilograms, the acceleration due to gravity is $9.8$ m/s$^2$ and the proportionality constant is $4$?

**Answer**

40.451 seconds

47) A more accurate way to describe terminal velocity is that the drag force is proportional to the square of velocity, with a proportionality constant $k$. Set up the differential equation and solve for the velocity.

48) Using your expression from the preceding problem, what is the terminal velocity? (Hint: Examine the limiting behavior: Does the velocity approach a value?)

**Answer**

$\sqrt{\frac{gm}{k}}$

49) [T] Using your equation for terminal velocity, solve for the distance fallen. How long does it take to fall 5000 meters if the mass is 100 kilograms, the acceleration due to gravity is 9.8 m/s$^2$ and the proportionality constant is 4? Does it take more or less time than your initial estimate?

**In exercises 50 - 54, determine how parameter $a$ affects the solution.**

50) Solve the generic equation $y' = ax + y$. How does varying $a$ change the behavior?

**Answer**

$y = Ce^x - a(x+1)$

51) Solve the generic equation $y' = ax + y$. How does varying $a$ change the behavior?

52) Solve the generic equation $y' = ax + xy$. How does varying $a$ change the behavior?

**Answer**

$y = Ce^{x^2/2} - a$

53) Solve the generic equation $y' = x + axy$. How does varying $a$ change the behavior?

54) Solve $y' - y = e^{kt}$ with the initial condition $y(0) = 0$. As $k$ approaches 1, what happens to your formula?

**Answer**

$y = \frac{e^{kt} - e^t}{k-1}$

# CHAPTER OVERVIEW

## 12: Vectors in Space

A quantity that has magnitude and direction is called a **vector**. Vectors have many real-life applications, including situations involving force or velocity. For example, consider the forces acting on a boat crossing a river. The boat's motor generates a force in one direction, and the current of the river generates a force in another direction. Both forces are vectors. We must take both the magnitude and direction of each force into account if we want to know where the boat will go.

# 12.1: Prelude to Vectors in Space

Modern astronomical observatories often consist of a large number of parabolic reflectors, connected by computers, used to analyze radio waves. Each dish focuses the incoming parallel beams of radio waves to a precise focal point, where they can be synchronized by computer. If the surface of one of the parabolic reflectors is described by the equation $\frac{x^2}{100} + \frac{y^2}{100} = \frac{z}{4}$, where is the focal point of the reflector?

Figure **12.1.1**: The Karl G. Jansky Very Large Array, located in Socorro, New Mexico, consists of a large number of radio telescopes that can collect radio waves and collate them as if they were gathering waves over a huge area with no gaps in coverage. (credit: modification of work by CGP Grey, Wikimedia Commons)

We are now about to begin a new part of the calculus course, when we study functions of two or three independent variables in multidimensional space. Many of the computations are similar to those in the study of single-variable functions, but there are also a lot of differences. In this first chapter, we examine coordinate systems for working in three-dimensional space, along with vectors, which are a key mathematical tool for dealing with quantities in more than one dimension. Let's start here with the basic ideas and work our way up to the more general and powerful tools of mathematics in later chapters.

# 12.2: Vectors in the Plane

**Learning Objectives**

- Describe a plane vector, using correct notation.
- Perform basic vector operations (scalar multiplication, addition, subtraction).
- Express a vector in component form.
- Explain the formula for the magnitude of a vector.
- Express a vector in terms of unit vectors.
- Give two examples of vector quantities.

When describing the movement of an airplane in flight, it is important to communicate two pieces of information: the direction in which the plane is traveling and the plane's speed. Together these form the plane's velocity. When measuring a force, such as the thrust of the plane's engines, it is important to describe not only the strength of that force, but also the direction in which it is applied. Some quantities, such as velocity and force, are defined in terms of both size (also called magnitude) and direction. A quantity that has magnitude and direction is called a **vector**. In textbooks, vectors are often denoted by boldface letters, such as $\mathbf{v}$. Since it is difficult to write in clear boldface when we write vectors by hand, we will also include an arrow or harpoon above the letter representing the vector. To make the vectors clearer in this textbook (and to reinforce the way you should write them by hand), we will generally use arrows or harpoons above boldface (or italic) letters to represent vectors, giving us $\vec{\boldsymbol{v}}$ or $\vec{\mathbf{v}}$. Note that some figures will still only use boldface letters to denote vectors.

**Definition: Vector**

A vector is a quantity that has both magnitude and direction.

## Vector Representation

A vector in a plane is represented by a directed line segment (an arrow). The endpoints of the segment are called the **initial point** and the **terminal point** of the vector. An arrow from the initial point to the terminal point indicates the direction of the vector. The length of the line segment represents its **magnitude**. We use the notation $\|\vec{\mathbf{v}}\|$ to denote the magnitude of the vector $\vec{\mathbf{v}}$. A vector with an initial point and terminal point that are the same is called the **zero vector**, denoted $\vec{\mathbf{0}}$. The zero vector is the only vector without a direction, and by convention can be considered to have any direction convenient to the problem at hand.

Vectors with the same magnitude and direction are called equivalent vectors. We treat equivalent vectors as equal, even if they have different initial points. Thus, if $\vec{\mathbf{v}}$ and $\vec{\mathbf{w}}$ are equivalent, we write

$$\vec{\mathbf{v}} = \vec{\mathbf{w}}.$$

**Definition: Equivalent Vectors**

Vectors are said to be *equivalent vectors* if they have the same magnitude and direction.

The arrows in Figure 12.2.1 are equivalent. Each arrow has the same length and direction. A closely related concept is the idea of parallel vectors. Two vectors are said to be parallel if they have the same or opposite directions. We explore this idea in more detail later in the chapter. A vector is defined by its magnitude and direction, regardless of where its initial point is located.

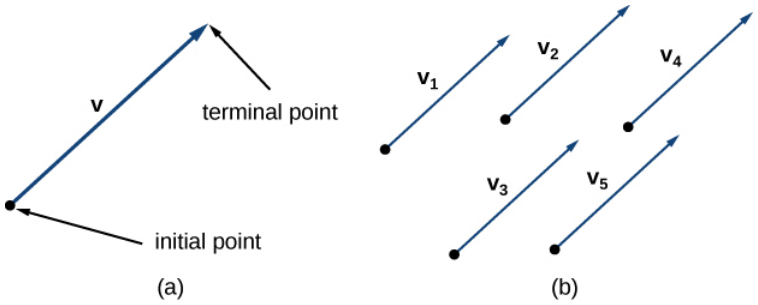

Figure 12.2.1: (a) A vector is represented by a directed line segment from its initial point to its terminal point. (b) Vectors $\vec{\mathbf{v}}_1$ through $\vec{\mathbf{v}}_5$ are equivalent.

The use of boldface, lowercase letters to name vectors is a common representation in print, but there are alternative notations. When writing the name of a vector by hand, for example, it is easier to sketch an arrow over the variable than to show it is a vector: $\vec{v}$. When a vector has initial point $P$ and terminal point $Q$, the notation $\overrightarrow{PQ}$ is useful because it indicates the direction and location of the vector.

### Example 12.2.1: Sketching Vectors

Sketch a vector in the plane from initial point $P(1,1)$ to terminal point $Q(8,5)$.

**Solution**

See Figure 12.2.2. Because the vector goes from point $P$ to point $Q$, we name it $\overrightarrow{PQ}$.

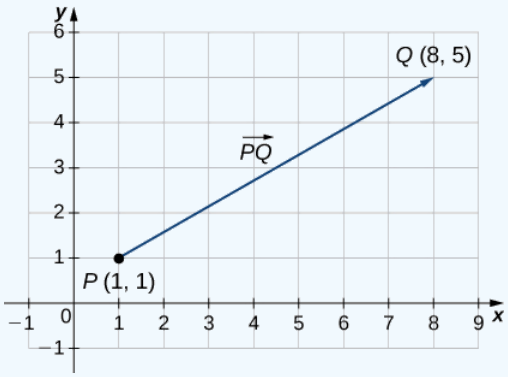

Figure 12.2.2: The vector with initial point $(1,1)$ and terminal point $(8,5)$ is named $\overrightarrow{PQ}$.

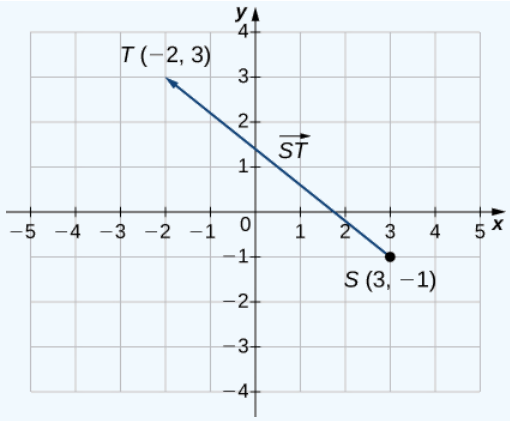
### Exercise 12.2.1

Sketch the vector $\overrightarrow{ST}$ where $S$ is point $(3,-1)$ and $T$ is point $(-2,3)$.

**Hint**

The first point listed in the name of the vector is the initial point of the vector.

**Answer**



## Combining Vectors

Vectors have many real-life applications, including situations involving force or velocity. For example, consider the forces acting on a boat crossing a river. The boat's motor generates a force in one direction, and the current of the river generates a force in another direction. Both forces are vectors. We must take both the magnitude and direction of each force into account if we want to know where the boat will go.

A second example that involves vectors is a quarterback throwing a football. The quarterback does not throw the ball parallel to the ground; instead, he aims up into the air. The velocity of his throw can be represented by a vector. If we know how hard he throws the ball (magnitude—in this case, speed), and the angle (direction), we can tell how far the ball will travel down the field.

A real number is often called a **scalar** in mathematics and physics. Unlike vectors, scalars are generally considered to have a magnitude only, but no direction. Multiplying a vector by a scalar changes the vector's magnitude. This is called scalar multiplication. Note that changing the magnitude of a vector does not indicate a change in its direction. For example, wind blowing from north to south might increase or decrease in speed while maintaining its direction from north to south.

**Definition: Scalar Multiplication**

The product $k\vec{\mathbf{v}}$ of a vector $\vec{\mathbf{v}}$ and a scalar $k$ is a vector with a magnitude that is $|k|$ times the magnitude of $\vec{\mathbf{v}}$, and with a direction that is the same as the direction of $\vec{\mathbf{v}}$ if $k > 0$, and opposite the direction of $\vec{\mathbf{v}}$ if $k < 0$. This is called *scalar multiplication*. If $k = 0$ or $\vec{\mathbf{v}} = \vec{\mathbf{0}}$, then $k\vec{\mathbf{v}} = \vec{\mathbf{0}}$.

As you might expect, if $k = -1$, we denote the product $k\vec{\mathbf{v}}$ as

$$k\vec{\mathbf{v}} = (-1)\vec{\mathbf{v}} = -\vec{\mathbf{v}}.$$

Note that $-\vec{\mathbf{v}}$ has the same magnitude as $\vec{\mathbf{v}}$, but has the opposite direction (Figure 12.2.3).

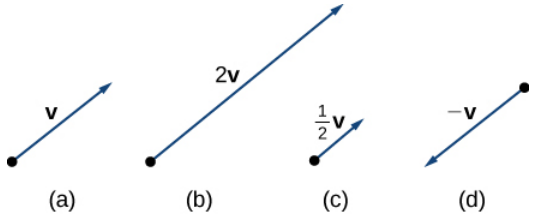


Figure 12.2.3: (a) The original vector $\vec{\mathbf{v}}$ has length $n$ units. (b) The length of $2\vec{\mathbf{v}}$ equals $2n$ units. (c) The length of $\vec{\mathbf{v}}/2$ is $n/2$ units. (d) The vectors $\vec{\mathbf{v}}$ and $-\vec{\mathbf{v}}$ have the same length but opposite directions.

Another operation we can perform on vectors is to add them together in vector addition, but because each vector may have its own direction, the process is different from adding two numbers. The most common graphical method for adding two vectors is to place the initial point of the second vector at the terminal point of the first, as in Figure 12.2.4. To see why this makes sense, suppose, for example, that both vectors represent displacement. If an object moves first from the initial point to the terminal point of vector $\vec{\mathbf{v}}$, then from the initial point to the terminal point of vector $\vec{\mathbf{w}}$, the overall displacement is the same as if the object had made just one

movement from the initial point to the terminal point of the vector $\vec{v} + \vec{w}$. For obvious reasons, this approach is called the **triangle method**. Notice that if we had switched the order, so that $\vec{w}$ was our first vector and $\vec{v}$ was our second vector, we would have ended up in the same place. (Again, see Figure 12.2.4.) Thus,

$$\vec{v} + \vec{w} = \vec{w} + \vec{v}.$$

A second method for adding vectors is called the **parallelogram method**. With this method, we place the two vectors so they have the same initial point, and then we draw a parallelogram with the vectors as two adjacent sides, as in Figure 12.2.4. The length of the diagonal of the parallelogram is the sum. Comparing Figure 12.2.4 and Figure 12.2.4, we can see that we get the same answer using either method. The vector $\vec{v} + \vec{w}$ is called the **vector sum.**

### Definition: Vector Addition

The sum of two vectors $\vec{v}$ and $\vec{w}$ can be constructed graphically by placing the initial point of $\vec{w}$ at the terminal point of $\vec{v}$. Then, the vector sum, $\vec{v} + \vec{w}$, is the vector with an initial point that coincides with the initial point of $\vec{v}$ and has a terminal point that coincides with the terminal point of $\vec{w}$. This operation is known as *vector addition*.

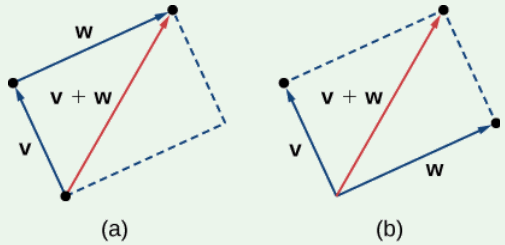

Figure 12.2.4: (a) When adding vectors by the triangle method, the initial point of $\vec{w}$ is the terminal point of $\vec{v}$. (b) When adding vectors by the parallelogram method, the vectors $\vec{v}$ and $\vec{w}$ have the same initial point.

It is also appropriate here to discuss vector subtraction. We define $\vec{v} - \vec{w}$ as $\vec{v} + (-\vec{w}) = \vec{v} + (-1)\vec{w}$. The vector $\vec{v} - \vec{w}$ is called the **vector difference**. Graphically, the vector $\vec{v} - \vec{w}$ is depicted by drawing a vector from the terminal point of $\vec{w}$ to the terminal point of $\vec{v}$ (Figure 12.2.5).

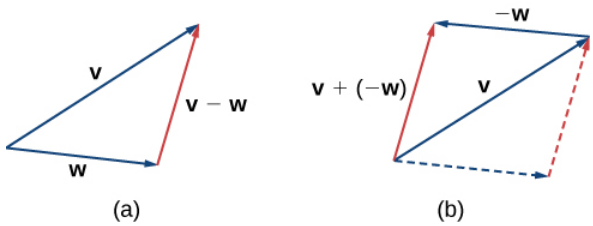

Figure 12.2.5: (a) The vector difference $\vec{v} - \vec{w}$ is depicted by drawing a vector from the terminal point of $\vec{w}$ to the terminal point of $\vec{v}$. (b) The vector$\vec{v} - \vec{w}$ is equivalent to the vector $\vec{v} + (-\vec{w})$.

In Figure 12.2.4, the initial point of $\vec{v} + \vec{w}$ is the initial point of $\vec{v}$. The terminal point of $\vec{v} + \vec{w}$ is the terminal point of $\vec{w}$. These three vectors form the sides of a triangle. It follows that the length of any one side is less than the sum of the lengths of the remaining sides. So we have

$$\|\vec{v} + \vec{w}\| \leq \|\vec{v}\| + \|\vec{w}\|.$$

This is known more generally as the **triangle inequality**. There is one case, however, when the resultant vector $\vec{u} + \vec{v}$ has the same magnitude as the sum of the magnitudes of $\vec{u}$ and $\vec{v}$. This happens only when $\vec{u}$ and $\vec{v}$ have the same direction.

### Example 12.2.2: Combining Vectors

Given the vectors $\vec{v}$ and $\vec{w}$ shown in Figure 12.2.6, sketch the vectors

a. $3\vec{w}$
b. $\vec{v} + \vec{w}$
c. $2\vec{v} - \vec{w}$

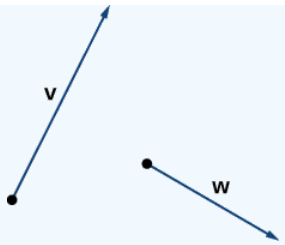

Figure 12.2.6: Vectors $\vec{v}$ and $\vec{w}$ lie in the same plane.

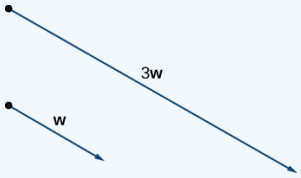
### Solution

a. The vector $3\vec{w}$ has the same direction as $\vec{w}$; it is three times as long as $\vec{w}$.



Vector $3\vec{w}$ has the same direction as $\vec{w}$ and is three times as long.

b. Use either addition method to find $\vec{v} + \vec{w}$.

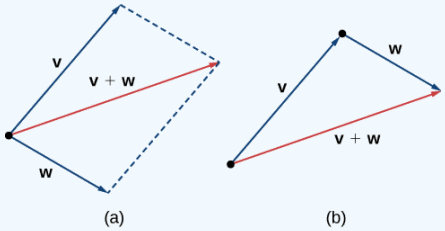


Figure 12.2.7: To find $\vec{v} + \vec{w}$, align the vectors at their initial points or place the initial point of one vector at the terminal point of the other. (a) The vector $\vec{v} + \vec{w}$ is the diagonal of the parallelogram with sides $\vec{v}$ and $\vec{w}$. (b) The vector $\vec{v} + \vec{w}$ is the third side of a triangle formed with $\vec{w}$ placed at the terminal point of $\vec{v}$.

c. To find $2\vec{v} - \vec{w}$, we can first rewrite the expression as $2\vec{v} + (-\vec{w})$. Then we can draw the vector $-\vec{w}$, then add it to the vector $2\vec{v}$.

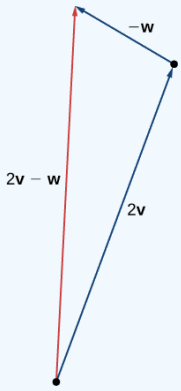

Figure 12.2.8: To find $2\vec{v} - \vec{w}$, simply add $2\vec{v} + (-\vec{w})$.

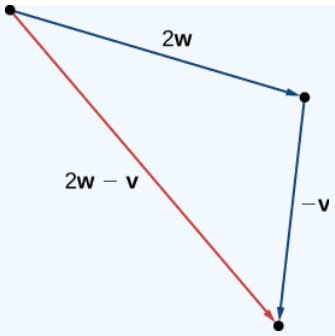
## ? Exercise 12.2.2

Using vectors $\vec{v}$ and $\vec{w}$ from Example 12.2.2, sketch the vector $2\vec{w} - \vec{v}$.

**Hint**

First sketch vectors $2\vec{w}$ and $-\vec{v}$.

**Answer**



## Vector Components

Working with vectors in a plane is easier when we are working in a coordinate system. When the initial points and terminal points of vectors are given in Cartesian coordinates, computations become straightforward.

### Example 12.2.3: Comparing Vectors

Are $\vec{v}$ and $\vec{w}$ equivalent vectors?

a.

- $\vec{v}$ has initial point $(3, 2)$ and terminal point $(7, 2)$
- $\vec{w}$ has initial point $(1, -4)$ and terminal point $(1, 0)$

b.

- $\vec{v}$ has initial point $(0, 0)$ and terminal point $(1, 1)$
- $\vec{w}$ has initial point $(-2, 2)$ and terminal point $(-1, 3)$

**Solution**

a. The vectors are each $4$ units long, but they are oriented in different directions. So $\vec{v}$ and $\vec{w}$ are not equivalent (Figure 12.2.9).

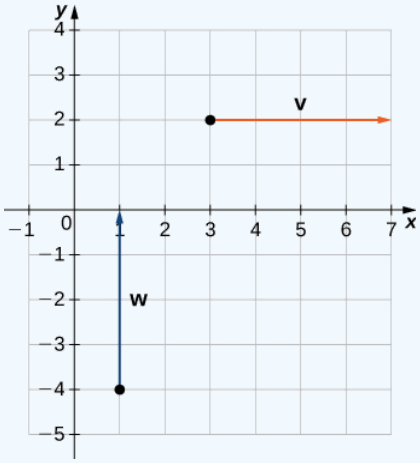


Figure 12.2.9: These vectors are not equivalent.

b. Based on Figure 12.2.10, and using a bit of geometry, it is clear these vectors have the same length and the same direction, so $\vec{v}$ and $\vec{w}$ are equivalent.

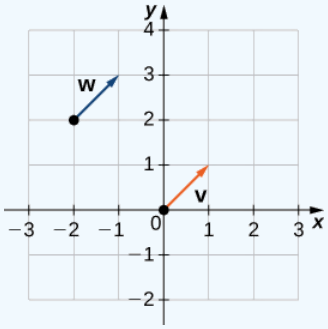

Figure **12.2.10**: These vectors are equivalent.

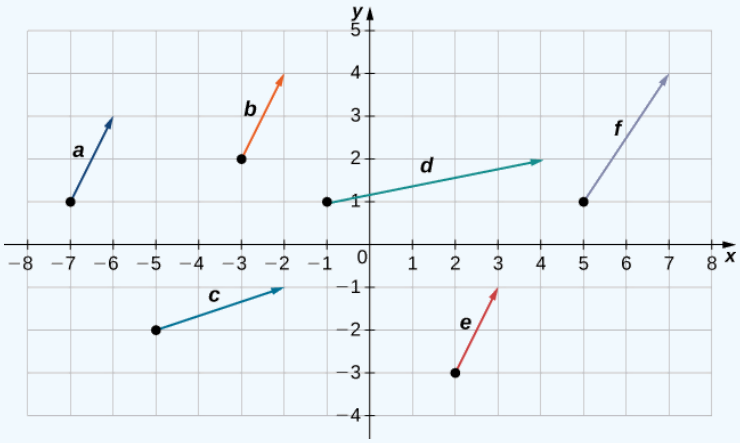
## Exercise 12.2.3

Which of the following vectors are equivalent?



**Hint**

Equivalent vectors have both the same magnitude and the same direction.

**Answer**

Vectors $\vec{\mathbf{a}}$, $\vec{\mathbf{b}}$, and $\vec{\mathbf{e}}$ are equivalent.

We have seen how to plot a vector when we are given an initial point and a terminal point. However, because a vector can be placed anywhere in a plane, it may be easier to perform calculations with a vector when its initial point coincides with the origin. We call a vector with its initial point at the origin a **standard-position vector.** Because the initial point of any vector in standard position is known to be $(0, 0)$, we can describe the vector by looking at the coordinates of its terminal point. Thus, if vector $\vec{\mathbf{v}}$ has its initial point at the origin and its terminal point at $(x, y)$, we write the vector in component form as

$$\vec{\mathbf{v}} = \langle x, y \rangle.$$

When a vector is written in component form like this, the scalars x and y are called the **components** of $\vec{\mathbf{v}}$.

### Definition: Vector components

The vector with initial point $(0, 0)$ and terminal point $(x, y)$ can be written in component form as

$$\vec{\mathbf{v}} = \langle x, y \rangle.$$

The scalars $x$ and $y$ are called the components of $\vec{\mathbf{v}}$.

Recall that vectors are named with lowercase letters in bold type or by drawing an arrow over their name. We have also learned that we can name a vector by its component form, with the coordinates of its terminal point in angle brackets. However, when writing the component form of a vector, it is important to distinguish between $\langle x, y \rangle$ and $(x, y)$. The first ordered pair uses angle brackets to describe a vector, whereas the second uses parentheses to describe a point in a plane. The initial point of $\langle x, y \rangle$ is $(0, 0)$; the terminal point of $\langle x, y \rangle$ is $(x, y)$.

When we have a vector not already in standard position, we can determine its component form in one of two ways. We can use a geometric approach, in which we sketch the vector in the coordinate plane, and then sketch an equivalent standard-position vector. Alternatively, we can find it algebraically, using the coordinates of the initial point and the terminal point. To find it algebraically, we subtract the $x$-coordinate of the initial point from the $x$-coordinate of the terminal point to get the $x$-component, and we subtract the $y$-coordinate of the initial point from the $y$-coordinate of the terminal point to get the $y$-component.

### Rule: Component Form of a Vector

Let $\vec{\mathbf{v}}$ be a vector with initial point $(x_i, y_i)$ and terminal point $(x_t, y_t)$. Then we can express $\vec{\mathbf{v}}$ in component form as $\vec{\mathbf{v}} = \langle x_t - x_i, y_t - y_i \rangle$.

### Example 12.2.4: Expressing Vectors in Component Form

Express vector $\vec{\mathbf{v}}$ with initial point $(-3, 4)$ and terminal point $(1, 2)$ in component form.

**Solution**:

a. Geometric

1. Sketch the vector in the coordinate plane (Figure 12.2.11).
2. The terminal point is 4 units to the right and 2 units down from the initial point.
3. Find the point that is 4 units to the right and 2 units down from the origin.
4. In standard position, this vector has initial point $(0, 0)$ and terminal point $(4, -2)$:

$$\vec{\mathbf{v}} = \langle 4, -2 \rangle.$$

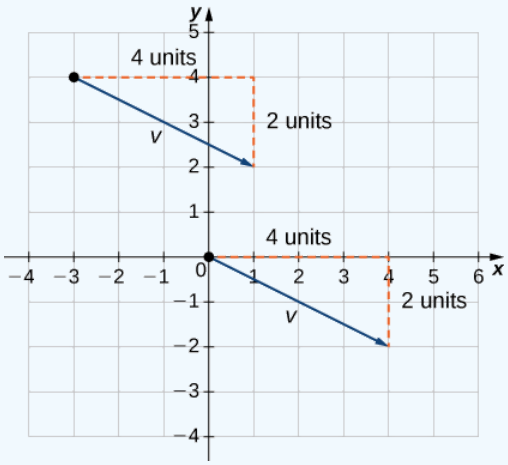


Figure 12.2.11: These vectors are equivalent.

b. Algebraic

In the first solution, we used a sketch of the vector to see that the terminal point lies 4 units to the right. We can accomplish this algebraically by finding the difference of the $x$-coordinates:

$$x_t - x_i = 1 - (-3) = 4.$$

Similarly, the difference of the $y$-coordinates shows the vertical length of the vector.

$$y_t - y_i = 2 - 4 = -2.$$

So, in component form,

$$\vec{\mathbf{v}} = \langle x_t - x_i, y_t - y_i \rangle = \langle 1 - (-3), 2 - 4 \rangle = \langle 4, -2 \rangle.$$

**Exercise 12.2.4**

Vector $\vec{\mathbf{w}}$ has initial point $(-4, -5)$ and terminal point $(-1, 2)$. Express $\vec{\mathbf{w}}$ in component form.

**Hint**

You may use either geometric or algebraic method.

**Answer**

$\langle 3, 7 \rangle$

To find the magnitude of a vector, we calculate the distance between its initial point and its terminal point. The **magnitude** of vector $\vec{\mathbf{v}} = \langle x, y \rangle$ is denoted $\|\vec{\mathbf{v}}\|$, or $|\vec{\mathbf{v}}|$, and can be computed using the formula

$$\|\vec{\mathbf{v}}\| = \sqrt{x^2 + y^2}.$$

Note that because this vector is written in component form, it is equivalent to a vector in standard position, with its initial point at the origin and terminal point $(x, y)$. Thus, it suffices to calculate the magnitude of the vector in standard position. Using the distance formula to calculate the distance between initial point $(0, 0)$ and terminal point $(x, y)$, we have

$$\|\vec{\mathbf{v}}\| = \sqrt{(x-0)^2 + (y-0)^2} = \sqrt{x^2 + y^2}.$$

Based on this formula, it is clear that for any vector $\vec{\mathbf{v}}$, $\|\vec{\mathbf{v}}\| \geq 0$, and $\|\vec{\mathbf{v}}\| = 0$ if and only if $\vec{\mathbf{v}} = \vec{\mathbf{0}}$.

The magnitude of a vector can also be derived using the Pythagorean theorem, as in the following figure.

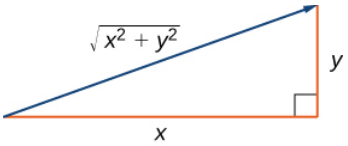

Figure 12.2.12: If you use the components of a vector to define a right triangle, the magnitude of the vector is the length of the triangle's hypotenuse.

We have defined scalar multiplication and vector addition geometrically. Expressing vectors in component form allows us to perform these same operations algebraically.

**Definition: Scalar multiplication and Vector addition**

Let $\vec{\mathbf{v}} = \langle x_1, y_1 \rangle$ and $\vec{\mathbf{w}} = \langle x_2, y_2 \rangle$ be vectors, and let $k$ be a scalar.

- *Scalar multiplication:*

$$k\vec{\mathbf{v}} = \langle kx_1, ky_1 \rangle$$

- *Vector addition:*

$$\vec{\mathbf{v}} + \vec{\mathbf{w}} = \langle x_1, y_1 \rangle + \langle x_2, y_2 \rangle = \langle x_1 + x_2, y_1 + y_2 \rangle$$

**Example 12.2.5: Performing Operations in Component Form**

Let $\vec{\mathbf{v}}$ be the vector with initial point $(2, 5)$ and terminal point $(8, 13)$, and let $\vec{\mathbf{w}} = \langle -2, 4 \rangle$.

a. Express $\vec{\mathbf{v}}$ in component form and find $\|\vec{\mathbf{v}}\|$. Then, using algebra, find
b. $\vec{\mathbf{v}} + \vec{\mathbf{w}}$,
c. $3\vec{\mathbf{v}}$, and

d. $\vec{\mathbf{v}} - 2\vec{\mathbf{w}}$.

### Solution

a. To place the initial point of $\vec{\mathbf{v}}$ at the origin, we must translate the vector $2$ units to the left and $5$ units down (Figure $12.2.13$). Using the algebraic method, we can express $\vec{\mathbf{v}}$ as $\vec{\mathbf{v}} = \langle 8-2, 13-5\rangle = \langle 6, 8\rangle$:

$$\|\vec{\mathbf{v}}\| = \sqrt{6^2+8^2} = \sqrt{36+64} = \sqrt{100} = 10.$$

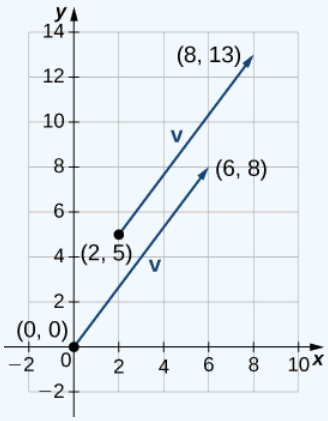

Figure $12.2.13$: In component form, $\vec{\mathbf{v}} = \langle 6, 8\rangle$.

b. To find $\vec{\mathbf{v}} + \vec{\mathbf{w}}$, add the $x$-components and the $y$-components separately:

$$\vec{\mathbf{v}} + \vec{\mathbf{w}} = \langle 6, 8\rangle + \langle -2, 4\rangle = \langle 4, 12\rangle.$$

c. To find $3\vec{\mathbf{v}}$, multiply $\vec{\mathbf{v}}$ by the scalar $k = 3$:

$$3\vec{\mathbf{v}} = 3 \cdot \langle 6, 8\rangle = \langle 3 \cdot 6, 3 \cdot 8\rangle = \langle 18, 24\rangle.$$

d. To find $\vec{\mathbf{v}} - 2\vec{\mathbf{w}}$, find $-2\vec{\mathbf{w}}$ and add it to $\vec{\mathbf{v}}$ :

$$\vec{\mathbf{v}} - 2\vec{\mathbf{w}} = \langle 6, 8\rangle - 2 \cdot \langle -2, 4\rangle = \langle 6, 8\rangle + \langle 4, -8\rangle = \langle 10, 0\rangle.$$

## ? Exercise $12.2.5A$

Let $\vec{\mathbf{a}} = \langle 7, 1\rangle$ and let $\vec{\mathbf{b}}$ be the vector with initial point $(3, 2)$ and terminal point $(-1, -1)$.

a. Find $\|\vec{\mathbf{a}}\|$.
b. Express $\vec{\mathbf{b}}$ in component form.
c. Find $3\vec{\mathbf{a}} - 4\vec{\mathbf{b}}$.

**Hint**

Use the Pythagorean Theorem to find $\|\vec{\mathbf{a}}\|$. To find $3\vec{\mathbf{a}} - 4\vec{\mathbf{b}}$, start by finding the scalar multiples $3\vec{\mathbf{a}}$ and $-4\vec{\mathbf{b}}$.

**Answer a**

$\|\vec{\mathbf{a}}\| = 5\sqrt{2}$,

**Answer b**

$\vec{\mathbf{b}} = \langle -4, -3\rangle$,

**Answer c**

$3\vec{\mathbf{a}} - 4\vec{\mathbf{b}} = \langle 37, 15\rangle$

Now that we have established the basic rules of vector arithmetic, we can state the properties of vector operations. We will prove two of these properties. The others can be proved in a similar manner.

## Properties of Vector Operations

Let $\vec{u}$, $\vec{v}$, and $\vec{w}$ be vectors in a plane. Let $r$ and $s$ be scalars.

i. *Commutative property*

$$\vec{u} + \vec{v} = \vec{v} + \vec{u} \tag{12.2.1}$$

ii. *Associative property*

$$(\vec{u} + \vec{v}) + \vec{w} = \vec{u} + (\vec{v} + \vec{w})$$

iii. *Additive identity property*

$$\vec{u} + \vec{0} = \vec{u}$$

iv. *Additive inverse property*

$$\vec{u} + (-\vec{u}) = \vec{0}$$

v. *Associativity of scalar multiplication*

$$r(s\vec{u}) = (rs)\vec{u}$$

vi. *Distributive property*

$$(r + s)\vec{u} = r\vec{u} + s\vec{u} \tag{12.2.2}$$

vii. *Distributive property*

$$r(\vec{u} + \vec{v}) = r\vec{u} + r\vec{v}$$

viii. *Identity and zero properties*

$$1\vec{u} = \vec{u},\ 0\vec{u} = \vec{0}$$

## Proof of Commutative Property

Let $\vec{u} = \langle x_1, y_1 \rangle$ and $\vec{v} = \langle x_2, y_2 \rangle$. Apply the commutative property for real numbers:

$$\begin{aligned} \vec{u} + \vec{v} &= \langle x_1 + x_2, y_1 + y_2 \rangle \\ &= \langle x_2 + x_1, y_2 + y_1 \rangle \\ &= \vec{v} + \vec{u}. \end{aligned}$$

□

## Proof of Distributive Property

Apply the distributive property for real numbers:

$$\begin{aligned} r(\vec{u} + \vec{v}) &= r \cdot \langle x_1 + x_2, y_1 + y_2 \rangle \\ &= \langle r(x_1 + x_2), r(y_1 + y_2) \rangle \\ &= \langle rx_1 + rx_2, ry_1 + ry_2 \rangle \\ &= \langle rx_1, ry_1 \rangle + \langle rx_2, ry_2 \rangle \\ &= r\vec{u} + r\vec{v}. \end{aligned}$$

□

**Exercise 12.2.5B**

Prove the additive inverse property.

**Hint**

Use the component form of the vectors.

We have found the components of a vector given its initial and terminal points. In some cases, we may only have the magnitude and direction of a vector, not the points. For these vectors, we can identify the horizontal and vertical components using trigonometry (Figure 12.2.14).

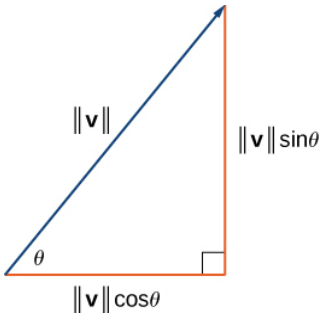

Figure 12.2.14: The components of a vector form the legs of a right triangle, with the vector as the hypotenuse.

Consider the angle $\theta$ formed by the vector $\vec{v}$ and the positive $x$-axis. We can see from the triangle that the components of vector $\vec{v}$ are $\langle \|\vec{v}\| \cos\theta, \|\vec{v}\| \sin\theta \rangle$. Therefore, given an angle and the magnitude of a vector, we can use the cosine and sine of the angle to find the components of the vector.

**Example 12.2.6: Finding the Component Form of a Vector Using Trigonometry**

Find the component form of a vector with magnitude 4 that forms an angle of $-45°$ with the $x$-axis.

**Solution**

Let $x$ and $y$ represent the components of the vector (Figure 12.2.15). Then $x = 4\cos(-45°) = 2\sqrt{2}$ and $y = 4\sin(-45°) = -2\sqrt{2}$. The component form of the vector is $\langle 2\sqrt{2}, -2\sqrt{2} \rangle$.

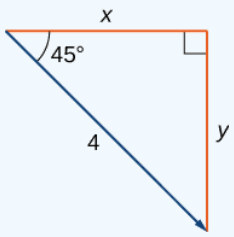

Figure 12.2.15: Use trigonometric ratios, $x = \|\vec{v}\| \cos\theta$ and $y = \|\vec{v}\| \sin\theta$, to identify the components of the vector.

**Exercise 12.2.6**

Find the component form of vector $\vec{v}$ with magnitude 10 that forms an angle of $120°$ with the positive $x$-axis.

**Hint**

$x = \|\vec{v}\| \cos\theta$ and $y = \|\vec{v}\| \sin\theta$

**Answer**

$\vec{v} = \langle -5, 5\sqrt{3} \rangle$

## Unit Vectors

A **unit vector** is a vector with magnitude $1$. For any nonzero vector $\vec{v}$, we can use scalar multiplication to find a unit vector $\vec{u}$ that has the same direction as $\vec{v}$. To do this, we multiply the vector by the reciprocal of its magnitude:

$$\vec{u} = \frac{1}{\|\vec{v}\|}\vec{v}.$$

Recall that when we defined scalar multiplication, we noted that $\|k\vec{v}\| = |k| \cdot \|\vec{v}\|$. For $\vec{u} = \frac{1}{\|\vec{v}\|}\vec{v}$, it follows that $\|\vec{u}\| = \frac{1}{\|\vec{v}\|}(\|\vec{v}\|) = 1$. We say that $\vec{u}$ is the *unit vector in the direction of* $\vec{v}$ (Figure 12.2.16). The process of using scalar multiplication to find a unit vector with a given direction is called **normalization.**

Figure 12.2.16: The vector $\vec{v}$ and associated unit vector $\vec{u} = \frac{1}{\|\vec{v}\|}\vec{v}$. In this case, $\|\vec{v}\| > 1$.

### Example 12.2.7: Finding a Unit Vector

Let $\vec{v} = \langle 1, 2\rangle$.

a. Find a unit vector with the same direction as $\vec{v}$.
b. Find a vector $\vec{w}$ with the same direction as $\vec{v}$ such that $\|\vec{w}\| = 7$.

**Solution**:

a. First, find the magnitude of $\vec{v}$, then divide the components of $\vec{v}$ by the magnitude:

$$\|\vec{v}\| = \sqrt{1^2 + 2^2} = \sqrt{1+4} = \sqrt{5}$$

$$\vec{u} = \frac{1}{\|\vec{v}\|}\vec{v} = \frac{1}{\sqrt{5}}\langle 1, 2\rangle = \langle \frac{1}{\sqrt{5}}, \frac{2}{\sqrt{5}}\rangle.$$

b. The vector $\vec{u}$ is in the same direction as $\vec{v}$ and $\|\vec{u}\| = 1$. Use scalar multiplication to increase the length of $\vec{u}$ without changing direction:

$$\vec{w} = 7\vec{u} = 7\langle \frac{1}{\sqrt{5}}, \frac{2}{\sqrt{5}}\rangle = \langle \frac{7}{\sqrt{5}}, \frac{14}{\sqrt{5}}\rangle.$$

### Exercise 12.2.7

Let $\vec{v} = \langle 9, 2\rangle$. Find a vector with magnitude $5$ in the opposite direction as $\vec{v}$.

**Hint**

First, find a unit vector in the same direction as $\vec{v}$.

**Answer**

$$\langle -\frac{45}{\sqrt{85}}, -\frac{10}{\sqrt{85}}\rangle$$

We have seen how convenient it can be to write a vector in component form. Sometimes, though, it is more convenient to write a vector as a sum of a horizontal vector and a vertical vector. To make this easier, let's look at standard unit vectors. The **standard unit vectors** are the vectors $\hat{i} = \langle 1, 0\rangle$ and $\hat{j} = \langle 0, 1\rangle$ (Figure 12.2.17).

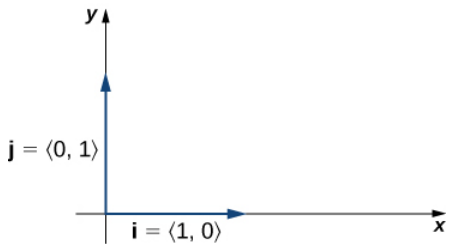

Figure 12.2.17: The standard unit vectors $\hat{\mathbf{i}}$ and $\hat{\mathbf{j}}$.

By applying the properties of vectors, it is possible to express any vector in terms of $\hat{\mathbf{i}}$ and $\hat{\mathbf{j}}$ in what we call a *linear combination:*

$$\vec{\mathbf{v}} = \langle x, y\rangle = \langle x, 0\rangle + \langle 0, y\rangle = x\langle 1, 0\rangle + y\langle 0, 1\rangle = x\hat{\mathbf{i}} + y\hat{\mathbf{j}}.$$

Thus, $\vec{\mathbf{v}}$ is the sum of a horizontal vector with magnitude $x$, and a vertical vector with magnitude $y$, as in Figure 12.2.18.

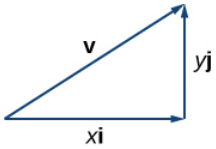

Figure 12.2.18: The vector $\vec{\mathbf{v}}$ is the sum of $x\hat{\mathbf{i}}$ and $y\hat{\mathbf{j}}$.

### Example 12.2.8: Using Standard Unit Vectors

a. Express the vector $\vec{\mathbf{w}} = \langle 3, -4\rangle$ in terms of standard unit vectors.

b. Vector $\vec{\mathbf{u}}$ is a unit vector that forms an angle of $60°$ with the positive $x$-axis. Use standard unit vectors to describe $\vec{\mathbf{u}}$.

**Solution**:

a. Resolve vector $\vec{\mathbf{w}}$ into a vector with a zero $y$-component and a vector with a zero $x$-component:

$$\vec{\mathbf{w}} = \langle 3, -4\rangle = 3\hat{\mathbf{i}} - 4\hat{\mathbf{j}}.$$

b. Because $\vec{\mathbf{u}}$ is a unit vector, the terminal point lies on the unit circle when the vector is placed in standard position (Figure 12.2.19).

$$\begin{aligned}\vec{\mathbf{u}} &= \langle \cos 60°, \sin 60°\rangle \\ &= \langle \frac{1}{2}, \frac{\sqrt{3}}{2}\rangle \\ &= \frac{1}{2}\hat{\mathbf{i}} + \frac{\sqrt{3}}{2}\hat{\mathbf{j}}.\end{aligned}$$

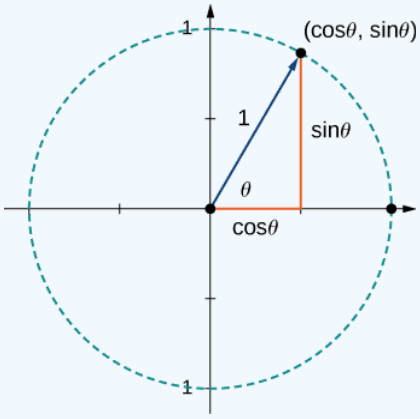

Figure 12.2.19: The terminal point of $\vec{\mathbf{u}}$ lies on the unit circle $(\cos\theta, \sin\theta)$.

**Exercise 12.2.8**

Let $\vec{\mathbf{a}} = \langle 16, -11 \rangle$ and let $\vec{\mathbf{b}}$ be a unit vector that forms an angle of $225°$ with the positive $x$-axis. Express $\vec{\mathbf{a}}$ and $\vec{\mathbf{b}}$ in terms of the standard unit vectors.

**Hint**

Use sine and cosine to find the components of $\vec{\mathbf{b}}$.

**Answer**

$$\vec{\mathbf{a}} = 16\hat{\mathbf{i}} - 11\hat{\mathbf{j}}, \quad \vec{\mathbf{b}} = -\frac{\sqrt{2}}{2}\hat{\mathbf{i}} - \frac{\sqrt{2}}{2}\hat{\mathbf{j}}$$

## Applications of Vectors

Because vectors have both direction and magnitude, they are valuable tools for solving problems involving such applications as motion and **force.** Recall the boat example and the quarterback example we described earlier. Here we look at two other examples in detail.

**Example 12.2.9*A*: Finding Resultant Force**

Jane's car is stuck in the mud. Lisa and Jed come along in a truck to help pull her out. They attach one end of a tow strap to the front of the car and the other end to the truck's trailer hitch, and the truck starts to pull. Meanwhile, Jane and Jed get behind the car and push. The truck generates a horizontal force of $300$ lb on the car. Jane and Jed are pushing at a slight upward angle and generate a force of $150$ lb on the car. These forces can be represented by vectors, as shown in Figure 12.2.20. The angle between these vectors is $15°$. Find the resultant force (the vector sum) and give its magnitude to the nearest tenth of a pound and its direction angle from the positive $x$-axis.

Figure 12.2.20: Two forces acting on a car in different directions.

**Solution**

To find the effect of combining the two forces, add their representative vectors. First, express each vector in component form or in terms of the standard unit vectors. For this purpose, it is easiest if we align one of the vectors with the positive $x$-axis. The horizontal vector, then, has initial point $(0, 0)$ and terminal point $(300, 0)$. It can be expressed as $\langle 300, 0 \rangle$ or $300\hat{\mathbf{i}}$.

The second vector has magnitude $150$ and makes an angle of $15°$ with the first, so we can express it as $\langle 150\cos(15°), 150\sin(15°) \rangle$, or $150\cos(15°)\hat{\mathbf{i}} + 150\sin(15°)\hat{\mathbf{j}}$. Then, the sum of the vectors, or resultant vector, is $\vec{\mathbf{r}} = \langle 300, 0 \rangle + \langle 150\cos(15°), 150\sin(15°) \rangle$, and we have

$$\|\vec{\mathbf{r}}\| = \sqrt{(300 + 150\cos(15°))^2 + (150\sin(15°))^2} \approx 446.6.$$

The angle $\theta$ made by $\vec{\mathbf{r}}$ and the positive $x$-axis has $\tan\theta = \dfrac{150\sin 15°}{(300 + 150\cos 15°)} \approx 0.09$, so $\theta \approx \tan^{-1}(0.09) \approx 5°$, which means the resultant force $\vec{\mathbf{r}}$ has an angle of $5°$ above the horizontal axis.

**Example 12.2.9*B*: Finding Resultant Velocity**

An airplane flies due west at an airspeed of $425$ mph. The wind is blowing from the northeast at $40$ mph. What is the ground speed of the airplane? What is the bearing of the airplane?

### Solution

Let's start by sketching the situation described (Figure 12.2.21).

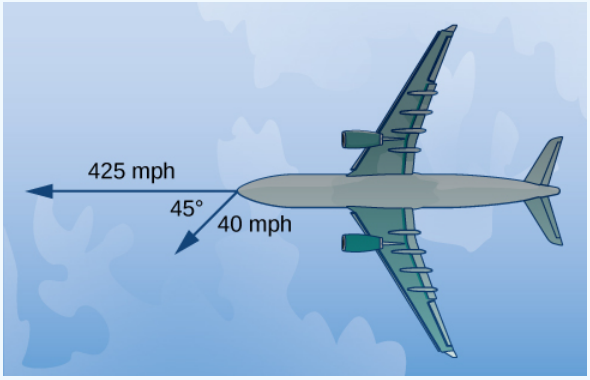

Figure 12.2.21: Initially, the plane travels due west. The wind is from the northeast, so it is blowing to the southwest. The angle between the plane's course and the wind is 45°. (Figure not drawn to scale.)

Set up a sketch so that the initial points of the vectors lie at the origin. Then, the plane's velocity vector is $\vec{\mathbf{p}} = -425\hat{\mathbf{i}}$. The vector describing the wind makes an angle of $225°$ with the positive $x$-axis:

$$\vec{\mathbf{w}} = \langle 40\cos(225°), 40\sin(225°)\rangle = \langle -\frac{40}{\sqrt{2}}, -\frac{40}{\sqrt{2}}\rangle = -\frac{40}{\sqrt{2}}\hat{\mathbf{i}} - \frac{40}{\sqrt{2}}\hat{\mathbf{j}}.$$

When the airspeed and the wind act together on the plane, we can add their vectors to find the resultant force:

$$\vec{\mathbf{p}} + \vec{\mathbf{w}} = -425\hat{\mathbf{i}} + (-\frac{40}{\sqrt{2}}\hat{\mathbf{i}} - \frac{40}{\sqrt{2}}\hat{\mathbf{j}}) = (-425 - \frac{40}{\sqrt{2}})\hat{\mathbf{i}} - \frac{40}{\sqrt{2}}\hat{\mathbf{j}}.$$

The magnitude of the resultant vector shows the effect of the wind on the ground speed of the airplane:

$$\|\vec{\mathbf{p}} + \vec{\mathbf{w}}\| = \sqrt{(-425 - \frac{40}{\sqrt{2}})^2 + (-\frac{40}{\sqrt{2}})^2} \approx 454.17 \text{ mph}$$

As a result of the wind, the plane is traveling at approximately 454 mph relative to the ground.

To determine the bearing of the airplane, we want to find the direction of the vector $\vec{\mathbf{p}} + \vec{\mathbf{w}}$:

$$\tan\theta = \frac{-\frac{40}{\sqrt{2}}}{(-425 - \frac{40}{\sqrt{2}})} \approx 0.06$$

$$\theta \approx 3.57°.$$

The overall direction of the plane is $3.57°$ south of west.

## Exercise 12.2.9

An airplane flies due north at an airspeed of 550 mph. The wind is blowing from the northwest at 50 mph. What is the ground speed of the airplane?

**Hint**

Sketch the vectors with the same initial point and find their sum.

**Answer**

Approximately 516 mph

## Key Concepts

- Vectors are used to represent quantities that have both magnitude and direction.
- We can add vectors by using the parallelogram method or the triangle method to find the sum. We can multiply a vector by a scalar to change its length or give it the opposite direction.
- Subtraction of vectors is defined in terms of adding the negative of the vector.
- A vector is written in component form as $\vec{\mathbf{v}} = \langle x, y \rangle$.
- The magnitude of a vector is a scalar: $\|\vec{\mathbf{v}}\| = \sqrt{x^2 + y^2}$.
- A unit vector $\vec{\mathbf{u}}$ has magnitude $1$ and can be found by dividing a vector by its magnitude: $\vec{\mathbf{u}} = \dfrac{1}{\|\vec{\mathbf{v}}\|}\vec{\mathbf{v}}$. The standard unit vectors are $\hat{\mathbf{i}} = \langle 1, 0 \rangle$ and $\hat{\mathbf{j}} = \langle 0, 1 \rangle$. A vector $\vec{\mathbf{v}} = \langle x, y \rangle$ can be expressed in terms of the standard unit vectors as $\vec{\mathbf{v}} = x\hat{\mathbf{i}} + y\hat{\mathbf{j}}$.
- Vectors are often used in physics and engineering to represent forces and velocities, among other quantities.

## Glossary

**component**
a scalar that describes either the vertical or horizontal direction of a vector

**equivalent vectors**
vectors that have the same magnitude and the same direction

**initial point**
the starting point of a vector

**magnitude**
the length of a vector

**normalization**
using scalar multiplication to find a unit vector with a given direction

**parallelogram method**
a method for finding the sum of two vectors; position the vectors so they share the same initial point; the vectors then form two adjacent sides of a parallelogram; the sum of the vectors is the diagonal of that parallelogram

**scalar**
a real number

**scalar multiplication**
a vector operation that defines the product of a scalar and a vector

**standard-position vector**
a vector with initial point $(0, 0)$

**standard unit vectors**
unit vectors along the coordinate axes: $\hat{\mathbf{i}} = \langle 1, 0 \rangle$, $\hat{\mathbf{j}} = \langle 0, 1 \rangle$

**terminal point**
the endpoint of a vector

**triangle inequality**
the length of any side of a triangle is less than the sum of the lengths of the other two sides

**triangle method**

a method for finding the sum of two vectors; position the vectors so the terminal point of one vector is the initial point of the other; these vectors then form two sides of a triangle; the sum of the vectors is the vector that forms the third side; the initial point of the sum is the initial point of the first vector; the terminal point of the sum is the terminal point of the second vector

**unit vector**

a vector with magnitude $1$

**vector**

a mathematical object that has both magnitude and direction

**vector addition**

a vector operation that defines the sum of two vectors

**vector difference**

the vector difference $\vec{\mathbf{v}} - \vec{\mathbf{w}}$ is defined as $\vec{\mathbf{v}} + (-\vec{\mathbf{w}}) = \vec{\mathbf{v}} + (-1)\vec{\mathbf{w}}$

**vector sum**

the sum of two vectors, $\vec{\mathbf{v}}$ and $\vec{\mathbf{w}}$, can be constructed graphically by placing the initial point of $\vec{\mathbf{w}}$ at the terminal point of $\vec{\mathbf{v}}$; then the vector sum $\vec{\mathbf{v}} + \vec{\mathbf{w}}$ is the vector with an initial point that coincides with the initial point of $\vec{\mathbf{v}}$, and with a terminal point that coincides with the terminal point of $\vec{\mathbf{w}}$

**zero vector**

the vector with both initial point and terminal point $(0, 0)$

# 12.2E: Exercises for Section 12.1

**For exercises 1 - 10, consider points $P(-1,3)$, $Q(1,5)$, and $R(-3,7)$. Determine the requested vectors and express each of them**

**a. in component form and**

**b. by using standard unit vectors.**

1) $\overrightarrow{PQ}$

**Answer**

a. $\overrightarrow{PQ} = \langle 2,2 \rangle$

b. $\overrightarrow{PQ} = 2\hat{\mathbf{i}} + 2\hat{\mathbf{j}}$

2) $\overrightarrow{PR}$

3) $\overrightarrow{QP}$

**Answer**

a. $\overrightarrow{QP} = \langle -2,-2 \rangle$

b. $\overrightarrow{QP} = -2\hat{\mathbf{i}} - 2\hat{\mathbf{j}}$

4) $\overrightarrow{RP}$

5) $\overrightarrow{PQ} + \overrightarrow{PR}$

**Answer**

a. $\overrightarrow{PQ} + \overrightarrow{PR} = \langle 0,6 \rangle$

b. $\overrightarrow{PQ} + \overrightarrow{PR} = 6\hat{\mathbf{j}}$

6) $\overrightarrow{PQ} - \overrightarrow{PR}$

7) $2\overrightarrow{PQ} - 2\overrightarrow{PR}$

**Answer**

a. $2\overrightarrow{PQ} \rightarrow -2\overrightarrow{PR} = \langle 8,-4 \rangle$

b. $2\overrightarrow{PQ} - 2\overrightarrow{PR} = 8\hat{\mathbf{i}} - 4\hat{\mathbf{j}}$

8) $2\overrightarrow{PQ} + \frac{1}{2}\overrightarrow{PR}$

9) The unit vector in the direction of $\overrightarrow{PQ}$

**Answer**

a. $\left\langle \frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2} \right\rangle$

b. $\frac{\sqrt{2}}{2}\hat{\mathbf{i}} + \frac{\sqrt{2}}{2}\hat{\mathbf{j}}$

10) The unit vector in the direction of $\overrightarrow{PR}$

11) A vector $\vec{\mathbf{v}}$ has initial point $(-1,-3)$ and terminal point $(2,1)$. Find the unit vector in the direction of $\vec{\mathbf{v}}$. Express the answer in component form.

**Answer**

$\langle \frac{3}{5}, \frac{4}{5} \rangle$

12) A vector $\vec{\mathbf{v}}$ has initial point $(-2,5)$ and terminal point $(3,-1)$. Find the unit vector in the direction of $\vec{\mathbf{v}}$. Express the answer in component form.

13) The vector $\vec{\mathbf{v}}$ has initial point $P(1,0)$ and terminal point $Q$ that is on the $y$-axis and above the initial point. Find the coordinates of terminal point $Q$ such that the magnitude of the vector $\vec{\mathbf{v}}$ is $\sqrt{5}$.

**Answer**

$Q(0,2)$

14) The vector $\vec{\mathbf{v}}$ has initial point $P(1,1)$ and terminal point $Q$ that is on the $x$-axis and left of the initial point. Find the coordinates of terminal point $Q$ such that the magnitude of the vector $\vec{\mathbf{v}}$ is $\sqrt{10}$.

**For exercises 15 and 16, use the given vectors $\vec{\mathbf{a}}$ and $\vec{\mathbf{b}}$.**

a. Determine the vector sum $\vec{\mathbf{a}}+\vec{\mathbf{b}}$ and express it in both the component form and by using the standard unit vectors.

b. Find the vector difference $\vec{\mathbf{a}}-\vec{\mathbf{b}}$ and express it in both the component form and by using the standard unit vectors.

c. Verify that the vectors $\vec{\mathbf{a}}$, $\vec{\mathbf{b}}$, and $\vec{\mathbf{a}}+\vec{\mathbf{b}}$, and, respectively, $\vec{\mathbf{a}}$, $\vec{\mathbf{b}}$, and $\vec{\mathbf{a}}-\vec{\mathbf{b}}$ satisfy the triangle inequality.

d. Determine the vectors $2\vec{\mathbf{a}}$, $-\vec{\mathbf{b}}$, and $2\vec{\mathbf{a}}-\vec{\mathbf{b}}$. Express the vectors in both the component form and by using standard unit vectors.

15) $\vec{\mathbf{a}}=2\hat{\mathbf{i}}+\hat{\mathbf{j}}, \quad \vec{\mathbf{b}}=\hat{\mathbf{i}}+3\hat{\mathbf{j}}$

**Answer**

*a.* $\vec{\mathbf{a}}+\vec{\mathbf{b}}=\langle 3,4\rangle, \quad \vec{\mathbf{a}}+\vec{\mathbf{b}}=3\hat{\mathbf{i}}+4\hat{\mathbf{j}}$
*b.* $\vec{\mathbf{a}}-\vec{\mathbf{b}}=\langle 1,-2\rangle, \quad \vec{\mathbf{a}}-\vec{\mathbf{b}}=\hat{\mathbf{i}}-2\hat{\mathbf{j}}$
*c.* Answers will vary
*d.* $2\vec{\mathbf{a}}=\langle 4,2\rangle, \quad 2\vec{\mathbf{a}}=4\hat{\mathbf{i}}+2\hat{\mathbf{j}}, \quad -\vec{\mathbf{b}}=\langle -1,-3\rangle, \quad -\vec{\mathbf{b}}=-\hat{\mathbf{i}}-3\hat{\mathbf{j}}, \quad 2\vec{\mathbf{a}}-\vec{\mathbf{b}}=\langle 3,-1\rangle, \quad 2\vec{\mathbf{a}}-\vec{\mathbf{b}}=3\hat{\mathbf{i}}-\hat{\mathbf{j}}$

16) $\vec{\mathbf{a}}=2\hat{\mathbf{i}}, \quad \vec{\mathbf{b}}=-2\hat{\mathbf{i}}+2\hat{\mathbf{j}}$

17) Let $\vec{\mathbf{a}}$ be a standard-position vector with terminal point $(-2,-4)$. Let $\vec{\mathbf{b}}$ be a vector with initial point $(1,2)$ and terminal point $(-1,4)$. Find the magnitude of vector $-3\vec{\mathbf{a}}+\vec{\mathbf{b}}-4\hat{\mathbf{i}}+\hat{\mathbf{j}}$.

**Answer**

15

18) Let $\vec{\mathbf{a}}$ be a standard-position vector with terminal point at $(2,5)$. Let $\vec{\mathbf{b}}$ be a vector with initial point $(-1,3)$ and terminal point $(1,0)$. Find the magnitude of vector $\vec{\mathbf{a}}-3\vec{\mathbf{b}}+14\hat{\mathbf{i}}-14\hat{\mathbf{j}}$.

19) Let $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ be two nonzero vectors that are nonequivalent. Consider the vectors $\vec{\mathbf{a}}=4\vec{\mathbf{u}}+5\vec{\mathbf{v}}$ and $\vec{\mathbf{b}}=\vec{\mathbf{u}}+2\vec{\mathbf{v}}$ defined in terms of $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$. Find the scalar $\lambda$ such that vectors $\vec{\mathbf{a}}+\lambda\vec{\mathbf{b}}$ and $\vec{\mathbf{u}}-\vec{\mathbf{v}}$ are equivalent.

**Answer**

$\lambda=-3$

20) Let $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ be two nonzero vectors that are nonequivalent. Consider the vectors $\vec{\mathbf{a}}=2\vec{\mathbf{u}}-4\vec{\mathbf{v}}$ and $\vec{\mathbf{b}}=3\vec{\mathbf{u}}-7\vec{\mathbf{v}}$ defined in terms of $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$. Find the scalars $\alpha$ and $\beta$ such that vectors $\alpha\vec{\mathbf{a}}+\beta\vec{\mathbf{b}}$ and $\vec{\mathbf{u}}-\vec{\mathbf{v}}$ are equivalent.

21) Consider the vector $\vec{\mathbf{a}}(t)=\langle \cos t, \sin t\rangle$ with components that depend on a real number $t$. As the number $t$ varies, the components of $\vec{\mathbf{a}}(t)$ change as well, depending on the functions that define them.

a. Write the vectors $\vec{\mathbf{a}}(0)$ and $\vec{\mathbf{a}}(\pi)$ in component form.

b. Show that the magnitude $\| \vec{\mathbf{a}}(t) \|$ of vector $\vec{\mathbf{a}}(t)$ remains constant for any real number $t$.

c. As $t$ varies, show that the terminal point of vector $\vec{\mathbf{a}}(t)$ describes a circle centered at the origin of radius $1$.

**Answer**

*a.* $\vec{\mathbf{a}}(0) = \langle 1, 0 \rangle, \quad \vec{\mathbf{a}}(\pi) = \langle -1, 0 \rangle$

*b.* Answers may vary

*c.* Answers may vary

22) Consider vector $\vec{\mathbf{a}}(x) = \langle x, \sqrt{1 - x^2} \rangle$ with components that depend on a real number $x \in [-1, 1]$. As the number $x$ varies, the components of $\vec{\mathbf{a}}(x)$ change as well, depending on the functions that define them.

a. Write the vectors $\vec{\mathbf{a}}(0)$ and $\vec{\mathbf{a}}(1)$ in component form.

b. Show that the magnitude $\| \vec{\mathbf{a}}(x) \|$ of vector $\vec{\mathbf{a}}(x)$ remains constant for any real number $x$.

c. As $x$ varies, show that the terminal point of vector $\vec{\mathbf{a}}(x)$ describes a circle centered at the origin of radius $1$.

23) Show that vectors $\vec{\mathbf{a}}(t) = \langle \cos t, \sin t \rangle$ and $\vec{\mathbf{a}}(x) = \langle x, \sqrt{1 - x^2} \rangle$ are equivalent for $x = 1$ and $t = 2k\pi$, where $k$ is an integer.

**Answer** Answers may vary

24) Show that vectors $\vec{\mathbf{a}}(t) = \langle \cos t, \sin t \rangle$ and $\vec{\mathbf{a}}(x) = \langle x, \sqrt{1 - x^2} \rangle$ are opposite for $x = 1$ and $t = \pi + 2k\pi$, where $k$ is an integer.

**For exercises 25-28, find a vector $\vec{\mathbf{v}}$ with the given magnitude and in the same direction as the vector $\vec{\mathbf{u}}$.**

25) $\| \vec{\mathbf{v}} \| = 7, \quad \vec{\mathbf{u}} = \langle 3, 4 \rangle$

**Answer**

$\vec{\mathbf{v}} = \langle \frac{21}{5}, \frac{28}{5} \rangle$

26) $\| \vec{\mathbf{v}} \| = 3, \quad \vec{\mathbf{u}} = \langle -2, 5 \rangle$

27) $\| \vec{\mathbf{v}} \| = 7, \quad \vec{\mathbf{u}} = \langle 3, -5 \rangle$

**Answer**

$\vec{\mathbf{v}} = \langle \frac{21\sqrt{34}}{34}, -\frac{35\sqrt{34}}{34} \rangle$

28) $\| \vec{\mathbf{v}} \| = 10, \quad \vec{\mathbf{u}} = \langle 2, -1 \rangle$

**For exercises 29-34, find the component form of vector $\vec{\mathbf{u}}$, given its magnitude and the angle the vector makes with the positive $x$-axis. Give exact answers when possible.**

29) $\| \vec{\mathbf{u}} \| = 2, \theta = 30°$

**Answer**

$\vec{\mathbf{u}} = \langle \sqrt{3}, 1 \rangle$

30) $\| \vec{\mathbf{u}} \| = 6, \theta = 60°$

31) $\| \vec{\mathbf{u}} \| = 5, \theta = \frac{\pi}{2}$

**Answer**

$\vec{\mathbf{u}} = \langle 0, 5 \rangle$

32) $\| \vec{\mathbf{u}} \| = 8, \theta = \pi$

33) $\| \vec{\mathbf{u}} \| = 10, \theta = \frac{5\pi}{6}$

**Answer**

$\vec{\mathbf{u}} = \langle -5\sqrt{3}, 5 \rangle$

34) $\| \vec{\mathbf{u}} \| = 50, \theta = \frac{3\pi}{4}$

**For exercises 35 and 36, vector $\vec{\mathbf{u}}$ is given. Find the angle $\theta \in [0, 2\pi)$ that vector $\vec{\mathbf{u}}$ makes with the positive direction of the $x$-axis, in a counter-clockwise direction.**

35) $\vec{\mathbf{u}} = 5\sqrt{2}\hat{\mathbf{i}} - 5\sqrt{2}\hat{\mathbf{j}}$

**Answer**

$\theta = \frac{7\pi}{4}$

36) $\vec{\mathbf{u}} = -\sqrt{3}\hat{\mathbf{i}} - \hat{\mathbf{j}}$

37) Let $\vec{\mathbf{a}} = \langle a_1, a_2 \rangle$, $\vec{\mathbf{b}} = \langle b_1, b_2 \rangle$, and $\vec{\mathbf{c}} = \langle c_1, c_2 \rangle$ be three nonzero vectors. If $a_1 b_2 - a_2 b_1 \neq 0$, then show there are two scalars, $\alpha$ and $\beta$, such that $\vec{\mathbf{c}} = \alpha\vec{\mathbf{a}} + \beta\vec{\mathbf{b}}$.

**Answer** Answers may vary

38) Consider vectors $\vec{\mathbf{a}} = \langle 2, -4 \rangle$, $\vec{\mathbf{b}} = \langle -1, 2 \rangle$, and $\vec{\mathbf{c}} = \vec{\mathbf{0}}$ Determine the scalars $\alpha$ and $\beta$ such that $\vec{\mathbf{c}} = \alpha\vec{\mathbf{a}} + \beta\vec{\mathbf{b}}$.

39) Let $P(x_0, f(x_0))$ be a fixed point on the graph of the differentiable function $f$ with a domain that is the set of real numbers.

a. Determine the real number $z_0$ such that point $Q(x_0 + 1, z_0)$ is situated on the line tangent to the graph of $f$ at point $P$.

b. Determine the unit vector $\vec{\mathbf{u}}$ with initial point $P$ and terminal point $Q$.

**Answer**

*a.* $z_0 = f(x_0) + f'(x_0)$; *b.* $\vec{\mathbf{u}} = \frac{1}{\sqrt{1+[f'(x_0)]^2}}\langle 1, f'(x_0) \rangle$

40) Consider the function $f(x) = x^4$, where $x \in R$.

a. Determine the real number $z_0$ such that point $Q(2, z_0)$ s situated on the line tangent to the graph of $f$ at point $P(1, 1)$.

b. Determine the unit vector $\vec{\mathbf{u}}$ with initial point $P$ and terminal point $Q$.

41) Consider $f$ and $g$ two functions defined on the same set of real numbers $D$. Let $\vec{\mathbf{a}} = \langle x, f(x) \rangle$ and $\vec{\mathbf{b}} = \langle x, g(x) \rangle$ be two vectors that describe the graphs of the functions, where $x \in D$. Show that if the graphs of the functions $f$ and $g$ do not intersect, then the vectors $\vec{\mathbf{a}}$ and $\vec{\mathbf{b}}$ are not equivalent.

42) Find $x \in R$ such that vectors $\vec{\mathbf{a}} = \langle x, \sin x \rangle$ and $\vec{\mathbf{b}} = \langle x, \cos x \rangle$ are equivalent.

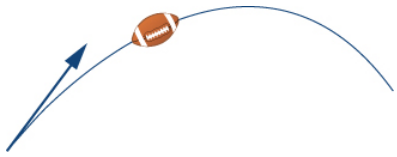
43) Calculate the coordinates of point $D$ such that $ABCD$ is a parallelogram, with $A(1, 1), B(2, 4)$, and $C(7, 4)$.

**Answer**

$D(6, 1)$

44) Consider the points $A(2, 1), B(10, 6), C(13, 4)$, and $D(16, -2)$. Determine the component form of vector $\overrightarrow{AD}$.

45) The **speed** of an object is the magnitude of its related velocity vector. A football thrown by a quarterback has an initial speed of 70 mph and an angle of elevation of 30°. Determine the velocity vector in mph and express it in component form. (Round to two decimal places.)

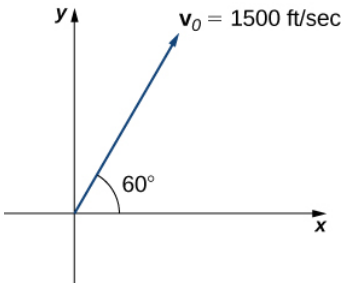


**Answer**

$\langle 60.62, 35 \rangle$

46) A baseball player throws a baseball at an angle of 30° with the horizontal. If the initial speed of the ball is 100 mph, find the horizontal and vertical components of the initial velocity vector of the baseball. (Round to two decimal places.)

47) A bullet is fired with an initial velocity of 1500 ft/sec at an angle of 60° with the horizontal. Find the horizontal and vertical components of the velocity vector of the bullet. (Round to two decimal places.)

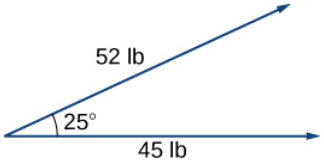


**Answer**

The horizontal and vertical components are 750 ft/sec and 1299.04 ft/sec, respectively.

48) [T] A 65-kg sprinter exerts a force of 798 N at a 19° angle with respect to the ground on the starting block at the instant a race begins. Find the horizontal component of the force. (Round to two decimal places.)

49) [T] Two forces, a horizontal force of 45 lb and another of 52 lb, act on the same object. The angle between these forces is 25°. Find the magnitude and direction angle from the positive $x$-axis of the resultant force that acts on the object. (Round to two decimal places.)



**Answer**

The magnitude of resultant force is 94.71 lb; the direction angle is 13.42°.

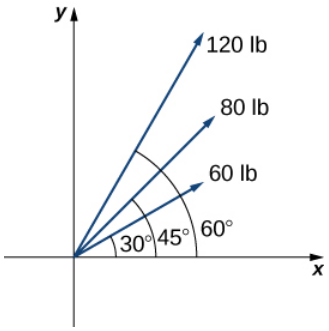
50) [T] Two forces, a vertical force of 26 lb and another of 45 lb, act on the same object. The angle between these forces is 55°. Find the magnitude and direction angle from the positive $x$-axis of the resultant force that acts on the object. (Round to two decimal places.)

51) [T] Three forces act on object. Two of the forces have the magnitudes 58 N and 27 N, and make angles 53° and 152°, respectively, with the positive $x$-axis. Find the magnitude and the direction angle from the positive $x$-axis of the third force such that the resultant force acting on the object is zero. (Round to two decimal places.)

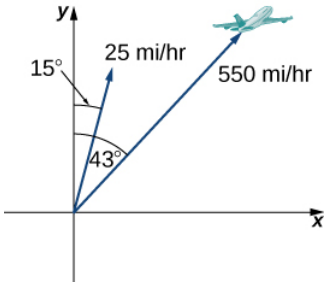
**Answer**

The magnitude of the third vector is 60.03 N; the direction angle is 259.38°.

52) Three forces with magnitudes 80 lb, 120 lb, and 60 lb act on an object at angles of 45°, 60° and 30°, respectively, with the positive $x$-axis. Find the magnitude and direction angle from the positive $x$-axis of the resultant force. (Round to two decimal places.)



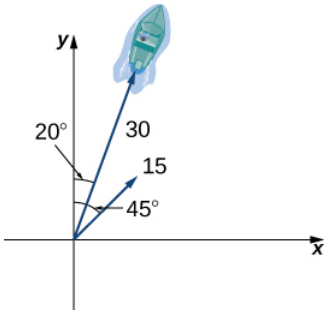
53) [T] An airplane is flying in the direction of $43°$ east of north (also abbreviated as $N43E$ at a speed of $550$ mph. A wind with speed $25$ mph comes from the southwest at a bearing of $N15E$. What are the ground speed and new direction of the airplane?



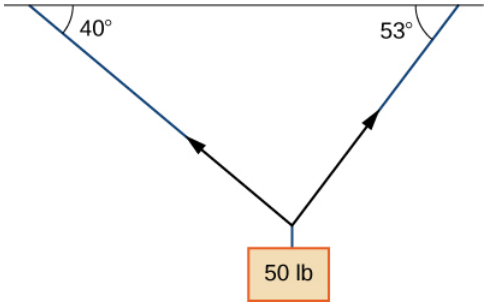
**Answer**

The new ground speed of the airplane is $572.19$ mph; the new direction is $N41.82E$.

54) [T] A boat is traveling in the water at $30$ mph in a direction of $N20E$ (that is, $20°$ east of north). A strong current is moving at $15$ mph in a direction of $N45E$. What are the new speed and direction of the boat?



55) [T] A 50-lb weight is hung by a cable so that the two portions of the cable make angles of $40°$ and $53°$, respectively, with the horizontal. Find the magnitudes of the forces of tension $\vec{\mathbf{T}}_1$ and $\vec{\mathbf{T}}_2$ in the cables if the resultant force acting on the object is zero. (Round to two decimal places.)

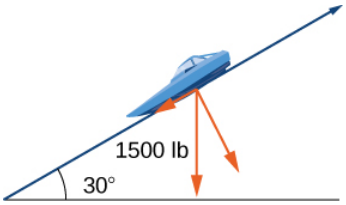


**Answer**

$\|\vec{\mathbf{T}}_1\| = 30.13\,lb, \quad \|\vec{\mathbf{T}}_2\| = 38.35\,lb$

56) [T] A 62-lb weight hangs from a rope that makes the angles of $29°$ and $61°$, respectively, with the horizontal. Find the magnitudes of the forces of tension $\vec{\mathbf{T}}_1$ and $\vec{\mathbf{T}}_2$ in the cables if the resultant force acting on the object is zero. (Round to two decimal places.)

57) [T] A 1500-lb boat is parked on a ramp that makes an angle of $30°$ with the horizontal. The boat's weight vector points downward and is a sum of two vectors: a horizontal vector $\vec{\mathbf{v}}_1$ that is parallel to the ramp and a vertical vector $\vec{\mathbf{v}}_2$ that is perpendicular to the inclined surface. The magnitudes of vectors $\vec{\mathbf{v}}_1$ and $\vec{\mathbf{v}}_2$ are the horizontal and vertical component, respectively, of the boat's weight vector. Find the magnitudes of $\vec{\mathbf{v}}_1$ and $\vec{\mathbf{v}}_2$. (Round to the nearest integer.)

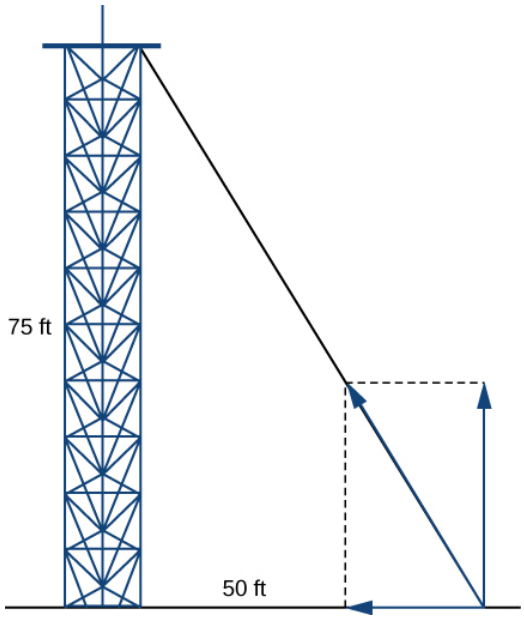


**Answer**

$\|\vec{v}_1\| = 750\,lb, \quad \|\vec{v}_2\| = 1299\,lb$

58) [T] An 85-lb box is at rest on a $26°$ incline. Determine the magnitude of the force parallel to the incline necessary to keep the box from sliding. (Round to the nearest integer.)

59) A guy-wire supports a pole that is $75$ ft high. One end of the wire is attached to the top of the pole and the other end is anchored to the ground $50$ ft from the base of the pole. Determine the horizontal and vertical components of the force of tension in the wire if its magnitude is $50$ lb. (Round to the nearest integer.)



**Answer**

The two horizontal and vertical components of the force of tension are $28$ lb and $42$ lb, respectively.

60) A telephone pole guy-wire has an angle of elevation of $35°$ with respect to the ground. The force of tension in the guy-wire is $120$ lb. Find the horizontal and vertical components of the force of tension. (Round to the nearest integer.)

# 12.3: Vectors in Three Dimensions

**Learning Objectives**

- Describe three-dimensional space mathematically.
- Locate points in space using coordinates.
- Write the distance formula in three dimensions.
- Write the equations for simple planes and spheres.
- Perform vector operations in $\mathbb{R}^3$.

Vectors are useful tools for solving two-dimensional problems. Life, however, happens in three dimensions. To expand the use of vectors to more realistic applications, it is necessary to create a framework for describing three-dimensional space. For example, although a two-dimensional map is a useful tool for navigating from one place to another, in some cases the topography of the land is important. Does your planned route go through the mountains? Do you have to cross a river? To appreciate fully the impact of these geographic features, you must use three dimensions. This section presents a natural extension of the two-dimensional Cartesian coordinate plane into three dimensions.

## Three-Dimensional Coordinate Systems

As we have learned, the two-dimensional rectangular coordinate system contains two perpendicular axes: the horizontal $x$-axis and the vertical $y$-axis. We can add a third dimension, the $z$-axis, which is perpendicular to both the $x$-axis and the $y$-axis. We call this system the three-dimensional rectangular coordinate system. It represents the three dimensions we encounter in real life.

**Definition: Three-dimensional Rectangular Coordinate System**

The three-dimensional rectangular coordinate system consists of three perpendicular axes: the $x$-axis, the $y$-axis, and the $z$-axis. Because each axis is a number line representing all real numbers in $\mathbb{R}$, the three-dimensional system is often denoted by $\mathbb{R}^3$.

In Figure **12.3.1***a*, the positive $z$-axis is shown above the plane containing the $x$- and $y$-axes. The positive $x$-axis appears to the left and the positive $y$-axis is to the right. A natural question to ask is: How was this arrangement determined? The system displayed follows the **right-hand rule**. If we take our right hand and align the fingers with the positive $x$-axis, then curl the fingers so they point in the direction of the positive $y$-axis, our thumb points in the direction of the positive $z$-axis (Figure **12.3.1***b*). In this text, we always work with coordinate systems set up in accordance with the right-hand rule. Some systems do follow a left-hand rule, but the right-hand rule is considered the standard representation.

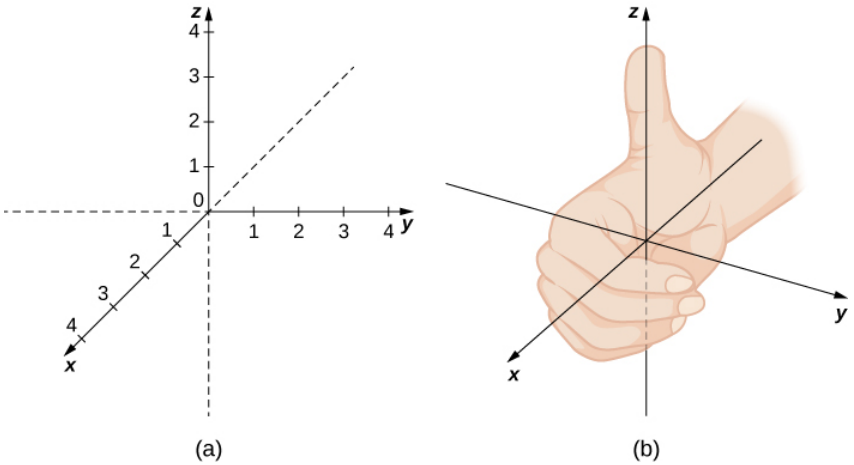

Figure **12.3.1**: (a) We can extend the two-dimensional rectangular coordinate system by adding a third axis, the $z$-axis, that is perpendicular to both the $x$-axis and the $y$-axis. (b) The right-hand rule is used to determine the placement of the coordinate axes in the standard Cartesian plane.

In two dimensions, we describe a point in the plane with the coordinates $(x, y)$. Each coordinate describes how the point aligns with the corresponding axis. In three dimensions, a new coordinate, $z$, is appended to indicate alignment with the $z$-axis: $(x, y, z)$. A point in space is identified by all three coordinates (Figure 12.3.2). To plot the point $(x, y, z)$, go $x$ units along the $x$-axis, then $y$ units in the direction of the $y$-axis, then $z$ units in the direction of the $z$-axis.

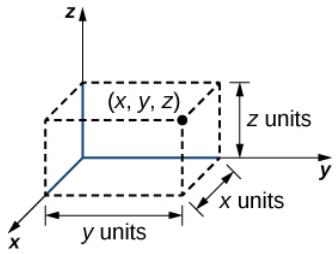

Figure 12.3.2: To plot the point $(x, y, z)$ go $x$ units along the $x$-axis, then $y$ units in the direction of the $y$-axis, then $z$ units in the direction of the $z$-axis.

## Example 12.3.1: Locating Points in Space

Sketch the point $(1, -2, 3)$ in three-dimensional space.

### Solution

To sketch a point, start by sketching three sides of a rectangular prism along the coordinate axes: one unit in the positive $x$ direction, 2 units in the negative $y$ direction, and 3 units in the positive $z$ direction. Complete the prism to plot the point (Figure 12.3.3).

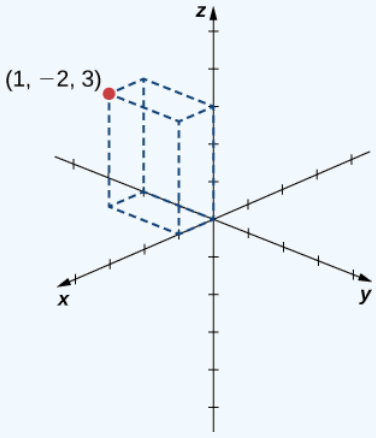

Figure 12.3.3: Sketching the point $(1, -2, 3)$.

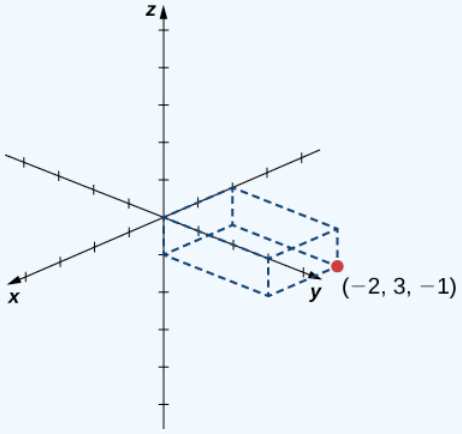
## Exercise 12.3.1

Sketch the point $(-2, 3, -1)$ in three-dimensional space.

**Hint**

Start by sketching the coordinate axes. e.g., Figure 12.3.3. Then sketch a rectangular prism to help find the point in space.

**Answer**



In two-dimensional space, the coordinate plane is defined by a pair of perpendicular axes. These axes allow us to name any location within the plane. In three dimensions, we define **coordinate planes** by the coordinate axes, just as in two dimensions. There are three axes now, so there are three intersecting pairs of axes. Each pair of axes forms a coordinate plane: the $xy$-plane, the $xz$-plane, and the $yz$-plane (Figure 12.3.4). We define the $xy$-plane formally as the following set: $\{(x, y, 0) : x, y \in \mathbb{R}\}$. Similarly, the $xz$-plane and the $yz$-plane are defined as $\{(x, 0, z) : x, z \in \mathbb{R}\}$ and $\{(0, y, z) : y, z \in \mathbb{R}\}$, respectively.

To visualize this, imagine you're building a house and are standing in a room with only two of the four walls finished. (Assume the two finished walls are adjacent to each other.) If you stand with your back to the corner where the two finished walls meet, facing out into the room, the floor is the $xy$-plane, the wall to your right is the $xz$-plane, and the wall to your left is the $yz$-plane.

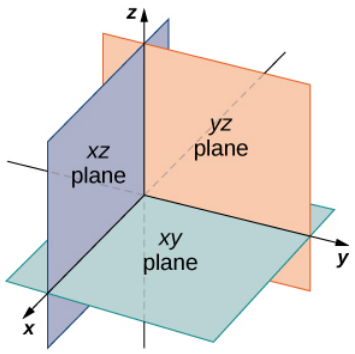


Figure 12.3.4: The plane containing the $x$- *and* $y$-axes is called the $xy$-plane. The plane containing the $x$- and $z$-axes is called the $xz$-plane, and the $y$- and $z$-axes define the $yz$-plane.

In two dimensions, the coordinate axes partition the plane into four quadrants. Similarly, the coordinate planes divide space between them into eight regions about the origin, called **octants.** The octants fill $\mathbb{R}^3$ in the same way that quadrants fill $\mathbb{R}^2$, as shown in Figure 12.3.5.

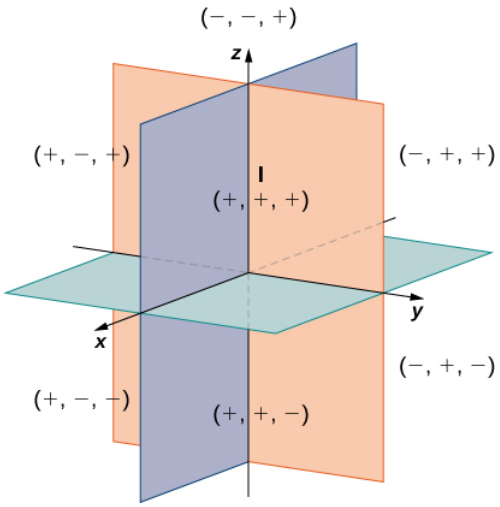

Figure 12.3.5: Points that lie in octants have three nonzero coordinates.

Most work in three-dimensional space is a comfortable extension of the corresponding concepts in two dimensions. In this section, we use our knowledge of circles to describe spheres, then we expand our understanding of vectors to three dimensions. To accomplish these goals, we begin by adapting the distance formula to three-dimensional space.

If two points lie in the same coordinate plane, then it is straightforward to calculate the distance between them. We know that the distance $d$ between two points $(x_1, y_1)$ and $(x_2, y_2)$ in the $xy$-coordinate plane is given by the formula

$$d = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}.$$

The formula for the distance between two points in space is a natural extension of this formula.

### The Distance between Two Points in Space

The distance $d$ between points $(x_1, y_1, z_1)$ and $(x_2, y_2, z_2)$ is given by the formula

$$d = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}. \tag{12.3.1}$$

The proof of this theorem is left as an exercise. (Hint: First find the distance $d_1$ between the points $(x_1, y_1, z_1)$ and $(x_2, y_2, z_1)$ as shown in Figure 12.3.6.)

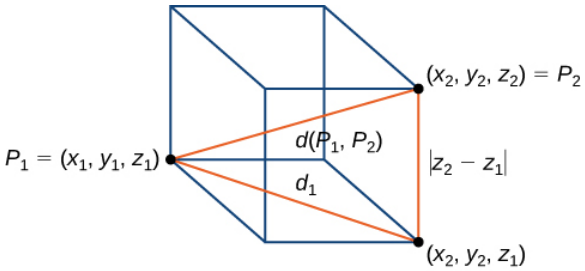

Figure 12.3.6: The distance between $P_1$ and $P_2$ is the length of the diagonal of the rectangular prism having $P_1$ and $P_2$ as opposite corners.

### Example 12.3.2: Distance in Space

Find the distance between points $P_1 = (3, -1, 5)$ and $P_2 = (2, 1, -1)$.

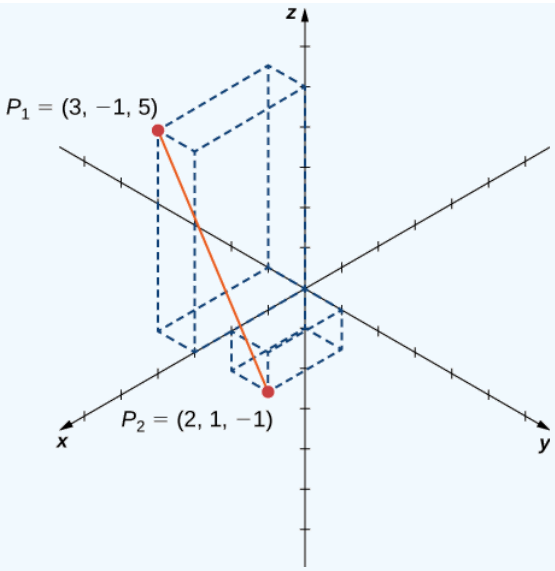

Figure 12.3.7: Find the distance between the two points.

### Solution

Substitute values directly into the distance formula (Equation 12.3.1):

$$\begin{aligned} d(P_1, P_2) &= \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2} \\ &= \sqrt{(2-3)^2 + (1-(-1))^2 + (-1-5)^2} \\ &= \sqrt{(-1)^2 + 2^2 + (-6)^2} \\ &= \sqrt{41}. \end{aligned}$$

## ? Exercise 12.3.2

Find the distance between points $P_1 = (1, -5, 4)$ and $P_2 = (4, -1, -1)$.

**Hint**

$d = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}$

**Answer**

$$5\sqrt{2}$$

Before moving on to the next section, let's get a feel for how $\mathbb{R}^3$ differs from $\mathbb{R}^2$. For example, in $\mathbb{R}^2$, lines that are not parallel must always intersect. This is not the case in $\mathbb{R}^3$. For example, consider the lines shown in Figure 12.3.8. These two lines are not parallel, nor do they intersect.

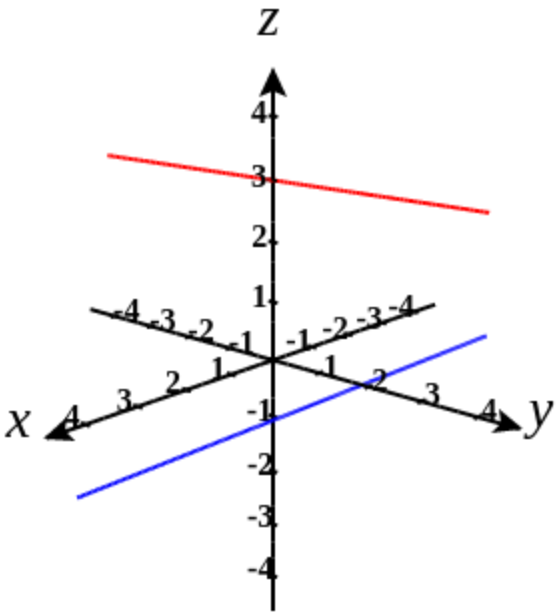

Figure 12.3.8: These two lines are not parallel, but still do not intersect.

You can also have circles that are interconnected but have no points in common, as in Figure 12.3.9.

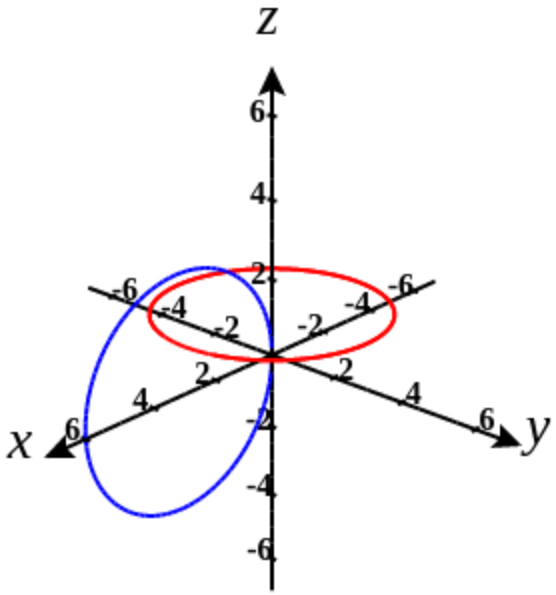

Figure 12.3.9: These circles are interconnected, but have no points in common.

We have a lot more flexibility working in three dimensions than we do if we stuck with only two dimensions.

## Writing Equations in $\mathbb{R}^3$

Now that we can represent points in space and find the distance between them, we can learn how to write equations of geometric objects such as lines, planes, and curved surfaces in $\mathbb{R}^3$. First, we start with a simple equation. Compare the graphs of the equation $x = 0$ in $\mathbb{R}$, $\mathbb{R}^2$,and $\mathbb{R}^3$ (Figure 12.3.10). From these graphs, we can see the same equation can describe a point, a line, or a plane.

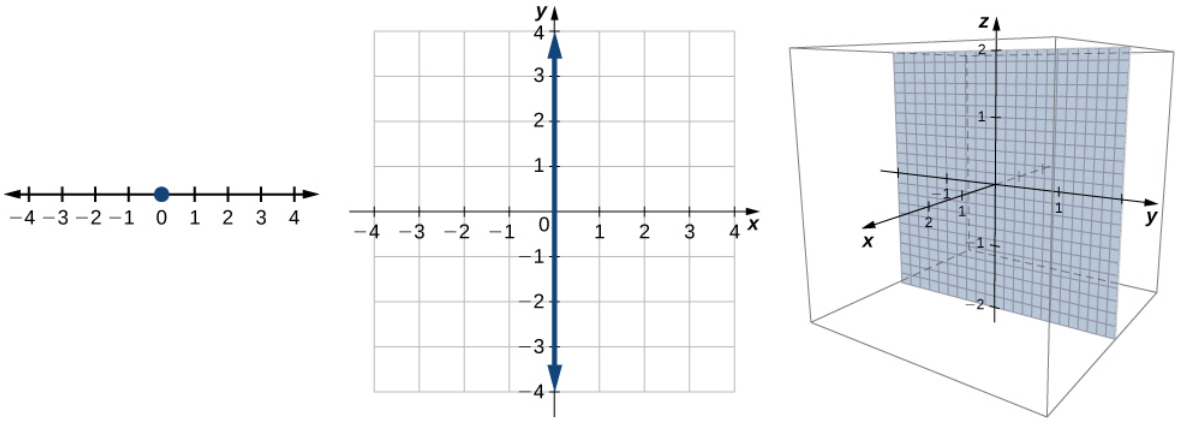

Figure 12.3.10: (a) In $\mathbb{R}$, the equation $x = 0$ describes a single point. (b) In $\mathbb{R}^2$, the equation $x = 0$ describes a line, the $y$-axis. (c) In $\mathbb{R}^3$, the equation $x = 0$ describes a plane, the $yz$-plane.

In space, the equation $x = 0$ describes all points $(0, y, z)$. This equation defines the $yz$-plane. Similarly, the $xy$-plane contains all points of the form $(x, y, 0)$. The equation $z = 0$ defines the $xy$-plane and the equation $y = 0$ describes the $xz$-plane (Figure 12.3.11).

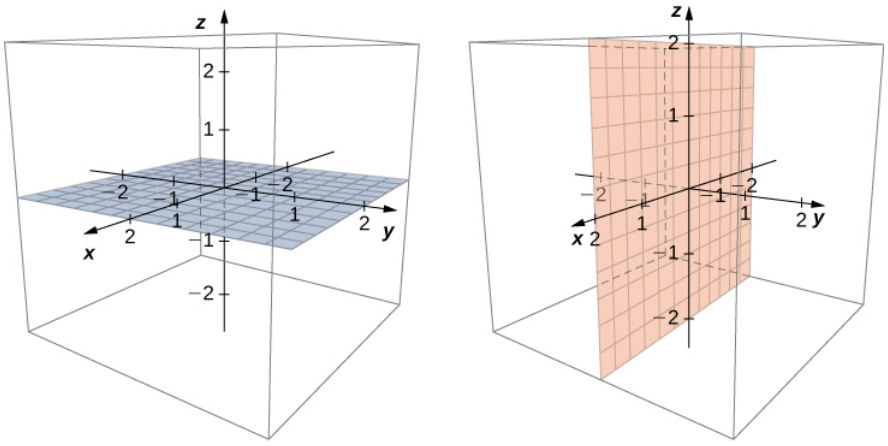

Figure 12.3.11: (a) In space, the equation $z = 0$ describes the $xy$-plane. (b) All points in the $xz$-plane satisfy the equation $y = 0$.

Understanding the equations of the coordinate planes allows us to write an equation for any plane that is parallel to one of the coordinate planes. When a plane is parallel to the $xy$-plane, for example, the $z$-coordinate of each point in the plane has the same constant value. Only the $x$- and $y$-coordinates of points in that plane vary from point to point.

### Equations of Planes Parallel to Coordinate Planes

1. The plane in space that is parallel to the $xy$-plane and contains point $(a, b, c)$ can be represented by the equation $z = c$.
2. The plane in space that is parallel to the $xz$-plane and contains point $(a, b, c)$ can be represented by the equation $y = b$.
3. The plane in space that is parallel to the $yz$-plane and contains point $(a, b, c)$ can be represented by the equation $x = a$.

### Example 12.3.3: Writing Equations of Planes Parallel to Coordinate Planes

a. Write an equation of the plane passing through point $(3, 11, 7)$ that is parallel to the $yz$-plane.
b. Find an equation of the plane passing through points $(6, -2, 9)$, $(0, -2, 4)$, and $(1, -2, -3)$.

**Solution**

a. When a plane is parallel to the $yz$-plane, only the $y$- and $z$-coordinates may vary. The $x$-coordinate has the same constant value for all points in this plane, so this plane can be represented by the equation $x = 3$.
b. Each of the points $(6, -2, 9)$, $(0, -2, 4)$, and $(1, -2, -3)$ has the same $y$-coordinate. This plane can be represented by the equation $y = -2$.

### Exercise 12.3.3

Write an equation of the plane passing through point $(1, -6, -4)$ that is parallel to the $xy$-plane.

**Hint**

If a plane is parallel to the $xy$-plane, the $z$-coordinates of the points in that plane do not vary.

**Answer**

$$z = -4$$

As we have seen, in $\mathbb{R}^2$ the equation $x = 5$ describes the vertical line passing through point $(5, 0)$. This line is parallel to the $y$-axis. In a natural extension, the equation $x = 5$ in $\mathbb{R}^3$ describes the plane passing through point $(5, 0, 0)$, which is parallel to the $yz$-plane. Another natural extension of a familiar equation is found in the equation of a sphere.

### Definition: Sphere

A sphere is the set of all points in space equidistant from a fixed point, the center of the sphere (Figure 12.3.12), just as the set of all points in a plane that are equidistant from the center represents a circle. In a sphere, as in a circle, the distance from the center to a point on the sphere is called the *radius*.

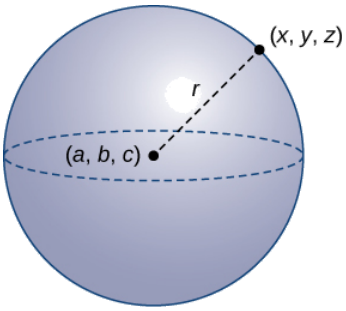

Figure 12.3.12: Each point $(x, y, z)$ on the surface of a sphere is $r$ units away from the center $(a, b, c)$.

The equation of a circle is derived using the distance formula in two dimensions. In the same way, the equation of a sphere is based on the three-dimensional formula for distance.

### Standard Equation of a Sphere

The sphere with center $(a, b, c)$ and radius $r$ can be represented by the equation

$$(x-a)^2+(y-b)^2+(z-c)^2=r^2.$$

This equation is known as the *standard equation of a sphere*.

### Example 12.3.4: Finding an Equation of a Sphere

Find the standard equation of the sphere with center $(10, 7, 4)$ and point $(-1, 3, -2)$, as shown in Figure 12.3.13.

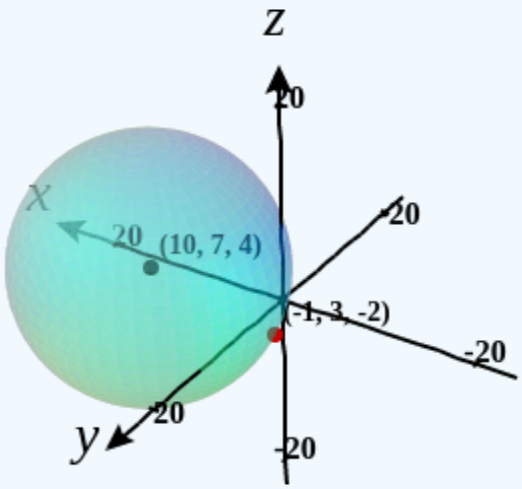

Figure 12.3.13: The sphere centered at $(10, 7, 4)$ containing point $(-1, 3, -2)$.

**Solution**

Use the distance formula to find the radius $r$ of the sphere:

$$\begin{aligned} r &= \sqrt{(-1-10)^2 + (3-7)^2 + (-2-4)^2} \\ &= \sqrt{(-11)^2 + (-4)^2 + (-6)^2} \\ &= \sqrt{173} \end{aligned}$$

The standard equation of the sphere is

$$(x-10)^2 + (y-7)^2 + (z-4)^2 = 173.$$

**? Exercise 12.3.4**

Find the standard equation of the sphere with center $(-2, 4, -5)$ containing point $(4, 4, -1)$.

**Hint**

First use the distance formula to find the radius of the sphere.

**Answer**

$$(x+2)^2 + (y-4)^2 + (z+5)^2 = 52$$

## Example 12.3.5: Finding the Equation of a Sphere

Let $P = (-5, 2, 3)$ and $Q = (3, 4, -1)$, and suppose line segment $\overline{PQ}$ forms the diameter of a sphere (Figure 12.3.14). Find the equation of the sphere.

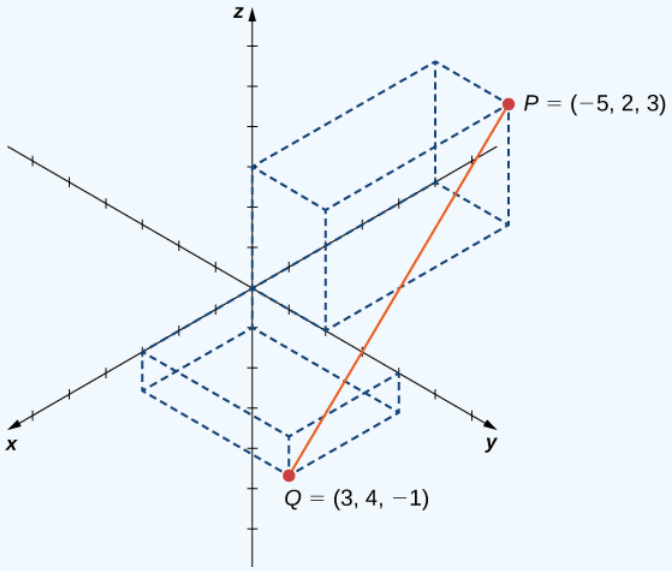

Figure 12.3.14: Line segment $\overline{PQ}$.

**Solution**:

Since $\overline{PQ}$ is a diameter of the sphere, we know the center of the sphere is the midpoint of $\overline{PQ}$.Then,

$$C = \left(\frac{-5+3}{2}, \frac{2+4}{2}, \frac{3+(-1)}{2}\right) = (-1, 3, 1).$$

Furthermore, we know the radius of the sphere is half the length of the diameter. This gives

$$\begin{aligned} r &= \frac{1}{2}\sqrt{(-5-3)^2 + (2-4)^2 + (3-(-1))^2} \\ &= \frac{1}{2}\sqrt{64+4+16} \\ &= \sqrt{21} \end{aligned}$$

Then, the equation of the sphere is $(x+1)^2 + (y-3)^2 + (z-1)^2 = 21$.

## Exercise 12.3.5

Find the equation of the sphere with diameter $\overline{PQ}$, where $P = (2, -1, -3)$ and $Q = (-2, 5, -1)$.

**Hint**

Find the midpoint of the diameter first.

**Answer**

$$x^2 + (y-2)^2 + (z+2)^2 = 14$$

## Example 12.3.6: Graphing Other Equations in Three Dimensions

Describe the set of points that satisfies $(x-4)(z-2) = 0$, and graph the set.

### Solution

We must have either $x - 4 = 0$ or $z - 2 = 0$, so the set of points forms the two planes $x = 4$ and $z = 2$ (Figure 12.3.15).

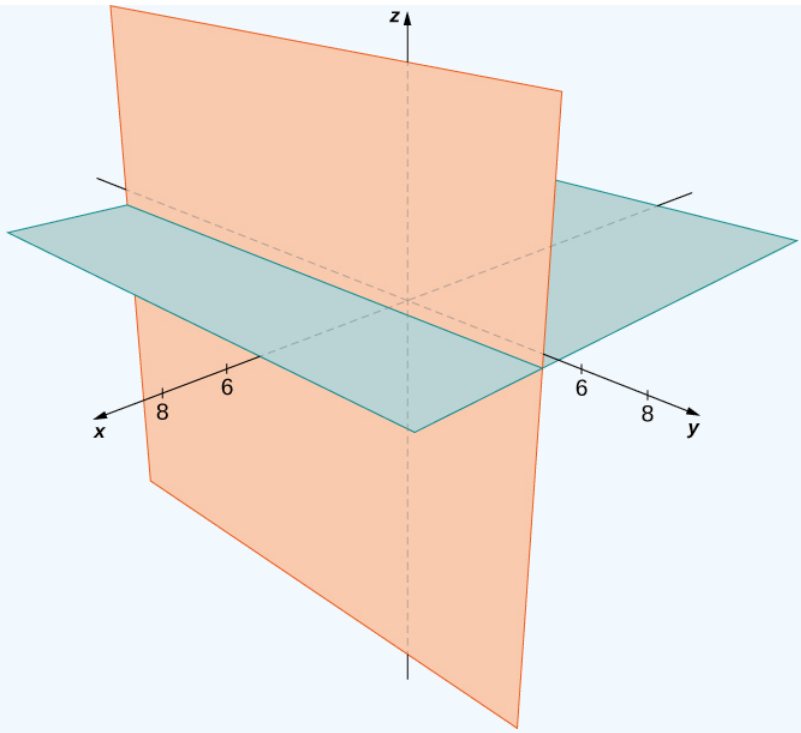

Figure 12.3.15: The set of points satisfying $(x-4)(z-2)=0$ forms the two planes $x=4$ and $z=2$.

## Exercise 12.3.6

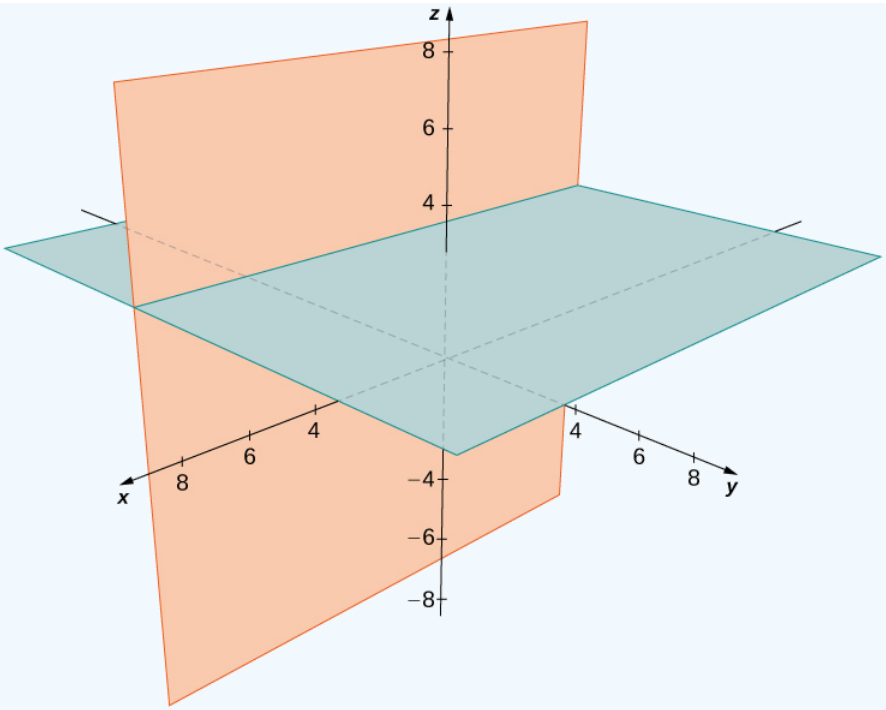
Describe the set of points that satisfies $(y+2)(z-3)=0$, and graph the set.

**Hint**

One of the factors must be zero.

**Answer**

The set of points forms the two planes $y=-2$ and $z=3$.



### Example 12.3.7: Graphing Other Equations in Three Dimensions

Describe the set of points in three-dimensional space that satisfies $(x-2)^2+(y-1)^2=4$, and graph the set.

**Solution**

The $x$- and $y$-coordinates form a circle in the $xy$-plane of radius $2$, centered at $(2,1)$. Since there is no restriction on the $z$-coordinate, the three-dimensional result is a circular cylinder of radius $2$ centered on the line with $x=2$ and $y=1$. The cylinder extends indefinitely in the $z$-direction (Figure 12.3.16).

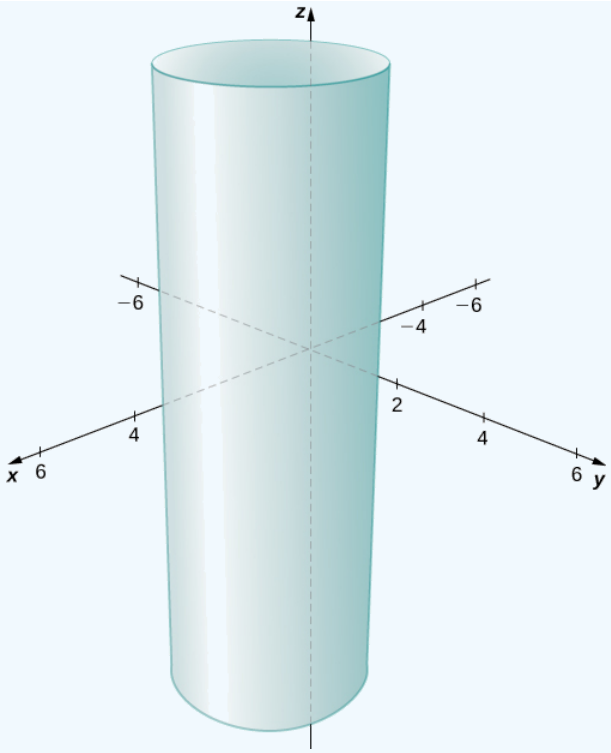


Figure 12.3.16: The set of points satisfying $(x-2)^2+(y-1)^2=4$. This is a cylinder of radius 2 centered on the line with $x=2$ and $y=1$.

## ? Exercise 12.3.7

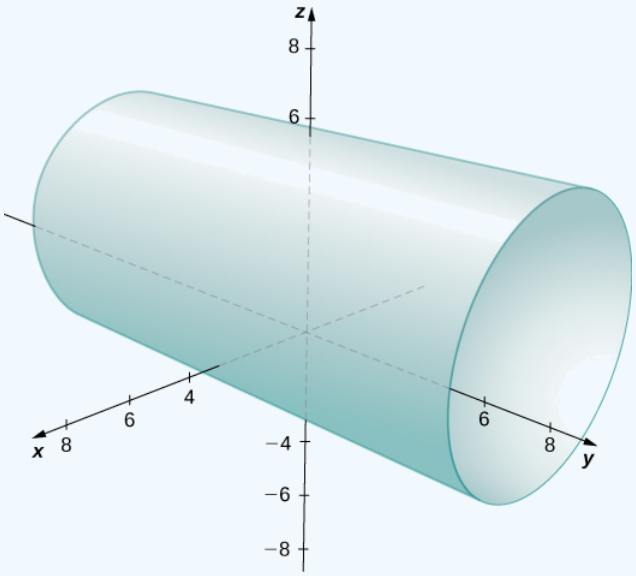
Describe the set of points in three dimensional space that satisfies $x^2+(z-2)^2=16$, and graph the surface.

**Hint**

Think about what happens if you plot this equation in two dimensions in the $xz$-plane.

**Answer**

A cylinder of radius 4 centered on the line with $x=0$ and $z=2$.



## Working with Vectors in $\mathbb{R}^3$

Just like two-dimensional vectors, three-dimensional vectors are quantities with both magnitude and direction, and they are represented by directed line segments (arrows). With a three-dimensional vector, we use a three-dimensional arrow.

Three-dimensional vectors can also be represented in component form. The notation $\vec{\mathbf{v}} = \langle x, y, z \rangle$ is a natural extension of the two-dimensional case, representing a vector with the initial point at the origin, $(0, 0, 0)$, and terminal point $(x, y, z)$. The zero vector is $\vec{\mathbf{0}} = \langle 0, 0, 0 \rangle$. So, for example, the three dimensional vector $\vec{\mathbf{v}} = \langle 2, 4, 1 \rangle$ is represented by a directed line segment from point $(0, 0, 0)$ to point $(2, 4, 1)$ (Figure 12.3.17).

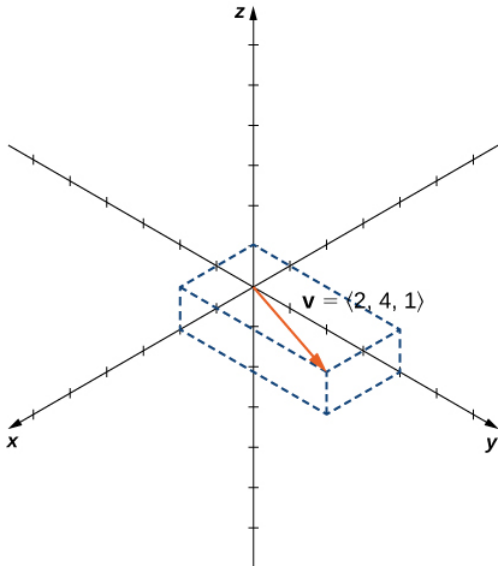


Figure 12.3.17: Vector $\vec{\mathbf{v}} = \langle 2, 4, 1 \rangle$ is represented by a directed line segment from point $(0, 0, 0)$ to point $(2, 4, 1)$.

Vector addition and scalar multiplication are defined analogously to the two-dimensional case. If $\vec{\mathbf{v}} = \langle x_1, y_1, z_1 \rangle$ and $\vec{\mathbf{w}} = \langle x_2, y_2, z_2 \rangle$ are vectors, and $k$ is a scalar, then

$$\vec{\mathbf{v}} + \vec{\mathbf{w}} = \langle x_1 + x_2, y_1 + y_2, z_1 + z_2 \rangle$$

and

$$k\vec{\mathbf{v}} = \langle kx_1, ky_1, kz_1 \rangle.$$

If $k = -1$, then $k\vec{\mathbf{v}} = (-1)\vec{\mathbf{v}}$ is written as $-\vec{\mathbf{v}}$, and vector subtraction is defined by $\vec{\mathbf{v}} - \vec{\mathbf{w}} = \vec{\mathbf{v}} + (-\vec{\mathbf{w}}) = \vec{\mathbf{v}} + (-1)\vec{\mathbf{w}}$.

The standard unit vectors extend easily into three dimensions as well, $\hat{\mathbf{i}} = \langle 1, 0, 0 \rangle$, $\hat{\mathbf{j}} = \langle 0, 1, 0 \rangle$, and $\hat{\mathbf{k}} = \langle 0, 0, 1 \rangle$, and we use them in the same way we used the standard unit vectors in two dimensions. Thus, we can represent a vector in $\mathbb{R}^3$ in the following ways:

$$\vec{\mathbf{v}} = \langle x, y, z \rangle = x\hat{\mathbf{i}} + y\hat{\mathbf{j}} + z\hat{\mathbf{k}}$$

.

### Example 12.3.8: Vector Representations

Let $\overrightarrow{PQ}$ be the vector with initial point $P = (3, 12, 6)$ and terminal point $Q = (-4, -3, 2)$ as shown in Figure 12.3.18. Express $\overrightarrow{PQ}$ in both component form and using standard unit vectors.

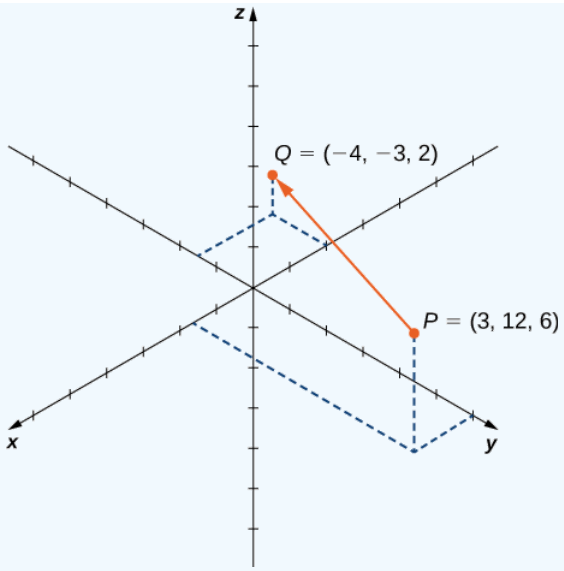

Figure 12.3.18: The vector with initial point $P = (3, 12, 6)$ and terminal point $Q = (-4, -3, 2)$.

**Solution**

In component form,

$$\begin{aligned}\overrightarrow{PQ} &= \langle x_2 - x_1, y_2 - y_1, z_2 - z_1 \rangle \\ &= \langle -4 - 3, -3 - 12, 2 - 6 \rangle \\ &= \langle -7, -15, -4 \rangle.\end{aligned}$$

In standard unit form,

$$\overrightarrow{PQ} = -7\hat{\mathbf{i}} - 15\hat{\mathbf{j}} - 4\hat{\mathbf{k}}.$$

**? Exercise 12.3.8**

Let $S = (3, 8, 2)$ and $T = (2, -1, 3)$. Express $\vec{ST}$ in component form and in standard unit form.

**Hint**

Write $\overrightarrow{ST}$ in component form first. $T$ is the terminal point of $\overrightarrow{ST}$.

**Answer**

$\overrightarrow{ST} = \langle -1, -9, 1 \rangle = -\hat{\mathbf{i}} - 9\hat{\mathbf{j}} + \hat{\mathbf{k}}$

As described earlier, vectors in three dimensions behave in the same way as vectors in a plane. The geometric interpretation of vector addition, for example, is the same in both two- and three-dimensional space (Figure 12.3.19).

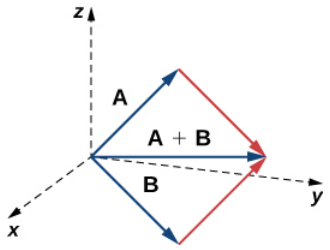

Figure 12.3.19: To add vectors in three dimensions, we follow the same procedures we learned for two dimensions.

We have already seen how some of the algebraic properties of vectors, such as vector addition and scalar multiplication, can be extended to three dimensions. Other properties can be extended in similar fashion. They are summarized here for our reference.

### Properties of Vectors in Space

Let $\vec{\mathbf{v}} = \langle x_1, y_1, z_1 \rangle$ and $\vec{\mathbf{w}} = \langle x_2, y_2, z_2 \rangle$ be vectors, and let $k$ be a scalar.

- **Scalar multiplication**:

$$k\vec{\mathbf{v}} = \langle kx_1, ky_1, kz_1 \rangle$$

- **Vector addition**:

$$\vec{\mathbf{v}} + \vec{\mathbf{w}} = \langle x_1, y_1, z_1 \rangle + \langle x_2, y_2, z_2 \rangle = \langle x_1 + x_2, y_1 + y_2, z_1 + z_2 \rangle$$

- **Vector subtraction**:

$$\vec{\mathbf{v}} - \vec{\mathbf{w}} = \langle x_1, y_1, z_1 \rangle - \langle x_2, y_2, z_2 \rangle = \langle x_1 - x_2, y_1 - y_2, z_1 - z_2 \rangle$$

- **Vector magnitude**:

$$\|\vec{\mathbf{v}}\| = \sqrt{x_1^2 + y_1^2 + z_1^2}$$

- **Unit vector in the direction of $\vec{\mathbf{v}}$**:

$$\frac{1}{\|\vec{\mathbf{v}}\|}\vec{\mathbf{v}} = \frac{1}{\|\vec{\mathbf{v}}\|}\langle x_1, y_1, z_1 \rangle = \langle \frac{x_1}{\|\vec{\mathbf{v}}\|}, \frac{y_1}{\|\vec{\mathbf{v}}\|}, \frac{z_1}{\|\vec{\mathbf{v}}\|} \rangle, \quad \text{if } \vec{\mathbf{v}} \neq \vec{\mathbf{0}}$$

We have seen that vector addition in two dimensions satisfies the commutative, associative, and additive inverse properties. These properties of vector operations are valid for three-dimensional vectors as well. Scalar multiplication of vectors satisfies the distributive property, and the zero vector acts as an additive identity. The proofs to verify these properties in three dimensions are straightforward extensions of the proofs in two dimensions.

### Example 12.3.9: Vector Operations in Three Dimensions

Let $\vec{\mathbf{v}} = \langle -2, 9, 5 \rangle$ and $\vec{\mathbf{w}} = \langle 1, -1, 0 \rangle$ (Figure 12.3.20). Find the following vectors.

a. $3\vec{\mathbf{v}} - 2\vec{\mathbf{w}}$
b. $5\|\vec{\mathbf{w}}\|$
c. $\|5\vec{\mathbf{w}}\|$
d. A unit vector in the direction of $\vec{\mathbf{v}}$

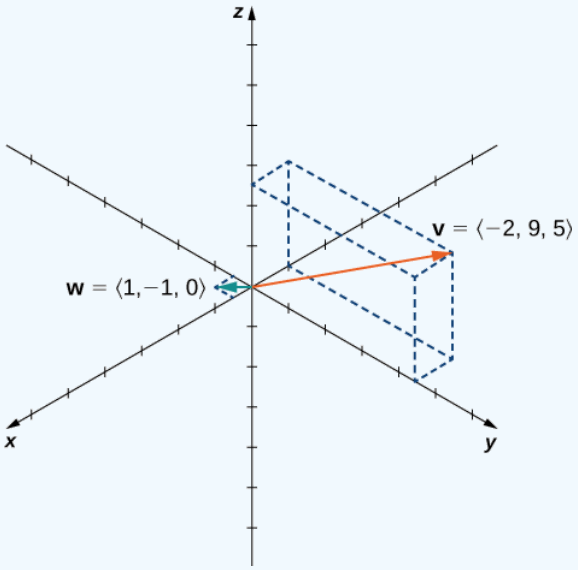

Figure 12.3.20: The vectors $\vec{\mathbf{v}} = \langle -2, 9, 5 \rangle$ and $\vec{\mathbf{w}} = \langle 1, -1, 0 \rangle$.

**Solution**

a. First, use scalar multiplication of each vector, then subtract:

$$\begin{aligned} 3\vec{\mathbf{v}} - 2\vec{\mathbf{w}} &= 3\langle -2, 9, 5\rangle - 2\langle 1, -1, 0\rangle \\ &= \langle -6, 27, 15\rangle - \langle 2, -2, 0\rangle \\ &= \langle -6-2, 27-(-2), 15-0\rangle \\ &= \langle -8, 29, 15\rangle. \end{aligned}$$

b. Write the equation for the magnitude of the vector, then use scalar multiplication:

$$5\|\vec{\mathbf{w}}\| = 5\sqrt{1^2 + (-1)^2 + 0^2} = 5\sqrt{2}.$$

c. First, use scalar multiplication, then find the magnitude of the new vector. Note that the result is the same as for part b.:

$$\|5\vec{\mathbf{w}}\| = \| \langle 5, -5, 0\rangle \| = \sqrt{5^2 + (-5)^2 + 0^2} = \sqrt{50} = 5\sqrt{2}$$

d. Recall that to find a unit vector in two dimensions, we divide a vector by its magnitude. The procedure is the same in three dimensions:

$$\begin{aligned} \frac{\vec{\mathbf{v}}}{\|\vec{\mathbf{v}}\|} &= \frac{1}{\|\vec{\mathbf{v}}\|}\langle -2, 9, 5\rangle \\ &= \frac{1}{\sqrt{(-2)^2 + 9^2 + 5^2}}\langle -2, 9, 5\rangle \\ &= \frac{1}{\sqrt{110}}\langle -2, 9, 5\rangle \\ &= \left\langle \frac{-2}{\sqrt{110}}, \frac{9}{\sqrt{110}}, \frac{5}{\sqrt{110}} \right\rangle. \end{aligned}$$

**? Exercise 12.3.9:**

Let $\vec{\mathbf{v}} = \langle -1, -1, 1\rangle$ and $\vec{\mathbf{w}} = \langle 2, 0, 1\rangle$. Find a unit vector in the direction of $5\vec{\mathbf{v}} + 3\vec{\mathbf{w}}$.

**Hint**

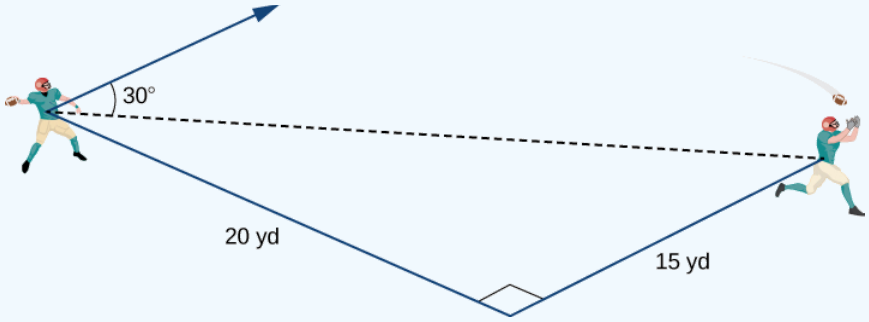
Start by writing $5\vec{\mathbf{v}} + 3\vec{\mathbf{w}}$ in component form.

**Answer**

$$\left\langle \frac{1}{3\sqrt{10}}, -\frac{5}{3\sqrt{10}}, \frac{8}{3\sqrt{10}} \right\rangle$$

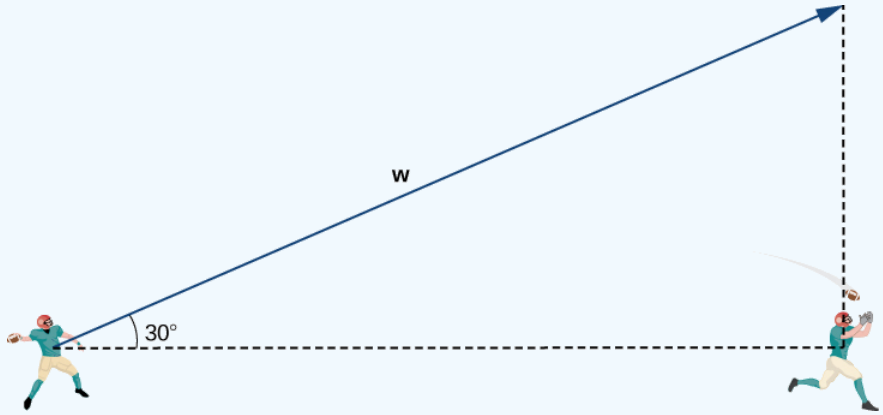
**✓ Example 12.3.10: Throwing a Forward Pass**

A quarterback is standing on the football field preparing to throw a pass. His receiver is standing 20 yd down the field and 15 yd to the quarterback's left. The quarterback throws the ball at a velocity of 60 mph toward the receiver at an upward angle of $30°$ (see the following figure). Write the initial velocity vector of the ball, $\vec{\mathbf{v}}$, in component form.



**Solution**

The first thing we want to do is find a vector in the same direction as the velocity vector of the ball. We then scale the vector appropriately so that it has the right magnitude. Consider the vector $\vec{\mathbf{w}}$ extending from the quarterback's arm to a point directly above the receiver's head at an angle of $30°$ (see the following figure). This vector would have the same direction as $\vec{\mathbf{v}}$, but it may not have the right magnitude.



The receiver is 20 yd down the field and 15 yd to the quarterback's left. Therefore, the straight-line distance from the quarterback to the receiver is

$$\textbf{Dist from QB to receiver} = \sqrt{15^2 + 20^2} = \sqrt{225 + 400} = \sqrt{625} = 25 \text{ yd}.$$

We have $\dfrac{25}{\|\vec{\mathbf{w}}\|} = \cos 30°$. Then the magnitude of $\vec{\mathbf{w}}$ is given by

$$\|\vec{\mathbf{w}}\| = \frac{25}{\cos 30°} = \frac{25 \cdot 2}{\sqrt{3}} = \frac{50}{\sqrt{3}} \text{ yd}$$

and the vertical distance from the receiver to the terminal point of $\vec{\mathbf{w}}$ is

$$\textbf{Vert dist from receiver to terminal point of } \vec{\mathbf{w}} = \|\vec{\mathbf{w}}\| \sin 30° = \frac{50}{\sqrt{3}} \cdot \frac{1}{2} = \frac{25}{\sqrt{3}} \text{ yd}.$$

Then $\vec{\mathbf{w}} = \langle 20, 15, \dfrac{25}{\sqrt{3}} \rangle$, and has the same direction as $\vec{\mathbf{v}}$.

Recall, though, that we calculated the magnitude of $\vec{\mathbf{w}}$ to be $\|\vec{\mathbf{w}}\| = \dfrac{50}{\sqrt{3}}$ yd, and $\vec{\mathbf{v}}$ has magnitude $60$ mph. So, we need to multiply vector $\vec{\mathbf{w}}$ by an appropriate constant, $k$. We want to find a value of $k$ so that $\| k\vec{\mathbf{w}} \| = 60$ mph*. We have

$$\|k\vec{\mathbf{w}}\| = k\|\vec{\mathbf{w}}\| = k\frac{50}{\sqrt{3}} \text{ yd},$$

so we want

$$k\left(\frac{50}{\sqrt{3}} \text{ yd}\right) = 60 \text{ mph}$$

$$k = \frac{60\sqrt{3}}{50} \text{ mph / yd}$$

$$k = \frac{6\sqrt{3}}{5} \text{ mph / yd}.$$

Then

$$\vec{\mathbf{v}} = k\vec{\mathbf{w}} = k\langle 20, 15, \frac{25}{\sqrt{3}} \rangle = \frac{6\sqrt{3}}{5} \langle 20, 15, \frac{25}{\sqrt{3}} \rangle = \langle 24\sqrt{3}, 18\sqrt{3}, 30 \rangle.$$

Let's double-check that $\|\vec{\mathbf{v}}\| = 60$ mph. We have

$$\|\vec{\mathbf{v}}\| = \sqrt{(24\sqrt{3})^2 + (18\sqrt{3})^2 + (30)^2} = \sqrt{1728 + 972 + 900} = \sqrt{3600} = 60 \text{ mph}.$$

So, we have found the correct components for $\vec{\mathbf{v}}$.

**Note ***

Readers who have been watching the units of measurement may be wondering what exactly is going on at this point: haven't we just mixed yards and miles per hour? We haven't, but the reason is subtle. One way to understand it is to realize that there are really two parallel coordinate systems in this problem: one gives positions down the field, across the field, and up into the air in units of yards; the other gives speeds down the field, across the field, and up into the air in units of miles per hour. The vector $\vec{\mathbf{w}}$ is calculated in the position coordinate system; vector $\vec{\mathbf{v}}$ will be in the speed system. Because corresponding axes in each system are parallel, directions in the two systems are also parallel, so the claim that $\vec{\mathbf{w}}$ and $\vec{\mathbf{v}}$ point in the same direction is correct. The constant $k$ that we're looking for is a conversion factor between the magnitudes of these two vectors, converting from the position system to the speed one in the process. And as seen above, our calculation of $k$ produces the right units for such a conversion, namely miles per hour per yard.

**? Exercise 12.3.10**

Assume the quarterback and the receiver are in the same place as in the previous example. This time, however, the quarterback throws the ball at velocity of $40$ mph and an angle of $45°$. Write the initial velocity vector of the ball, $\vec{\mathbf{v}}$, in component form.

**Hint**

Follow the process used in the previous example.

**Answer**

$v = \langle 16\sqrt{2}, 12\sqrt{2}, 20\sqrt{2} \rangle$

## Key Concepts

- The three-dimensional coordinate system is built around a set of three axes that intersect at right angles at a single point, the origin. Ordered triples $(x, y, z)$ are used to describe the location of a point in space.
- The distance $d$ between points $(x_1, y_1, z_1)$ and $(x_2, y_2, z_2)$ is given by the formula

$$d = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}.$$

- In three dimensions, the equations $x = a,\ y = b$, and $z = c$ describe planes that are parallel to the coordinate planes.
- The standard equation of a sphere with center $(a, b, c)$ and radius $r$ is

$$(x - a)^2 + (y - b)^2 + (z - c)^2 = r^2.$$

- In three dimensions, as in two, vectors are commonly expressed in component form, $\vec{\mathbf{v}} = \langle x, y, z \rangle$, or in terms of the standard unit vectors, $\vec{\mathbf{v}} = x\,\hat{\mathbf{i}} + y\,\hat{\mathbf{j}} + z\,\hat{\mathbf{k}}$.
- Properties of vectors in space are a natural extension of the properties for vectors in a plane. Let $\vec{\mathbf{v}} = \langle x_1, y_1, z_1 \rangle$ and $\vec{\mathbf{w}} = \langle x_2, y_2, z_2 \rangle$ be vectors, and let $k$ be a scalar.

  **Scalar multiplication:**

$$k\vec{\mathbf{v}} = \langle kx_1, ky_1, kz_1 \rangle$$

  **Vector addition:**

$$\vec{\mathbf{v}} + \vec{\mathbf{w}} = \langle x_1, y_1, z_1 \rangle + \langle x_2, y_2, z_2 \rangle = \langle x_1 + x_2, y_1 + y_2, z_1 + z_2 \rangle$$

  **Vector subtraction:**

$$\vec{\mathbf{v}} - \vec{\mathbf{w}} = \langle x_1, y_1, z_1 \rangle - \langle x_2, y_2, z_2 \rangle = \langle x_1 - x_2, y_1 - y_2, z_1 - z_2 \rangle$$

  **Vector magnitude:**

$$\|\vec{\mathbf{v}}\| = \sqrt{x_1^2 + y_1^2 + z_1^2}$$

**Unit vector in the direction of $\vec{\mathbf{v}}$:**

$$\frac{\vec{\mathbf{v}}}{\|\vec{\mathbf{v}}\|} = \frac{1}{\|\vec{\mathbf{v}}\|}\langle x_1, y_1, z_1\rangle = \langle \frac{x_1}{\|\vec{\mathbf{v}}\|}, \frac{y_1}{\|\vec{\mathbf{v}}\|}, \frac{z_1}{\|\vec{\mathbf{v}}\|}\rangle, \ \vec{\mathbf{v}} \neq \vec{\mathbf{0}}$$

## Key Equations

**Distance between two points in space:**

$$d = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}$$

**Sphere with center $(a, b, c)$ and radius $r$:**

$$(x - a)^2 + (y - b)^2 + (z - c)^2 = r^2$$

## Glossary

**coordinate plane**
a plane containing two of the three coordinate axes in the three-dimensional coordinate system, named by the axes it contains: the $xy$-plane, $xz$-plane, or the $yz$-plane

**right-hand rule**
a common way to define the orientation of the three-dimensional coordinate system; when the right hand is curved around the $z$-axis in such a way that the fingers curl from the positive $x$-axis to the positive $y$-axis, the thumb points in the direction of the positive $z$-axis

**octants**
the eight regions of space created by the coordinate planes

**sphere**
the set of all points equidistant from a given point known as the *center*

**standard equation of a sphere**
$(x - a)^2 + (y - b)^2 + (z - c)^2 = r^2$ describes a sphere with center $(a, b, c)$ and radius $r$

**three-dimensional rectangular coordinate system**
a coordinate system defined by three lines that intersect at right angles; every point in space is described by an ordered triple $(x, y, z)$ that plots its location relative to the defining axes

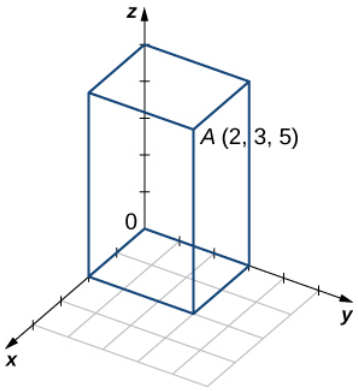
# 12.3E: Exercises for Section 12.2

1) Consider a rectangular box with one of the vertices at the origin, as shown in the following figure. If point $A(2,3,5)$ is the opposite vertex to the origin, then find

a. the coordinates of the other six vertices of the box and

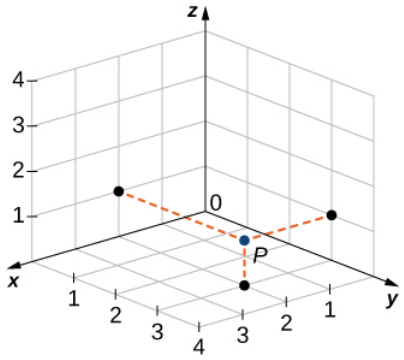
b. the length of the diagonal of the box determined by the vertices $O$ and $A$.



**Answer**

a. $(2,0,5),(2,0,0),(2,3,0),(0,3,0),(0,3,5),(0,0,5)$ b. $\sqrt{38}$

2) Find the coordinates of point $P$ and determine its distance to the origin.

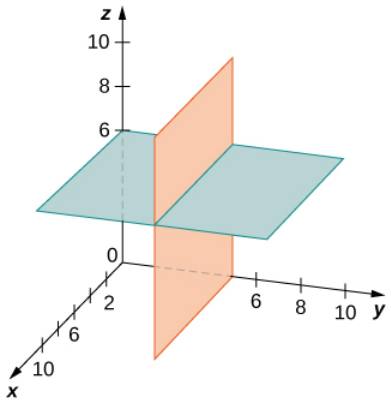


**For exercises 3-6, describe and graph the set of points that satisfies the given equation.**

3) $(y-5)(z-6)=0$

**Answer**

A union of two planes: $y=5$ (a plane parallel to the $xz$-plane) and $z=6$ (a plane parallel to the $xy$-plane)

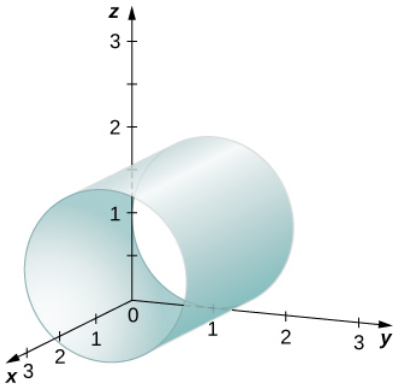


4) $(z-2)(z-5)=0$

5) $(y-1)^2+(z-1)^2=1$

**Answer**

A cylinder of radius $1$ centered on the line $y=1, z=1$



6) $(x-2)^2+(z-5)^2=4$

7) Write the equation of the plane passing through point $(1,1,1)$ that is parallel to the $xy$-plane.

**Answer**

$z=1$

8) Write the equation of the plane passing through point $(1,-3,2)$ that is parallel to the $xz$-plane.

9) Find an equation of the plane passing through points $(1,-3,-2), (0,3,-2)$, and $(1,0,-2)$.

**Answer**

$z=-2$

10) Find an equation of the plane passing through points $(1,9,2), (1,3,6)$, and $(1,-7,8)$.

**For exercises 11-14, find the equation of the sphere in standard form that satisfies the given conditions.**

11) Center $C(-1,7,4)$ and radius $4$

**Answer**

$(x+1)^2+(y-7)^2+(z-4)^2=16$

12) Center $C(-4,7,2)$ and radius $6$

13) Diameter $PQ$, where $P(-1,5,7)$ and $Q(-5,2,9)$

**Answer**

$x+3)^2+(y-3.5)^2+(z-8)^2=\dfrac{29}{4}$

14) Diameter $PQ$, where $P(-16,-3,9)$ and $Q(-2,3,5)$

**For exercises 15 and 16, find the center and radius of the sphere with an equation in general form that is given.**

15) $x^2+y^2+z^2-4z+3=0$

**Answer**

Center $C(0,0,2)$ and radius $1$

16) $x^2+y^2+z^2-6x+8y-10z+25=0$

**For exercises 17-20, express vector $\overrightarrow{PQ}$ with the initial point at $P$ and the terminal point at $Q$**

**a. in component form and**

**b. by using standard unit vectors.**

17) $P(3,0,2)$ and $Q(-1,-1,4)$

**Answer**

$a.\overrightarrow{PQ}=\langle -4,-1,2\rangle$
$b.\overrightarrow{PQ}=-4\hat{\mathbf{i}}-\hat{\mathbf{j}}+2\hat{\mathbf{k}}$

18) $P(0,10,5)$ and $Q(1,1,-3)$

19) $P(-2,5,-8)$ and $M(1,-7,4)$, where $M$ is the midpoint of the line segment $\overline{PQ}$

**Answer**

$a.\overrightarrow{PQ}=\langle 6,-24,24\rangle$
$b.\overrightarrow{PQ}=6\hat{\mathbf{i}}-24\hat{\mathbf{j}}+24\hat{\mathbf{k}}$

20) $Q(0,7,-6)$ and $M(-1,3,2)$, where $M$ is the midpoint of the line segment $\overline{PQ}$

21) Find terminal point $Q$ of vector $\overrightarrow{PQ}=\langle 7,-1,3\rangle$ with the initial point at $P(-2,3,5)$.

**Answer**

$Q(5,2,8)$

22) Find initial point $P$ of vector $\overrightarrow{PQ}=\langle -9,1,2\rangle$ with the terminal point at $Q(10,0,-1)$.

**For exercises 23-26, use the given vectors $\vec{\mathbf{a}}$ and $\vec{\mathbf{b}}$ to find and express the vectors $\vec{\mathbf{a}}+\vec{\mathbf{b}}$, $4\vec{\mathbf{a}}$, and $-5\vec{\mathbf{a}}+3\vec{\mathbf{b}}$ in component form.**

23) $\vec{\mathbf{a}}=\langle -1,-2,4\rangle$, $\vec{\mathbf{b}}=\langle -5,6,-7\rangle$

**Answer**

$\vec{\mathbf{a}}+\vec{\mathbf{b}}=\langle -6,4,-3\rangle, 4\vec{\mathbf{a}}=\langle -4,-8,16\rangle, -5\vec{\mathbf{a}}+3\vec{\mathbf{b}}=\langle -10,28,-41\rangle$

24) $\vec{\mathbf{a}}=\langle 3,-2,4\rangle$, $\vec{\mathbf{b}}=\langle -5,6,-9\rangle$

25) $\vec{\mathbf{a}}=-\hat{\mathbf{k}}$, $\vec{\mathbf{b}}=-\hat{\mathbf{i}}$

**Answer**

$\vec{\mathbf{a}}+\vec{\mathbf{b}}=\langle -1,0,-1\rangle, 4\vec{\mathbf{a}}=\langle 0,0,-4\rangle, -5\vec{\mathbf{a}}+3\vec{\mathbf{b}}=\langle -3,0,5\rangle$

26) $\vec{a} = \hat{i} + \hat{j} + \hat{k}, \quad \vec{b} = 2\hat{i} - 3\hat{j} + 2\hat{k}$

**For exercises 27-30, vectors $\vec{u}$ and $\vec{v}$ are given. Find the magnitudes of vectors $\vec{u} - \vec{v}$ and $-2\vec{u}$.**

27) $\vec{u} = 2\hat{i} + 3\hat{j} + 4\hat{k}, \quad \vec{v} = -\hat{i} + 5\hat{j} - \hat{k}$

**Answer**

$\|\vec{u} - \vec{v}\| = \sqrt{38}, \quad \|-2\vec{u}\| = 2\sqrt{29}$

28) $\vec{u} = \hat{i} + \hat{j}, \quad \vec{v} = \hat{j} - \hat{k}$

29) $\vec{u} = \langle 2\cos t, -2\sin t, 3\rangle, \quad \vec{v} = \langle 0, 0, 3\rangle,$ where $t$ is a real number.

**Answer**

$\|\vec{u} - \vec{v}\| = 2, \quad \|-2\vec{u}\| = 2\sqrt{13}$

30) $\vec{u} = \langle 0, 1, \sinh t\rangle, \quad \vec{v} = \langle 1, 1, 0\rangle,$ where $t$ is a real number.

**For exercises 31-36, find the unit vector in the direction of the given vector $\vec{a}$ and express it using standard unit vectors.**

31) $\vec{a} = 3\hat{i} - 4\hat{j}$

**Answer**

$\frac{3}{5}\hat{i} - \frac{4}{5}\hat{j}$

32) $\vec{a} = \langle 4, -3, 6\rangle$

33) $\vec{a} = \overrightarrow{PQ}$, where $P(-2, 3, 1)$ and $Q(0, -4, 4)$

**Answer**

$\frac{\sqrt{62}}{31}\hat{i} - \frac{7\sqrt{62}}{62}\hat{j} + \frac{3\sqrt{62}}{62}\hat{k}$

34) $\vec{a} = \overrightarrow{OP}$, where $P(-1, -1, 1)$

35) $\vec{a} = \vec{u} - \vec{v} + \vec{w}$, where $\vec{u} = \hat{i} - \hat{j} - \hat{k}, \quad \vec{v} = 2\hat{i} - \hat{j} + \hat{k},$ and $\vec{w} = -\hat{i} + \hat{j} + 3\hat{k}$

**Answer**

$-\frac{\sqrt{6}}{3}\hat{i} + \frac{\sqrt{6}}{6}\hat{j} + \frac{\sqrt{6}}{6}\hat{k}$

36) $\vec{a} = 2\vec{u} + \vec{v} - \vec{w},$ where $\vec{u} = \hat{i} - \hat{k}, \quad \vec{v} = 2\hat{j}$ , and $\vec{w} = \hat{i} - \hat{j}$

37) Determine whether $\overrightarrow{AB}$ and $\overrightarrow{PQ}$ are equivalent vectors, where $A(1, 1, 1)$, $B(3, 3, 3)$, $P(1, 4, 5)$, and $Q(3, 6, 7)$.

**Answer**

Equivalent vectors

38) Determine whether the vectors $\overrightarrow{AB}$ and $\overrightarrow{PQ}$ are equivalent, where $A(1, 4, 1)$, $B(-2, 2, 0)$, $P(2, 5, 7)$, and $Q(-3, 2, 1)$.

**For exercises 39-42, find vector $\vec{u}$ with a magnitude that is given and satisfies the given conditions.**

39) $\vec{v} = \langle 7, -1, 3\rangle$, $\|\vec{u}\| = 10$, and $\vec{u}$ and $\vec{v}$ have the same direction

**Answer**

$\vec{u} = \langle \frac{70\sqrt{59}}{59}, -\frac{10\sqrt{59}}{59}, \frac{30\sqrt{59}}{59}\rangle$

40) $\vec{v} = \langle 2, 4, 1\rangle$, $\|\vec{u}\| = 15$, and $\vec{u}$ and $\vec{v}$ have the same direction

41) $\vec{v} = \langle 2\sin t,\ 2\cos t, 1\rangle, \|\vec{u}\| = 2, \vec{u}$ and $\vec{v}$ have opposite directions for any $t$, where $t$ is a real number

**Answer**

$$\vec{\mathbf{u}} = \langle -\tfrac{4\sqrt{5}}{5}\sin t, -\tfrac{4\sqrt{5}}{5}\cos t, -\tfrac{2\sqrt{5}}{5}\rangle$$

42) $\vec{\mathbf{v}} = \langle 3\sinh t, 0, 3\rangle$, $\|\vec{\mathbf{u}}\| = 5$, and $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ have opposite directions for any $t$, where $t$ is a real number

43) Determine a vector of magnitude $5$ in the direction of vector $\overrightarrow{AB}$, where $A(2,1,5)$ and $B(3,4,-7)$.

**Answer**

$\langle \frac{5\sqrt{154}}{154}, \frac{15\sqrt{154}}{154}, -\frac{30\sqrt{154}}{77}\rangle$

44) Find a vector of magnitude $2$ that points in the opposite direction than vector $\overrightarrow{AB}$, where $A(-1,-1,1)$ and $B(0,1,1)$. Express the answer in component form.

45) Consider the points $A(2,\alpha,0)$, $B(0,1,\beta)$, and $C(1,1,\beta)$, where $\alpha$ and $\beta$ are negative real numbers. Find $\alpha$ and $\beta$ such that $\|\overrightarrow{OA} - \overrightarrow{OB} + \overrightarrow{OC}\| = \|\overrightarrow{OB}\| = 4$.

**Answer**

$\alpha = -\sqrt{7}$, $\beta = -\sqrt{15}$

46) Consider points $A(\alpha,0,0)$, $B(0,\beta,0)$, and $C(\alpha,\beta,\beta)$, where $\alpha$ and $\beta$ are positive real numbers. Find $\alpha$ and $\beta$ such that $\|\overrightarrow{OA} + \overrightarrow{OB}\| = \sqrt{2}$ and $\|\overrightarrow{OC}\| = \sqrt{3}$.

47) Let $P(x,y,z)$ be a point situated at an equal distance from points $A(1,-1,0)$ and $B(-1,2,1)$. Show that point $P$ lies on the plane of equation $-2x + 3y + z = 2$.

48) Let $P(x,y,z)$ be a point situated at an equal distance from the origin and point $A(4,1,2)$. Show that the coordinates of point P satisfy the equation $8x + 2y + 4z = 21$.

49) The points $A, B$, and $C$ are collinear (in this order) if the relation $\|\overrightarrow{AB}\| + \|\overrightarrow{BC}\| = \|\overrightarrow{AC}\|$ is satisfied. Show that $A(5,3,-1)$, $B(-5,-3,1)$, and $C(-15,-9,3)$ are collinear points.

50) Show that points $A(1,0,1)$, $B(0,1,1)$, and $C(1,1,1)$ are not collinear.

51) [T] A force $\vec{\mathbf{F}}$ of $50\,N$ acts on a particle in the direction of the vector $\overrightarrow{OP}$, where $P(3,4,0)$.

a. Express the force as a vector in component form.

b. Find the angle between force $\vec{\mathbf{F}}$ and the positive direction of the $x$-axis. Express the answer in degrees rounded to the nearest integer.

**Answer**

$a. \vec{\mathbf{F}} = \langle 30, 40, 0\rangle$; $\quad b. 53°$

52) [T] A force $\vec{\mathbf{F}}$ of $40\,N$ acts on a box in the direction of the vector $\overrightarrow{OP}$, where $P(1,0,2)$.

a. Express the force as a vector by using standard unit vectors.

b. Find the angle between force $\vec{\mathbf{F}}$ and the positive direction of the $x$-axis.

53) If $\vec{\mathbf{F}}$ is a force that moves an object from point $P_1(x_1,y_1,z_1)$ to another point $P_2(x_2,y_2,z_2)$, then the displacement vector is defined as $\vec{\mathbf{D}} = (x_2 - x_1)\hat{\mathbf{i}} + (y_2 - y_1)\hat{\mathbf{j}} + (z_2 - z_1)\hat{\mathbf{k}}$. A metal container is lifted $10$ m vertically by a constant force $\vec{\mathbf{F}}$. Express the displacement vector $\vec{\mathbf{D}}$ by using standard unit vectors.

**Answer**

$\vec{\mathbf{D}} = 10\hat{\mathbf{k}}$

54) A box is pulled $4$ yd horizontally in the $x$-direction by a constant force $\vec{\mathbf{F}}$. Find the displacement vector in component form.

55) The sum of the forces acting on an object is called the resultant or net force. An object is said to be in static equilibrium if the resultant force of the forces that act on it is zero. Let $\vec{\mathbf{F}}_1 = \langle 10,6,3\rangle$, $\vec{\mathbf{F}}_2 = \langle 0,4,9\rangle$, and $\vec{\mathbf{F}}_3 = \langle 10,-3,-9\rangle$ be three forces acting on a box. Find the force $\vec{\mathbf{F}}_4$ acting on the box such that the box is in static equilibrium. Express the answer in component form.

**Answer**

$\vec{\mathbf{F}}_4 = \langle -20, -7, -3 \rangle$

56) [T] Let $\vec{\mathbf{F}}_k = \langle 1, k, k^2 \rangle, k = 1, ..., n$ be $n$ forces acting on a particle, with $n \geq 2$.

a. Find the net force $\vec{\mathbf{F}} = \sum_{k=1}^{n} \vec{\mathbf{F}}_k$. Express the answer using standard unit vectors.

b. Use a computer algebra system (CAS) to find $n$ such that $\|\vec{\mathbf{F}}\| < 100$.

57) The force of gravity $\vec{\mathbf{F}}$ acting on an object is given by $\vec{\mathbf{F}} = m\vec{\mathbf{g}}$, where $m$ is the mass of the object (expressed in kilograms) and $\vec{\mathbf{g}}$ is acceleration resulting from gravity, with $\|\vec{\mathbf{g}}\| = 9.8\, N/kg$. A 2-kg disco ball hangs by a chain from the ceiling of a room.

a. Find the force of gravity $\vec{\mathbf{F}}$ acting on the disco ball and find its magnitude.

b. Find the force of tension $\vec{\mathbf{T}}$ in the chain and its magnitude.

Express the answers using standard unit vectors.

Figure 18: (credit: modification of work by Kenneth Lu, Flickr)

**Answer**

$a. \vec{\mathbf{F}} = -19.6\hat{\mathbf{k}}, \quad \|\vec{\mathbf{F}}\| = 19.6\ N$

$b. \vec{\mathbf{T}} = 19.6\hat{\mathbf{k}}, \quad \|\vec{\mathbf{T}}\| = 19.6\ N$

58) A 5-kg pendant chandelier is designed such that the alabaster bowl is held by four chains of equal length, as shown in the following figure.

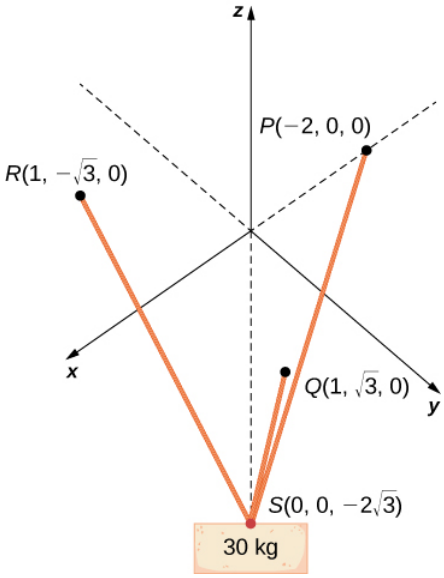
a. Find the magnitude of the force of gravity acting on the chandelier.

b. Find the magnitudes of the forces of tension for each of the four chains (assume chains are essentially vertical).

59) [T] A 30-kg block of cement is suspended by three cables of equal length that are anchored at points $P(-2,0,0), Q(1,\sqrt{3},0)$, and $R(1,-\sqrt{3},0)$. The load is located at $S(0,0,-2\sqrt{3})$, as shown in the following figure. Let $\vec{\mathbf{F}}_1, \vec{\mathbf{F}}_2$, and $\vec{\mathbf{F}}_3$ be the forces of tension resulting from the load in cables $RS, QS$, and $PS$, respectively.

a. Find the gravitational force $\vec{\mathbf{F}}$ acting on the block of cement that counterbalances the sum $\vec{\mathbf{F}}_1 + \vec{\mathbf{F}}_2 + \vec{\mathbf{F}}_3$ of the forces of tension in the cables.

b. Find forces $\vec{\mathbf{F}}_1, \vec{\mathbf{F}}_2$, and $\vec{\mathbf{F}}_3$. Express the answer in component form.

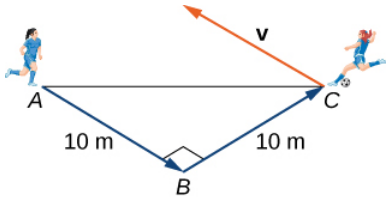


**Answer**

a. $\vec{\mathbf{F}} = -294\hat{\mathbf{k}}$ N;

b. $\vec{\mathbf{F}}_1 = \langle -\frac{49\sqrt{3}}{3}, 49, -98\rangle, \vec{\mathbf{F}}_2 = \langle -\frac{49\sqrt{3}}{3}, -49, -98\rangle$, and $\vec{\mathbf{F}}_3 = \langle \frac{98\sqrt{3}}{3}, 0, -98\rangle$ (each component is expressed in newtons)

60) Two soccer players are practicing for an upcoming game. One of them runs 10 m from point A to point B. She then turns left at $90°$ and runs 10 m until she reaches point C. Then she kicks the ball with a speed of 10 m/sec at an upward angle of $45°$ to her teammate, who is located at point A. Write the velocity of the ball in component form.



61) Let $\vec{\mathbf{r}}(t) = \langle x(t),\ y(t),\ z(t)\rangle$ be the position vector of a particle at the time $t \in [0, T]$, where $x, y$, and $z$ are smooth functions on $[0, T]$. The instantaneous velocity of the particle at time $t$ is defined by vector $\vec{\mathbf{v}}(t) = \langle x'(t),\ y'(t),\ z'(t)\rangle$, with components that are the derivatives with respect to $t$, of the functions $x, y$, and $z$, respectively. The magnitude $\| \vec{\mathbf{v}}(t) \|$ of the instantaneous velocity vector is called the speed of the particle at time $t$. Vector $\vec{\mathbf{a}}(t) = \langle x''(t),\ y''(t),\ z''(t)\rangle$, with components that are the second derivatives with respect to $t$, of the functions $x, y$, and $z$, respectively, gives the acceleration of the particle at time $t$. Consider $\vec{\mathbf{r}}(t) = \langle \cos t,\ \sin t,\ 2t\rangle$ the position vector of a particle at time $t \in [0, 30]$, where the components of $\vec{\mathbf{r}}$ are expressed in centimeters and time is expressed in seconds.

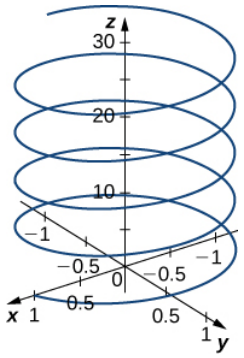
a. Find the instantaneous velocity, speed, and acceleration of the particle after the first second. Round your answer to two decimal places.

b. Use a CAS to visualize the path of the particle—that is, the set of all points of coordinates $(\cos t, \sin t, 2t)$, where $t \in [0, 30]$.

**Answer**

*a.* $\vec{\mathbf{v}}(1) = \langle -0.84, 0.54, 2\rangle$ (each component is expressed in centimeters per second); $\| \vec{\mathbf{v}}(1) \| = 2.24$ (expressed in centimeters per second); $\vec{\mathbf{a}}(1) = \langle -0.54, -0.84, 0\rangle$ (each component expressed in centimeters per second squared);

*b.*



62) [T] Let $\vec{\mathbf{r}}(t) = \langle t, 2t^2, 4t^2\rangle$ be the position vector of a particle at time $t$ (in seconds), where $t \in [0, 10]$ (here the components of $\vec{\mathbf{r}}$ are expressed in centimeters).

a. Find the instantaneous velocity, speed, and acceleration of the particle after the first two seconds. Round your answer to two decimal places.

b. Use a CAS to visualize the path of the particle defined by the points $(t,\ 2t^2,\ 4t^2)$, where $t \in [0,\ 60]$.

# 12.4: The Dot Product

**Learning Objectives**

- Calculate the dot product of two given vectors.
- Determine whether two given vectors are perpendicular.
- Find the direction cosines of a given vector.
- Explain what is meant by the vector projection of one vector onto another vector, and describe how to compute it.
- Calculate the work done by a given force.

If we apply a force to an object so that the object moves, we say that work is done by the force. Previously, we looked at a constant force and we assumed the force was applied in the direction of motion of the object. Under those conditions, work can be expressed as the product of the force acting on an object and the distance the object moves. In this chapter, however, we have seen that both force and the motion of an object can be represented by vectors.

In this section, we develop an operation called the dot product, which allows us to calculate work in the case when the force vector and the motion vector have different directions. The dot product essentially tells us how much of the force vector is applied in the direction of the motion vector. The dot product can also help us measure the angle formed by a pair of vectors and the position of a vector relative to the coordinate axes. It even provides a simple test to determine whether two vectors meet at a right angle.

## The Dot Product and Its Properties

We have already learned how to add and subtract vectors. In this chapter, we investigate two types of vector multiplication. The first type of vector multiplication is called the dot product, based on the notation we use for it, and it is defined as follows:

**Definition: dot product**

The *dot product* of vectors $\vec{\mathbf{u}} = \langle u_1, u_2, u_3 \rangle$ and $\vec{\mathbf{v}} = \langle v_1, v_2, v_3 \rangle$ is given by the sum of the products of the components

$$\vec{\mathbf{u}} \cdot \vec{\mathbf{v}} = u_1 v_1 + u_2 v_2 + u_3 v_3.$$

Note that if $u$ and $v$ are two-dimensional vectors, we calculate the dot product in a similar fashion. Thus, if $\vec{\mathbf{u}} = \langle u_1, u_2 \rangle$ and $\vec{\mathbf{v}} = \langle v_1, v_2 \rangle$, then

$$\vec{\mathbf{u}} \cdot \vec{\mathbf{v}} = u_1 v_1 + u_2 v_2.$$

When two vectors are combined under addition or subtraction, the result is a vector. When two vectors are combined using the dot product, the result is a scalar. For this reason, the dot product is often called the *scalar product*. It may also be called the *inner product*.

**Example 12.4.1: Calculating Dot Products**

a. Find the dot product of $\vec{\mathbf{u}} = \langle 3, 5, 2 \rangle$ and $\vec{\mathbf{v}} = \langle -1, 3, 0 \rangle$.
b. Find the scalar product of $\vec{\mathbf{p}} = 10\hat{\mathbf{i}} - 4\hat{\mathbf{j}} + 7\hat{\mathbf{k}}$ and $\vec{\mathbf{q}} = -2\hat{\mathbf{i}} + \hat{\mathbf{j}} + 6\hat{\mathbf{k}}$.

**Solution**:

a. Substitute the vector components into the formula for the dot product:

$$\begin{aligned} \vec{\mathbf{u}} \cdot \vec{\mathbf{v}} &= u_1 v_1 + u_2 v_2 + u_3 v_3 \\ &= 3(-1) + 5(3) + 2(0) \\ &= -3 + 15 + 0 \\ &= 12. \end{aligned}$$

b. The calculation is the same if the vectors are written using standard unit vectors. We still have three components for each vector to substitute into the formula for the dot product:

$$\begin{aligned}\vec{\mathbf{p}} \cdot \vec{\mathbf{q}} &= p_1q_1 + p_2q_2 + p_3q_3 \\ &= 10(-2) + (-4)(1) + (7)(6) \\ &= -20 - 4 + 42 \\ &= 18.\end{aligned}$$

**? Exercise 12.4.1**

Find $\vec{\mathbf{u}} \cdot \vec{\mathbf{v}}$, where $\vec{\mathbf{u}} = \langle 2, 9, -1 \rangle$ and $\vec{\mathbf{v}} = \langle -3, 1, -4 \rangle$.

**Hint**

Multiply corresponding components and then add their products.

**Answer**

7

Like vector addition and subtraction, the dot product has several algebraic properties. We prove three of these properties and leave the rest as exercises.

**Properties of the Dot Product**

Let $\vec{\mathbf{u}}$, $\vec{\mathbf{v}}$, and $\vec{\mathbf{w}}$ be vectors, and let $c$ be a scalar.

i. *Commutative property*

$$\vec{\mathbf{u}} \cdot \vec{\mathbf{v}} = \vec{\mathbf{v}} \cdot \vec{\mathbf{u}}$$

ii. *Distributive property*

$$\vec{\mathbf{u}} \cdot (\vec{\mathbf{v}} + \vec{\mathbf{w}}) = \vec{\mathbf{u}} \cdot \vec{\mathbf{v}} + \vec{\mathbf{u}} \cdot \vec{\mathbf{w}}$$

iii. *Associative property*

$$c(\vec{\mathbf{u}} \cdot \vec{\mathbf{v}}) = (c\vec{\mathbf{u}}) \cdot \vec{\mathbf{v}} = \vec{\mathbf{u}} \cdot (c\vec{\mathbf{v}})$$

iv. *Property of magnitude*

$$\vec{\mathbf{v}} \cdot \vec{\mathbf{v}} = \|\vec{\mathbf{v}}\|^2$$

**Proof**

Let $\vec{\mathbf{u}} = \langle u_1, u_2, u_3 \rangle$ and $\vec{\mathbf{v}} = \langle v_1, v_2, v_3 \rangle$. Then

$$\begin{aligned}\vec{\mathbf{u}} \cdot \vec{\mathbf{v}} &= \langle u_1, u_2, u_3 \rangle \cdot \langle v_1, v_2, v_3 \rangle \\ &= u_1v_1 + u_2v_2 + u_3v_3 \\ &= v_1u_1 + v_2u_2 + v_3u_3 \\ &= \langle v_1, v_2, v_3 \rangle \cdot \langle u_1, u_2, u_3 \rangle \\ &= \vec{\mathbf{v}} \cdot \vec{\mathbf{u}}.\end{aligned}$$

The associative property looks like the associative property for real-number multiplication, but pay close attention to the difference between scalar and vector objects:

$$\begin{aligned} c(\vec{\mathbf{u}} \cdot \vec{\mathbf{v}}) &= c(u_1v_1 + u_2v_2 + u_3v_3) \\ &= c(u_1v_1) + c(u_2v_2) + c(u_3v_3) \\ &= (cu_1)v_1 + (cu_2)v_2 + (cu_3)v_3 \\ &= \langle cu_1, cu_2, cu_3 \rangle \cdot \langle v_1, v_2, v_3 \rangle \\ &= c\langle u_1, u_2, u_3 \rangle \cdot \langle v_1, v_2, v_3 \rangle \\ &= (c\vec{\mathbf{u}}) \cdot \vec{\mathbf{v}}. \end{aligned}$$

The proof that $c(\vec{\mathbf{u}} \cdot \vec{\mathbf{v}}) = \vec{\mathbf{u}} \cdot (c\vec{\mathbf{v}})$ is similar.

The fourth property shows the relationship between the magnitude of a vector and its dot product with itself:

$$\begin{aligned} \vec{\mathbf{v}} \cdot \vec{\mathbf{v}} &= \langle v_1, v_2, v_3 \rangle \cdot \langle v_1, v_2, v_3 \rangle \\ &= (v_1)^2 + (v_2)^2 + (v_3)^2 \\ &= \left[\sqrt{(v_1)^2 + (v_2)^2 + (v_3)^2}\right]^2 \\ &= \|\vec{\mathbf{v}}\|^2. \end{aligned}$$

□

Note that the definition of the dot product yields $\vec{\mathbf{0}} \cdot \vec{\mathbf{v}} = 0$. By property iv. if $\vec{\mathbf{v}} \cdot \vec{\mathbf{v}} = 0$, then $\vec{\mathbf{v}} = \vec{\mathbf{0}}$.

### Example 12.4.2: Using Properties of the Dot Product

Let $\vec{\mathbf{a}} = \langle 1, 2, -3 \rangle$, $\vec{\mathbf{b}} = \langle 0, 2, 4 \rangle$, and $\vec{\mathbf{c}} = \langle 5, -1, 3 \rangle$.

Find each of the following products.

a. $(\vec{\mathbf{a}} \cdot \vec{\mathbf{b}})\vec{\mathbf{c}}$
b. $\vec{\mathbf{a}} \cdot (2\vec{\mathbf{c}})$
c. $\|\vec{\mathbf{b}}\|^2$

**Solution**

a. Note that this expression asks for the scalar multiple of $\vec{\mathbf{c}}$ by $\vec{\mathbf{a}} \cdot \vec{\mathbf{b}}$:

$$\begin{aligned} (\vec{\mathbf{a}} \cdot \vec{\mathbf{b}})\vec{\mathbf{c}} &= (\langle 1, 2, -3 \rangle \cdot \langle 0, 2, 4 \rangle)\langle 5, -1, 3 \rangle \\ &= (1(0) + 2(2) + (-3)(4))\langle 5, -1, 3 \rangle \\ &= -8\langle 5, -1, 3 \rangle \\ &= \langle -40, 8, -24 \rangle. \end{aligned}$$

b. This expression is a dot product of vector $\vec{\mathbf{a}}$ and scalar multiple $2\vec{\mathbf{c}}$:

$$\begin{aligned} \vec{\mathbf{a}} \cdot (2\vec{\mathbf{c}}) &= 2(\vec{\mathbf{a}} \cdot \vec{\mathbf{c}}) \\ &= 2(\langle 1, 2, -3 \rangle \cdot \langle 5, -1, 3 \rangle) \\ &= 2(1(5) + 2(-1) + (-3)(3)) \\ &= 2(-6) = -12. \end{aligned}$$

c. Simplifying this expression is a straightforward application of the dot product:

$$\begin{aligned} \|\vec{\mathbf{b}}\|^2 &= \vec{\mathbf{b}} \cdot \vec{\mathbf{b}} \\ &= \langle 0, 2, 4 \rangle \cdot \langle 0, 2, 4 \rangle \\ &= 0^2 + 2^2 + 4^2 \\ &= 0 + 4 + 16 \\ &= 20. \end{aligned}$$

**Exercise 12.4.2**

Find the following products for $\vec{\mathbf{p}} = \langle 7, 0, 2\rangle$, $\vec{\mathbf{q}} = \langle -2, 2, -2\rangle$, and $\vec{\mathbf{r}} = \langle 0, 2, -3\rangle$.

a. $(\vec{\mathbf{r}} \cdot \vec{\mathbf{p}})\vec{\mathbf{q}}$
b. $\|\vec{\mathbf{p}}\|^2$

**Hint**

$\vec{\mathbf{r}} \cdot \vec{\mathbf{p}}$ is a scalar.

**Answer**

*a.* $(\vec{\mathbf{r}} \cdot \vec{\mathbf{p}})\vec{\mathbf{q}} = \langle 12, -12, 12\rangle$; *b.* $\|\vec{\mathbf{p}}\|^2 = 53$

## Using the Dot Product to Find the Angle between Two Vectors

When two nonzero vectors are placed in standard position, whether in two dimensions or three dimensions, they form an angle between them (Figure 12.4.1). The dot product provides a way to find the measure of this angle. This property is a result of the fact that we can express the dot product in terms of the cosine of the angle formed by two vectors.

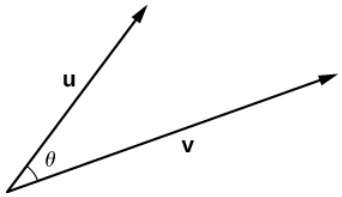

Figure 12.4.1: Let $\theta$ be the angle between two nonzero vectors $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ such that $0 \le \theta \le \pi$.

**Evaluating a Dot Product**

The dot product of two vectors is the product of the magnitude of each vector and the cosine of the angle between them:

$$\vec{\mathbf{u}} \cdot \vec{\mathbf{v}} = \|\vec{\mathbf{u}}\|\|\vec{\mathbf{v}}\| \cos\theta. \tag{12.4.1}$$

**Proof**

Place vectors $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ in standard position and consider the vector $\vec{\mathbf{v}} - \vec{\mathbf{u}}$ (Figure 12.4.2). These three vectors form a triangle with side lengths $\|\vec{\mathbf{u}}\|, \|\vec{\mathbf{v}}\|$, and $\|\vec{\mathbf{v}} - \vec{\mathbf{u}}\|$.

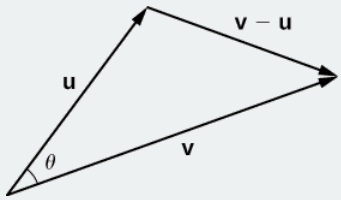

Figure 12.4.2: The lengths of the sides of the triangle are given by the magnitudes of the vectors that form the triangle.

Recall from trigonometry that the law of cosines describes the relationship among the side lengths of the triangle and the angle $\theta$. Applying the law of cosines here gives

$$\|\vec{\mathbf{v}} - \vec{\mathbf{u}}\|^2 = \|\vec{\mathbf{u}}\|^2 + \|\vec{\mathbf{v}}\|^2 - 2\|\vec{\mathbf{u}}\|\|\vec{\mathbf{v}}\| \cos\theta. \tag{12.4.2}$$

The dot product provides a way to rewrite the left side of Equation 12.4.2:

$$\begin{aligned}
\|\vec{\mathbf{v}} - \vec{\mathbf{u}}\|^2 &= (\vec{\mathbf{v}} - \vec{\mathbf{u}}) \cdot (\vec{\mathbf{v}} - \vec{\mathbf{u}}) \\
&= (\vec{\mathbf{v}} - \vec{\mathbf{u}}) \cdot \vec{\mathbf{v}} - (\vec{\mathbf{v}} - \vec{\mathbf{u}}) \cdot \vec{\mathbf{u}} \\
&= \vec{\mathbf{v}} \cdot \vec{\mathbf{v}} - \vec{\mathbf{u}} \cdot \vec{\mathbf{v}} - \vec{\mathbf{v}} \cdot \vec{\mathbf{u}} + \vec{\mathbf{u}} \cdot \vec{\mathbf{u}} \\
&= \vec{\mathbf{v}} \cdot \vec{\mathbf{v}} - \vec{\mathbf{u}} \cdot \vec{\mathbf{v}} - \vec{\mathbf{u}} \cdot \vec{\mathbf{v}} + \vec{\mathbf{u}} \cdot \vec{\mathbf{u}} \\
&= \|\vec{\mathbf{v}}\|^2 - 2\vec{\mathbf{u}} \cdot \vec{\mathbf{v}} + \|\vec{\mathbf{u}}\|^2.
\end{aligned}$$

Substituting into the law of cosines yields

$$\begin{aligned}\|\vec{\mathbf{v}}-\vec{\mathbf{u}}\|^2 &= \|\vec{\mathbf{u}}\|^2+\|\vec{\mathbf{v}}\|^2-2\|\vec{\mathbf{u}}\|\|\vec{\mathbf{v}}\|\cos\theta\\ \|\vec{\mathbf{v}}\|^2-2\vec{\mathbf{u}}\cdot\vec{\mathbf{v}}+\|\vec{\mathbf{u}}\|^2 &= \|\vec{\mathbf{u}}\|^2+\|\vec{\mathbf{v}}\|^2-2\|\vec{\mathbf{u}}\|\|\vec{\mathbf{v}}\|\cos\theta\\ -2\vec{\mathbf{u}}\cdot\vec{\mathbf{v}} &= -2\|\vec{\mathbf{u}}\|\|\vec{\mathbf{v}}\|\cos\theta\\ \vec{\mathbf{u}}\cdot\vec{\mathbf{v}} &= \|\vec{\mathbf{u}}\|\|\vec{\mathbf{v}}\|\cos\theta.\end{aligned}$$

□

We can use the form of the dot product in Equation 12.4.1 to find the measure of the angle between two nonzero vectors by rearranging Equation 12.4.1 to solve for the cosine of the angle:

$$\cos\theta=\frac{\vec{\mathbf{u}}\cdot\vec{\mathbf{v}}}{\|\vec{\mathbf{u}}\|\|\vec{\mathbf{v}}\|}. \tag{12.4.3}$$

Using this equation, we can find the cosine of the angle between two nonzero vectors. Since we are considering the smallest angle between the vectors, we assume $0°\leq\theta\leq 180°$ (or $0\leq\theta\leq\pi$ if we are working in radians). The inverse cosine is unique over this range, so we are then able to determine the measure of the angle $\theta$.

### Example 12.4.3: Finding the Angle between Two Vectors

Find the measure of the angle between each pair of vectors.

a. $\hat{\mathbf{i}}+\hat{\mathbf{j}}+\hat{\mathbf{k}}$ and $2\hat{\mathbf{i}}-\hat{\mathbf{j}}-3\hat{\mathbf{k}}$

b. $\langle 2,5,6\rangle$ and $\langle -2,-4,4\rangle$

**Solution**

a. To find the cosine of the angle formed by the two vectors, substitute the components of the vectors into Equation 12.4.3:

$$\begin{aligned}\cos\theta &= \frac{(\hat{\mathbf{i}}+\hat{\mathbf{j}}+\hat{\mathbf{k}})\cdot(2\hat{\mathbf{i}}-\hat{\mathbf{j}}-3\hat{\mathbf{k}})}{\|\,\hat{\mathbf{i}}+\hat{\mathbf{j}}+\hat{\mathbf{k}}\,\|\cdot\|\,2\hat{\mathbf{i}}-\hat{\mathbf{j}}-3\hat{\mathbf{k}}\,\|}\\ &= \frac{1(2)+(1)(-1)+(1)(-3)}{\sqrt{1^2+1^2+1^2}\sqrt{2^2+(-1)^2+(-3)^2}}\\ &= \frac{-2}{\sqrt{3}\sqrt{14}}=\frac{-2}{\sqrt{42}}.\end{aligned}$$

Therefore, $\theta=\arccos\dfrac{-2}{\sqrt{42}}$ rad.

b. Start by finding the value of the cosine of the angle between the vectors:

$$\begin{aligned}\cos\theta &= \frac{\langle 2,5,6\rangle\cdot\langle -2,-4,4\rangle}{\|\,\langle 2,5,6\rangle\,\|\cdot\|\,\langle -2,-4,4\rangle\,\|}\\ &= \frac{2(-2)+(5)(-4)+(6)(4)}{\sqrt{2^2+5^2+6^2}\sqrt{(-2)^2+(-4)^2+4^2}}\\ &= \frac{0}{\sqrt{65}\sqrt{36}}=0.\end{aligned}$$

Now, $\cos\theta=0$ and $0\leq\theta\leq\pi$, so $\theta=\pi/2$.

### Exercise 12.4.3

Find the measure of the angle, in radians, formed by vectors $\vec{\mathbf{a}}=\langle 1,2,0\rangle$ and $\vec{\mathbf{b}}=\langle 2,4,1\rangle$. Round to the nearest hundredth.

**Hint**

Use the Equation 12.4.3.

**Answer**

$\theta \approx 0.22$ rad

The angle between two vectors can be acute ($0 < \cos\theta < 1$), obtuse ($-1 < \cos\theta < 0$), or straight ($\cos\theta = -1$). If $\cos\theta = 1$, then both vectors have the same direction. If $\cos\theta = 0$, then the vectors, when placed in standard position, form a right angle (Figure 12.4.3). We can formalize this result into a theorem regarding orthogonal (perpendicular) vectors.

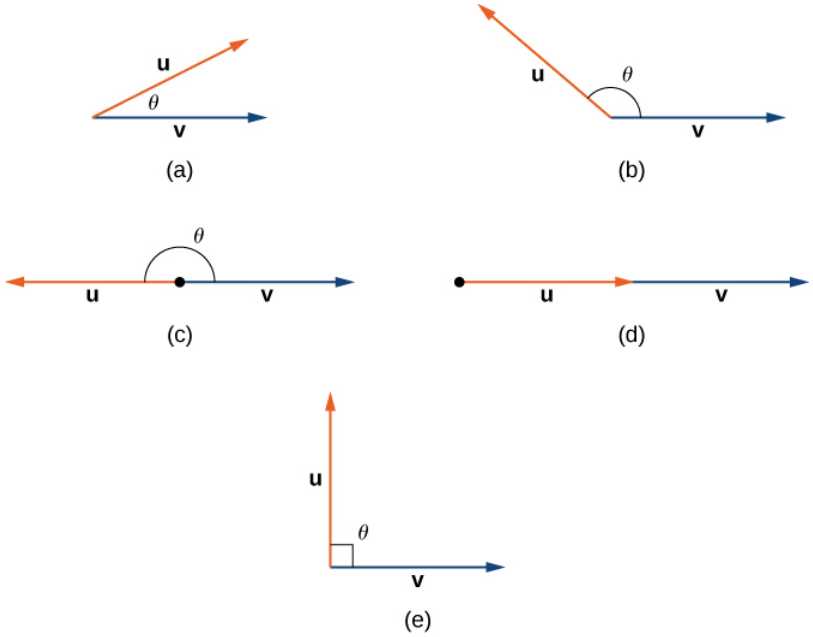

Figure 12.4.3: (a) An acute angle has $0 < \cos\theta < 1$. (b) An obtuse angle has $-1 < \cos\theta < 0$. (c) A straight line has $\cos\theta = -1$. (d) If the vectors have the same direction, $\cos\theta = 1$. (e) If the vectors are orthogonal (perpendicular), $\cos\theta = 0$.

### Orthogonal Vectors

The nonzero vectors $\vec{u}$ and $\vec{v}$ are **orthogonal vectors** if and only if $\vec{u} \cdot \vec{v} = 0$.

### Proof

Let $\vec{u}$ and $\vec{v}$ be nonzero vectors, and let $\theta$ denote the angle between them. First, assume $\vec{u} \cdot \vec{v} = 0$.Then

$$\|\vec{u}\|\|\vec{v}\| \cos\theta = 0.$$

However, $\|\vec{u}\| \neq 0$ and $\|\vec{v}\| \neq 0$, so we must have $\cos\theta = 0$. Hence, $\theta = 90°$, and the vectors are orthogonal.

Now assume $\vec{u}$ and $\vec{v}$ are orthogonal. Then $\theta = 90°$ and we have

$$\begin{aligned} \vec{u} \cdot \vec{v} &= \|\vec{u}\|\|\vec{v}\| \cos\theta \\ &= \|\vec{u}\|\|\vec{v}\| \cos 90° \\ &= \|\vec{u}\|\|\vec{v}\|(0) \\ &= 0. \end{aligned}$$

□

The terms **orthogonal, perpendicular,** and **normal** each indicate that mathematical objects are intersecting at right angles. The use of each term is determined mainly by its context. We say that vectors are orthogonal and lines are perpendicular. The term *normal* is used most often when measuring the angle made with a plane or other surface.

## Example 12.4.4: Identifying Orthogonal Vectors

Determine whether $\vec{\mathbf{p}} = \langle 1, 0, 5 \rangle$ and $\vec{\mathbf{q}} = \langle 10, 3, -2 \rangle$ are orthogonal vectors.

### Solution

Using the definition, we need only check the dot product of the vectors:

$$\vec{\mathbf{p}} \cdot \vec{\mathbf{q}} = 1(10) + (0)(3) + (5)(-2) = 10 + 0 - 10 = 0.$$

Because $\vec{\mathbf{p}} \cdot \vec{\mathbf{q}} = 0$, the vectors are orthogonal (Figure 12.4.4).

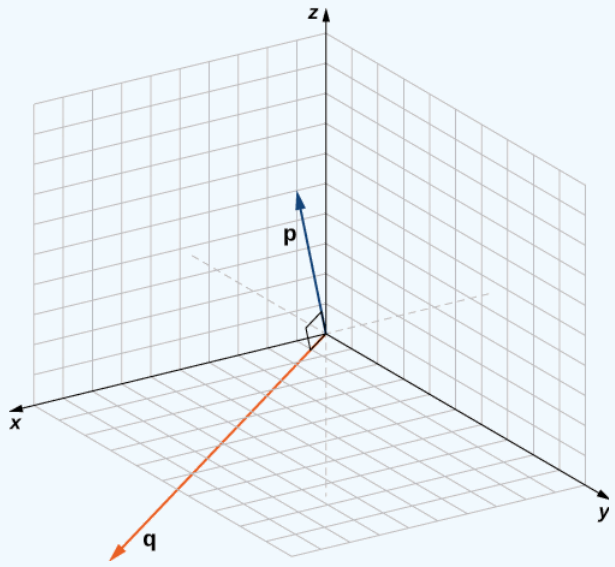

Figure 12.4.4: Vectors $\vec{\mathbf{p}}$ and $\vec{\mathbf{q}}$ form a right angle when their initial points are aligned.

## Exercise 12.4.4

For which value of $x$ is $\vec{\mathbf{p}} = \langle 2, 8, -1 \rangle$ orthogonal to $\vec{\mathbf{q}} = \langle x, -1, 2 \rangle$?

**Hint**

Vectors $\vec{\mathbf{p}}$ and $\vec{\mathbf{q}}$ are orthogonal if and only if $\vec{\mathbf{p}} \cdot \vec{\mathbf{q}} = 0$.

**Answer**

$x = 5$

## Example 12.4.5: Measuring the Angle Formed by Two Vectors

Let $\vec{\mathbf{v}} = \langle 2, 3, 3 \rangle$. Find the measures of the angles formed by the following vectors.

a. $\vec{\mathbf{v}}$ and $\hat{\mathbf{i}}$
b. $\vec{\mathbf{v}}$ and $\hat{\mathbf{j}}$
c. $\vec{\mathbf{v}}$ and $\hat{\mathbf{k}}$

### Solution

a.Let $\alpha$ be the angle formed by $\vec{\mathbf{v}}$ and $\hat{\mathbf{i}}$:

$$\cos\alpha = \frac{\vec{\mathbf{v}} \cdot \hat{\mathbf{i}}}{\|\vec{\mathbf{v}}\| \cdot \|\hat{\mathbf{i}}\|} = \frac{\langle 2, 3, 3 \rangle \cdot \langle 1, 0, 0 \rangle}{\sqrt{2^2 + 3^2 + 3^2}\sqrt{1}} = \frac{2}{\sqrt{22}}$$

$$\alpha = \arccos \frac{2}{\sqrt{22}} \approx 1.130 \text{ rad}.$$

b. Let $\beta$ represent the angle formed by $\vec{\mathbf{v}}$ and $\hat{\mathbf{j}}$:

$$\cos\beta = \frac{\vec{\mathbf{v}} \cdot \hat{\mathbf{j}}}{\|\vec{\mathbf{v}}\| \cdot \|\hat{\mathbf{j}}\|} = \frac{\langle 2,3,3\rangle \cdot \langle 0,1,0\rangle}{\sqrt{2^2+3^2+3^2}\sqrt{1}} = \frac{3}{\sqrt{22}}$$

$$\beta = \arccos\frac{3}{\sqrt{22}} \approx 0.877 \text{ rad.}$$

c. Let $\gamma$ represent the angle formed by $\vec{\mathbf{v}}$ and $\hat{\mathbf{k}}$:

$$\cos\gamma = \frac{\vec{\mathbf{v}} \cdot \hat{\mathbf{k}}}{\|\vec{\mathbf{v}}\| \cdot \|\hat{\mathbf{k}}\|} = \frac{\langle 2,3,3\rangle \cdot \langle 0,0,1\rangle}{\sqrt{2^2+3^2+3^2}\sqrt{1}} = \frac{3}{\sqrt{22}}$$

$$\gamma = \arccos\frac{3}{\sqrt{22}} \approx 0.877 \text{ rad.}$$

## Exercise 12.4.5

Let $\vec{\mathbf{v}} = \langle 3,-5,1\rangle$. Find the measure of the angles formed by each pair of vectors.

a. $\vec{\mathbf{v}}$ and $\hat{\mathbf{i}}$
b. $\vec{\mathbf{v}}$ and $\hat{\mathbf{j}}$
c. $\vec{\mathbf{v}}$ and $\hat{\mathbf{k}}$

**Hint**

$\hat{\mathbf{i}} = \langle 1,0,0\rangle, \hat{\mathbf{j}} = \langle 0,1,0\rangle$, and $\hat{\mathbf{k}} = \langle 0,0,1\rangle$

**Answer**

$a.\alpha \approx 1.04$ rad; b. $\beta \approx 2.58$ rad; c. $\gamma \approx 1.40$ rad

The angle a vector makes with each of the coordinate axes, called a direction angle, is very important in practical computations, especially in a field such as engineering. For example, in astronautical engineering, the angle at which a rocket is launched must be determined very precisely. A very small error in the angle can lead to the rocket going hundreds of miles off course. Direction angles are often calculated by using the dot product and the cosines of the angles, called the direction cosines. Therefore, we define both these angles and their cosines.

## Definition: direction angles

The angles formed by a nonzero vector and the coordinate axes are called the **direction angles** for the vector (Figure 12.4.5). The cosines for these angles are called the **direction cosines.**

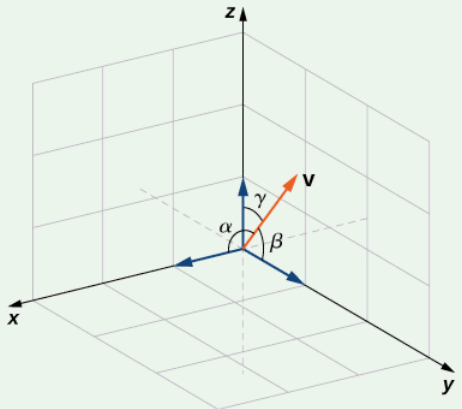

Figure 12.4.5: Angle $\alpha$ is formed by vector $\vec{\mathbf{v}}$ and unit vector $\hat{\mathbf{i}}$. Angle β is formed by vector $\vec{\mathbf{v}}$ and unit vector $\hat{\mathbf{j}}$. Angle γ is formed by vector $\vec{\mathbf{v}}$ and unit vector $\hat{\mathbf{k}}$.

In Example 12.4.5, the direction cosines of $\vec{\mathbf{v}} = \langle 2, 3, 3 \rangle$ are $\cos\alpha = \frac{2}{\sqrt{22}}, \cos\beta = \frac{3}{\sqrt{22}}$, and $\cos\gamma = \frac{3}{\sqrt{22}}$. The direction angles of $\vec{\mathbf{v}}$ are $\alpha = 1.130$ rad, $\beta = 0.877$ rad, and $\gamma = 0.877$ rad.

So far, we have focused mainly on vectors related to force, movement, and position in three-dimensional physical space. However, vectors are often used in more abstract ways. For example, suppose a fruit vendor sells apples, bananas, and oranges. On a given day, he sells 30 apples, 12 bananas, and 18 oranges. He might use a quantity vector, $\vec{\mathbf{q}} = \langle 30, 12, 18 \rangle$, to represent the quantity of fruit he sold that day. Similarly, he might want to use a price vector, $\vec{\mathbf{p}} = \langle 0.50, 0.25, 1 \rangle$, to indicate that he sells his apples for 50¢ each, bananas for 25¢ each, and oranges for $1 apiece. In this example, although we could still graph these vectors, we do not interpret them as literal representations of position in the physical world. We are simply using vectors to keep track of particular pieces of information about apples, bananas, and oranges.

This idea might seem a little strange, but if we simply regard vectors as a way to order and store data, we find they can be quite a powerful tool. Going back to the fruit vendor, let's think about the dot product, $\vec{\mathbf{q}} \cdot \vec{\mathbf{p}}$. We compute it by multiplying the number of apples sold (30) by the price per apple (50¢), the number of bananas sold by the price per banana, and the number of oranges sold by the price per orange. We then add all these values together. So, in this example, the dot product tells us how much money the fruit vendor had in sales on that particular day.

When we use vectors in this more general way, there is no reason to limit the number of components to three. What if the fruit vendor decides to start selling grapefruit? In that case, he would want to use four-dimensional quantity and price vectors to represent the number of apples, bananas, oranges, and grapefruit sold, and their unit prices. As you might expect, to calculate the dot product of four-dimensional vectors, we simply add the products of the components as before, but the sum has four terms instead of three.

### Example 12.4.6: Using Vectors in an Economic Context

AAA Party Supply Store sells invitations, party favors, decorations, and food service items such as paper plates and napkins. When AAA buys its inventory, it pays 25¢ per package for invitations and party favors. Decorations cost AAA 50¢ each, and food service items cost 20¢ per package. AAA sells invitations for $2.50 per package and party favors for $1.50 per package. Decorations sell for $4.50 each and food service items for $1.25 per package.

During the month of May, AAA Party Supply Store sells 1258 invitations, 342 party favors, 2426 decorations, and 1354 food service items. Use vectors and dot products to calculate how much money AAA made in sales during the month of May. How much did the store make in profit?

#### Solution

The cost, price, and quantity vectors are

$$\vec{\mathbf{c}} = \langle 0.25, 0.25, 0.50, 0.20 \rangle$$
$$\vec{\mathbf{p}} = \langle 2.50, 1.50, 4.50, 1.25 \rangle$$
$$\vec{\mathbf{q}} = \langle 1258, 342, 2426, 1354 \rangle.$$

AAA sales for the month of May can be calculated using the dot product $\vec{\mathbf{p}} \cdot \vec{\mathbf{q}}$. We have

$$\begin{aligned} \vec{\mathbf{p}} \cdot \vec{\mathbf{q}} &= \langle 2.50, 1.50, 4.50, 1.25 \rangle \cdot \langle 1258, 342, 2426, 1354 \rangle \\ &= 3145 + 513 + 10917 + 1692.5 \\ &= 16267.5. \end{aligned}$$

So, AAA took in $16,267.50 during the month of May. To calculate the profit, we must first calculate how much AAA paid for the items sold. We use the dot product $\vec{\mathbf{c}} \cdot \vec{\mathbf{q}}$ to get

$$\begin{aligned} \vec{\mathbf{c}} \cdot \vec{\mathbf{q}} &= \langle 0.25, 0.25, 0.50, 0.20 \rangle \cdot \langle 1258, 342, 2426, 1354 \rangle \\ &= 314.5 + 85.5 + 1213 + 270.8 \\ &= 1883.8. \end{aligned}$$

So, AAA paid $1,883.80 for the items they sold. Their profit, then, is given by

$$\vec{p} \cdot \vec{q} - \vec{c} \cdot \vec{q} = 16267.5 - 1883.8 = 14383.7.$$

Therefore, AAA Party Supply Store made $14,383.70 in May.

**Exercise 12.4.6**

On June 1, AAA Party Supply Store decided to increase the price they charge for party favors to $2 per package. They also changed suppliers for their invitations, and are now able to purchase invitations for only 10¢ per package. All their other costs and prices remain the same. If AAA sells 1408 invitations, 147 party favors, 2112 decorations, and 1894 food service items in the month of June, use vectors and dot products to calculate their total sales and profit for June.

**Hint**

Use four-dimensional vectors for cost, price, and quantity sold.

**Answer**

Sales = $15,685.50; profit = $14,073.15

## Projections

As we have seen, addition combines two vectors to create a resultant vector. But what if we are given a vector and we need to find its component parts? We use vector projections to perform the opposite process; they can break down a vector into its components. The magnitude of a vector projection is a scalar projection. For example, if a child is pulling the handle of a wagon at a 55° angle, we can use projections to determine how much of the force on the handle is actually moving the wagon forward (**12.4.6**). We return to this example and learn how to solve it after we see how to calculate projections.

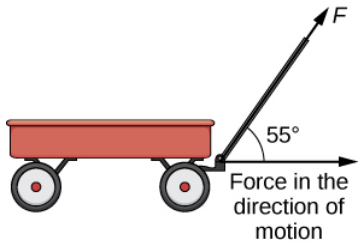

Figure **12.4.6**: When a child pulls a wagon, only the horizontal component of the force propels the wagon forward.

**Definition: Vector and Projection**

The **vector projection** of $\vec{v}$ onto $\vec{u}$ is the vector labeled $\text{proj}_{\vec{u}}\vec{v}$ in Figure **12.4.7**. It has the same initial point as $\vec{u}$ and $\vec{v}$ and the same direction as $\vec{u}$, and represents the component of $\vec{v}$ that acts in the direction of $\vec{u}$. If $\theta$ represents the angle between $\vec{u}$ and $\vec{v}$, then, by properties of triangles, we know the length of $\text{proj}_{\vec{u}}\vec{v}$ is $\|\text{proj}_{\vec{u}}\vec{v}\| = \|\vec{v}\|\cos\theta$. When expressing $\cos\theta$ in terms of the dot product, this becomes

$$\|\text{proj}_{\vec{u}}\vec{v}\| = \|\vec{v}\|\cos\theta = \|\vec{v}\|\left(\frac{\vec{u}\cdot\vec{v}}{\|\vec{u}\|\|\vec{v}\|}\right) = \frac{\vec{u}\cdot\vec{v}}{\|\vec{u}\|}.$$

We now multiply by a unit vector in the direction of $\vec{u}$ to get $\text{proj}_{\vec{u}}\vec{v}$:

$$\text{proj}_{\vec{u}}\vec{v} = \frac{\vec{u}\cdot\vec{v}}{\|\vec{u}\|}\left(\frac{1}{\|\vec{u}\|}\vec{u}\right) = \frac{\vec{u}\cdot\vec{v}}{\|\vec{u}\|^2}\vec{u}.$$

The length of this vector is also known as the **scalar projection** of $\vec{v}$ onto $\vec{u}$ and is denoted by

$$\|\text{proj}_{\vec{u}}\vec{v}\| = \text{comp}_{\vec{u}}\vec{v} = \frac{\vec{u}\cdot\vec{v}}{\|\vec{u}\|}.$$

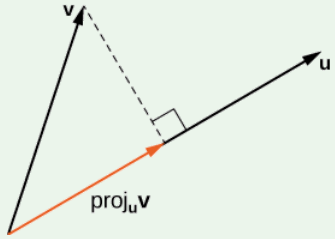

Figure 12.4.7: The projection of $\vec{\mathbf{v}}$ onto $\vec{\mathbf{u}}$ shows the component of vector $\vec{\mathbf{v}}$ in the direction of $\vec{\mathbf{u}}$.

### Example 12.4.7: Finding Projections

Find the projection of $\vec{\mathbf{v}}$ onto $\vec{\mathbf{u}}$.

a. $\vec{\mathbf{v}} = \langle 3, 5, 1 \rangle$ and $\vec{\mathbf{u}} = \langle -1, 4, 3 \rangle$
b. $\vec{\mathbf{v}} = 3\hat{\mathbf{i}} - 2\hat{\mathbf{j}}$ and $\vec{\mathbf{u}} = \hat{\mathbf{i}} + 6\hat{\mathbf{j}}$

**Solution**

a. Substitute the components of $\vec{\mathbf{v}}$ and $\vec{\mathbf{u}}$ into the formula for the projection:

$$\begin{aligned} \text{proj}_{\vec{\mathbf{u}}}\vec{\mathbf{v}} &= \frac{\vec{\mathbf{u}} \cdot \vec{\mathbf{v}}}{\|\vec{\mathbf{u}}\|^2}\vec{\mathbf{u}} \\ &= \frac{\langle -1, 4, 3 \rangle \cdot \langle 3, 5, 1 \rangle}{\| \langle -1, 4, 3 \rangle \|^2}\langle -1, 4, 3 \rangle \\ &= \frac{-3 + 20 + 3}{(-1)^2 + 4^2 + 3^2}\langle -1, 4, 3 \rangle \\ &= \frac{20}{26}\langle -1, 4, 3 \rangle \\ &= \langle -\frac{10}{13}, \frac{40}{13}, \frac{30}{13} \rangle. \end{aligned}$$

b. To find the two-dimensional projection, simply adapt the formula to the two-dimensional case:

$$\begin{aligned} \text{proj}_{\vec{\mathbf{u}}}\vec{\mathbf{v}} &= \frac{\vec{\mathbf{u}} \cdot \vec{\mathbf{v}}}{\|\vec{\mathbf{u}}\|^2}\vec{\mathbf{u}} \\ &= \frac{(\hat{\mathbf{i}} + 6\hat{\mathbf{j}}) \cdot (3\hat{\mathbf{i}} - 2\hat{\mathbf{j}})}{\| \hat{\mathbf{i}} + 6\hat{\mathbf{j}} \|^2}(\hat{\mathbf{i}} + 6\hat{\mathbf{j}}) \\ &= \frac{1(3) + 6(-2)}{1^2 + 6^2}(\hat{\mathbf{i}} + 6\hat{\mathbf{j}}) \\ &= -\frac{9}{37}(\hat{\mathbf{i}} + 6\hat{\mathbf{j}}) \\ &= -\frac{9}{37}\hat{\mathbf{i}} - \frac{54}{37}\hat{\mathbf{j}}. \end{aligned}$$

Sometimes it is useful to decompose vectors—that is, to break a vector apart into a sum. This process is called the **resolution of a vector into components.** Projections allow us to identify two orthogonal vectors having a desired sum. For example, let $\vec{\mathbf{v}} = \langle 6, -4 \rangle$ and let $\vec{\mathbf{u}} = \langle 3, 1 \rangle$. We want to decompose the vector $\vec{\mathbf{v}}$ into orthogonal components such that one of the component vectors has the same direction as $\vec{\mathbf{u}}$.

We first find the component that has the same direction as $\vec{\mathbf{u}}$ by projecting $\vec{\mathbf{v}}$ onto $\vec{\mathbf{u}}$. Let $\vec{\mathbf{p}} = \text{proj}_{\vec{\mathbf{u}}}\vec{\mathbf{v}}$. Then, we have

$$\begin{aligned} \vec{\mathbf{p}} &= \frac{\vec{\mathbf{u}} \cdot \vec{\mathbf{v}}}{\|\vec{\mathbf{u}}\|^2}\vec{\mathbf{u}} \\ &= \frac{18 - 4}{9 + 1}\vec{\mathbf{u}} \\ = \frac{7}{5}\vec{\mathbf{u}} = \frac{7}{5}\langle 3, 1 \rangle &= \langle \frac{21}{5}, \frac{7}{5} \rangle. \end{aligned}$$

Now consider the vector $\vec{\mathbf{q}} = \vec{\mathbf{v}} - \vec{\mathbf{p}}$. We have

$$\begin{aligned}\vec{\mathbf{q}} &= \vec{\mathbf{v}} - \vec{\mathbf{p}} \\ &= \langle 6, -4\rangle - \langle \frac{21}{5}, \frac{7}{5}\rangle \\ &= \langle \frac{9}{5}, -\frac{27}{5}\rangle.\end{aligned}$$

Clearly, by the way we defined $\vec{\mathbf{q}}$, we have $\vec{\mathbf{v}} = \vec{\mathbf{q}} + \vec{\mathbf{p}}$, and

$$\begin{aligned}\vec{\mathbf{q}} \cdot \vec{\mathbf{p}} &= \langle \frac{9}{5}, -\frac{27}{5}\rangle \cdot \langle \frac{21}{5}, \frac{7}{5}\rangle \\ &= \frac{9(21)}{25} + -\frac{27(7)}{25} \\ &= \frac{189}{25} - \frac{189}{25} = 0.\end{aligned}$$

Therefore, $\vec{\mathbf{q}}$ and $\vec{\mathbf{p}}$ are orthogonal.

### Example 12.4.8: Resolving Vectors into Components

Express $\vec{\mathbf{v}} = \langle 8, -3, -3\rangle$ as a sum of orthogonal vectors such that one of the vectors has the same direction as $\vec{\mathbf{u}} = \langle 2, 3, 2\rangle$.

**Solution**

Let $\vec{\mathbf{p}}$ represent the projection of $\vec{\mathbf{v}}$ onto $\vec{\mathbf{u}}$:

$$\begin{aligned}\vec{\mathbf{p}} &= \text{proj}_{\vec{\mathbf{u}}}\vec{\mathbf{v}} \\ &= \frac{\vec{\mathbf{u}} \cdot \vec{\mathbf{v}}}{\|\vec{\mathbf{u}}\|^2}\vec{\mathbf{u}} \\ &= \frac{\langle 2, 3, 2\rangle \cdot \langle 8, -3, -3\rangle}{\| \langle 2, 3, 2\rangle \|^2}\langle 2, 3, 2\rangle \\ &= \frac{16 - 9 - 6}{2^2 + 3^2 + 2^2}\langle 2, 3, 2\rangle \\ &= \frac{1}{17}\langle 2, 3, 2\rangle \\ &= \langle \frac{2}{17}, \frac{3}{17}, \frac{2}{17}\rangle.\end{aligned}$$

Then,

$$\begin{aligned}\vec{\mathbf{q}} = \vec{\mathbf{v}} - \vec{\mathbf{p}} &= \langle 8, -3, -3\rangle - \langle \frac{2}{17}, \frac{3}{17}, \frac{2}{17}\rangle \\ &= \langle \frac{134}{17}, -\frac{54}{17}, -\frac{53}{17}\rangle.\end{aligned}$$

To check our work, we can use the dot product to verify that $\vec{\mathbf{p}}$ and $\vec{\mathbf{q}}$ are orthogonal vectors:

$$\begin{aligned}\vec{\mathbf{p}} \cdot \vec{\mathbf{q}} &= \langle \frac{2}{17}, \frac{3}{17}, \frac{2}{17}\rangle \cdot \langle \frac{134}{17}, -\frac{54}{17}, -\frac{53}{17}\rangle \\ &= \frac{268}{289} - \frac{162}{289} - \frac{106}{289} = 0.\end{aligned}$$

Then,

$$\vec{\mathbf{v}} = \vec{\mathbf{p}} + \vec{\mathbf{q}} = \langle \frac{2}{17}, \frac{3}{17}, \frac{2}{17}\rangle + \langle \frac{134}{17}, -\frac{54}{17}, -\frac{53}{17}\rangle.$$

## Exercise 12.4.7

Express $\vec{\mathbf{v}} = 5\hat{\mathbf{i}} - \hat{\mathbf{j}}$ as a sum of orthogonal vectors such that one of the vectors has the same direction as $\vec{\mathbf{u}} = 4\hat{\mathbf{i}} + 2\hat{\mathbf{j}}$.

**Hint**

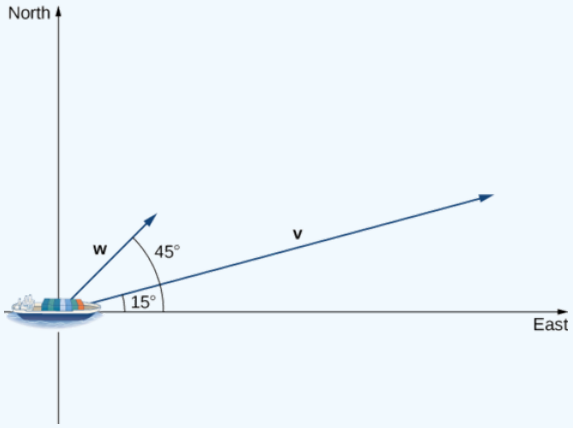
Start by finding the projection of $\vec{\mathbf{v}}$ onto $\vec{\mathbf{u}}$.

**Answer**

$\vec{\mathbf{v}} = \vec{\mathbf{p}} + \vec{\mathbf{q}}$, where $\vec{\mathbf{p}} = \frac{18}{5}\hat{\mathbf{i}} + \frac{9}{5}\hat{\mathbf{j}}$ and $\vec{\mathbf{q}} = \frac{7}{5}\hat{\mathbf{i}} - \frac{14}{5}\hat{\mathbf{j}}$

## Example 12.4.9: Scalar Projection of Velocity

A container ship leaves port traveling $15°$ north of east. Its engine generates a speed of 20 knots along that path (see the following figure). In addition, the ocean current moves the ship northeast at a speed of 2 knots. Considering both the engine and the current, how fast is the ship moving in the direction $15°$ north of east? Round the answer to two decimal places.



### Solution

Let $\vec{\mathbf{v}}$ be the velocity vector generated by the engine, and let $\vec{\mathbf{w}}$ be the velocity vector of the current. We already know $\|\vec{\mathbf{v}}\| = 20$ along the desired route. We just need to add in the scalar projection of $\vec{\mathbf{w}}$ onto $\vec{\mathbf{v}}$. We get

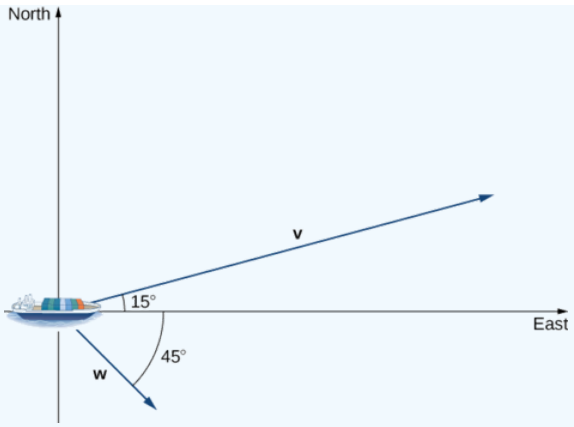
$$\text{comp}_{\vec{\mathbf{v}}}\vec{\mathbf{w}} = \frac{\vec{\mathbf{v}} \cdot \vec{\mathbf{w}}}{\|\vec{\mathbf{v}}\|}$$

$$= \frac{\|\vec{\mathbf{v}}\|\|\vec{\mathbf{w}}\|\cos(30°)}{\|\vec{\mathbf{v}}\|} = \|\vec{\mathbf{w}}\|\cos(30°) = 2\frac{\sqrt{3}}{2} = \sqrt{3} \approx 1.73 \text{ knots.}$$

The ship is moving at 21.73 knots in the direction $15°$ north of east.

## Exercise 12.4.8

Repeat the previous example, but assume the ocean current is moving southeast instead of northeast, as shown in the following figure.



**Hint**

Compute the scalar projection of $\vec{\mathbf{w}}$ onto $\vec{\mathbf{v}}$.

**Answer**

21 knots

## Work

Now that we understand dot products, we can see how to apply them to real-life situations. The most common application of the dot product of two vectors is in the calculation of work.

From physics, we know that work is done when an object is moved by a force. When the force is constant and applied in the same direction the object moves, then we define the work done as the product of the force and the distance the object travels: $W = Fd$. We saw several examples of this type in earlier chapters. Now imagine the direction of the force is different from the direction of motion, as with the example of a child pulling a wagon. To find the work done, we need to multiply the component of the force that acts in the direction of the motion by the magnitude of the displacement. The dot product allows us to do just that. If we represent an applied force by a vector $\vec{\mathbf{F}}$ and the displacement of an object by a vector $\vec{\mathbf{s}}$, then the **work done by the force** is the dot product of $\vec{\mathbf{F}}$ and $\vec{\mathbf{s}}$.

**Definition: Constant Force**

When a constant force is applied to an object so the object moves in a straight line from point $P$ to point $Q$, the work $W$ done by the force $\vec{\mathbf{F}}$, acting at an angle $\theta$ from the line of motion, is given by

$$W = \vec{\mathbf{F}} \cdot \overrightarrow{PQ} = \| \vec{\mathbf{F}} \| \| \overrightarrow{PQ} \| \cos\theta.$$

Let's revisit the problem of the child's wagon introduced earlier. Suppose a child is pulling a wagon with a force having a magnitude of 8 lb on the handle at an angle of $55°$. If the child pulls the wagon 50 ft, find the work done by the force (Figure 12.4.8).

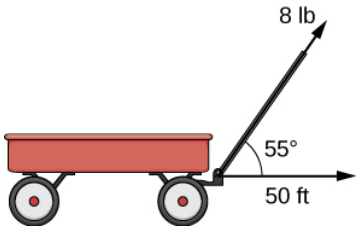


Figure 12.4.8: The horizontal component of the force is the projection of $\vec{\mathbf{F}}$ onto the positive $x$-axis.

We have

$$W = \| \vec{\mathbf{F}} \| \| \overrightarrow{PQ} \| \cos\theta = 8(50)(\cos(55°)) \approx 229 \text{ ft·lb}.$$

In U.S. standard units, we measure the magnitude of force $\| \vec{\mathbf{F}} \|$ in pounds. The magnitude of the displacement vector $\| \overrightarrow{PQ} \|$ tells us how far the object moved, and it is measured in feet. The customary unit of measure for work, then, is the foot-pound. One foot-pound is the amount of work required to move an object weighing 1 lb a distance of 1 ft straight up. In the metric system, the unit of measure for force is the newton (N), and the unit of measure of magnitude for work is a newton-meter (N·m), or a joule (J).

### Example 12.4.10: Calculating Work

A conveyor belt generates a force $\vec{\mathbf{F}} = 5\hat{\mathbf{i}} - 3\hat{\mathbf{j}} + \hat{\mathbf{k}}$ that moves a suitcase from point $(1, 1, 1)$ to point $(9, 4, 7)$ along a straight line. Find the work done by the conveyor belt. The distance is measured in meters and the force is measured in newtons.

**Solution**

The displacement vector $\overrightarrow{PQ}$ has initial point $(1, 1, 1)$ and terminal point $(9, 4, 7)$:

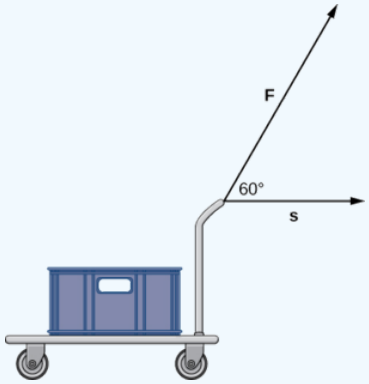
$$\overrightarrow{PQ} = \langle 9 - 1, 4 - 1, 7 - 1 \rangle = \langle 8, 3, 6 \rangle = 8\hat{\mathbf{i}} + 3\hat{\mathbf{j}} + 6\hat{\mathbf{k}}.$$

Work is the dot product of force and displacement:

$$\begin{aligned} W &= \vec{\mathbf{F}} \cdot \overrightarrow{PQ} \\ &= (5\hat{\mathbf{i}} - 3\hat{\mathbf{j}} + \hat{\mathbf{k}}) \cdot (8\hat{\mathbf{i}} + 3\hat{\mathbf{j}} + 6\hat{\mathbf{k}}) \\ &= 5(8) + (-3)(3) + 1(6) \\ &= 37\,\text{N·m} \\ &= 37\,\text{J} \end{aligned}$$

### Exercise 12.4.9

A constant force of 30 lb is applied at an angle of 60° to pull a handcart 10 ft across the ground. What is the work done by this force?



**Hint**

Use the definition of work as the dot product of force and distance.

**Answer**

150 ft-lb

## Key Concepts

- The dot product, or scalar product, of two vectors $\vec{\mathbf{u}} = \langle u_1, u_2, u_3 \rangle$ and $\vec{\mathbf{v}} = \langle v_1, v_2, v_3 \rangle$ is $\vec{\mathbf{u}} \cdot \vec{\mathbf{v}} = u_1 v_1 + u_2 v_2 + u_3 v_3$.
- The dot product satisfies the following properties:
  - $\vec{\mathbf{u}} \cdot \vec{\mathbf{v}} = \vec{\mathbf{v}} \cdot \vec{\mathbf{u}}$
  - $\vec{\mathbf{u}} \cdot (\vec{\mathbf{v}} + \vec{\mathbf{w}}) = \vec{\mathbf{u}} \cdot \vec{\mathbf{v}} + \vec{\mathbf{u}} \cdot \vec{\mathbf{w}}$
  - $c(\vec{\mathbf{u}} \cdot \vec{\mathbf{v}}) = (c\vec{\mathbf{u}}) \cdot \vec{\mathbf{v}} = \vec{\mathbf{u}} \cdot (c\vec{\mathbf{v}})$

- $\vec{\mathbf{v}} \cdot \vec{\mathbf{v}} = \|\vec{\mathbf{v}}\|^2$

- The dot product of two vectors can be expressed, alternatively, as $\vec{\mathbf{u}} \cdot \vec{\mathbf{v}} = \|\vec{\mathbf{u}}\|\|\vec{\mathbf{v}}\| \cos\theta$. This form of the dot product is useful for finding the measure of the angle formed by two vectors.
- Vectors $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ are orthogonal if $\vec{\mathbf{u}} \cdot \vec{\mathbf{v}} = 0$.
- The angles formed by a nonzero vector and the coordinate axes are called the *direction angles* for the vector. The cosines of these angles are known as the *direction cosines.*
- The vector projection of $\vec{\mathbf{v}}$ onto $\vec{\mathbf{u}}$ is the vector $\text{proj}_{\vec{\mathbf{u}}}\vec{\mathbf{v}} = \dfrac{\vec{\mathbf{u}} \cdot \vec{\mathbf{v}}}{\|\vec{\mathbf{u}}\|^2}\vec{\mathbf{u}}$. The magnitude of this vector is known as the *scalar projection* of $\vec{\mathbf{v}}$ onto $\vec{\mathbf{u}}$, given by $\text{comp}_{\vec{\mathbf{u}}}\vec{\mathbf{v}} = \dfrac{\vec{\mathbf{u}} \cdot \vec{\mathbf{v}}}{\|\vec{\mathbf{u}}\|}$.
- Work is done when a force is applied to an object, causing displacement. When the force is represented by the vector $\vec{\mathbf{F}}$ and the displacement is represented by the vector $\vec{\mathbf{s}}$, then the work done $W$ is given by the formula $W = \vec{\mathbf{F}} \cdot \vec{\mathbf{s}} = \| \vec{\mathbf{F}} \| \, \|\vec{\mathbf{s}}\| \cos\theta$.

## Key Equations

- **Dot product of $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$**

  $$\vec{\mathbf{u}} \cdot \vec{\mathbf{v}} = u_1v_1 + u_2v_2 + u_3v_3 = \|\vec{\mathbf{u}}\|\|\vec{\mathbf{v}}\| \cos\theta$$

- **Cosine of the angle formed by $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$**

  $$\cos\theta = \frac{\vec{\mathbf{u}} \cdot \vec{\mathbf{v}}}{\|\vec{\mathbf{u}}\|\|\vec{\mathbf{v}}\|}$$

- **Vector projection of $\vec{\mathbf{v}}$ onto $\vec{\mathbf{u}}$**

  $$\text{proj}_{\vec{\mathbf{u}}}\vec{\mathbf{v}} = \frac{\vec{\mathbf{u}} \cdot \vec{\mathbf{v}}}{\|\vec{\mathbf{u}}\|^2}\vec{\mathbf{u}}$$

- **Scalar projection of $\vec{\mathbf{v}}$ onto $\vec{\mathbf{u}}$**

  $$\text{comp}_{\vec{\mathbf{u}}}\vec{\mathbf{v}} = \frac{\vec{\mathbf{u}} \cdot \vec{\mathbf{v}}}{\|\vec{\mathbf{u}}\|}$$

- **Work done by a force $\vec{\mathbf{F}}$ to move an object through displacement vector $\overrightarrow{PQ}$**

  $$W = \vec{\mathbf{F}} \cdot \overrightarrow{PQ} = \| \vec{\mathbf{F}} \| \, \| \overrightarrow{PQ} \| \cos\theta$$

## Glossary

**direction angles**
the angles formed by a nonzero vector and the coordinate axes

**direction cosines**
the cosines of the angles formed by a nonzero vector and the coordinate axes

**dot product or scalar product**
$\vec{\mathbf{u}} \cdot \vec{\mathbf{v}} = u_1v_1 + u_2v_2 + u_3v_3$ where $\vec{\mathbf{u}} = \langle u_1, u_2, u_3 \rangle$ and $\vec{\mathbf{v}} = \langle v_1, v_2, v_3 \rangle$

**scalar projection**
the magnitude of the vector projection of a vector

**orthogonal vectors**
vectors that form a right angle when placed in standard position

**vector projection**
the component of a vector that follows a given direction

**work done by a force**

work is generally thought of as the amount of energy it takes to move an object; if we represent an applied force by a vector $\vec{\mathbf{F}}$ and the displacement of an object by a vector $\vec{\mathbf{s}}$, then the work done by the force is the dot product of $\vec{\mathbf{F}}$ and $\vec{\mathbf{s}}$.

# 12.4E: Exercises for Section 12.3

**For exercises 1-4, the vectors $\vec{u}$ and $\vec{v}$ are given. Calculate the dot product $\vec{u} \cdot \vec{v}$.**

1) $\vec{u} = \langle 3, 0 \rangle, \quad \vec{v} = \langle 2, 2 \rangle$

**Answer**

$\vec{u} \cdot \vec{v} = 6$

2) $\vec{u} = \langle 3, -4 \rangle, \quad \vec{v} = \langle 4, 3 \rangle$

3) $\vec{u} = \langle 2, 2, -1 \rangle, \quad \vec{v} = \langle -1, 2, 2 \rangle$

**Answer**

$\vec{u} \cdot \vec{v} = 0$

4) $\vec{u} = \langle 4, 5, -6 \rangle, \quad \vec{v} = \langle 0, -2, -3 \rangle$

**For exercises 5-8, the vectors $\vec{a}$, $\vec{b}$, and $\vec{c}$ are given. Determine the vectors $(\vec{a} \cdot \vec{b})\vec{c}$ and $(\vec{a} \cdot \vec{c})\vec{b}$. Express the vectors in component form.**

5) $\vec{a} = \langle 2, 0, -3 \rangle, \quad \vec{b} = \langle -4, -7, 1 \rangle, \quad \vec{c} = \langle 1, 1, -1 \rangle$

**Answer**

$(\vec{a} \cdot \vec{b})\vec{c} = \langle -11, -11, 11 \rangle; (\vec{a} \cdot \vec{c})\vec{b} = \langle -20, -35, 5 \rangle$

6) $\vec{a} = \langle 0, 1, 2 \rangle, \quad \vec{b} = \langle -1, 0, 1 \rangle, \quad \vec{c} = \langle 1, 0, -1 \rangle$

7) $\vec{a} = \hat{i} + \hat{j}, \quad \vec{b} = \hat{i} - \hat{k}, \quad \vec{c} = \hat{i} - 2\hat{k}$

**Answer**

$(\vec{a} \cdot \vec{b})\vec{c} = \langle 1, 0, -2 \rangle; (\vec{a} \cdot \vec{c})\vec{b} = \langle 1, 0, -1 \rangle$

8) $\vec{a} = \hat{i} - \hat{j} + \hat{k}, \quad \vec{b} = \hat{j} + 3\hat{k}, \quad \vec{c} = -\hat{i} + 2\hat{j} - 4\hat{k}$

**For exercises 9-12, two vectors are given.**

**a. Find the measure of the angle $\theta$ between these two vectors. Express the answer in radians rounded to two decimal places, if it is not possible to express it exactly.**

**b. Is $\theta$ an acute angle?**

9) [T] $\vec{a} = \langle 3, -1 \rangle, \quad \vec{b} = \langle -4, 0 \rangle$

**Answer**

$a. \theta = 2.82$ rad; $b. \theta$ is not acute.

10) [T] $\vec{a} = \langle 2, 1 \rangle, \quad \vec{b} = \langle -1, 3 \rangle$

11) $\vec{u} = 3\hat{i}, \quad \vec{v} = 4\hat{i} + 4\hat{j}$

**Answer**

$a. \theta = \frac{\pi}{4}$ rad; $b. \theta$ is acute.

12) $\vec{u} = 5\hat{i}, \quad \vec{v} = -6\hat{i} + 6\hat{j}$

**For exercises 13-18, find the measure of the angle between the three-dimensional vectors $\vec{a}$ and $\vec{b}$. Express the answer in radians rounded to two decimal places, if it is not possible to express it exactly.**

13) $\vec{a} = \langle 3, -1, 2 \rangle, \quad \vec{b} = \langle 1, -1, -2 \rangle$

**Answer**

$\theta = \frac{\pi}{2}$

14) $\vec{a} = \langle 0, -1, -3 \rangle, \quad \vec{b} = \langle 2, 3, -1 \rangle$

15) $\vec{a} = \hat{i} + \hat{j}, \quad \vec{b} = \hat{j} - \hat{k}$

**Answer**

$\theta = \frac{\pi}{3}$

16) $\vec{a} = \hat{i} - 2\hat{j} + \hat{k}, \quad \vec{b} = \hat{i} + \hat{j} - 2\hat{k}$

17) [T] $\vec{a} = 3\hat{i} - \hat{j} - 2\hat{k}, \quad \vec{b} = \vec{v} + \vec{w}$, where $\vec{v} = -2\hat{i} - 3\hat{j} + 2\hat{k}$ and $\vec{w} = \hat{i} + 2\hat{k}$

**Answer**

$\theta = 2$ rad

18) [T] $\vec{a} = 3\hat{i} - \hat{j} + 2\hat{k}, \quad \vec{b} = \vec{v} - \vec{w}$, where $\vec{v} = 2\hat{i} + \hat{j} + 4\hat{k}$ and $\vec{w} = 6\hat{i} + \hat{j} + 2\hat{k}$

**For exercises 19-22, determine whether the given vectors are orthogonal.**

19) $\vec{a} = \langle x, y \rangle, \quad \vec{b} = \langle -y, x \rangle$, where $x$ and $y$ are nonzero real numbers

**Answer**

Orthogonal

20) $\vec{a} = \langle x, x \rangle, \quad \vec{b} = \langle -y, y \rangle$, where $x$ and $y$ are nonzero real numbers

21) $\vec{a} = 3\hat{i} - \hat{j} - 2\hat{k}, \quad \vec{b} = -2\hat{i} - 3\hat{j} + \hat{k}$

**Answer**

Not orthogonal

22) $\vec{a} = \hat{i} - \hat{j}, \quad \vec{b} = 7\hat{i} + 2\hat{j} - \hat{k}$

23) Find all two-dimensional vectors $\vec{a}$ orthogonal to vector $\vec{b} = \langle 3, 4 \rangle$. Express the answer in component form.

**Answer**

$\vec{a} = \langle -\frac{4\alpha}{3}, \alpha \rangle$, where $\alpha \neq 0$ is a real number

24) Find all two-dimensional vectors $\vec{a}$ orthogonal to vector $\vec{b} = \langle 5, -6 \rangle$. Express the answer by using standard unit vectors.

25) Determine all three-dimensional vectors $\vec{u}$ orthogonal to vector $\vec{v} = \langle 1, 1, 0 \rangle$. Express the answer by using standard unit vectors.

**Answer**

$\vec{u} = -\alpha\hat{i} + \alpha\hat{j} + \beta\hat{k}$, where $\alpha$ and $\beta$ are real numbers such that $\alpha^2 + \beta^2 \neq 0$

26) Determine all three-dimensional vectors $\vec{u}$ orthogonal to vector $\vec{v} = \hat{i} - \hat{j} - \hat{k}$. Express the answer in component form.

27) Determine the real number $\alpha$ such that vectors $\vec{a} = 2\hat{i} + 3\hat{j}$ and $\vec{b} = 9\hat{i} + \alpha\hat{j}$ are orthogonal.

**Answer**

$\alpha = -6$

28) Determine the real number $\alpha$ such that vectors $\vec{a} = -3\hat{i} + 2\hat{j}$ and $\vec{b} = 2\hat{i} + \alpha\hat{j}$ are orthogonal.

29) [T] Consider the points $P(4, 5)$ and $Q(5, -7)$, and note that $O$ represents the origin.

a. Determine vectors $\overrightarrow{OP}$ and $\overrightarrow{OQ}$. Express the answer by using standard unit vectors.

b. Determine the measure of angle $O$ in triangle $OPQ$. Express the answer in degrees rounded to two decimal places.

**Answer**

$a. \overrightarrow{OP} = 4\hat{\mathbf{i}} + 5\hat{\mathbf{j}}, \quad \overrightarrow{OQ} = 5\hat{\mathbf{i}} - 7\hat{\mathbf{j}}; \quad b. 105.8°$

30) [T] Consider points $A(1,1), B(2,-7)$, and $C(6,3)$.

a. Determine vectors $\overrightarrow{BA}$ and $\overrightarrow{BC}$. Express the answer in component form.

b. Determine the measure of angle $B$ in triangle $ABC$. Express the answer in degrees rounded to two decimal places.

31) Determine the measure of angle $A$ in triangle $ABC$, where $A(1,1,8), B(4,-3,-4)$, and $C(-3,1,5)$. Express your answer in degrees rounded to two decimal places.

**Answer**

$68.33°$

32) Consider points $P(3,7,-2)$ and $Q(1,1,-3)$. Determine the angle between vectors $\overrightarrow{OP}$ and $\overrightarrow{OQ}$. [Remember that $O$ represents the origin.] Express the answer in degrees rounded to two decimal places.

**For exercises 33-34, determine which (if any) pairs of the following vectors are orthogonal.**

33) $\vec{\mathbf{u}} = \langle 3,7,-2\rangle, \quad \vec{\mathbf{v}} = \langle 5,-3,-3\rangle, \quad \vec{\mathbf{w}} = \langle 0,1,-1\rangle$

**Answer**

$\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ are orthogonal; $\vec{\mathbf{v}}$ and $\vec{\mathbf{w}}$ are orthogonal, but $\vec{\mathbf{u}}$ and $\vec{\mathbf{w}}$ are **not** orthogonal.

34) $\vec{\mathbf{u}} = \hat{\mathbf{i}} - \hat{\mathbf{k}}, \quad \vec{\mathbf{v}} = 5\hat{\mathbf{j}} - 5\hat{\mathbf{k}}, \quad \vec{\mathbf{w}} = 10\hat{\mathbf{j}}$

35) Use vectors to show that a parallelogram with equal diagonals is a **rectangle**.

36) Use vectors to show that the diagonals of a **rhombus** are perpendicular.

37) Show that $\vec{\mathbf{u}} \cdot (\vec{\mathbf{v}} + \vec{\mathbf{w}}) = \vec{\mathbf{u}} \cdot \vec{\mathbf{v}} + \vec{\mathbf{u}} \cdot \vec{\mathbf{w}}$ is true for any vectors $\vec{\mathbf{u}}, \vec{\mathbf{v}}$, and $\vec{\mathbf{w}}$.

38) Verify the identity $\vec{\mathbf{u}} \cdot (\vec{\mathbf{v}} + \vec{\mathbf{w}}) = \vec{\mathbf{u}} \cdot \vec{\mathbf{v}} + \vec{\mathbf{u}} \cdot \vec{\mathbf{w}}$ for vectors $\vec{\mathbf{u}} = \langle 1,0,4\rangle, \vec{\mathbf{v}} = \langle -2,3,5\rangle$, and $\vec{\mathbf{w}} = \langle 4,-2,6\rangle$.

**For exercises 39-41, determine $\vec{\mathbf{u}} \cdot \vec{\mathbf{v}}$ using the given information.**

39) $\|\vec{\mathbf{u}}\| = 5, \quad \|\vec{\mathbf{v}}\| = 3$, and the angle between $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ is $\pi/6$ rad.

**Answer**

$\vec{\mathbf{u}} \cdot \vec{\mathbf{v}} = (5)(3)\cos\frac{\pi}{6} = 15 \cdot \frac{\sqrt{3}}{2} = \frac{15\sqrt{3}}{2}$

40) $\|\vec{\mathbf{u}}\| = 20, \quad \|\vec{\mathbf{v}}\| = 15$, and the angle between $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ is $5\pi/4$ rad.

41) $\|\vec{\mathbf{u}}\| = 7, \quad \|\vec{\mathbf{v}}\| = 12$, and the angle between $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ is $\pi/2$ rad.

**Answer**

$\vec{\mathbf{u}} \cdot \vec{\mathbf{v}} = (7)(12)\cos\frac{\pi}{2} = 84 \cdot 0 = 0$

42) Considering the definition of the dot product, $\vec{\mathbf{u}} \cdot \vec{\mathbf{v}} = \|\vec{\mathbf{u}}\|\|\vec{\mathbf{v}}\|\cos\theta$, where $\theta$ is the angle between $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$, what can you say about the angle $\theta$ between two nonzero vectors $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ if:

a. $\vec{\mathbf{u}} \cdot \vec{\mathbf{v}} > 0$?

b. $\vec{\mathbf{u}} \cdot \vec{\mathbf{v}} < 0$?

c. $\vec{\mathbf{u}} \cdot \vec{\mathbf{v}} = 0$?

**In exercises 43-45, you are given the vertices of a triangle. Use dot products to determine whether each triangle is *acute*, *obtuse*, or *right*.**

43) $(2,3,0)$, $(3,1,-2)$, $(-1,4,5)$

**Answer**

Label the points $P$, $Q$ and $R$. Then determine the vectors $\overrightarrow{PQ}$ and $\overrightarrow{PR}$.

Here we see that, if $P=(2,3,0)$, $Q=(3,1,-2)$ and $R=(-1,4,5)$, so we have $\overrightarrow{PQ}=<1,-2,-2>$ and $\overrightarrow{PR}=<-3,1,5>$.

Then $\overrightarrow{PQ}\cdot\overrightarrow{PR}=-15<0$, so angle $QPR$ is obtuse. Therefore this triangle must be an ***obtuse triangle***.

44) $(5,1,0)$, $(7,1,1)$, $(6,3,2)$

45) $(6,1,4)$, $(3,2,-1)$, $(2,3,1)$

**Solution:**

Label the points $P$, $Q$ and $R$. Then determine the vectors $\overrightarrow{PQ}$ and $\overrightarrow{PR}$.

Here we see that, if $P=(6,1,4)$, $Q=(3,2,-1)$ and $R=(2,3,1)$, so we have $\overrightarrow{PQ}=<-3,1,-5>$ and $\overrightarrow{PR}=<-4,2,-3>$.

Then $\overrightarrow{PQ}\cdot\overrightarrow{PR}=29>0$, so angle $QPR$ is **acute**. This triangle could still be any of the three types, so we need to check another angle.

Considering angle $PQR$ we find $\overrightarrow{QP}=<3,-1,5>$ and $\overrightarrow{QR}=<-1,1,2>$, so $\overrightarrow{QP}\cdot\overrightarrow{QR}=6>0$, showing angle $PQR$ is also **acute**.

We then must check the third angle to determine whether this is a right triangle or an acute triangle.

To check angle $PRQ$ we find $\overrightarrow{RP}=<4,-2,3>$ and $\overrightarrow{RQ}=<1,-1,-2>$, giving us $\overrightarrow{RP}\cdot\overrightarrow{RQ}=0$. Angle $PRQ$ is thus a **right** angle.

Therefore this triangle is a ***right triangle***.

46) Which of the following operations are allowed for nonzero vectors $\vec{u}$, $\vec{v}$, and $\vec{w}$, and which are not. Explain your reasoning.

a. $\vec{u}+(\vec{v}\cdot\vec{w})$ b. $(\vec{u}\cdot\vec{v})\cdot\vec{w}$ c. $(\vec{u}\cdot\vec{v})\,\vec{w}$
d. $(\vec{u}+\vec{v})\cdot\vec{w}$ e. $(\vec{u}+\vec{v})\cdot\|\vec{w}\|$ f. $\|\vec{u}+\vec{v}\|\|\vec{w}\|$

## Projections

**For the exercises 47-50, given the vectors $\vec{u}$ and $\vec{v}$:**

a. Find the vector projection $\text{Proj}_{\vec{u}}\vec{v}$ of vector $\vec{v}$ onto vector $\vec{u}$ and the component of $\vec{v}$ that is orthogonal to $\vec{u}$, i.e., $\vec{v}_{\text{perp}}$. Express your answers in component form.

b. Find the scalar projection $\text{comp}_{\vec{u}}\vec{v}=\|\text{Proj}_{\vec{u}}\vec{v}\|$ of vector $\vec{v}$ onto vector $\vec{u}$.

c. Find the vector projection $\text{Proj}_{\vec{v}}\vec{u}$ of vector $\vec{u}$ onto vector $\vec{v}$ and the component of $\vec{u}$ that is orthogonal to $\vec{v}$, i.e., $\vec{u}_{\text{perp}}$. Express your answers in unit vector form.

d. Find the scalar projection $\text{comp}_{\vec{v}}\vec{u}$ of vector $\vec{u}$ onto vector $\vec{v}$.

47) $\vec{u}=5\hat{i}+2\hat{j}$, $\vec{v}=2\hat{i}+3\hat{j}$

**Answer**

a. $\text{Proj}_{\vec{u}}\vec{v}=\langle\frac{80}{29},\frac{32}{29}\rangle$ and $\vec{v}_{\text{perp}}=<-\frac{22}{29},\frac{55}{29}>$; b. $\text{comp}_{\vec{u}}\vec{v}=\frac{16}{\sqrt{29}}=\frac{16\sqrt{29}}{29}$;
c. $\text{Proj}_{\vec{v}}\vec{u}=\frac{32}{13}\hat{i}+\frac{48}{13}\hat{j}$ and $\vec{u}_{\text{perp}}=\frac{33}{13}\hat{i}-\frac{22}{13}\hat{j}$; d. $\text{comp}_{\vec{v}}\vec{u}=\frac{16}{\sqrt{13}}=\frac{16\sqrt{13}}{13}$

48) $\vec{u}=\langle-4,7\rangle$, $\vec{v}=\langle3,5\rangle$

49) $\vec{u}=3\hat{i}+2\hat{k}$, $\vec{v}=2\hat{j}+4\hat{k}$

**Answer**

a. $\text{Proj}_{\vec{u}}\vec{v}=\langle\frac{24}{13},0,\frac{16}{13}\rangle$ and $\vec{v}_{\text{perp}}=<-\frac{24}{13},2,\frac{36}{13}>$; b. $\text{comp}_{\vec{u}}\vec{v}=\frac{8}{\sqrt{13}}=\frac{8\sqrt{13}}{13}$
c. $\text{Proj}_{\vec{v}}\vec{u}=\frac{4}{5}\hat{j}+\frac{8}{5}\hat{k}$ and $\vec{u}_{\text{perp}}=3\hat{i}-\frac{4}{5}\hat{j}+\frac{2}{5}\hat{k}$; d. $\text{comp}_{\vec{v}}\vec{u}=\frac{\sqrt{80}}{5}=\frac{4\sqrt{5}}{5}$;

50) $\vec{u}=\langle4,4,0\rangle$, $\vec{v}=\langle0,4,1\rangle$

51) Consider the vectors $\vec{\mathbf{u}} = 4\hat{\mathbf{i}} - 3\hat{\mathbf{j}}$ and $\vec{\mathbf{v}} = 3\hat{\mathbf{i}} + 2\hat{\mathbf{j}}$.

a. Find the component form of vector $\text{Proj}_{\vec{\mathbf{u}}}\vec{\mathbf{v}}$ that represents the projection of $\vec{\mathbf{v}}$ onto $\vec{\mathbf{u}}$.

b. Write the decomposition $\vec{\mathbf{v}} = \vec{\mathbf{w}} + \vec{\mathbf{q}}$ of vector $\vec{\mathbf{v}}$ into the orthogonal components $\vec{\mathbf{w}}$ and $\vec{\mathbf{q}}$, where $\vec{\mathbf{w}}$ is the projection of $\vec{\mathbf{v}}$ onto $\vec{\mathbf{u}}$ and $\vec{\mathbf{q}}$ is the vector component of $\vec{\mathbf{v}}$ orthogonal to the direction of $\vec{\mathbf{u}}$. That is, $\vec{\mathbf{q}} = \vec{\mathbf{v}}_{\text{perp}}$.

**Answer**

a. $\text{Proj}_{\vec{\mathbf{u}}}\vec{\mathbf{v}} = \langle \frac{24}{25}, -\frac{18}{25} \rangle$; b. $\vec{\mathbf{q}} = \vec{\mathbf{v}}_{\text{perp}} = \langle \frac{51}{25}, \frac{68}{25} \rangle$,
$\vec{\mathbf{v}} = \vec{\mathbf{w}} + \vec{\mathbf{q}} = \text{Proj}_{\vec{\mathbf{u}}}\vec{\mathbf{v}} + \vec{\mathbf{v}}_{\text{perp}} = \langle \frac{24}{25}, -\frac{18}{25} \rangle + \langle \frac{51}{25}, \frac{68}{25} \rangle$
So we have that, $\vec{\mathbf{v}} = \langle \frac{24}{25}, -\frac{18}{25} \rangle + \langle \frac{51}{25}, \frac{68}{25} \rangle$.

52) Consider vectors $\vec{\mathbf{u}} = 2\hat{\mathbf{i}} + 4\hat{\mathbf{j}}$ and $\vec{\mathbf{v}} = 4\hat{\mathbf{j}} + 2\hat{\mathbf{k}}$.

a. Find the component form of vector $\vec{\mathbf{w}} = \text{Proj}_{\vec{\mathbf{u}}}\vec{\mathbf{v}}$ that represents the projection of $\vec{\mathbf{v}}$ onto $\vec{\mathbf{u}}$.

b. Write the decomposition $\vec{\mathbf{v}} = \vec{\mathbf{w}} + \vec{\mathbf{q}}$ of vector $\vec{\mathbf{v}}$ into the orthogonal components $\vec{\mathbf{w}}$ and $\vec{\mathbf{q}}$, where $\vec{\mathbf{w}}$ is the projection of $\vec{\mathbf{v}}$ onto $\vec{\mathbf{u}}$ and $\vec{\mathbf{q}}$ is a vector orthogonal to the direction of $\vec{\mathbf{u}}$.

53) A $50,000$-pound truck is parked on a hill with a $5°$ slope above the horizontal (in the positive $x$-direction). Considering only the force due to gravity, find

a. the component of the weight of the truck that is pulling the truck down the hill (aligned with the road)

b. the component of the weight of the truck that is perpendicular to the road.

c. the magnitude of the force needed to keep the truck from rolling down the hill

d. the magnitude of the force that is perpendicular to the road.

**Solution:**

Let $\vec{\mathbf{F}}$ be the force due to gravity on the truck (its weight) and let $\vec{\mathbf{r}}$ be the unit vector pointing up the hill to the right.

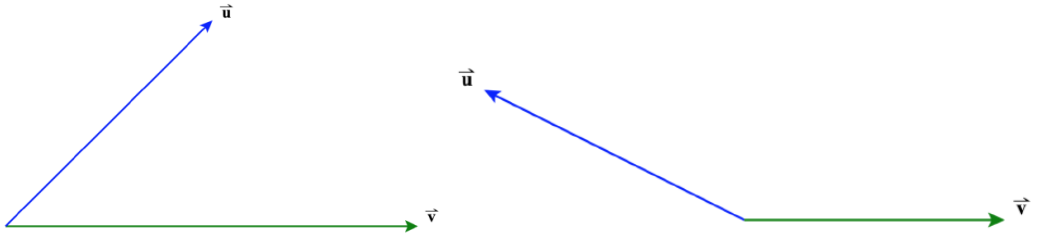
Then
a. the component of the weight of the truck that is pulling the truck down the hill is $\text{Proj}_{\vec{\mathbf{r}}}\vec{\mathbf{F}}$.
Now $\vec{\mathbf{F}} = -50,000\hat{\mathbf{j}}$ and $\vec{\mathbf{r}} = \cos 5°\,\hat{\mathbf{i}} + \sin 5°\,\hat{\mathbf{j}}$ and $\vec{\mathbf{F}} \cdot \vec{\mathbf{r}} = -50,000 \sin 5° \approx -4357.78714$
Note that $\|\vec{\mathbf{r}}\| = 1$.
Then: $\text{Proj}_{\vec{\mathbf{r}}}\vec{\mathbf{F}} = \left(\frac{\vec{\mathbf{F}} \cdot \vec{\mathbf{r}}}{\|\vec{\mathbf{r}}\|^2}\right)\vec{\mathbf{r}} = (-50,000 \sin 5°)\,\vec{\mathbf{r}} = -50000 \sin 5° \cos 5°\,\hat{\mathbf{i}} - 50000 \sin^2 5°\,\hat{\mathbf{j}}$.
Using the identity, $\sin 2\theta = 2 \cos\theta \sin\theta$, we can simplify this as
$\text{Proj}_{\vec{\mathbf{r}}}\vec{\mathbf{F}} = -25000 \sin 10°\,\hat{\mathbf{i}} - 50000 \sin^2 5°\,\hat{\mathbf{j}} \approx -4341.2\,\hat{\mathbf{i}} - 379.8\,\hat{\mathbf{j}}$.

b. the component of the weight of the truck that is perpendicular to the road is $\vec{\mathbf{F}}_{\text{perp}}$.
Since we know that $\vec{\mathbf{F}} = \text{Proj}_{\vec{\mathbf{r}}}\vec{\mathbf{F}} + \vec{\mathbf{F}}_{\text{perp}}$, we have that $\vec{\mathbf{F}}_{\text{perp}} = \vec{\mathbf{F}} - \text{Proj}_{\vec{\mathbf{r}}}\vec{\mathbf{F}}$.
So $\vec{\mathbf{F}}_{\text{perp}} = -50000\hat{\mathbf{j}} - \left(-25000 \sin 10°\,\hat{\mathbf{i}} - 50000 \sin^2 5°\,\hat{\mathbf{j}}\right)$
$= 25000 \sin 10°\,\hat{\mathbf{i}} + (50000 \sin^2 5° - 50000)\,\hat{\mathbf{j}} = 25000 \sin 10°\,\hat{\mathbf{i}} - 50000 \cos^2 5°\,\hat{\mathbf{j}} \approx 4341.2\,\hat{\mathbf{i}} - 49620.2\,\hat{\mathbf{j}}$.

c. the magnitude of the force needed to keep the truck from rolling down the hill is $\|\text{Proj}_{\vec{\mathbf{r}}}\vec{\mathbf{F}}\| = 50,000 \sin 5°$ lbs $\approx 4357.8$ lbs. Note that this force is actually the negative of the projection vector, but its magnitude is the same.

d. the magnitude of the truck's weight that is perpendicular to the road is $\|\vec{\mathbf{F}}_{\text{perp}}\| \approx 49809.7$ lbs.

54) Given the vectors $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ shown in each diagram below, draw in $\text{Proj}_{\vec{\mathbf{v}}}\vec{\mathbf{u}}$ and $\vec{\mathbf{u}}_{\text{perp}}$.



## Work

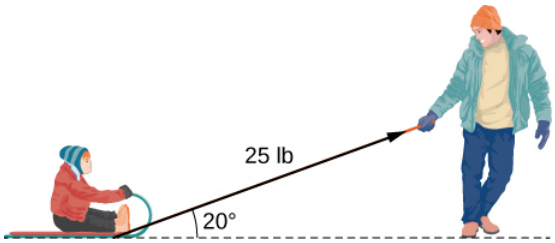
55) Find the work done by force $\vec{\mathbf{F}} = \langle 5, 6, -2 \rangle$ (measured in Newtons) that moves a particle from point $P(3, -1, 0)$ to point $Q(2, 3, 1)$ along a straight line (the distance is measured in meters).

**Answer**

$17\ \text{N·m}$

56) [T] A sled is pulled by exerting a force of 100 N on a rope that makes an angle of $25°$ with the horizontal. Find the work done in pulling the sled 40 m. (Round the answer to one decimal place.)

57) [T] A father is pulling his son on a sled at an angle of $20°$ with the horizontal with a force of 25 lb (see the following image). He pulls the sled in a straight path of 50 ft. How much work was done by the man pulling the sled? (Round the answer to the nearest integer.)



**Answer**

1175 ft·lb

58) [T] A car is towed using a force of 1600 N. The rope used to pull the car makes an angle of 25° with the horizontal. Find the work done in towing the car 2 km. Express the answer in joules ($1$ J$= 1$ N·m) rounded to the nearest integer.

59) [T] A boat sails north aided by a wind blowing in a direction of $N30°E$ with a magnitude of 500 lb. How much work is performed by the wind as the boat moves 100 ft? (Round the answer to two decimal places.)

**Answer**

$25000\sqrt{3}$ ft-lbs $\approx 43,301.27$ ft-lbs

**Solution:**

Vector representing the wind: $\vec{\mathbf{w}} = 500 \cos 60° \hat{\mathbf{i}} + 500 \sin 60° \hat{\mathbf{j}}$

Vector representing the displacement to the north: $\vec{\mathbf{d}} = 100\hat{\mathbf{j}}$

Work done by the wind: $W = \vec{\mathbf{w}} \cdot \vec{\mathbf{d}} = 25000\sqrt{3}$ ft-lbs $\approx 43,301.27$ ft-lbs

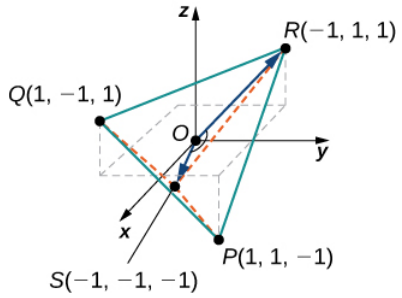
## Other Applications of the Dot Product

60) [T] Find the vectors that join the center of a clock to the hours 1:00, 2:00, and 3:00. Assume the clock is circular with a radius of 1 unit.

61) A methane molecule has a carbon atom situated at the origin and four hydrogen atoms located at points $P(1, 1, -1), Q(1, -1, 1), R(-1, 1, 1)$, and $S(-1, -1, -1)$ (see figure).

a. Find the distance between the hydrogen atoms located at $P$and $R$.

b. Find the angle between vectors $\overrightarrow{OS}$ and $\overrightarrow{OR}$ that connect the carbon atom with the hydrogen atoms located at $S$ and $R$, which is also called the *bond angle*. Express the answer in degrees rounded to two decimal places.



**Answer**

$a. 2\sqrt{2}; \quad b. 109.47°$

62) Vector $\vec{\mathbf{p}} = \langle 150, 225, 375 \rangle$ represents the price of certain models of bicycles sold by a bicycle shop. Vector $\vec{\mathbf{n}} = \langle 10, 7, 9 \rangle$ represents the number of bicycles sold of each model, respectively. Compute the dot product $\vec{\mathbf{p}} \cdot \vec{\mathbf{n}}$ and state its meaning.

63) [T] Two forces $\vec{\mathbf{F}}_1$ and $\vec{\mathbf{F}}_2$ are represented by vectors with initial points that are at the origin. The first force has a magnitude of 20 lb and passes through the point $P(1, 1, 0)$. The second force has a magnitude of 40 lb and passes through the point $Q(0, 1, 1)$. Let $\vec{\mathbf{F}}$ be the resultant force of forces $\vec{\mathbf{F}}_1$ and $\vec{\mathbf{F}}_2$.

a. Find the magnitude of $\vec{\mathbf{F}}$. (Round the answer to one decimal place.)

b. Find the direction angles of $\vec{\mathbf{F}}$. (Express the answer in degrees rounded to one decimal place.)

**Answer**

$a. \| \vec{\mathbf{F}}_1 + \vec{\mathbf{F}}_2 \| = 52.9$ lb; b. The direction angles are $\alpha = 74.5°$, $\beta = 36.7°$, and $\gamma = 57.7°$.

64) [T] Consider $\vec{\mathbf{r}}(t) = \langle \cos t, \sin t, 2t \rangle$ the position vector of a particle at time $t \in [0, 30]$, where the components of $\vec{\mathbf{r}}$ are expressed in centimeters and time in seconds. Let $\overrightarrow{OP}$ be the position vector of the particle after 1 sec.

a. Show that all vectors $\overrightarrow{PQ}$, where $Q(x, y, z)$ is an arbitrary point, orthogonal to the instantaneous velocity vector $\vec{\mathbf{v}}(1)$ of the particle after 1 sec, can be expressed as $\overrightarrow{PQ} = \langle x - \cos 1, y - \sin 1, z - 2 \rangle$, where $x \sin 1 - y \cos 1 - 2z + 4 = 0$. The set of point $Q$ describes a plane called the *normal plane* to the path of the particle at point $P$.

b. Use a CAS to visualize the instantaneous velocity vector and the normal plane at point $P$ along with the path of the particle.

# 12.5: The Cross Product

**Learning Objectives**

- Calculate the cross product of two given vectors.
- Use determinants to calculate a cross product.
- Find a vector orthogonal to two given vectors.
- Determine areas and volumes by using the cross product.
- Calculate the torque of a given force and position vector.

Imagine a mechanic turning a wrench to tighten a bolt. The mechanic applies a force at the end of the wrench. This creates rotation, or torque, which tightens the bolt. We can use vectors to represent the force applied by the mechanic, and the distance (radius) from the bolt to the end of the wrench. Then, we can represent torque by a vector oriented along the axis of rotation. Note that the torque vector is orthogonal to both the force vector and the radius vector.

In this section, we develop an operation called the **cross product**, which allows us to find a vector orthogonal to two given vectors. Calculating torque is an important application of cross products, and we examine torque in more detail later in the section.

## The Cross Product and Its Properties

The dot product is a multiplication of two vectors that results in a scalar. In this section, we introduce a product of two vectors that generates a third vector orthogonal to the first two. Consider how we might find such a vector. Let $\vec{\mathbf{u}} = \langle u_1, u_2, u_3 \rangle$ and $\vec{\mathbf{v}} = \langle v_1, v_2, v_3 \rangle$ be nonzero vectors. We want to find a vector $\vec{\mathbf{w}} = \langle w_1, w_2, w_3 \rangle$ orthogonal to both $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$—that is, we want to find $\vec{\mathbf{w}}$ such that $\vec{\mathbf{u}} \cdot \vec{\mathbf{w}} = 0$ and $\vec{\mathbf{v}} \cdot \vec{\mathbf{w}} = 0$. Therefore, $w_1$, $w_2$, and $w_3$ must satisfy

$$u_1 w_1 + u_2 w_2 + u_3 w_3 = 0 \tag{12.5.1}$$

$$v_1 w_1 + v_2 w_2 + v_3 w_3 = 0. \tag{12.5.2}$$

If we multiply the top equation by $v_3$ and the bottom equation by $u_3$ and subtract, we can eliminate the variable $w_3$, which gives

$$(u_1 v_3 - v_1 u_3) w_1 + (u_2 v_3 - v_2 u_3) w_2 = 0.$$

If we select

$$w_1 = u_2 v_3 - u_3 v_2$$
$$w_2 = -(u_1 v_3 - u_3 v_1),$$

we get a possible solution vector. Substituting these values back into the original equations (Equations 12.5.1 and 12.5.2) gives

$$w_3 = u_1 v_2 - u_2 v_1.$$

That is, vector

$$\vec{\mathbf{w}} = \langle u_2 v_3 - u_3 v_2, -(u_1 v_3 - u_3 v_1), u_1 v_2 - u_2 v_1 \rangle$$

is orthogonal to both $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$, which leads us to define the following operation, called the *cross product*.

**Definition: Cross Product**

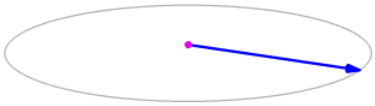
Let $\vec{\mathbf{u}} = \langle u_1, u_2, u_3 \rangle$ and $\vec{\mathbf{v}} = \langle v_1, v_2, v_3 \rangle$. Then, the *cross product* $\vec{\mathbf{u}} \times \vec{\mathbf{v}}$ is vector

$$\begin{aligned} \vec{\mathbf{u}} \times \vec{\mathbf{v}} &= (u_2 v_3 - u_3 v_2)\hat{\mathbf{i}} - (u_1 v_3 - u_3 v_1)\hat{\mathbf{j}} + (u_1 v_2 - u_2 v_1)\hat{\mathbf{k}} \\ &= \langle u_2 v_3 - u_3 v_2, -(u_1 v_3 - u_3 v_1), u_1 v_2 - u_2 v_1 \rangle. \end{aligned} \tag{12.5.3}$$

From the way we have developed $\vec{\mathbf{u}} \times \vec{\mathbf{v}}$, it should be clear that the cross product is orthogonal to both $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$. However, it never hurts to check. To show that $\vec{\mathbf{u}} \times \vec{\mathbf{v}}$ is orthogonal to $\vec{\mathbf{u}}$, we calculate the dot product of $\vec{\mathbf{u}}$ and $\vec{\mathbf{u}} \times \vec{\mathbf{v}}$.

$$\begin{aligned}\vec{\mathbf{u}} \cdot (\vec{\mathbf{u}} \times \vec{\mathbf{v}}) &= \langle u_1, u_2, u_3 \rangle \cdot \langle u_2v_3 - u_3v_2, -u_1v_3 + u_3v_1, u_1v_2 - u_2v_1 \rangle \\ &= u_1(u_2v_3 - u_3v_2) + u_2(-u_1v_3 + u_3v_1) + u_3(u_1v_2 - u_2v_1) \\ &= u_1u_2v_3 - u_1u_3v_2 - u_1u_2v_3 + u_2u_3v_1 + u_1u_3v_2 - u_2u_3v_1 \\ &= (u_1u_2v_3 - u_1u_2v_3) + (-u_1u_3v_2 + u_1u_3v_2) + (u_2u_3v_1 - u_2u_3v_1) \\ &= 0\end{aligned}$$

In a similar manner, we can show that the cross product is also orthogonal to $\vec{\mathbf{v}}$.



The cross product $\vec{\mathbf{a}} \times \vec{\mathbf{b}}$ (vertical, in pink) changes as the angle between the vectors $\vec{\mathbf{a}}$ (blue) and $\vec{\mathbf{b}}$ (red) changes. The cross product (purple) is always perpendicular to both vectors, and has magnitude zero when the vectors are parallel and maximum magnitude $\|\vec{\mathbf{a}}\|\|\vec{\mathbf{b}}\|$ when they are perpendicular. (Public Domain; LucasVB).

### Example 12.5.1: Finding a Cross Product

Let $\vec{\mathbf{p}} = \langle -1, 2, 5 \rangle$ and $\vec{\mathbf{q}} = \langle 4, 0, -3 \rangle$ (Figure 12.5.1). Find $\vec{\mathbf{p}} \times \vec{\mathbf{q}}$.

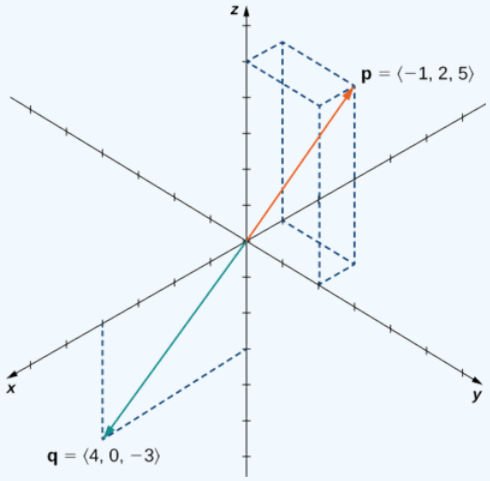


Figure 12.5.1: Finding a cross product to two given vectors.

**Solution**

Substitute the components of the vectors into Equation 12.5.3:

$$\begin{aligned}\vec{\mathbf{p}} \times \vec{\mathbf{q}} &= \langle -1, 2, 5 \rangle \times \langle 4, 0, -3 \rangle \\ &= \langle p_2q_3 - p_3q_2, -(p_1q_3 - p_3q_1), p_1q_2 - p_2q_1 \rangle \\ &= \langle 2(-3) - 5(0), -(-1)(-3) + 5(4), (-1)(0) - 2(4) \rangle \\ &= \langle -6, 17, -8 \rangle.\end{aligned}$$

**? Exercise 12.5.1**

Find $\vec{p} \times \vec{q}$ for $\vec{p} = \langle 5, 1, 2 \rangle$ and $\vec{q} = \langle -2, 0, 1 \rangle$. Express the answer using standard unit vectors.

**Hint**

Use the formula $\vec{u} \times \vec{v} = (u_2v_3 - u_3v_2)\hat{i} - (u_1v_3 - u_3v_1)\hat{j} + (u_1v_2 - u_2v_1)\hat{k}$.

**Answer**

$\vec{p} \times \vec{q} = \hat{i} - 9\hat{j} + 2\hat{k}$

Although it may not be obvious from Equation 12.5.3, the direction of $\vec{u} \times \vec{v}$ is given by the right-hand rule. If we hold the right hand out with the fingers pointing in the direction of $\vec{u}$, then curl the fingers toward vector $\vec{v}$, the thumb points in the direction of the cross product, as shown in Figure 12.5.2.

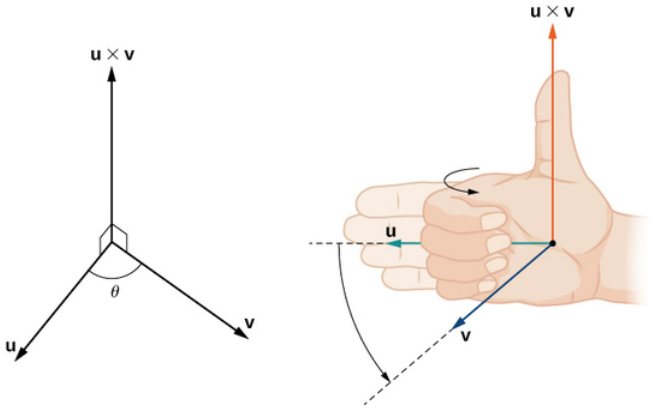

Figure 12.5.2: The direction of $\vec{u} \times \vec{v}$ is determined by the right-hand rule.

Notice what this means for the direction of $\vec{v} \times \vec{u}$. If we apply the right-hand rule to $\vec{v} \times \vec{u}$, we start with our fingers pointed in the direction of $\vec{v}$, then curl our fingers toward the vector $\vec{u}$. In this case, the thumb points in the opposite direction of $\vec{u} \times \vec{v}$. (Try it!)

**✓ Example 12.5.2: Anticommutativity of the Cross Product**

Let $\vec{u} = \langle 0, 2, 1 \rangle$ and $\vec{v} = \langle 3, -1, 0 \rangle$. Calculate $\vec{u} \times \vec{v}$ and $\vec{v} \times \vec{u}$ and graph them.

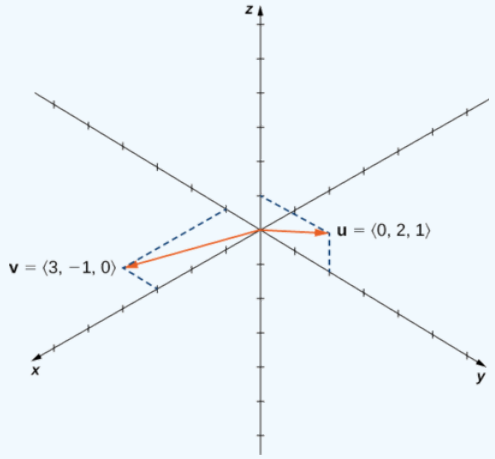

Figure 12.5.3: Are the cross products $\vec{u} \times \vec{v}$ and $\vec{v} \times \vec{u}$ in the same direction?

**Solution**

We have

$$\vec{u} \times \vec{v} = \langle (0 + 1), -(0 - 3), (0 - 6) \rangle = \langle 1, 3, -6 \rangle$$

$$\vec{v} \times \vec{u} = \langle (-1 - 0), -(3 - 0), (6 - 0) \rangle = \langle -1, -3, 6 \rangle.$$

We see that, in this case, $\vec{\mathbf{u}} \times \vec{\mathbf{v}} = -(\vec{\mathbf{v}} \times \vec{\mathbf{u}})$ (Figure 12.5.4). We prove this in general later in this section.

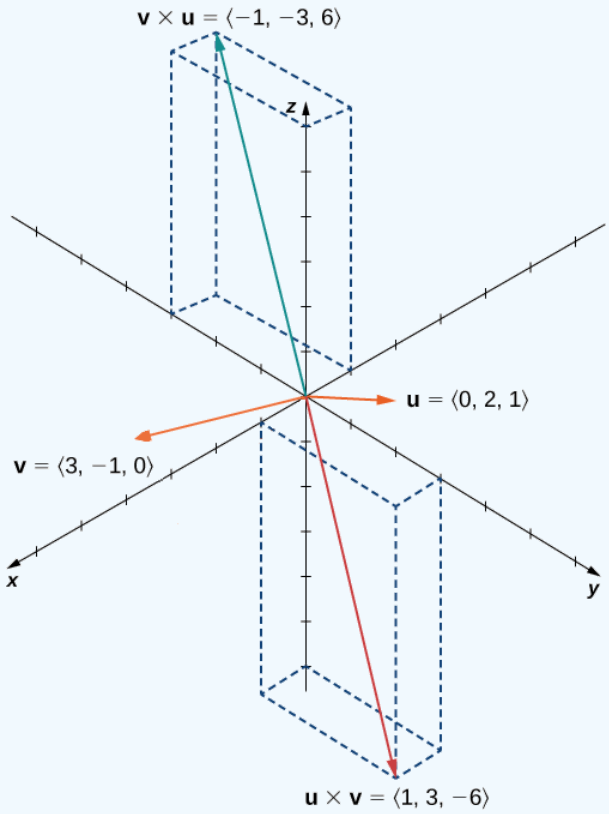

Figure 12.5.4: The cross products $\vec{\mathbf{u}} \times \vec{\mathbf{v}}$ and $\vec{\mathbf{v}} \times \vec{\mathbf{u}}$ are both orthogonal to $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$, but in opposite directions.

## ? Exercise 12.5.2

Suppose vectors $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ lie in the $xy$-plane (the $z$-component of each vector is zero). Now suppose the $x$- and $y$-components of $\vec{\mathbf{u}}$ and the $y$-component of $\vec{\mathbf{v}}$ are all positive, whereas the $x$-component of $\vec{\mathbf{v}}$ is negative. Assuming the coordinate axes are oriented in the usual positions, in which direction does $\vec{\mathbf{u}} \times \vec{\mathbf{v}}$ point?

**Hint**

Remember the right-hand rule (Figure 12.5.2).

**Answer**

Up (the positive $z$-direction)

The cross products of the standard unit vectors $\hat{\mathbf{i}}$, $\hat{\mathbf{j}}$, and $\hat{\mathbf{k}}$ can be useful for simplifying some calculations, so let's consider these cross products. A straightforward application of the definition shows that

$$\hat{\mathbf{i}} \times \hat{\mathbf{i}} = \hat{\mathbf{j}} \times \hat{\mathbf{j}} = \hat{\mathbf{k}} \times \hat{\mathbf{k}} = \vec{\mathbf{0}}.$$

(The cross product of two vectors is a vector, so each of these products results in the zero vector, not the scalar 0.) It's up to you to verify the calculations on your own.

Furthermore, because the cross product of two vectors is orthogonal to each of these vectors, we know that the cross product of $\hat{\mathbf{i}}$ and $\hat{\mathbf{j}}$ is parallel to $\hat{\mathbf{k}}$. Similarly, the vector product of $\hat{\mathbf{i}}$ and $\hat{\mathbf{k}}$ is parallel to $\hat{\mathbf{j}}$, and the vector product of $\hat{\mathbf{j}}$ and $\hat{\mathbf{k}}$ is parallel to $\hat{\mathbf{i}}$.

We can use the right-hand rule to determine the direction of each product. Then we have

$$\hat{\mathbf{i}} \times \hat{\mathbf{j}} = \hat{\mathbf{k}}$$
$$\hat{\mathbf{j}} \times \hat{\mathbf{i}} = -\hat{\mathbf{k}}$$
$$\hat{\mathbf{j}} \times \hat{\mathbf{k}} = \hat{\mathbf{i}}$$
$$\hat{\mathbf{k}} \times \hat{\mathbf{j}} = -\hat{\mathbf{i}}$$
$$\hat{\mathbf{k}} \times \hat{\mathbf{i}} = \hat{\mathbf{j}}$$
$$\hat{\mathbf{i}} \times \hat{\mathbf{k}} = -\hat{\mathbf{j}}.$$

These formulas come in handy later.

**Example 12.5.3: Cross Product of Standard Unit Vectors**

Find $\hat{\mathbf{i}} \times (\hat{\mathbf{j}} \times \hat{\mathbf{k}})$.

**Solution**

We know that $\hat{\mathbf{j}} \times \hat{\mathbf{k}} = \hat{\mathbf{i}}$. Therefore, $\hat{\mathbf{i}} \times (\hat{\mathbf{j}} \times \hat{\mathbf{k}}) = \hat{\mathbf{i}} \times \hat{\mathbf{i}} = \vec{\mathbf{0}}$.

**Exercise 12.5.3**

Find $(\hat{\mathbf{i}} \times \hat{\mathbf{j}}) \times (\hat{\mathbf{k}} \times \hat{\mathbf{i}})$.

**Hint**

Remember the right-hand rule (Figure 12.5.2).

**Answer**

$-\hat{\mathbf{i}}$

As we have seen, the dot product is often called the *scalar product* because it results in a scalar. The cross product results in a vector, so it is sometimes called the **vector product.** These operations are both versions of vector multiplication, but they have very different properties and applications. Let's explore some properties of the cross product. We prove only a few of them. Proofs of the other properties are left as exercises.

**Properties of the Cross Product**

Let $\vec{\mathbf{u}}, \vec{\mathbf{v}}$, and $\vec{\mathbf{w}}$ be vectors in space, and let $c$ be a scalar.

i. Anticommutative property:

$$\vec{\mathbf{u}} \times \vec{\mathbf{v}} = -(\vec{\mathbf{v}} \times \vec{\mathbf{u}})$$

ii. Distributive property:

$$\vec{\mathbf{u}} \times (\vec{\mathbf{v}} + \vec{\mathbf{w}}) = \vec{\mathbf{u}} \times \vec{\mathbf{v}} + \vec{\mathbf{u}} \times \vec{\mathbf{w}}$$

iii. Multiplication by a constant:

$$c(\vec{\mathbf{u}} \times \vec{\mathbf{v}}) = (c\vec{\mathbf{u}}) \times \vec{\mathbf{v}} = \vec{\mathbf{u}} \times (c\vec{\mathbf{v}})$$

iv. Cross product of the zero vector:

$$\vec{\mathbf{u}} \times \vec{\mathbf{0}} = \vec{\mathbf{0}} \times \vec{\mathbf{u}} = \vec{\mathbf{0}}$$

v. Cross product of a vector with itself:

$$\vec{\mathbf{v}} \times \vec{\mathbf{v}} = \vec{\mathbf{0}}$$

vi. Triple scalar product:

$$\vec{\mathbf{u}} \cdot (\vec{\mathbf{v}} \times \vec{\mathbf{w}}) = (\vec{\mathbf{u}} \times \vec{\mathbf{v}}) \cdot \vec{\mathbf{w}}$$

vii. Triple cross product:

$$\vec{\mathbf{u}} \times (\vec{\mathbf{v}} \times \vec{\mathbf{w}}) = (\vec{\mathbf{u}} \cdot \vec{\mathbf{w}})\,\vec{\mathbf{v}} - (\vec{\mathbf{u}} \cdot \vec{\mathbf{v}})\,\vec{\mathbf{w}}$$

**Proof**

For property *i*, we want to show $\vec{\mathbf{u}} \times \vec{\mathbf{v}} = -(\vec{\mathbf{v}} \times \vec{\mathbf{u}})$. We have

$$\begin{aligned}\vec{\mathbf{u}} \times \vec{\mathbf{v}} &= \langle u_1, u_2, u_3\rangle \times \langle v_1, v_2, v_3\rangle \\ &= \langle u_2v_3 - u_3v_2, -u_1v_3 + u_3v_1, u_1v_2 - u_2v_1\rangle \\ &= -\langle u_3v_2 - u_2v_3, -u_3v_1 + u_1v_3, u_2v_1 - u_1v_2\rangle \\ &= -\langle v_1, v_2, v_3\rangle \times \langle u_1, u_2, u_3\rangle \\ &= -(\vec{\mathbf{v}} \times \vec{\mathbf{u}}).\end{aligned}$$

Unlike most operations we've seen, the cross product is not commutative. This makes sense if we think about the right-hand rule.

For property *iv*., this follows directly from the definition of the cross product. We have

$$\vec{\mathbf{u}} \times \vec{\mathbf{0}} = \langle u_2(0) - u_3(0), -(u_1(0) - u_3(0)), u_1(0) - u_2(0)\rangle = \langle 0, 0, 0\rangle = \vec{\mathbf{0}}.$$

Then, by property i., $\vec{\mathbf{0}} \times \vec{\mathbf{u}} = \vec{\mathbf{0}}$ as well. Remember that the dot product of a vector and the zero vector is the *scalar* $0$, whereas the cross product of a vector with the zero vector is the *vector* $\vec{\mathbf{0}}$.

Property *vi*. looks like the associative property, but note the change in operations:

$$\begin{aligned}\vec{\mathbf{u}} \cdot (\vec{\mathbf{v}} \times \vec{\mathbf{w}}) &= u \cdot \langle v_2w_3 - v_3w_2, -v_1w_3 + v_3w_1, v_1w_2 - v_2w_1\rangle \\ &= u_1(v_2w_3 - v_3w_2) + u_2(-v_1w_3 + v_3w_1) + u_3(v_1w_2 - v_2w_1) \\ &= u_1v_2w_3 - u_1v_3w_2 - u_2v_1w_3 + u_2v_3w_1 + u_3v_1w_2 - u_3v_2w_1 \\ &= (u_2v_3 - u_3v_2)w_1 + (u_3v_1 - u_1v_3)w_2 + (u_1v_2 - u_2v_1)w_3 \\ &= \langle u_2v_3 - u_3v_2, u_3v_1 - u_1v_3, u_1v_2 - u_2v_1\rangle \cdot \langle w_1, w_2, w_3\rangle = (\vec{\mathbf{u}} \times \vec{\mathbf{v}}) \cdot \vec{\mathbf{w}}.\end{aligned}$$

□

**Example 12.5.4: Using the Properties of the Cross Product**

Use the cross product properties to calculate $(2\hat{\mathbf{i}} \times 3\hat{\mathbf{j}}) \times \hat{\mathbf{j}}$.

**Solution**

$$\begin{aligned}(2\hat{\mathbf{i}} \times 3\hat{\mathbf{j}}) \times \hat{\mathbf{j}} &= 2(\hat{\mathbf{i}} \times 3\hat{\mathbf{j}}) \times \hat{\mathbf{j}} \\ &= 2(3)(\hat{\mathbf{i}} \times \hat{\mathbf{j}}) \times \hat{\mathbf{j}} \\ &= (6\hat{\mathbf{k}}) \times \hat{\mathbf{j}} \\ &= 6(\hat{\mathbf{k}} \times \hat{\mathbf{j}}) \\ &= 6(-\hat{\mathbf{i}}) = -6\hat{\mathbf{i}}.\end{aligned}$$

**Exercise 12.5.4**

Use the properties of the cross product to calculate $(\hat{\mathbf{i}} \times \hat{\mathbf{k}}) \times (\hat{\mathbf{k}} \times \hat{\mathbf{j}})$.

**Hint**

$\vec{\mathbf{u}} \times \vec{\mathbf{v}} = -(\vec{\mathbf{v}} \times \vec{\mathbf{u}})$

**Answer**

$-\hat{\mathbf{k}}$

So far in this section, we have been concerned with the direction of the vector $\vec{\mathbf{u}} \times \vec{\mathbf{v}}$, but we have not discussed its magnitude. It turns out there is a simple expression for the magnitude of $\vec{\mathbf{u}} \times \vec{\mathbf{v}}$ involving the magnitudes of $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$, and the sine of the angle between them.

### Magnitude of the Cross Product

Let $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ be vectors, and let $\theta$ be the angle between them. Then, $\|\vec{\mathbf{u}} \times \vec{\mathbf{v}}\| = \|\vec{\mathbf{u}}\| \cdot \|\vec{\mathbf{v}}\| \cdot \sin\theta$.

### Proof

Let $\vec{\mathbf{u}} = \langle u_1, u_2, u_3 \rangle$ and $\vec{\mathbf{v}} = \langle v_1, v_2, v_3 \rangle$ be vectors, and let $\theta$ denote the angle between them. Then

$$\begin{aligned}
\|\vec{\mathbf{u}} \times \vec{\mathbf{v}}\|^2 &= (u_2v_3 - u_3v_2)^2 + (u_3v_1 - u_1v_3)^2 + (u_1v_2 - u_2v_1)^2 \\
&= u_2^2v_3^2 - 2u_2u_3v_2v_3 + u_3^2v_2^2 + u_3^2v_1^2 - 2u_1u_3v_1v_3 + u_1^2v_3^2 + u_1^2v_2^2 - 2u_1u_2v_1v_2 + u_2^2v_1^2 \\
&= u_1^2v_1^2 + u_1^2v_2^2 + u_1^2v_3^2 + u_2^2v_1^2 + u_2^2v_2^2 + u_2^2v_3^2 + u_3^2v_1^2 + u_3^2v_2^2 + u_3^2v_3^2 \\
&\quad - (u_1^2v_1^2 + u_2^2v_2^2 + u_3^2v_3^2 + 2u_1u_2v_1v_2 + 2u_1u_3v_1v_3 + 2u_2u_3v_2v_3) \\
&= (u_1^2 + u_2^2 + u_3^2)(v_1^2 + v_2^2 + v_3^2) - (u_1v_1 + u_2v_2 + u_3v_3)^2 \\
&= \|\vec{\mathbf{u}}\|^2\|\vec{\mathbf{v}}\|^2 - (\vec{\mathbf{u}} \cdot \vec{\mathbf{v}})^2 \\
&= \|\vec{\mathbf{u}}\|^2\|\vec{\mathbf{v}}\|^2 - \|\vec{\mathbf{u}}\|^2\|\vec{\mathbf{v}}\|^2\cos^2\theta \\
&= \|\vec{\mathbf{u}}\|^2\|\vec{\mathbf{v}}\|^2(1 - \cos^2\theta) \\
&= \|\vec{\mathbf{u}}\|^2\|\vec{\mathbf{v}}\|^2(\sin^2\theta).
\end{aligned}$$

Taking square roots and noting that $\sqrt{\sin^2\theta} = \sin\theta$ for $0 \le \theta \le 180°$, we have the desired result:

$$\|\vec{\mathbf{u}} \times \vec{\mathbf{v}}\| = \|\vec{\mathbf{u}}\|\|\vec{\mathbf{v}}\|\sin\theta.$$

□

This definition of the cross product allows us to visualize or interpret the product geometrically. It is clear, for example, that the cross product is defined only for vectors in three dimensions, not for vectors in two dimensions. In two dimensions, it is impossible to generate a vector simultaneously orthogonal to two nonparallel vectors.

### Example 12.5.5: Calculating the Cross Product

Use "Magnitude of the Cross Product" to find the magnitude of the cross product of $\vec{\mathbf{u}} = \langle 0, 4, 0 \rangle$ and $\vec{\mathbf{v}} = \langle 0, 0, -3 \rangle$.

**Solution**

We have

$$\begin{aligned}
\|\vec{\mathbf{u}} \times \vec{\mathbf{v}}\| &= \|\vec{\mathbf{u}}\| \cdot \|\vec{\mathbf{v}}\| \cdot \sin\theta \\
&= \sqrt{0^2 + 4^2 + 0^2} \cdot \sqrt{0^2 + 0^2 + (-3)^2} \cdot \sin\frac{\pi}{2} \\
&= 4(3)(1) = 12
\end{aligned}$$

### Exercise 12.5.5

Use "Magnitude of the Cross Product" to find the magnitude of $\vec{\mathbf{u}} \times \vec{\mathbf{v}}$, where $\vec{\mathbf{u}} = \langle -8, 0, 0 \rangle$ and $\vec{\mathbf{v}} = \langle 0, 2, 0 \rangle$.

**Hint**

Vectors $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ are orthogonal.

**Answer**

## Determinants and the Cross Product

Using Equation 12.5.3 to find the cross product of two vectors is straightforward, and it presents the cross product in the useful component form. The formula, however, is complicated and difficult to remember. Fortunately, we have an alternative. We can calculate the cross product of two vectors using determinant notation.

A $2 \times 2$ determinant is defined by

$$\begin{vmatrix} a_1 & b_1 \\ a_2 & b_2 \end{vmatrix} = a_1 b_2 - b_1 a_2.$$

For example,

$$\begin{vmatrix} 3 & -2 \\ 5 & 1 \end{vmatrix} = 3(1) - 5(-2) = 3 + 10 = 13.$$

A $3 \times 3$ determinant is defined in terms of $2 \times 2$ determinants as follows:

$$\begin{vmatrix} a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \\ c_1 & c_2 & c_3 \end{vmatrix} = a_1 \begin{vmatrix} b_2 & b_3 \\ c_2 & c_3 \end{vmatrix} - a_2 \begin{vmatrix} b_1 & b_3 \\ c_1 & c_3 \end{vmatrix} + a_3 \begin{vmatrix} b_1 & b_2 \\ c_1 & c_2 \end{vmatrix}. \tag{12.5.4}$$

Equation 12.5.4 is referred to as the expansion of the determinant along the first row. Notice that the multipliers of each of the $2 \times 2$ determinants on the right side of this expression are the entries in the first row of the $3 \times 3$ determinant. Furthermore, each of the $2 \times 2$ determinants contains the entries from the $3 \times 3$ determinant that would remain if you crossed out the row and column containing the multiplier. Thus, for the first term on the right, $a_1$ is the multiplier, and the $2 \times 2$ determinant contains the entries that remain if you cross out the first row and first column of the $3 \times 3$ determinant. Similarly, for the second term, the multiplier is $a_2$, and the $2 \times 2$ determinant contains the entries that remain if you cross out the first row and second column of the $3 \times 3$ determinant. Notice, however, that the coefficient of the second term is negative. The third term can be calculated in similar fashion.

### Example 12.5.6: Using Expansion Along the First Row to Compute a $3 \times 3$ Determinant

Evaluate the determinant $\begin{vmatrix} 2 & 5 & -1 \\ -1 & 1 & 3 \\ -2 & 3 & 4 \end{vmatrix}$.

**Solution**

We have

$$\begin{aligned} \begin{vmatrix} 2 & 5 & -1 \\ -1 & 1 & 3 \\ -2 & 3 & 4 \end{vmatrix} &= 2 \begin{vmatrix} 1 & 3 \\ 3 & 4 \end{vmatrix} - 5 \begin{vmatrix} -1 & 3 \\ -2 & 4 \end{vmatrix} - 1 \begin{vmatrix} -1 & 1 \\ -2 & 3 \end{vmatrix} \\ &= 2(4-9) - 5(-4+6) - 1(-3+2) \\ &= 2(-5) - 5(2) - 1(-1) = -10 - 10 + 1 \\ &= -19 \end{aligned}$$

### Exercise 12.5.6

Evaluate the determinant $\begin{vmatrix} 1 & -2 & -1 \\ 3 & 2 & -3 \\ 1 & 5 & 4 \end{vmatrix}$.

**Hint**

Expand along the first row. Don't forget the second term is negative!

**Answer**

Technically, determinants are defined only in terms of arrays of real numbers. However, the determinant notation provides a useful mnemonic device for the cross product formula.

**Rule: Cross Product Calculated by a Determinant**

Let $\vec{\mathbf{u}} = \langle u_1, u_2, u_3 \rangle$ and $\vec{\mathbf{v}} = \langle v_1, v_2, v_3 \rangle$ be vectors. Then the cross product $\vec{\mathbf{u}} \times \vec{\mathbf{v}}$ is given by

$$\vec{\mathbf{u}} \times \vec{\mathbf{v}} = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ u_1 & u_2 & u_3 \\ v_1 & v_2 & v_3 \end{vmatrix} = \begin{vmatrix} u_2 & u_3 \\ v_2 & v_3 \end{vmatrix} \hat{\mathbf{i}} - \begin{vmatrix} u_1 & u_3 \\ v_1 & v_3 \end{vmatrix} \hat{\mathbf{j}} + \begin{vmatrix} u_1 & u_2 \\ v_1 & v_2 \end{vmatrix} \hat{\mathbf{k}}.$$

**Example 12.5.7: Using Determinant Notation to find $\vec{\mathbf{p}} \times \vec{\mathbf{q}}$**

Let $\vec{\mathbf{p}} = \langle -1, 2, 5 \rangle$ and $\vec{\mathbf{q}} = \langle 4, 0, -3 \rangle$. Find $\vec{\mathbf{p}} \times \vec{\mathbf{q}}$.

**Solution**

We set up our determinant by putting the standard unit vectors across the first row, the components of $\vec{\mathbf{u}}$ in the second row, and the components of $\vec{\mathbf{v}}$ in the third row. Then, we have

$$\begin{aligned} \vec{\mathbf{p}} \times \vec{\mathbf{q}} &= \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ -1 & 2 & 5 \\ 4 & 0 & -3 \end{vmatrix} = \begin{vmatrix} 2 & 5 \\ 0 & -3 \end{vmatrix} \hat{\mathbf{i}} - \begin{vmatrix} -1 & 5 \\ 4 & -3 \end{vmatrix} \hat{\mathbf{j}} + \begin{vmatrix} -1 & 2 \\ 4 & 0 \end{vmatrix} \hat{\mathbf{k}} \\ &= (-6 - 0)\hat{\mathbf{i}} - (3 - 20)\hat{\mathbf{j}} + (0 - 8)\hat{\mathbf{k}} \\ &= -6\hat{\mathbf{i}} + 17\hat{\mathbf{j}} - 8\hat{\mathbf{k}}. \end{aligned}$$

Notice that this answer confirms the calculation of the cross product in Example 12.5.1.

**Exercise 12.5.7**

Use determinant notation to find $\vec{\mathbf{a}} \times \vec{\mathbf{b}}$, where $\vec{\mathbf{a}} = \langle 8, 2, 3 \rangle$ and $\vec{\mathbf{b}} = \langle -1, 0, 4 \rangle$.

**Hint**

Calculate the determinant $\begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 8 & 2 & 3 \\ -1 & 0 & 4 \end{vmatrix}$.

**Answer**

$\vec{\mathbf{a}} \times \vec{\mathbf{b}} = 8\hat{\mathbf{i}} - 35\hat{\mathbf{j}} + 2\hat{\mathbf{k}}$

## Using the Cross Product

The cross product is very useful for several types of calculations, including finding a vector orthogonal to two given vectors, computing areas of triangles and parallelograms, and even determining the volume of the three-dimensional geometric shape made of parallelograms known as a *parallelepiped*. The following examples illustrate these calculations.

**Example 12.5.8: Finding a Unit Vector Orthogonal to Two Given Vectors**

Let $\vec{\mathbf{a}} = \langle 5, 2, -1 \rangle$ and $\vec{\mathbf{b}} = \langle 0, -1, 4 \rangle$. Find a unit vector orthogonal to both $\vec{\mathbf{a}}$ and $\vec{\mathbf{b}}$.

**Solution**

The cross product $\vec{\mathbf{a}} \times \vec{\mathbf{b}}$ is orthogonal to both vectors $\vec{\mathbf{a}}$ and $\vec{\mathbf{b}}$. We can calculate it with a determinant:

$$\vec{\mathbf{a}} \times \vec{\mathbf{b}} = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 5 & 2 & -1 \\ 0 & -1 & 4 \end{vmatrix} = \begin{vmatrix} 2 & -1 \\ -1 & 4 \end{vmatrix}\hat{\mathbf{i}} - \begin{vmatrix} 5 & -1 \\ 0 & 4 \end{vmatrix}\hat{\mathbf{j}} + \begin{vmatrix} 5 & 2 \\ 0 & -1 \end{vmatrix}\hat{\mathbf{k}}$$
$$= (8-1)\hat{\mathbf{i}} - (20-0)\hat{\mathbf{j}} + (-5-0)\hat{\mathbf{k}}$$
$$= 7\hat{\mathbf{i}} - 20\hat{\mathbf{j}} - 5\hat{\mathbf{k}}.$$

Normalize this vector to find a unit vector in the same direction:

$$\|\vec{\mathbf{a}} \times \vec{\mathbf{b}}\| = \sqrt{(7)^2 + (-20)^2 + (-5)^2} = \sqrt{474}.$$

Thus, $\left\langle \frac{7}{\sqrt{474}}, \frac{-20}{\sqrt{474}}, \frac{-5}{\sqrt{474}} \right\rangle$ is a unit vector orthogonal to $\vec{\mathbf{a}}$ and $\vec{\mathbf{b}}$.

Simplified, this vector becomes $\left\langle \frac{7\sqrt{474}}{474}, \frac{-10\sqrt{474}}{237}, \frac{-5\sqrt{474}}{474} \right\rangle$.

## Exercise 12.5.8

Find a unit vector orthogonal to both $\vec{\mathbf{a}}$ and $\vec{\mathbf{b}}$, where $\vec{\mathbf{a}} = \langle 4, 0, 3 \rangle$ and $\vec{\mathbf{b}} = \langle 1, 1, 4 \rangle$.

**Hint**

Normalize the cross product.

**Answer**

$\left\langle \frac{-3}{\sqrt{194}}, \frac{-13}{\sqrt{194}}, \frac{4}{\sqrt{194}} \right\rangle$ or, simplified as $\left\langle \frac{-3\sqrt{194}}{194}, \frac{-13\sqrt{194}}{194}, \frac{2\sqrt{194}}{97} \right\rangle$

To use the cross product for calculating areas, we state and prove the following theorem.

## Area of a Parallelogram

If we locate vectors $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ such that they form adjacent sides of a parallelogram, then the area of the parallelogram is given by $\|\vec{\mathbf{u}} \times \vec{\mathbf{v}}\|$ (Figure 12.5.5).

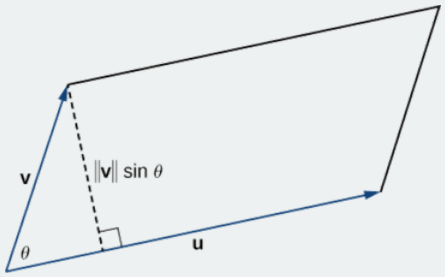

Figure 12.5.5: The parallelogram with adjacent sides $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ has base $\|\vec{\mathbf{u}}\|$ and height $\|\vec{\mathbf{v}}\| \sin\theta$.

## Proof

We show that the magnitude of the cross product is equal to the base times height of the parallelogram.

$$\begin{aligned} \text{Area of a parallelogram} &= \text{base} \times \text{height} \\ &= \|\vec{\mathbf{u}}\|(\|\vec{\mathbf{v}}\| \sin\theta) \\ &= \|\vec{\mathbf{u}} \times \vec{\mathbf{v}}\| \end{aligned}$$

□

## Example 12.5.9: Finding the Area of a Triangle

Let $P = (1, 0, 0), Q = (0, 1, 0)$, and $R = (0, 0, 1)$ be the vertices of a triangle (Figure 12.5.6). Find its area.

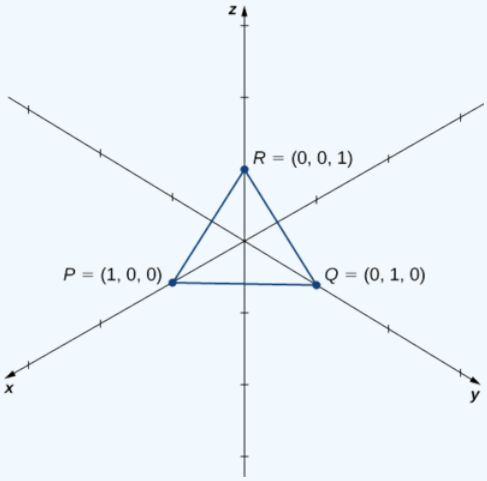

Figure 12.5.6: Finding the area of a triangle by using the cross product.

### Solution

We have $\overrightarrow{PQ} = \langle 0-1, 1-0, 0-0\rangle = \langle -1, 1, 0\rangle$ and $\overrightarrow{PR} = \langle 0-1, 0-0, 1-0\rangle = \langle -1, 0, 1\rangle$. The area of the parallelogram with adjacent sides $\overrightarrow{PQ}$ and $\overrightarrow{PR}$ is given by $\| \overrightarrow{PQ} \times \overrightarrow{PR} \|$:

$$\begin{aligned} \overrightarrow{PQ} \times \overrightarrow{PR} &= \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ -1 & 1 & 0 \\ -1 & 0 & 1 \end{vmatrix} \\ &= (1-0)\hat{\mathbf{i}} - (-1-0)\hat{\mathbf{j}} + (0-(-1))\hat{\mathbf{k}} \\ &= \hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}} \end{aligned}$$

$$\begin{aligned} \| \overrightarrow{PQ} \times \overrightarrow{PR} \| &= \| \langle 1, 1, 1\rangle \| \\ &= \sqrt{1^2 + 1^2 + 1^2} \\ &= \sqrt{3}. \end{aligned}$$

The area of $\Delta PQR$ is half the area of the parallelogram or $\sqrt{3}/2$ units$^2$.

## Exercise 12.5.9

Find the area of the parallelogram $PQRS$ with vertices $P(1, 1, 0)$, $Q(7, 1, 0)$, $R(9, 4, 2)$, and $S(3, 4, 2)$.

**Hint**

Sketch the parallelogram and identify two vectors that form adjacent sides of the parallelogram.

**Answer**

$6\sqrt{13}$ units$^2$

## The Triple Scalar Product

Because the cross product of two vectors is a vector, it is possible to combine the dot product and the cross product. The dot product of a vector with the cross product of two other vectors is called the **triple scalar product** because the result is a scalar.

### Definition: Triple Scalar Product

The triple scalar product of vectors $\vec{u}$, $\vec{v}$, and $\vec{w}$ is

$$\vec{u} \cdot (\vec{v} \times \vec{w}).$$

### Calculating a Triple Scalar Product

The triple scalar product of vectors

$$\vec{u} = u_1\hat{i} + u_2\hat{j} + u_3\hat{k}$$

$$\vec{v} = v_1\hat{i} + v_2\hat{j} + v_3\hat{k}$$

and

$$\vec{w} = w_1\hat{i} + w_2\hat{j} + w_3\hat{k}$$

is the determinant of the $3 \times 3$ matrix formed by the components of the vectors:

$$\vec{u} \cdot (\vec{v} \times \vec{w}) = \begin{vmatrix} u_1 & u_2 & u_3 \\ v_1 & v_2 & v_3 \\ w_1 & w_2 & w_3 \end{vmatrix}. \tag{12.5.5}$$

### Proof

The calculation is straightforward.

$$\begin{aligned} \vec{u} \cdot (\vec{v} \times \vec{w}) &= \langle u_1, u_2, u_3 \rangle \cdot \langle v_2w_3 - v_3w_2, -v_1w_3 + v_3w_1, v_1w_2 - v_2w_1 \rangle \\ &= u_1(v_2w_3 - v_3w_2) + u_2(-v_1w_3 + v_3w_1) + u_3(v_1w_2 - v_2w_1) \\ &= u_1(v_2w_3 - v_3w_2) - u_2(v_1w_3 - v_3w_1) + u_3(v_1w_2 - v_2w_1) \\ &= \begin{vmatrix} u_1 & u_2 & u_3 \\ v_1 & v_2 & v_3 \\ w_1 & w_2 & w_3 \end{vmatrix}. \end{aligned}$$

□

### Example 12.5.10: Calculating the Triple Scalar Product

Let $\vec{u} = \langle 1, 3, 5 \rangle$, $\vec{v} = \langle 2, -1, 0 \rangle$ and $\vec{w} = \langle -3, 0, -1 \rangle$. Calculate the triple scalar product $\vec{u} \cdot (\vec{v} \times \vec{w})$.

**Solution**

Apply Equation 12.5.5 directly:

$$\begin{aligned} \vec{u} \cdot (\vec{v} \times \vec{w}) &= \begin{vmatrix} 1 & 3 & 5 \\ 2 & -1 & 0 \\ -3 & 0 & -1 \end{vmatrix} \\ &= 1\begin{vmatrix} -1 & 0 \\ 0 & -1 \end{vmatrix} - 3\begin{vmatrix} 2 & 0 \\ -3 & -1 \end{vmatrix} + 5\begin{vmatrix} 2 & -1 \\ -3 & 0 \end{vmatrix} \\ &= (1 - 0) - 3(-2 - 0) + 5(0 - 3) \\ &= 1 + 6 - 15 = -8. \end{aligned}$$

### Exercise 12.5.10

Calculate the triple scalar product $\vec{a} \cdot (\vec{b} \times \vec{c})$, where $\vec{a} = \langle 2, -4, 1 \rangle$, $\vec{b} = \langle 0, 3, -1 \rangle$, and $\vec{c} = \langle 5, -3, 3 \rangle$.

**Hint**

Place the vectors as the rows of a $3 \times 3$ matrix, then calculate the determinant.

**Answer**

**17**

When we create a matrix from three vectors, we must be careful about the order in which we list the vectors. If we list them in a matrix in one order and then rearrange the rows, the absolute value of the determinant remains unchanged. However, each time two rows switch places, the determinant changes sign:

$$\begin{vmatrix} a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \\ c_1 & c_2 & c_3 \end{vmatrix} = d \qquad \begin{vmatrix} b_1 & b_2 & b_3 \\ a_1 & a_2 & a_3 \\ c_1 & c_2 & c_3 \end{vmatrix} = -d \qquad \begin{vmatrix} b_1 & b_2 & b_3 \\ c_1 & c_2 & c_3 \\ a_1 & a_2 & a_3 \end{vmatrix} = d \qquad \begin{vmatrix} c_1 & c_2 & c_3 \\ b_1 & b_2 & b_3 \\ a_1 & a_2 & a_3 \end{vmatrix} = -d$$

Verifying this fact is straightforward, but rather messy. Let's take a look at this with an example:

$$\begin{aligned} \begin{vmatrix} 1 & 2 & 1 \\ -2 & 0 & 3 \\ 4 & 1 & -1 \end{vmatrix} &= \begin{vmatrix} 0 & 3 \\ 1 & -1 \end{vmatrix} - 2\begin{vmatrix} -2 & 3 \\ 4 & -1 \end{vmatrix} + \begin{vmatrix} -2 & 0 \\ 4 & 1 \end{vmatrix} \\ &= (0-3) - 2(2-12) + (-2-0) \\ &= -3 + 20 - 2 = 15. \end{aligned}$$

Switching the top two rows we have

$$\begin{aligned} \begin{vmatrix} -2 & 0 & 3 \\ 1 & 2 & 1 \\ 4 & 1 & -1 \end{vmatrix} &= -2\begin{vmatrix} 2 & 1 \\ 1 & -1 \end{vmatrix} + 3\begin{vmatrix} 1 & 2 \\ 4 & 1 \end{vmatrix} \\ &= -2(-2-1) + 3(1-8) \\ &= 6 - 21 = -15. \end{aligned}$$

Rearranging vectors in the triple products is equivalent to reordering the rows in the matrix of the determinant. Let $\vec{\mathbf{u}} = u_1\hat{\mathbf{i}} + u_2\hat{\mathbf{j}} + u_3\hat{\mathbf{k}}$, $\vec{\mathbf{v}} = v_1\hat{\mathbf{i}} + v_2\hat{\mathbf{j}} + v_3\hat{\mathbf{k}}$, and $\vec{\mathbf{w}} = w_1\hat{\mathbf{i}} + w_2\hat{\mathbf{j}} + w_3\hat{\mathbf{k}}$. Applying Calculating a Triple Scalar Product, we have

$$\vec{\mathbf{u}} \cdot (\vec{\mathbf{v}} \times \vec{\mathbf{w}}) = \begin{vmatrix} u_1 & u_2 & u_3 \\ v_1 & v_2 & v_3 \\ w_1 & w_2 & w_3 \end{vmatrix}$$

and

$$\vec{\mathbf{u}} \cdot (\vec{\mathbf{w}} \times \vec{\mathbf{v}}) = \begin{vmatrix} u_1 & u_2 & u_3 \\ w_1 & w_2 & w_3 \\ v_1 & v_2 & v_3 \end{vmatrix}.$$

We can obtain the determinant for calculating $\vec{\mathbf{u}} \cdot (\vec{\mathbf{w}} \times \vec{\mathbf{v}})$ by switching the bottom two rows of $\vec{\mathbf{u}} \cdot (\vec{\mathbf{v}} \times \vec{\mathbf{w}})$. Therefore, $\vec{\mathbf{u}} \cdot (\vec{\mathbf{v}} \times \vec{\mathbf{w}}) = -\vec{\mathbf{u}} \cdot (\vec{\mathbf{w}} \times \vec{\mathbf{v}})$.

Following this reasoning and exploring the different ways we can interchange variables in the triple scalar product lead to the following identities:

$$\vec{\mathbf{u}} \cdot (\vec{\mathbf{v}} \times \vec{\mathbf{w}}) = -\vec{\mathbf{u}} \cdot (\vec{\mathbf{w}} \times \vec{\mathbf{v}}) \tag{12.5.6}$$

$$\vec{\mathbf{u}} \cdot (\vec{\mathbf{v}} \times \vec{\mathbf{w}}) = \vec{\mathbf{v}} \cdot (\vec{\mathbf{w}} \times \vec{\mathbf{u}}) = \vec{\mathbf{w}} \cdot (\vec{\mathbf{u}} \times \vec{\mathbf{v}}). \tag{12.5.7}$$

Let $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ be two vectors in standard position. If $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ are not scalar multiples of each other, then these vectors form adjacent sides of a parallelogram. We saw in Area of a Parallelogram that the area of this parallelogram is $\|\vec{\mathbf{u}} \times \vec{\mathbf{v}}\|$. Now suppose we add a third vector $\vec{\mathbf{w}}$ that does not lie in the same plane as $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ but still shares the same initial point. Then these vectors form three edges of a **parallelepiped**, a three-dimensional prism with six faces that are each parallelograms, as shown in Figure 12.5.7. The volume of this prism is the product of the figure's height and the area of its base. The triple scalar product of $\vec{\mathbf{u}}, \vec{\mathbf{v}}$, and $\vec{\mathbf{w}}$ provides a simple method for calculating the volume of the parallelepiped defined by these vectors.

## Volume of a Parallelepiped

The volume of a parallelepiped with adjacent edges given by the vectors $\vec{u}, \vec{v}$, and $\vec{w}$ is the absolute value of the triple scalar product (Figure 12.5.7):

$$V = |\vec{u} \cdot (\vec{v} \times \vec{w})|.$$

Note that, as the name indicates, the triple scalar product produces a scalar. The volume formula just presented uses the absolute value of a scalar quantity.

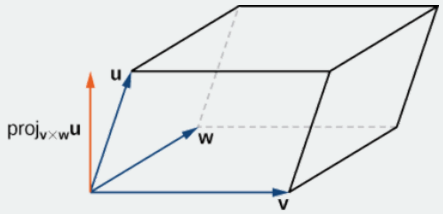

Figure 12.5.7: The height of the parallelepiped is given by $\|\text{proj}_{\vec{v}\times\vec{w}}\vec{u}\|$.

## Proof

The area of the base of the parallelepiped is given by $\|\vec{v} \times \vec{w}\|$. The height of the figure is given by $\|\text{proj}_{\vec{v}\times\vec{w}}\vec{u}\|$. The volume of the parallelepiped is the product of the height and the area of the base, so we have

$$\begin{aligned} V &= \| \text{proj}_{\vec{v}\times\vec{w}}\vec{u} \| \, \|\vec{v} \times \vec{w}\| \\ &= \left| \frac{\vec{u} \cdot (\vec{v} \times \vec{w})}{\|\vec{v} \times \vec{w}\|} \right| \|\vec{v} \times \vec{w}\| \\ &= |\vec{u} \cdot (\vec{v} \times \vec{w})|. \end{aligned}$$

□

## Example 12.5.11: Calculating the Volume of a Parallelepiped

Let $\vec{u} = \langle -1, -2, 1 \rangle, \vec{v} = \langle 4, 3, 2 \rangle$, and $\vec{w} = \langle 0, -5, -2 \rangle$. Find the volume of the parallelepiped with adjacent edges $\vec{u}, \vec{v}$, and $\vec{w}$ (Figure 12.5.8).

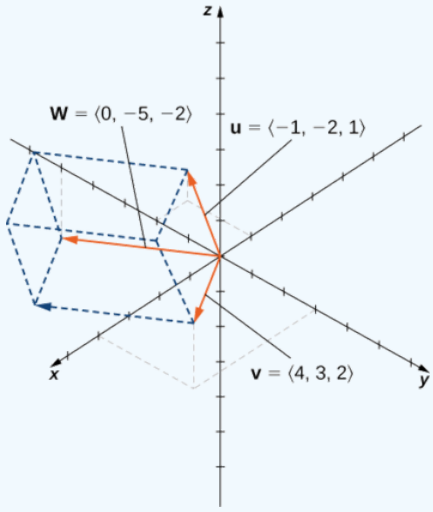

Figure 12.5.8

**Solution**

We have

$$\vec{u}\cdot(\vec{v}\times\vec{w}) = \begin{vmatrix} -1 & -2 & 1 \\ 4 & 3 & 2 \\ 0 & -5 & -2 \end{vmatrix}$$
$$= (-1)\begin{vmatrix} 3 & 2 \\ -5 & -2 \end{vmatrix} + 2\begin{vmatrix} 4 & 2 \\ 0 & -2 \end{vmatrix} + \begin{vmatrix} 4 & 3 \\ 0 & -5 \end{vmatrix}$$
$$= (-1)(-6+10) + 2(-8-0) + (-20-0)$$
$$= -4 - 16 - 20$$
$$= -40.$$

Thus, the volume of the parallelepiped is $|-40| = 40$ units$^3$

**? Exercise 12.5.11**

Find the volume of the parallelepiped formed by the vectors $\vec{a} = 3\hat{i} + 4\hat{j} - \hat{k}$, $\vec{b} = 2\hat{i} - \hat{j} - \hat{k}$, and $\vec{c} = 3\hat{j} + \hat{k}$.

**Hint**

Calculate the triple scalar product by finding a determinant.

**Answer**

8 units$^3$

## Applications of the Cross Product

The cross product appears in many practical applications in mathematics, physics, and engineering. Let's examine some of these applications here, including the idea of torque, with which we began this section. Other applications show up in later chapters, particularly in our study of vector fields such as gravitational and electromagnetic fields (Introduction to Vector Calculus).

**✓ Example 12.5.12: Using the Triple Scalar Product**

Use the triple scalar product to show that vectors $\vec{u} = \langle 2, 0, 5\rangle, \vec{v} = \langle 2, 2, 4\rangle$, and $\vec{w} = \langle 1, -1, 3\rangle$ are coplanar—that is, show that these vectors lie in the same plane.

**Solution**

Start by calculating the triple scalar product to find the volume of the parallelepiped defined by $\vec{u}, \vec{v}$, and $\vec{w}$:

$$\vec{u}\cdot(\vec{v}\times\vec{w}) = \begin{vmatrix} 2 & 0 & 5 \\ 2 & 2 & 4 \\ 1 & -1 & 3 \end{vmatrix}$$
$$= [2(2)(3) + (0)(4)(1) + 5(2)(-1)] - [5(2)(1) + (2)(4)(-1) + (0)(2)(3)]$$
$$= 2 - 2 = 0.$$

The volume of the parallelepiped is 0 units$^3$, so one of the dimensions must be zero. Therefore, the three vectors all lie in the same plane.

**? Exercise 12.5.12**

Are the vectors $\vec{a} = \hat{i} + \hat{j} - \hat{k}$, $\vec{b} = \hat{i} - \hat{j} + \hat{k}$, and $\vec{c} = \hat{i} + \hat{j} + \hat{k}$ coplanar?

**Hint**

Calculate the triple scalar product.

**Answer**

No, the triple scalar product is $-4 \neq 0$, so the three vectors form the adjacent edges of a parallelepiped. They are not coplanar.

### Example 12.5.13: Finding an Orthogonal Vector

Only a single plane can pass through any set of three noncolinear points. Find a vector orthogonal to the plane containing points $P = (9, -3, -2), Q = (1, 3, 0)$, and $R = (-2, 5, 0)$.

**Solution**

The plane must contain vectors $\overrightarrow{PQ}$ and $\overrightarrow{QR}$:

$$\overrightarrow{PQ} = \langle 1 - 9, 3 - (-3), 0 - (-2) \rangle = \langle -8, 6, 2 \rangle$$

$$\overrightarrow{QR} = \langle -2 - 1, 5 - 3, 0 - 0 \rangle = \langle -3, 2, 0 \rangle.$$

The cross product $\overrightarrow{PQ} \times \overrightarrow{QR}$ produces a vector orthogonal to both $\overrightarrow{PQ}$ and $\overrightarrow{QR}$. Therefore, the cross product is orthogonal to the plane that contains these two vectors:

$$\begin{aligned} \overrightarrow{PQ} \times \overrightarrow{QR} &= \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ -8 & 6 & 2 \\ -3 & 2 & 0 \end{vmatrix} \\ &= 0\hat{\mathbf{i}} - 6\hat{\mathbf{j}} - 16\hat{\mathbf{k}} - (-18\hat{\mathbf{k}} + 4\hat{\mathbf{i}} + 0\hat{\mathbf{j}}) \\ &= -4\hat{\mathbf{i}} - 6\hat{\mathbf{j}} + 2\hat{\mathbf{k}}. \end{aligned}$$

We have seen how to use the triple scalar product and how to find a vector orthogonal to a plane. Now we apply the cross product to real-world situations.

Sometimes a force causes an object to rotate. For example, turning a screwdriver or a wrench creates this kind of rotational effect, called torque.

### Definition: Torque

*Torque*, $\vec{\tau}$ (the Greek letter tau), measures the tendency of a force to produce rotation about an axis of rotation. Let $\vec{\mathbf{r}}$ be a vector with an initial point located on the axis of rotation and with a terminal point located at the point where the force is applied, and let vector $\vec{\mathbf{F}}$ represent the force. Then torque is equal to the cross product of $\vec{\mathbf{r}}$ and $\vec{\mathbf{F}}$:

$$\vec{\tau} = \vec{\mathbf{r}} \times \vec{\mathbf{F}}.$$

See Figure 12.5.9.

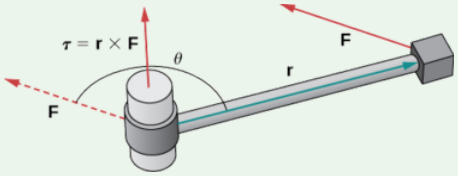

Figure 12.5.9: Torque measures how a force causes an object to rotate.

Think about using a wrench to tighten a bolt. The torque τ applied to the bolt depends on how hard we push the wrench (force) and how far up the handle we apply the force (distance). The torque increases with a greater force on the wrench at a greater distance from the bolt. Common units of torque are the newton-meter or foot-pound. Although torque is dimensionally equivalent to work (it has the same units), the two concepts are distinct. Torque is used specifically in the context of rotation, whereas work typically involves motion along a line.

### Example 12.5.14: Evaluating Torque

A bolt is tightened by applying a force of 6 N to a 0.15-m wrench (Figure 12.5.10). The angle between the wrench and the force vector is 40°. Find the magnitude of the torque about the center of the bolt. Round the answer to two decimal places.

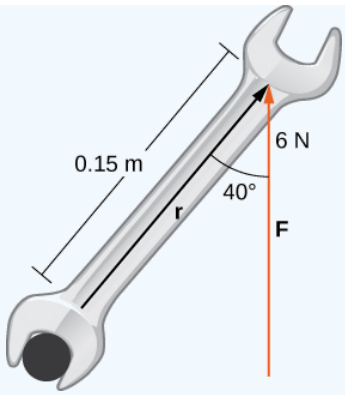

Figure 12.5.10: Torque describes the twisting action of the wrench.

**Solution**:

Substitute the given information into the equation defining torque:

$$\begin{aligned} \|\vec{\tau}\| &= \|\vec{r} \times \vec{F}\| \\ &= \|\vec{r}\| \, \|\vec{F}\| \sin\theta \\ &= (0.15\,\text{m})(6\,\text{N}) \sin 40° \\ &\approx 0.58\,\text{N·m}. \end{aligned}$$

## Exercise 12.5.14

Calculate the force required to produce 15 N·m torque at an angle of 30º from a 150-cm rod.

**Hint**

$\|\vec{\tau}\| = 15$ N·m and $\|\vec{r}\| = 1.5$ m

**Answer**

20 N

## Key Concepts

- The cross product $\vec{u} \times \vec{v}$ of two vectors $\vec{u} = \langle u_1, u_2, u_3 \rangle$ and $\vec{v} = \langle v_1, v_2, v_3 \rangle$ is a vector orthogonal to both $\vec{u}$ and $\vec{v}$. Its length is given by $\|\vec{u} \times \vec{v}\| = \|\vec{u}\| \cdot \|\vec{v}\| \cdot \sin\theta$, where $\theta$ is the angle between $\vec{u}$ and $\vec{v}$. Its direction is given by the right-hand rule.
- The algebraic formula for calculating the cross product of two vectors,

  $\vec{u} = \langle u_1, u_2, u_3 \rangle$ and $\vec{v} = \langle v_1, v_2, v_3 \rangle$, is

  $\vec{u} \times \vec{v} = (u_2 v_3 - u_3 v_2)\hat{i} - (u_1 v_3 - u_3 v_1)\hat{j} + (u_1 v_2 - u_2 v_1)\hat{k}$.
- The cross product satisfies the following properties for vectors $\vec{u}, \vec{v}$, and $\vec{w}$, and scalar $c$:

  $$\vec{u} \times \vec{v} = -(\vec{v} \times \vec{u})$$

  $$\vec{u} \times (\vec{v} + \vec{w}) = \vec{u} \times \vec{v} + \vec{u} \times \vec{w}$$

  $$c(\vec{u} \times \vec{v}) = (c\vec{u}) \times \vec{v} = \vec{u} \times (c\vec{v})$$

  $$\vec{u} \times \vec{0} = \vec{0} \times \vec{u} = \vec{0}$$

  $$\vec{v} \times \vec{v} = \vec{0}$$

  $$\vec{u} \cdot (\vec{v} \times \vec{w}) = (\vec{u} \times \vec{v}) \cdot \vec{w}$$
- The cross product of vectors $\vec{u} = \langle u_1, u_2, u_3 \rangle$ and $\vec{v} = \langle v_1, v_2, v_3 \rangle$ is the determinant $\begin{vmatrix} \hat{i} & \hat{j} & \hat{k} \\ u_1 & u_2 & u_3 \\ v_1 & v_2 & v_3 \end{vmatrix}$

- If vectors $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ form adjacent sides of a parallelogram, then the area of the parallelogram is given by $\|\vec{\mathbf{u}} \times \vec{\mathbf{v}}\|$.
- The triple scalar product of vectors $\vec{\mathbf{u}}, \vec{\mathbf{v}}$, and $\vec{\mathbf{w}}$ is $\vec{\mathbf{u}} \cdot (\vec{\mathbf{v}} \times \vec{\mathbf{w}})$.
- The volume of a parallelepiped with adjacent edges given by vectors $\vec{\mathbf{u}}, \vec{\mathbf{v}}$, and $\vec{\mathbf{w}}$ is $V = |\vec{\mathbf{u}} \cdot (\vec{\mathbf{v}} \times \vec{\mathbf{w}})|$.
- If the triple scalar product of vectors $\vec{\mathbf{u}}, \vec{\mathbf{v}}$, and $\vec{\mathbf{w}}$ is zero, then the vectors are coplanar. The converse is also true: If the vectors are coplanar, then their triple scalar product is zero.
- The cross product can be used to identify a vector orthogonal to two given vectors or to a plane.
- Torque $\vec{\boldsymbol{\tau}}$ measures the tendency of a force to produce rotation about an axis of rotation. If force $\vec{\mathbf{F}}$ is acting at a distance (displacement) $\vec{\mathbf{r}}$ from the axis, then torque is equal to the cross product of $\vec{\mathbf{r}}$ and $\vec{\mathbf{F}}$ : $\vec{\boldsymbol{\tau}} = \vec{\mathbf{r}} \times \vec{\mathbf{F}}$.

## Key Equations

- **The cross product of two vectors in terms of the unit vectors**

$$\vec{\mathbf{u}} \times \vec{\mathbf{v}} = (u_2 v_3 - u_3 v_2)\hat{\mathbf{i}} - (u_1 v_3 - u_3 v_1)\hat{\mathbf{j}} + (u_1 v_2 - u_2 v_1)\hat{\mathbf{k}}$$

## Glossary

**cross product**

$\vec{\mathbf{u}} \times \vec{\mathbf{v}} = (u_2 v_3 - u_3 v_2)\hat{\mathbf{i}} - (u_1 v_3 - u_3 v_1)\hat{\mathbf{j}} + (u_1 v_2 - u_2 v_1)\hat{\mathbf{k}}$, where $\vec{\mathbf{u}} = \langle u_1, u_2, u_3 \rangle$ and $\vec{\mathbf{v}} = \langle v_1, v_2, v_3 \rangle$

**determinant**

a real number associated with a square matrix

**parallelepiped**

a three-dimensional prism with six faces that are parallelograms

**torque**

the effect of a force that causes an object to rotate

**triple scalar product**

the dot product of a vector with the cross product of two other vectors: $\vec{\mathbf{u}} \cdot (\vec{\mathbf{v}} \times \vec{\mathbf{w}})$

**vector product**

the cross product of two vectors

# 12.5E: Exercises for Section 12.4

**For exercises 1-4, the vectors $\vec{u}$ and $\vec{v}$ are given.**

**a. Find the cross product $\vec{u} \times \vec{v}$ of the vectors $\vec{u}$ and $\vec{v}$. Express the answer in component form.**

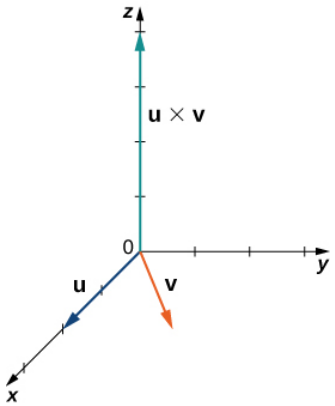
**b. Sketch the vectors $\vec{u}$, $\vec{v}$, and $\vec{u} \times \vec{v}$.**

1) $\vec{u} = \langle 2, 0, 0 \rangle, \quad \vec{v} = \langle 2, 2, 0 \rangle$

**Answer**

*a.* $\vec{u} \times \vec{v} = \langle 0, 0, 4 \rangle$;

*b.*



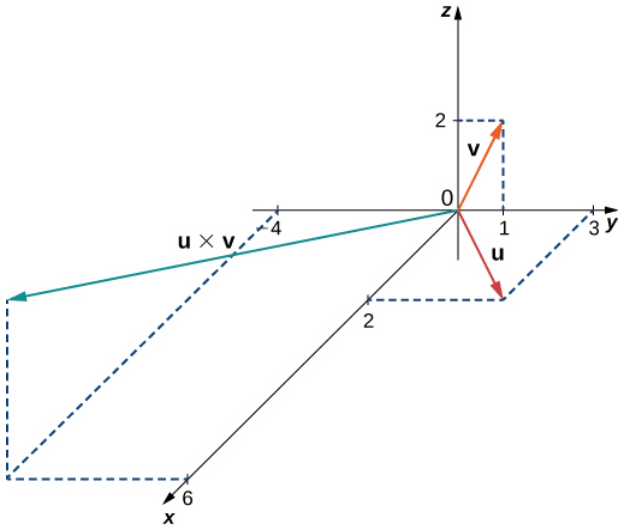
2) $\vec{u} = \langle 3, 2, -1 \rangle, \quad \vec{v} = \langle 1, 1, 0 \rangle$

3) $\vec{u} = 2\hat{i} + 3\hat{j}, \quad \vec{v} = \hat{j} + 2\hat{k}$

**Answer**

*a.* $\vec{u} \times \vec{v} = \langle 6, -4, 2 \rangle$;

*b.*



4) $\vec{u} = 2\hat{j} + 3\hat{k}, \quad \vec{v} = 3\hat{i} + \hat{k}$

5) Simplify $(\hat{i} \times \hat{i} - 2\hat{i} \times \hat{j} - 4\hat{i} \times \hat{k} + 3\hat{j} \times \hat{k}) \times \hat{i}$.

**Answer**

$-2\hat{\mathbf{j}} - 4\hat{\mathbf{k}}$

6) Simplify $\hat{\mathbf{j}} \times (\hat{\mathbf{k}} \times \hat{\mathbf{j}} + 2\hat{\mathbf{j}} \times \hat{\mathbf{i}} - 3\hat{\mathbf{j}} \times \hat{\mathbf{j}} + 5\hat{\mathbf{i}} \times \hat{\mathbf{k}})$.

**In exercises 7-10, vectors $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ are given. Find unit vector $\vec{\mathbf{w}}$ in the direction of the cross product vector $\vec{\mathbf{u}} \times \vec{\mathbf{v}}$. Express your answer using standard unit vectors.**

7) $\vec{\mathbf{u}} = \langle 3, -1, 2 \rangle$, $\vec{\mathbf{v}} = \langle -2, 0, 1 \rangle$

**Answer**

$\vec{\mathbf{w}} = -\frac{\sqrt{6}}{18}\hat{\mathbf{i}} - \frac{7\sqrt{6}}{18}\hat{\mathbf{j}} - \frac{\sqrt{6}}{9}\hat{\mathbf{k}}$

8) $\vec{\mathbf{u}} = \langle 2, 6, 1 \rangle$, $\vec{\mathbf{v}} = \langle 3, 0, 1 \rangle$

9) $\vec{\mathbf{u}} = \overrightarrow{AB}$, $\vec{\mathbf{v}} = \overrightarrow{AC}$, where $A(1, 0, 1)$, $B(1, -1, 3)$, and $C(0, 0, 5)$

**Answer**

$\vec{\mathbf{w}} = -\frac{4\sqrt{21}}{21}\hat{\mathbf{i}} - \frac{2\sqrt{21}}{21}\hat{\mathbf{j}} - \frac{\sqrt{21}}{21}\hat{\mathbf{k}}$

10) $\vec{\mathbf{u}} = \overrightarrow{OP}$, $\vec{\mathbf{v}} = \overrightarrow{PQ}$, where $P(-1, 1, 0)$ and $Q(0, 2, 1)$

11) Determine the real number $\alpha$ such that $\vec{\mathbf{u}} \times \vec{\mathbf{v}}$ and $\hat{\mathbf{i}}$ are orthogonal, where $\vec{\mathbf{u}} = 3\hat{\mathbf{i}} + \hat{\mathbf{j}} - 5\hat{\mathbf{k}}$ and $\vec{\mathbf{v}} = 4\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + \alpha\hat{\mathbf{k}}$.

**Answer**

$\alpha = 10$

12) Show that $\vec{\mathbf{u}} \times \vec{\mathbf{v}}$ and $2\hat{\mathbf{i}} - 14\hat{\mathbf{j}} + 2\hat{\mathbf{k}}$ cannot be orthogonal for any α real number, where $\vec{\mathbf{u}} = \hat{\mathbf{i}} + 7\hat{\mathbf{j}} - \hat{\mathbf{k}}$ and $\vec{\mathbf{v}} = \alpha\hat{\mathbf{i}} + 5\hat{\mathbf{j}} + \hat{\mathbf{k}}$.

13) Show that $\vec{\mathbf{u}} \times \vec{\mathbf{v}}$ is orthogonal to $\vec{\mathbf{u}} + \vec{\mathbf{v}}$ and $\vec{\mathbf{u}} - \vec{\mathbf{v}}$, where $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ are nonzero vectors.

14) Show that $\vec{\mathbf{v}} \times \vec{\mathbf{u}}$ is orthogonal to $(\vec{\mathbf{u}} \cdot \vec{\mathbf{v}})(\vec{\mathbf{u}} + \vec{\mathbf{v}}) + \vec{\mathbf{u}}$, where $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ are nonzero vectors.

15) Calculate the determinant $\begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 1 & -1 & 7 \\ 2 & 0 & 3 \end{vmatrix}$.

**Answer**

$-3\hat{\mathbf{i}} + 11\hat{\mathbf{j}} + 2\hat{\mathbf{k}}$

16) Calculate the determinant $\begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 0 & 3 & -4 \\ 1 & 6 & -1 \end{vmatrix}$.

**For exercises 17-18, the vectors $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ are given. Use determinant notation to find vector $\vec{\mathbf{w}}$ orthogonal to vectors $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$.**

17) $\vec{\mathbf{u}} = \langle -1, 0, e^t \rangle$, $\vec{\mathbf{v}} = \langle 1, e^{-t}, 0 \rangle$, where $t$ is a real number

**Answer**

$\vec{\mathbf{w}} = \langle -1, e^t, -e^{-t} \rangle$

18) $\vec{\mathbf{u}} = \langle 1, 0, x \rangle$, $\vec{\mathbf{v}} = \langle \frac{2}{x}, 1, 0 \rangle$, where $x$ is a nonzero real number

19) Find vector $(\vec{\mathbf{a}} - 2\vec{\mathbf{b}}) \times \vec{\mathbf{c}}$, where $\vec{\mathbf{a}} = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 2 & -1 & 5 \\ 0 & 1 & 8 \end{vmatrix}$, $\vec{\mathbf{b}} = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 0 & 1 & 1 \\ 2 & -1 & -2 \end{vmatrix}$, and $\vec{\mathbf{c}} = \hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}$.

**Answer**

$-26\hat{\mathbf{i}} + 17\hat{\mathbf{j}} + 9\hat{\mathbf{k}}$

20) Find vector $\vec{c} \times (\vec{a} + 3\vec{b})$, where $\vec{a} = \begin{vmatrix} \hat{i} & \hat{j} & \hat{k} \\ 5 & 0 & 9 \\ 0 & 1 & 0 \end{vmatrix}$, $\vec{b} = \begin{vmatrix} \hat{i} & \hat{j} & \hat{k} \\ 0 & -1 & 1 \\ 7 & 1 & -1 \end{vmatrix}$, and $\vec{c} = \hat{i} - \hat{k}$.

21) [T] Use the cross product $\vec{u} \times \vec{v}$ to find the acute angle between vectors $\vec{u}$ and $\vec{v}$, where $\vec{u} = \hat{i} + 2\hat{j}$ and $\vec{v} = \hat{i} + \hat{k}$. Express the answer in degrees rounded to the nearest integer.

**Answer**

$72°$

22) [T] Use the cross product $\vec{u} \times \vec{v}$ to find the obtuse angle between vectors $\vec{u}$ and $\vec{v}$, where $\vec{u} = -\hat{i} + 3\hat{j} + \hat{k}$ and $\vec{v} = \hat{i} - 2\hat{j}$. Express the answer in degrees rounded to the nearest integer.

23) Use the sine and cosine of the angle between two nonzero vectors $\vec{u}$ and $\vec{v}$ to prove Lagrange's identity: $\|\vec{u} \times \vec{v}\|^2 = \|\vec{u}\|^2\|\vec{v}\|^2 - (\vec{u} \cdot \vec{v})^2$.

24) Verify Lagrange's identity $\|\vec{u} \times \vec{v}\|^2 = \|\vec{u}\|^2\|\vec{v}\|^2 - (\vec{u} \cdot \vec{v})^2$ for vectors $\vec{u} = -\hat{i} + \hat{j} - 2\hat{k}$ and $\vec{v} = 2\hat{i} - \hat{j}$.

25) Nonzero vectors $\vec{u}$ and $\vec{v}$ are called collinear if there exists a nonzero scalar $\alpha$ such that $\vec{v} = \alpha\vec{u}$. Show that $\vec{u}$ and $\vec{v}$ are collinear if and only if $\vec{u} \times \vec{v} = 0$.

26) Nonzero vectors $\vec{u}$ and $\vec{v}$ are called *collinear* if there exists a nonzero scalar $\alpha$ such that $\vec{v} = \alpha\vec{u}$. Show that vectors $\overrightarrow{AB}$ and $\overrightarrow{AC}$ are collinear, where $A(4, 1, 0)$, $B(6, 5, -2)$, and $C(5, 3, -1)$.

27) Find the area of the parallelogram with adjacent sides $\vec{u} = \langle 3, 2, 0 \rangle$ and $\vec{v} = \langle 0, 2, 1 \rangle$.

**Answer**

7

28) Find the area of the parallelogram with adjacent sides $\vec{u} = \hat{i} + \hat{j}$ and $\vec{v} = \hat{i} + \hat{k}$.

29) Consider points $A(3, -1, 2)$, $B(2, 1, 5)$, and $C(1, -2, -2)$.

a. Find the area of parallelogram $ABCD$ with adjacent sides $\overrightarrow{AB}$ and $\overrightarrow{AC}$.

b. Find the area of triangle $ABC$.

c. Find the distance from point $A$ to line $BC$.

**Answer**

a. $5\sqrt{6}$; b. $\frac{5\sqrt{6}}{2}$; c. $\frac{5\sqrt{6}}{\sqrt{59}} = \frac{5\sqrt{354}}{59}$

30) Consider points $A(2, -3, 4)$, $B(0, 1, 2)$, and $C(-1, 2, 0)$.

a. Find the area of parallelogram $ABCD$ with adjacent sides $\overrightarrow{AB}$ and $\overrightarrow{AC}$.

b. Find the area of triangle $ABC$.

c. Find the distance from point $B$ to line $AC$.

**In exercises 31-32, vectors $\vec{u}$, $\vec{v}$, and $\vec{w}$ are given.**

**a. Find the triple scalar product $\vec{u} \cdot (\vec{v} \times \vec{w})$.**

**b. Find the volume of the parallelepiped with the adjacent edges $\vec{u}$, $\vec{v}$, and $\vec{w}$.**

31) $\vec{u} = \hat{i} + \hat{j}$, $\vec{v} = \hat{j} + \hat{k}$, and $\vec{w} = \hat{i} + \hat{k}$

**Answer**

$a. 2$; $b. 2$ units$^3$

32) $\vec{u} = \langle -3, 5, -1 \rangle$, $\vec{v} = \langle 0, 2, -2 \rangle$, and $\vec{w} = \langle 3, 1, 1 \rangle$

33) Calculate the triple scalar products $\vec{\mathbf{v}} \cdot (\vec{\mathbf{u}} \times \vec{\mathbf{w}})$ and $\vec{\mathbf{w}} \cdot (\vec{\mathbf{u}} \times \vec{\mathbf{v}})$, where $\vec{\mathbf{u}} = \langle 1, 1, 1 \rangle, \vec{\mathbf{v}} = \langle 7, 6, 9 \rangle$, and $\vec{\mathbf{w}} = \langle 4, 2, 7 \rangle$.

**Answer**

$\vec{\mathbf{v}} \cdot (\vec{\mathbf{u}} \times \vec{\mathbf{w}}) = -1, \quad \vec{\mathbf{w}} \cdot (\vec{\mathbf{u}} \times \vec{\mathbf{v}}) = 1$

34) Calculate the triple scalar products $\vec{\mathbf{w}} \cdot (\vec{\mathbf{v}} \times \vec{\mathbf{u}})$ and $\vec{\mathbf{u}} \cdot (\vec{\mathbf{w}} \times \vec{\mathbf{v}})$, where $\vec{\mathbf{u}} = \langle 4, 2, -1 \rangle, \vec{\mathbf{v}} = \langle 2, 5, -3 \rangle$, and $\vec{\mathbf{w}} = \langle 9, 5, -10 \rangle$.

35) Find vectors $\vec{\mathbf{a}}$, $\vec{\mathbf{b}}$, and $\vec{\mathbf{c}}$ with a triple scalar product given by the determinant $\begin{vmatrix} 1 & 2 & 3 \\ 0 & 2 & 5 \\ 8 & 9 & 2 \end{vmatrix}$. Determine their triple scalar product.

**Answer**

$\vec{\mathbf{a}} = \langle 1, 2, 3 \rangle, \quad \vec{\mathbf{b}} = \langle 0, 2, 5 \rangle, \quad \vec{\mathbf{c}} = \langle 8, 9, 2 \rangle; \quad \vec{\mathbf{a}} \cdot (\vec{\mathbf{b}} \times \vec{\mathbf{c}}) = -9$

36) The triple scalar product of vectors $\vec{\mathbf{a}}$, $\vec{\mathbf{b}}$, and $\vec{\mathbf{c}}$ is given by the determinant $\begin{vmatrix} 0 & -2 & 1 \\ 0 & 1 & 4 \\ 1 & -3 & 7 \end{vmatrix}$. Find vector $\vec{\mathbf{a}} - \vec{\mathbf{b}} + \vec{\mathbf{c}}$.

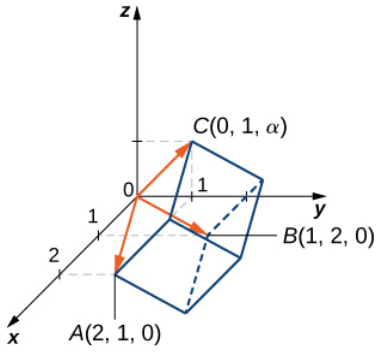
37) Consider the parallelepiped with edges $OA, OB$, and $OC$, where $A(2, 1, 0), B(1, 2, 0)$, and $C(0, 1, \alpha)$.

a. Find the real number $\alpha > 0$ such that the volume of the parallelepiped is $3$ units$^3$.

b. For $\alpha = 1$, find the height $h$ from vertex $C$ of the parallelepiped. Sketch the parallelepiped.

**Answer**

*a.* $\alpha = 1$; *b.* $h = 1$ unit,



38) Consider points $A(\alpha, 0, 0), B(0, \beta, 0)$, and $C(0, 0, \gamma)$, with $\alpha, \beta$, and $\gamma$ positive real numbers.

a. Determine the volume of the parallelepiped with adjacent sides $\overrightarrow{OA}, \overrightarrow{OB}$, and $\overrightarrow{OC}$.

b. Find the volume of the tetrahedron with vertices $O, A, B$, and $C$. (Hint: The volume of the tetrahedron is $1/6$ of the volume of the parallelepiped.)

c. Find the distance from the origin to the plane determined by $A, B$, and $C$. Sketch the parallelepiped and tetrahedron.

39) Let $u, v$, and $w$ be three-dimensional vectors and $c$ be a real number. Prove the following properties of the cross product.

a. $\vec{\mathbf{u}} \times \vec{\mathbf{u}} = \vec{\mathbf{0}}$

b. $\vec{\mathbf{u}} \times (\vec{\mathbf{v}} + \vec{\mathbf{w}}) = (\vec{\mathbf{u}} \times \vec{\mathbf{v}}) + (\vec{\mathbf{u}} \times \vec{\mathbf{w}})$

c. $c(\vec{\mathbf{u}} \times \vec{\mathbf{v}}) = (c\vec{\mathbf{u}}) \times \vec{\mathbf{v}} = \vec{\mathbf{u}} \times (c\vec{\mathbf{v}})$

d. $\vec{\mathbf{u}} \cdot (\vec{\mathbf{u}} \times \vec{\mathbf{v}}) = \vec{\mathbf{0}}$

40) Show that vectors $\vec{\mathbf{u}} = \langle 1, 0, -8 \rangle$, $\vec{\mathbf{v}} = \langle 0, 1, 6 \rangle$, and $\vec{\mathbf{w}} = \langle -1, 9, 3 \rangle$ satisfy the following properties of the cross product.

a. $\vec{\mathbf{u}} \times \vec{\mathbf{u}} = \vec{\mathbf{0}}$

b. $\vec{\mathbf{u}} \times (\vec{\mathbf{v}} + \vec{\mathbf{w}}) = (\vec{\mathbf{u}} \times \vec{\mathbf{v}}) + (\vec{\mathbf{u}} \times \vec{\mathbf{w}})$

c. $c(\vec{\mathbf{u}} \times \vec{\mathbf{v}}) = (c\vec{\mathbf{u}}) \times \vec{\mathbf{v}} = \vec{\mathbf{u}} \times (c\vec{\mathbf{v}})$

d. $\vec{\mathbf{u}} \cdot (\vec{\mathbf{u}} \times \vec{\mathbf{v}}) = \vec{\mathbf{0}}$

41) Nonzero vectors $\vec{\mathbf{u}}$, $\vec{\mathbf{v}}$, and $\vec{\mathbf{w}}$ are said to be linearly dependent if one of the vectors is a linear combination of the other two. For instance, there exist two nonzero real numbers $\alpha$ and $\beta$ such that $\vec{\mathbf{w}} = \alpha\vec{\mathbf{u}} + \beta\vec{\mathbf{v}}$. Otherwise, the vectors are called linearly independent. Show that $\vec{\mathbf{u}}, \vec{\mathbf{v}}$, and $\vec{\mathbf{w}}$ could be placed on the same plane if and only if they are linear dependent.

42) Consider vectors $\vec{\mathbf{u}} = \langle 1, 4, -7 \rangle$, $\vec{\mathbf{v}} = \langle 2, -1, 4 \rangle$, $\vec{\mathbf{w}} = \langle 0, -9, 18 \rangle$, and $\vec{\mathbf{p}} = \langle 0, -9, 17 \rangle$.

a. Show that $\vec{\mathbf{u}}$, $\vec{\mathbf{v}}$, and $\vec{\mathbf{w}}$ can be placed on the same plane by using their triple scalar product

b. Show that $\vec{\mathbf{u}}$, $\vec{\mathbf{v}}$, and $\vec{\mathbf{w}}$ can be placed on the same plane by using the definition that there exist two nonzero real numbers $\alpha$ and $\beta$ such that $w = \alpha u + \beta v$.

c. Show that $\vec{\mathbf{u}}$, $\vec{\mathbf{v}}$, and $\vec{\mathbf{p}}$ are linearly independent—that is, none of the vectors is a linear combination of the other two.

43) Consider points $A(0, 0, 2), B(1, 0, 2), C(1, 1, 2)$, and $D(0, 1, 2)$. Are vectors $\overrightarrow{AB}, \overrightarrow{AC}$, and $\overrightarrow{AD}$ linearly dependent (that is, one of the vectors is a linear combination of the other two)?

**Answer**

Yes, $\overrightarrow{AD} = \alpha\overrightarrow{AB} + \beta\overrightarrow{AC}$, where $\alpha = -1$ and $\beta = 1$.

44) Show that vectors $\hat{\mathbf{i}} + \hat{\mathbf{j}}, \hat{\mathbf{i}} - \hat{\mathbf{j}}$, and $\hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}$ are linearly independent—that is, there exist two nonzero real numbers $\alpha$ and $\beta$ such that $\hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}} = \alpha(\hat{\mathbf{i}} + \hat{\mathbf{j}}) + \beta(\hat{\mathbf{i}} - \hat{\mathbf{j}})$.

45) Let $\vec{\mathbf{u}} = \langle u_1, u_2 \rangle$ and $\vec{\mathbf{v}} = \langle v_1, v_2 \rangle$ be two-dimensional vectors. The cross product of vectors $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ is not defined. However, if the vectors are regarded as the three-dimensional vectors $\tilde{\vec{\mathbf{u}}} = \langle u_1, u_2, 0 \rangle$ and $\tilde{\vec{\mathbf{v}}} = \langle v_1, v_2, 0 \rangle$, respectively, then, in this case, we can define the cross product of $\tilde{\vec{\mathbf{u}}}$ and $\tilde{\vec{\mathbf{v}}}$. In particular, in determinant notation, the cross product of $\tilde{\vec{\mathbf{u}}}$ and $\tilde{\vec{\mathbf{v}}}$ is given by

$$\tilde{\vec{\mathbf{u}}} \times \tilde{\vec{\mathbf{v}}} = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ u_1 & u_2 & 0 \\ v_1 & v_2 & 0 \end{vmatrix}.$$

Use this result to compute $(\cos\theta\,\hat{\mathbf{i}} + \sin\theta\,\hat{\mathbf{j}}) \times (\sin\theta\,\hat{\mathbf{i}} - \cos\theta\,\hat{\mathbf{j}})$, where $\theta$ is a real number.

**Answer**

$-\hat{\mathbf{k}}$

46) Consider points $P(2, 1), Q(4, 2)$, and $R(1, 2)$.

a. Find the area of triangle $PQR$.

b. Determine the distance from point $R$ to the line passing through $P$ and $Q$.

47) Determine a vector of magnitude $10$ perpendicular to the plane passing through the x-axis and point $P(1, 2, 4)$.

**Answer**

$\langle 0, \pm 4\sqrt{5}, 2\sqrt{5} \rangle$

48) Determine a unit vector perpendicular to the plane passing through the $z$-axis and point $A(3, 1, -2)$.

49) Consider $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ two three-dimensional vectors. If the magnitude of the cross product vector $\vec{\mathbf{u}} \times \vec{\mathbf{v}}$ is $k$ times larger than the magnitude of vector $\vec{\mathbf{u}}$, show that the magnitude of $\vec{\mathbf{v}}$ is greater than or equal to $k$, where $k$ is a natural number.

50) [T] Assume that the magnitudes of two nonzero vectors $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ are known. The function $f(\theta) = \|\vec{\mathbf{u}}\|\|\vec{\mathbf{v}}\| \sin\theta$ defines the magnitude of the cross product vector $\vec{\mathbf{u}} \times \vec{\mathbf{v}}$, where $\theta \in [0, \pi]$ is the angle between $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$.

a. Graph the function $f$.

b. Find the absolute minimum and maximum of function $f$. Interpret the results.

c. If $\|\vec{\mathbf{u}}\| = 5$ and $\|\vec{\mathbf{v}}\| = 2$, find the angle between $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ if the magnitude of their cross product vector is equal to $9$.

51) Find all vectors $\vec{\mathbf{w}} = \langle w_1, w_2, w_3 \rangle$ that satisfy the equation $\langle 1, 1, 1 \rangle \times \vec{\mathbf{w}} = \langle -1, -1, 2 \rangle$. Hint: You should be able to write all components of $\vec{\mathbf{w}}$ in terms of one of the constants $w_1, w_2$, or $w_3$.

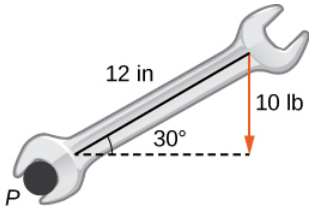
**Answer**

Writing all components in terms of the constant $w_3$, one way to represent these vectors is: $\vec{\mathbf{w}} = \langle w_3 - 1, w_3 + 1, w_3 \rangle$, where $w_3$ is any real number.

Note that we could use any parameter we wish here. We could set $w_3 = a$. Then $\vec{\mathbf{w}} = \langle a - 1, a + 1, a \rangle$ would also represent these vectors.

52) Solve the equation $\vec{\mathbf{w}} \times \langle 1, 0, -1 \rangle = \langle 3, 0, 3 \rangle$, where $\vec{\mathbf{w}} = \langle w_1, w_2, w_3 \rangle$ is a nonzero vector with a magnitude of $3$.

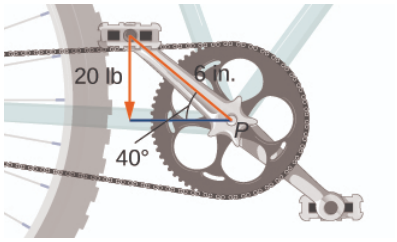
53) [T] A mechanic uses a 12-in. wrench to turn a bolt. The wrench makes a $30°$ angle with the horizontal. If the mechanic applies a vertical force of $10$ lb on the wrench handle, what is the magnitude of the torque at point $P$ (see the following figure)? Express the answer in foot-pounds rounded to two decimal places.



**Answer**

8.66 ft-lb

54) [T] A boy applies the brakes on a bicycle by applying a downward force of 20 lb on the pedal when the 6-in. crank makes a $40°$ angle with the horizontal (see the following figure). Find the torque at point $P$. Express your answer in foot-pounds rounded to two decimal places.



55) [T] Find the magnitude of the force that needs to be applied to the end of a 20-cm wrench located on the positive direction of the $y$-axis if the force is applied in the direction $\langle 0, 1, -2 \rangle$ and it produces a $100$ N·m torque to the bolt located at the origin.

**Answer**

$250\sqrt{5}$ N $\approx 559$ N

56) [T] What is the magnitude of the force required to be applied to the end of a 1-ft wrench at an angle of $35°$ to produce a torque of $20$ N·m?

57) [T] The force vector $\vec{\mathbf{F}}$ acting on a proton with an electric charge of $1.6 \times 10^{-19}\ C$ (in coulombs) moving in a magnetic field $\vec{\mathbf{B}}$ where the velocity vector $\vec{\mathbf{v}}$ is given by $\vec{\mathbf{F}} = 1.6 \times 10^{-19}(\vec{\mathbf{v}} \times \vec{\mathbf{B}})$ (here, $\vec{\mathbf{v}}$ is expressed in meters per second, $\vec{\mathbf{B}}$ is in tesla [T], and $\vec{\mathbf{F}}$ is in newtons [N]). Find the force that acts on a proton that moves in the $xy$-plane at velocity $\vec{\mathbf{v}} = 10^5\hat{\mathbf{i}} + 10^5\hat{\mathbf{j}}$ (in meters per second) in a magnetic field given by $\vec{\mathbf{B}} = 0.3\hat{\mathbf{j}}$.

**Answer**

$\vec{\mathbf{F}} = 4.8 \times 10^{-15}\ kN$

58) [T] The force vector $\vec{\mathbf{F}}$ acting on a proton with an electric charge of $1.6 \times 10^{-19}\ C$ moving in a magnetic field $\vec{\mathbf{B}}$ where the velocity vector $\vec{\mathbf{v}}$ is given by $\vec{\mathbf{F}} = 1.6 \times 10^{-19}(\vec{\mathbf{v}} \times \vec{\mathbf{B}})$ (here, $\vec{\mathbf{v}}$ is expressed in meters per second, $\vec{\mathbf{B}}$ in $T$, and $\vec{\mathbf{F}}$ in $N$). If the magnitude of force $\vec{\mathbf{F}}$ acting on a proton is $5.9 \times 10^{-17}\ N$ and the proton is moving at the speed of 300 m/sec in magnetic field $\vec{\mathbf{B}}$ of magnitude 2.4 T, find the angle between velocity vector $\vec{\mathbf{v}}$ of the proton and magnetic field $\vec{\mathbf{B}}$. Express the answer in degrees rounded to the nearest integer.

59) [T] Consider $\vec{\mathbf{r}}(t) = \langle \cos t,\ \sin t,\ 2t \rangle$ the position vector of a particle at time $t \in [0, 30]$, where the components of $\vec{\mathbf{r}}$ are expressed in centimeters and time in seconds. Let $\overrightarrow{OP}$ be the position vector of the particle after 1 sec.

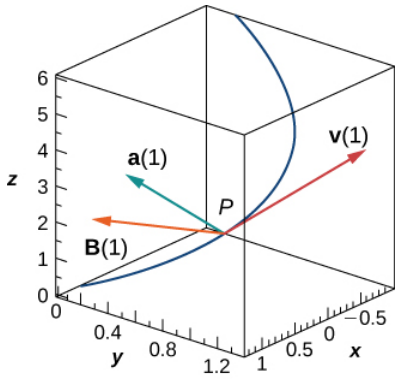
a. Determine unit vector $\vec{\mathbf{B}}(t)$ (called the binormal unit vector) that has the direction of cross product vector $\vec{\mathbf{v}}(t) \times \vec{\mathbf{a}}(t)$, where $\vec{\mathbf{v}}(t)$ and $\vec{\mathbf{a}}(t)$ are the instantaneous velocity vector and, respectively, the acceleration vector of the particle after $t$ seconds.

b. Use a CAS to visualize vectors $\vec{\mathbf{v}}(1)$, $\vec{\mathbf{a}}(1)$, and $\vec{\mathbf{B}}(1)$ as vectors starting at point $P$ along with the path of the particle.

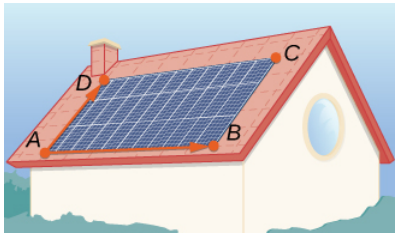
**Answer**

a. $\vec{\mathbf{B}}(t) = \langle \frac{2\sqrt{5}\sin t}{5}, -\frac{2\sqrt{5}\cos t}{5}, \frac{\sqrt{5}}{5} \rangle$;

b.



60) A solar panel is mounted on the roof of a house. The panel may be regarded as positioned at the points of coordinates (in meters) $A(8, 0, 0), B(8, 18, 0), C(0, 18, 8)$, and $D(0, 0, 8)$ (see the following figure).



a. Find vector $\vec{\mathbf{n}} = \overrightarrow{AB} \times \overrightarrow{AD}$ perpendicular to the surface of the solar panels. Express the answer using standard unit vectors. Note that the magnitude of this vector should give us the area of rectangle $ABCD$.

b. Assume unit vector $\vec{\mathbf{s}} = \frac{1}{\sqrt{3}}\hat{\mathbf{i}} + \frac{1}{\sqrt{3}}\hat{\mathbf{j}} + \frac{1}{\sqrt{3}}\hat{\mathbf{k}}$ points toward the Sun at a particular time of the day and the flow of solar energy is $\vec{\mathbf{F}} = 900\vec{\mathbf{s}}$ (in watts per square meter $[W/m^2]$). Find the predicted amount of electrical power the panel can produce, which is given by the dot product of vectors $\vec{\mathbf{F}}$ and $\vec{\mathbf{n}}$ (expressed in watts).

c. Determine the angle of elevation of the Sun above the solar panel. Express the answer in degrees rounded to the nearest whole number. (Hint: The angle between vectors $\vec{\mathbf{n}}$ and $\vec{\mathbf{s}}$ and the angle of elevation are complementary.)

# 12.6: Equations of Lines and Planes in Space

**Learning Objectives**

- Write the vector, parametric, and symmetric equations of a line through a given point in a given direction, and a line through two given points.
- Find the distance from a point to a given line.
- Write the vector and scalar equations of a plane through a given point with a given normal.
- Find the distance from a point to a given plane.
- Find the angle between two planes.

By now, we are familiar with writing equations that describe a line in two dimensions. To write an equation for a line, we must know two points on the line, or we must know the direction of the line and at least one point through which the line passes. In two dimensions, we use the concept of slope to describe the orientation, or direction, of a line. In three dimensions, we describe the direction of a line using a vector parallel to the line. In this section, we examine how to use equations to describe lines and planes in space.

## Equations for a Line in Space

Let's first explore what it means for two vectors to be parallel. Recall that parallel vectors must have the same or opposite directions. If two nonzero vectors, $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$, are parallel, we claim there must be a scalar, $k$, such that $\vec{\mathbf{u}} = k\vec{\mathbf{v}}$. If $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ have the same direction, simply choose

$$k = \frac{\|\vec{\mathbf{u}}\|}{\|\vec{\mathbf{v}}\|}.$$

If $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ have opposite directions, choose

$$k = -\frac{\|\vec{\mathbf{u}}\|}{\|\vec{\mathbf{v}}\|}.$$

Note that the converse holds as well. If $\vec{\mathbf{u}} = k\vec{\mathbf{v}}$ for some scalar $k$, then either $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ have the same direction ($k > 0$) or opposite directions ($k < 0$), so $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ are parallel. Therefore, two nonzero vectors $\vec{\mathbf{u}}$ and $\vec{\mathbf{v}}$ are parallel if and only if $\vec{\mathbf{u}} = k\vec{\mathbf{v}}$ for some scalar $k$. By convention, the zero vector $\vec{\mathbf{0}}$ is considered to be parallel to all vectors.

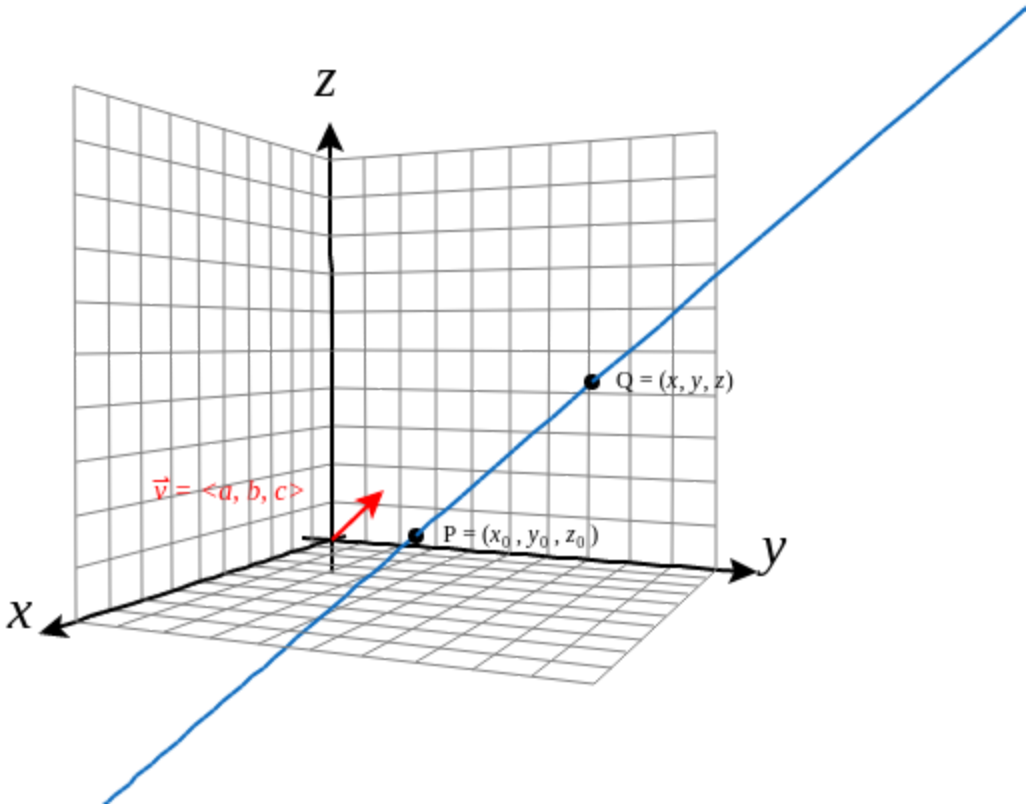

Figure 12.6.1: Vector $\vec{\mathbf{v}}$ is the direction vector for $\overrightarrow{PQ}$.

As in two dimensions, we can describe a line in space using a point on the line and the direction of the line, or a parallel vector, which we call the **direction vector** (Figure 12.6.1). Let $L$ be a line in space passing through point $P(x_0, y_0, z_0)$. Let $\vec{\mathbf{v}} = \langle a, b, c \rangle$ be a vector parallel to $L$. Then, for any point on line $Q(x, y, z)$, we know that $\overrightarrow{PQ}$ is parallel to $\vec{\mathbf{v}}$. Thus, as we just discussed, there is a scalar, $t$, such that $\overrightarrow{PQ} = t\vec{\mathbf{v}}$, which gives

$$\begin{aligned} \overrightarrow{PQ} &= t\vec{\mathbf{v}} \\ \langle x - x_0, y - y_0, z - z_0 \rangle &= t\langle a, b, c \rangle \\ \langle x - x_0, y - y_0, z - z_0 \rangle &= \langle ta, tb, tc \rangle. \end{aligned} \tag{12.6.1}$$

Using vector operations, we can rewrite Equation 12.6.1

$$\begin{aligned} \langle x - x_0, y - y_0, z - z_0 \rangle &= \langle ta, tb, tc \rangle \\ \langle x, y, z \rangle - \langle x_0, y_0, z_0 \rangle &= t\langle a, b, c \rangle \\ \underbrace{\langle x, y, z \rangle}_{\vec{\mathbf{r}}} &= \underbrace{\langle x_0, y_0, z_0 \rangle}_{\vec{\mathbf{r}}_0} + t\underbrace{\langle a, b, c \rangle}_{\vec{\mathbf{v}}}. \end{aligned}$$

Setting $\vec{\mathbf{r}} = \langle x, y, z \rangle$ and $\vec{\mathbf{r}}_0 = \langle x_0, y_0, z_0 \rangle$, we now have the **vector equation of a line:**

$$\vec{\mathbf{r}} = \vec{\mathbf{r}}_0 + t\vec{\mathbf{v}}. \tag{12.6.2}$$

Equating components, Equation 12.6.2 shows that the following equations are simultaneously true: $x - x_0 = ta, y - y_0 = tb$, and $z - z_0 = tc$. If we solve each of these equations for the component variables $x, y$, and $z$, we get a set of equations in which each variable is defined in terms of the parameter $t$ and that, together, describe the line. This set of three equations forms a set of **parametric equations of a line:**

$$x = x_0 + ta$$

$$y = y_0 + tb$$

$$z = z_0 + tc.$$

If we solve each of the equations for $t$ assuming $a, b$, and $c$ are nonzero, we get a different description of the same line:

$$\frac{x - x_0}{a} = t$$
$$\frac{y - y_0}{b} = t$$
$$\frac{z - z_0}{c} = t.$$

Because each expression equals $t$, they all have the same value. We can set them equal to each other to create **symmetric equations of a line:**

$$\frac{x - x_0}{a} = \frac{y - y_0}{b} = \frac{z - z_0}{c}.$$

We summarize the results in the following theorem.

**Theorem: Parametric and Symmetric Equations of a Line**

A line $L$ parallel to vector $\vec{\mathbf{v}} = \langle a, b, c \rangle$ and passing through point $P(x_0, y_0, z_0)$ can be described by the following parametric equations:

$$x = x_0 + ta, y = y_0 + tb,$$

and

$$z = z_0 + tc.$$

If the constants $a, b$, and $c$ are all nonzero, then $L$ can be described by the symmetric equation of the line:

$$\frac{x - x_0}{a} = \frac{y - y_0}{b} = \frac{z - z_0}{c}.$$

The parametric equations of a line are not unique. Using a different parallel vector or a different point on the line leads to a different, equivalent representation. Each set of parametric equations leads to a related set of symmetric equations, so it follows that a symmetric equation of a line is not unique either.

**Example 12.6.1: Equations of a Line in Space**

Find parametric and symmetric equations of the line passing through points $(1, 4, -2)$ and $(-3, 5, 0)$.

**Solution**

First, identify a vector parallel to the line:

$$\vec{\mathbf{v}} = \langle -3 - 1, 5 - 4, 0 - (-2) \rangle = \langle -4, 1, 2 \rangle.$$

Use either of the given points on the line to complete the parametric equations:

$$x = 1 - 4t$$
$$y = 4 + t,$$

and

$$z = -2 + 2t.$$

Solve each equation for $t$ to create the symmetric equation of the line:

$$\frac{x-1}{-4} = y-4 = \frac{z+2}{2}.$$

**Exercise 12.6.1**

Find parametric and symmetric equations of the line passing through points $(1,-3,2)$ and $(5,-2,8)$.

**Hint:**

Start by finding a vector parallel to the line.

**Answer**

Possible set of parametric equations: $x = 1+4t,\ y = -3+t,\ z = 2+6t$; related set of symmetric equations:

$$\frac{x-1}{4} = y+3 = \frac{z-2}{6}$$

Sometimes we don't want the equation of a whole line, just a line segment. In this case, we limit the values of our parameter $t$. For example, let $P(x_0,y_0,z_0)$ and $Q(x_1,y_1,z_1)$ be points on a line, and let $\vec{\mathbf{p}} = \langle x_0,y_0,z_0\rangle$ and $\vec{\mathbf{q}} = \langle x_1,y_1,z_1\rangle$ be the associated position vectors. In addition, let $\vec{\mathbf{r}} = \langle x,y,z\rangle$. We want to find a vector equation for the line segment between $P$ and $Q$. Using $P$ as our known point on the line, and $\overrightarrow{PQ} = \langle x_1-x_0, y_1-y_0, z_1-z_0\rangle$ as the direction vector equation, Equation 12.6.2 gives

$$\vec{\mathbf{r}} = \vec{\mathbf{p}} + t(\overrightarrow{PQ}). \tag{12.6.3}$$

Equation 12.6.3 can be expanded using properties of vectors:

$$\begin{aligned}
\vec{\mathbf{r}} &= \vec{\mathbf{p}} + t(\overrightarrow{PQ}) \\
&= \langle x_0,y_0,z_0\rangle + t\langle x_1-x_0, y_1-y_0, z_1-z_0\rangle \\
&= \langle x_0,y_0,z_0\rangle + t(\langle x_1,y_1,z_1\rangle - \langle x_0,y_0,z_0\rangle) \\
&= \langle x_0,y_0,z_0\rangle + t\langle x_1,y_1,z_1\rangle - t\langle x_0,y_0,z_0\rangle \\
&= (1-t)\langle x_0,y_0,z_0\rangle + t\langle x_1,y_1,z_1\rangle \\
&= (1-t)\vec{\mathbf{p}} + t\vec{\mathbf{q}}.
\end{aligned}$$

Thus, the vector equation of the line passing through $P$ and $Q$ is

$$\vec{\mathbf{r}} = (1-t)\vec{\mathbf{p}} + t\vec{\mathbf{q}}.$$

Remember that we did not want the equation of the whole line, just the line segment between $P$ and $Q$. Notice that when $t=0$, we have $\vec{\mathbf{r}} = \vec{\mathbf{p}}$, and when $t=1$, we have $\vec{\mathbf{r}} = \vec{\mathbf{q}}$. Therefore, the vector equation of the line segment between $P$ and $Q$ is

$$\vec{\mathbf{r}} = (1-t)\vec{\mathbf{p}} + t\vec{\mathbf{q}}, 0 \le t \le 1.$$

Going back to Equation 12.6.2, we can also find parametric equations for this line segment. We have

$$\begin{aligned}
\vec{\mathbf{r}} &= \vec{\mathbf{p}} + t(\overrightarrow{PQ}) \\
\langle x,y,z\rangle &= \langle x_0,y_0,z_0\rangle + t\langle x_1-x_0, y_1-y_0, z_1-z_0\rangle \\
&= \langle x_0+t(x_1-x_0), y_0+t(y_1-y_0), z_0+t(z_1-z_0)\rangle.
\end{aligned}$$

Then, the parametric equations are

$$\begin{aligned}
x &= x_0 + t(x_1-x_0) \\
y &= y_0 + t(y_1-y_0) \\
z &= z_0 + t(z_1-z_0), \quad 0 \le t \le 1.
\end{aligned} \tag{12.6.4}$$

**Example 12.6.2: Parametric Equations of a Line Segment**

Find parametric equations of the line segment between the points $P(2,1,4)$ and $Q(3,-1,3)$.

**Solution**

Start with the parametric equations for a line (Equations 12.6.4) and work with each component separately:

$$\begin{aligned} x &= x_0 + t(x_1 - x_0) \\ &= 2 + t(3-2) \\ &= 2 + t, \end{aligned}$$

$$\begin{aligned} y &= y_0 + t(y_1 - y_0) \\ &= 1 + t(-1-1) \\ &= 1 - 2t, \end{aligned}$$

and

$$\begin{aligned} z &= z_0 + t(z_1 - z_0) \\ &= 4 + t(3-4) \\ &= 4 - t. \end{aligned}$$

Therefore, the parametric equations for the line segment are

$$\begin{aligned} x &= 2 + t \\ y &= 1 - 2t \\ z &= 4 - t, \quad 0 \le t \le 1. \end{aligned}$$

**Exercise 12.6.2**

Find parametric equations of the line segment between points $P(-1,3,6)$ and $Q(-8,2,4)$.

**Answer**

$x = -1 - 7t,\ y = 3 - t,\ z = 6 - 2t, \quad 0 \le t \le 1$

## Distance between a Point and a Line

We already know how to calculate the distance between two points in space. We now expand this definition to describe the distance between a point and a line in space. Several real-world contexts exist when it is important to be able to calculate these distances. When building a home, for example, builders must consider "setback" requirements, when structures or fixtures have to be a certain distance from the property line. Air travel offers another example. Airlines are concerned about the distances between populated areas and proposed flight paths.

Let $L$ be a line in the plane and let $M$ be any point not on the line. Then, we define distance $d$ from $M$ to $L$ as the length of line segment $\overline{MP}$, where $P$ is a point on $L$ such that $\overline{MP}$ is perpendicular to $L$ (Figure 12.6.2).

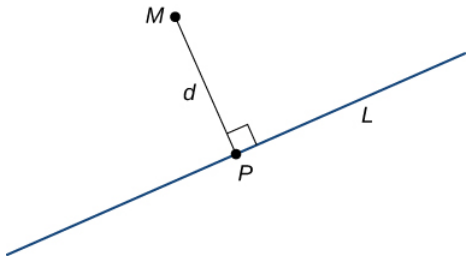

Figure 12.6.2: The distance from point $M$ to line $L$ is the length of $\overline{MP}$.

When we're looking for the distance between a line and a point in space, Figure 12.6.2 still applies. We still define the distance as the length of the perpendicular line segment connecting the point to the line. In space, however, there is no clear way to know

which point on the line creates such a perpendicular line segment, so we select an arbitrary point on the line and use properties of vectors to calculate the distance. Therefore, let $P$ be an arbitrary point on line $L$ and let $\vec{\mathbf{v}}$ be a direction vector for $L$ (Figure 12.6.3).

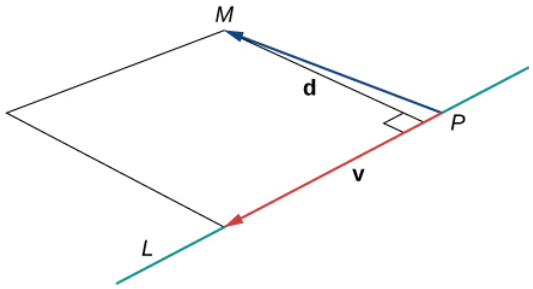

Figure 12.6.3: Vectors $\overrightarrow{PM}$ and $\vec{\mathbf{v}}$ form two sides of a parallelogram with base $\|\vec{\mathbf{v}}\|$ and height $d$, which is the distance between a line and a point in space.

Vectors $\overrightarrow{PM}$ and $\vec{\mathbf{v}}$ form two sides of a parallelogram with area $\|\overrightarrow{PM} \times \vec{\mathbf{v}}\|$. Using a formula from geometry, the area of this parallelogram can also be calculated as the product of its base and height:

$$\|\overrightarrow{PM} \times \vec{\mathbf{v}}\| = \|\vec{\mathbf{v}}\| d.$$

We can use this formula to find a general formula for the distance between a line in space and any point not on the line.

### Distance from a Point to a Line

Let $L$ be a line in space passing through point $P$ with direction vector $\vec{\mathbf{v}}$. If $M$ is any point not on $L$, then the distance from $M$ to $L$ is

$$d = \frac{\|\overrightarrow{PM} \times \vec{\mathbf{v}}\|}{\|\vec{\mathbf{v}}\|}.$$

### Example 12.6.3: Calculating the Distance from a Point to a Line

Find the distance between the point $M = (1, 1, 3)$ and line $\frac{x-3}{4} = \frac{y+1}{2} = z - 3$.

**Solution**:

From the symmetric equations of the line, we know that vector $\vec{\mathbf{v}} = \langle 4, 2, 1 \rangle$ is a direction vector for the line. Setting the symmetric equations of the line equal to zero, we see that point $P(3, -1, 3)$ lies on the line. Then,

$$\begin{aligned} \overrightarrow{PM} &= \langle 1-3, 1-(-1), 3-3 \rangle \\ &= \langle -2, 2, 0 \rangle. \end{aligned}$$

To calculate the distance, we need to find $\overrightarrow{PM} \times \vec{\mathbf{v}}$ :

$$\begin{aligned} \overrightarrow{PM} \times \vec{\mathbf{v}} &= \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ -2 & 2 & 0 \\ 4 & 2 & 1 \end{vmatrix} \\ &= (2-0)\hat{\mathbf{i}} - (-2-0)\hat{\mathbf{j}} + (-4-8)\hat{\mathbf{k}} \\ &= 2\hat{\mathbf{i}} + 2\hat{\mathbf{j}} - 12\hat{\mathbf{k}}. \end{aligned}$$

Therefore, the distance between the point and the line is (Figure 12.6.4)

$$d = \frac{\|\vec{PM} \times \vec{\mathbf{v}}\|}{\|\vec{\mathbf{v}}\|}$$
$$= \frac{\sqrt{2^2 + 2^2 + 12^2}}{\sqrt{4^2 + 2^2 + 1^2}}$$
$$= \frac{2\sqrt{38}}{\sqrt{21}}$$
$$= \frac{2\sqrt{798}}{21} \text{ units}$$

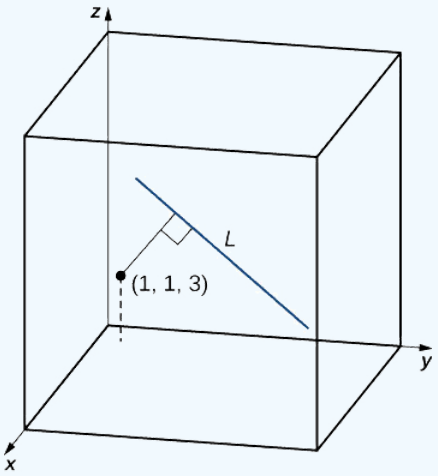

Figure 12.6.4: Point $(1, 1, 3)$ is approximately 2.7 units from the line with symmetric equations $\frac{x-3}{4} = \frac{y+1}{2} = z - 3$.

**? Exercise 12.6.3**

Find the distance between point $(0, 3, 6)$ and the line with parametric equations $x = 1 - t,\ y = 1 + 2t,\ z = 5 + 3t$.

**Hint**

Find a vector with initial point $(0, 3, 6)$ and a terminal point on the line, and then find a direction vector for the line.

**Answer**

$$\sqrt{\frac{10}{7}} = \frac{\sqrt{70}}{7} \text{ units}$$

## Relationships between Lines

Given two lines in the two-dimensional plane, the lines are equal, they are parallel but not equal, or they intersect in a single point. In three dimensions, a fourth case is possible. If two lines in space are not parallel, but do not intersect, then the lines are said to be **skew lines** (Figure 12.6.5).

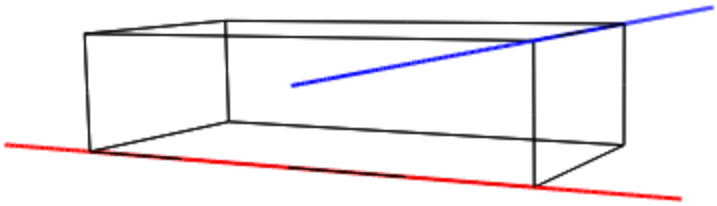

Figure 12.6.5: In three dimensions, it is possible that two lines do not cross, even when they have different directions.

To classify lines as parallel but not equal, equal, intersecting, or skew, we need to know two things: whether the direction vectors are parallel and whether the lines share a point (Figure 12.6.6).

| Direction Vectors Are Parallel? \ Lines Share A Common Point? | Yes | No |
|---|---|---|
| Yes | Equal | Parallel but not equal |
| No | Intersecting | Skew |

Figure 12.6.6: Determine the relationship between two lines based on whether their direction vectors are parallel and whether they share a point.

**Example 12.6.4: Classifying Lines in Space**

For each pair of lines, determine whether the lines are equal, parallel but not equal, skew, or intersecting.

a.

- $L_1: \ x = 2s - 1, \ y = s - 1, \ z = s - 4$
- $L_2: \ x = t - 3, \ y = 3t + 8, \ z = 5 - 2t$

b.

- $L_1: \ x = -y = z$
- $L_2: \ \dfrac{x-3}{2} = y = z - 2$

c.

- $L_1: \ x = 6s - 1, \ y = -2s, \ z = 3s + 1$
- $L_2: \ \dfrac{x-4}{6} = \dfrac{y+3}{-2} = \dfrac{z-1}{3}$

**Solution**

a. Line $L_1$ has direction vector $\vec{\mathbf{v}}_1 = \langle 2, 1, 1 \rangle$; line $L_2$ has direction vector $\vec{\mathbf{v}}_2 = \langle 1, 3, -2 \rangle$. Because the direction vectors are not parallel vectors, the lines are either intersecting or skew. To determine whether the lines intersect, we see if there is a point, $(x, y, z)$, that lies on both lines. To find this point, we use the parametric equations to create a system of equalities:

$$2s - 1 = t - 3;$$

$$s - 1 = 3t + 8;$$

$$s - 4 = 5 - 2t.$$

By the first equation, $t = 2s + 2$. Substituting into the second equation yields

$$s - 1 = 3(2s + 2) + 8$$

$$s - 1 = 6s + 6 + 8$$

$$5s = -15$$

$$s = -3.$$

Substitution into the third equation, however, yields a contradiction:

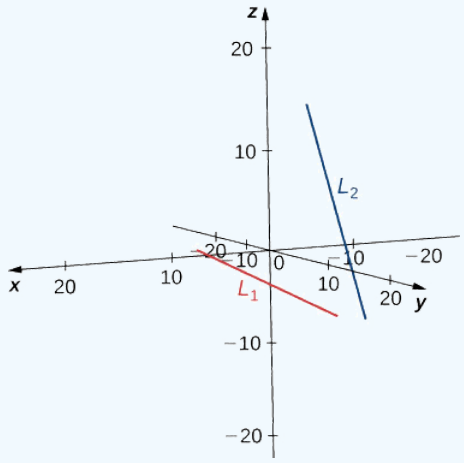
$$s - 4 = 5 - 2(2s + 2)$$

$$s - 4 = 5 - 4s - 4$$

$$5s = 5$$

$$s = 1.$$

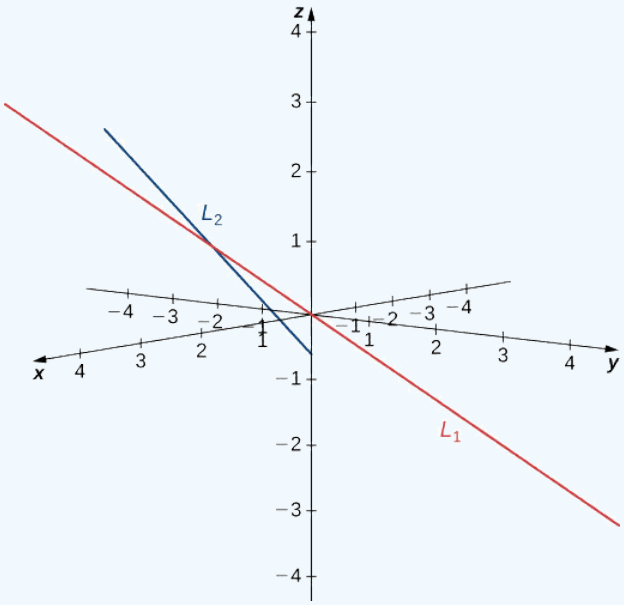
There is no single point that satisfies the parametric equations for $L_1$ and $L_2$ simultaneously. These lines do not intersect, so they are skew (see the following figure).



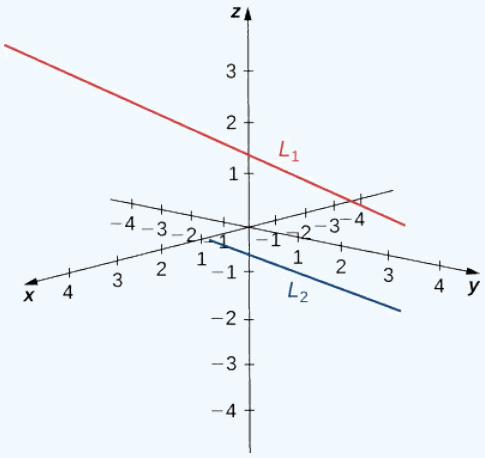
b. Line $L_1$ has direction vector $\vec{\mathbf{v}}_1 = \langle 1, -1, 1 \rangle$ and passes through the origin, $(0, 0, 0)$. Line $L_2$ has a different direction vector, $\vec{\mathbf{v}}_2 = \langle 2, 1, 1 \rangle$, so these lines are not parallel or equal. Let $r$ represent the parameter for line $L_1$ and let $s$ represent the parameter for $L_2$:

$$\begin{array}{ll} \textbf{Line } L_1: & \textbf{Line } L_2: \\ x = r & x = 2s + 3 \\ y = -r & y = s \\ z = r & z = s + 2 \end{array}$$

Solve the system of equations to find $r = 1$ and $s = -1$. If we need to find the point of intersection, we can substitute these parameters into the original equations to get $(1, -1, 1)$ (see the following figure).



c. Lines $L_1$ and $L_2$ have equivalent direction vectors: $\vec{\mathbf{v}} = \langle 6, -2, 3 \rangle$. These two lines are parallel (see the following figure).



## ? Exercise 12.6.4

Describe the relationship between the lines with the following parametric equations:

$$x = 1 - 4t,\ y = 3 + t,\ z = 8 - 6t$$

$$x = 2 + 3s,\ y = 2s,\ z = -1 - 3s.$$

**Hint**

Start by identifying direction vectors for each line. Is one a multiple of the other?

**Answer**

These lines are skew because their direction vectors are not parallel and there is no point $(x, y, z)$ that lies on both lines.

## Equations for a Plane

We know that a line is determined by two points. In other words, for any two distinct points, there is exactly one line that passes through those points, whether in two dimensions or three. Similarly, given any three points that do not all lie on the same line, there is a unique plane that passes through these points. Just as a line is determined by two points, a plane is determined by three.

This may be the simplest way to characterize a plane, but we can use other descriptions as well. For example, given two distinct, intersecting lines, there is exactly one plane containing both lines. A plane is also determined by a line and any point that does not lie on the line. These characterizations arise naturally from the idea that a plane is determined by three points. Perhaps the most surprising characterization of a plane is actually the most useful.

Imagine a pair of orthogonal vectors that share an initial point. Visualize grabbing one of the vectors and twisting it. As you twist, the other vector spins around and sweeps out a plane. Here, we describe that concept mathematically. Let $\vec{\mathbf{n}} = \langle a, b, c \rangle$ be a vector and $P = (x_0, y_0, z_0)$ be a point. Then the set of all points $Q = (x, y, z)$ such that $\overrightarrow{PQ}$ is orthogonal to $\vec{\mathbf{n}}$ forms a plane (Figure 12.6.7). We say that $\vec{\mathbf{n}}$ is a **normal vector**, or perpendicular to the plane. Remember, the dot product of orthogonal vectors is zero. This fact generates the **vector equation of a plane**:

$$\vec{\mathbf{n}} \cdot \overrightarrow{PQ} = 0.$$

Rewriting this equation provides additional ways to describe the plane:

$$\begin{aligned} \vec{\mathbf{n}} \cdot \overrightarrow{PQ} &= 0 \\ \langle a, b, c \rangle \cdot \langle x - x_0, y - y_0, z - z_0 \rangle &= 0 \\ a(x - x_0) + b(y - y_0) + c(z - z_0) &= 0. \end{aligned}$$

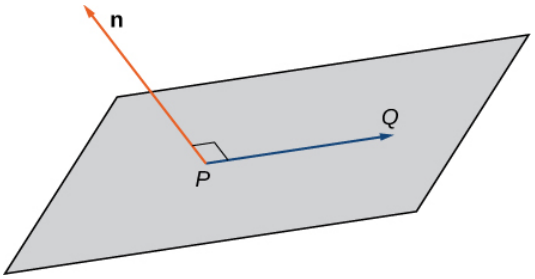


Figure 12.6.7: Given a point $P$ and vector $\vec{\mathbf{n}}$, the set of all points $Q$ with $\overrightarrow{PQ}$ orthogonal to $\vec{\mathbf{n}}$ forms a plane.

### Definition: Scalar Equation of a Plane

Given a point $P$ and vector $\vec{\mathbf{n}}$, the set of all points $Q$ satisfying the equation $\vec{\mathbf{n}} \cdot \overrightarrow{PQ} = 0$ forms a plane. The equation

$$\vec{\mathbf{n}} \cdot \overrightarrow{PQ} = 0$$

is known as the *vector equation of a plane*.

The *scalar equation of a plane* (sometimes also called the *standard equation of a plane*) containing point $P = (x_0, y_0, z_0)$ with normal vector $\vec{n} = \langle a, b, c \rangle$ is

$$a(x - x_0) + b(y - y_0) + c(z - z_0) = 0.$$

This equation can be expressed as $ax + by + cz + d = 0$, where $d = -ax_0 - by_0 - cz_0$. This form of the equation is sometimes called the *general form of the equation of a plane.*

As described earlier in this section, any three points that do not all lie on the same line determine a plane. Given three such points, we can find an equation for the plane containing these points.

### Example 12.6.5: Writing an Equation of a Plane Given Three Points in the Plane

Write an equation for the plane containing points $P=(1,1,-2), Q=(0,2,1)$, and $R=(-1,-1,0)$ in both standard and general forms.

**Solution**

To write an equation for a plane, we must find a normal vector for the plane. We start by identifying two vectors in the plane:

$$\begin{aligned}\overrightarrow{PQ} &= \langle 0-1, 2-1, 1-(-2)\rangle \\ &= \langle -1, 1, 3\rangle \\ \overrightarrow{QR} &= \langle -1-0, -1-2, 0-1\rangle \\ &= \langle -1, -3, -1\rangle.\end{aligned}$$

The cross product $\overrightarrow{PQ}\times\overrightarrow{QR}$ is orthogonal to both $\overrightarrow{PQ}$ and $\overrightarrow{QR}$, so it is normal to the plane that contains these two vectors:

$$\begin{aligned}\vec{\mathbf{n}} &= \overrightarrow{PQ}\times\overrightarrow{QR} \\ &= \begin{vmatrix}\hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ -1 & 1 & 3 \\ -1 & -3 & -1\end{vmatrix} \\ &= (-1+9)\hat{\mathbf{i}} - (1+3)\hat{\mathbf{j}} + (3+1)\hat{\mathbf{k}} \\ &= 8\hat{\mathbf{i}} - 4\hat{\mathbf{j}} + 4\hat{\mathbf{k}}.\end{aligned}$$

Thus, $\vec{\mathbf{n}}=\langle 8,-4,4\rangle$, and we can choose any of the three given points to write an equation of the plane:

$$\begin{aligned}8(x-1)-4(y-1)+4(z+2) &= 0 \\ 8x-4y+4z+4 &= 0.\end{aligned}$$

The scalar equations of a plane vary depending on the normal vector and point chosen.

### Example 12.6.6: Writing an Equation for a Plane Given a Point and a Line

Find an equation of the plane that passes through point $(1,4,3)$ and contains the line given by $x=\dfrac{y-1}{2}=z+1$.

**Solution**

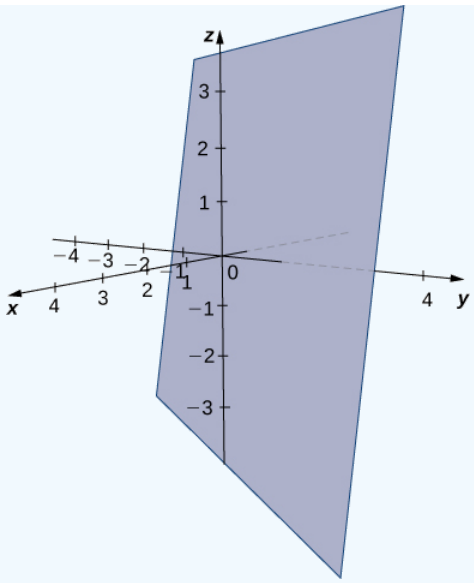
Symmetric equations describe the line that passes through point $(0,1,-1)$ parallel to vector $\vec{\mathbf{v}}_1=\langle 1,2,1\rangle$ (see the following figure). Use this point and the given point, $(1,4,3)$, to identify a second vector parallel to the plane:

$$\vec{\mathbf{v}}_2=\langle 1-0, 4-1, 3-(-1)\rangle=\langle 1,3,4\rangle.$$

Use the cross product of these vectors to identify a normal vector for the plane:

$$\begin{aligned}\vec{\mathbf{n}} &= \vec{\mathbf{v}}_1\times\vec{\mathbf{v}}_2 \\ &= \begin{vmatrix}\hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 1 & 2 & 1 \\ 1 & 3 & 4\end{vmatrix} \\ &= (8-3)\hat{\mathbf{i}} - (4-1)\hat{\mathbf{j}} + (3-2)\hat{\mathbf{k}} \\ &= 5\hat{\mathbf{i}} - 3\hat{\mathbf{j}} + \hat{\mathbf{k}}.\end{aligned}$$

The scalar equations for the plane are $5x-3(y-1)+(z+1)=0$ and $5x-3y+z+4=0$.



**? Exercise 12.6.6**

Find an equation of the plane containing the lines $L_1$ and $L_2$:

$$L_1 : \ x = -y = z$$

$$L_2 : \ \frac{x-3}{2} = y = z - 2.$$

**Hint**

Hint: The cross product of the lines' direction vectors gives a normal vector for the plane.

**Answer**

$$-2(x-1) + (y+1) + 3(z-1) = 0$$

or

$$-2x + y + 3z = 0$$

Now that we can write an equation for a plane, we can use the equation to find the distance $d$ between a point $P$ and the plane. It is defined as the shortest possible distance from $P$ to a point on the plane.

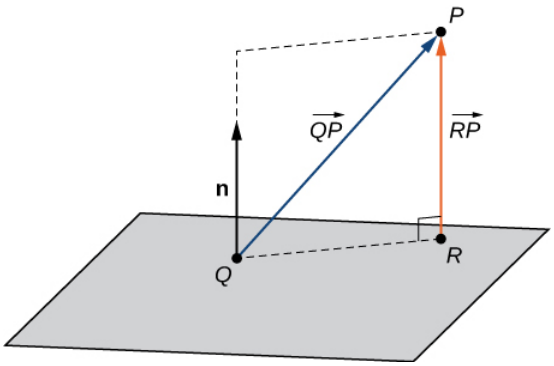


Figure 12.6.8: We want to find the shortest distance from point P to the plane. Let point $R$ be the point in the plane such that, for any other point in the plane $Q$, $\|\overrightarrow{RP}\| < \|\overrightarrow{QP}\|$.

Just as we find the two-dimensional distance between a point and a line by calculating the length of a line segment perpendicular to the line, we find the three-dimensional distance between a point and a plane by calculating the length of a line segment

perpendicular to the plane. Let $R$ be the point in the plane such that $\overrightarrow{RP}$ is orthogonal to the plane, and let $Q$ be an arbitrary point in the plane. Then the projection of vector $\overrightarrow{QP}$ onto the normal vector describes vector $\overrightarrow{RP}$, as shown in Figure 12.6.8.

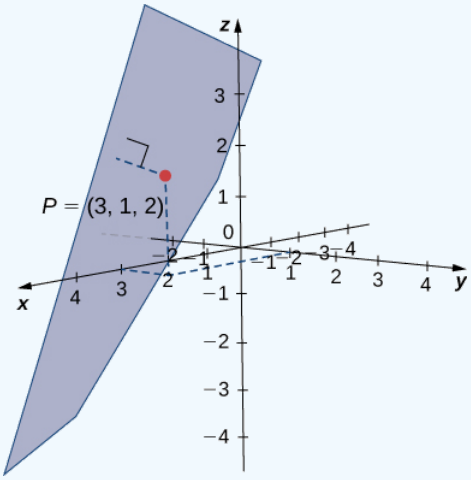
### The Distance between a Plane and a Point

Suppose a plane with normal vector $\vec{\mathbf{n}}$ passes through point $Q$. The distance $d$ from the plane to a point $P$ not in the plane is given by

$$d = \|\text{proj}_{\vec{\mathbf{n}}}\, \overrightarrow{QP}\| = |\, \text{comp}_{\vec{\mathbf{n}}}\, \overrightarrow{QP}\,| = \frac{|\, \overrightarrow{QP} \cdot \vec{\mathbf{n}}\,|}{\|\vec{\mathbf{n}}\|}. \tag{12.6.5}$$

### Example 12.6.7: Distance between a Point and a Plane

Find the distance between point $P = (3, 1, 2)$ and the plane given by $x - 2y + z = 5$ (see the following figure).



**Solution**

The coefficients of the plane's equation provide a normal vector for the plane: $\vec{\mathbf{n}} = \langle 1, -2, 1\rangle$. To find vector $\overrightarrow{QP}$, we need a point in the plane. Any point will work, so set $y = z = 0$ to see that point $Q = (5, 0, 0)$ lies in the plane. Find the component form of the vector from $Q$ to $P$:

$$\overrightarrow{QP} = \langle 3 - 5, 1 - 0, 2 - 0\rangle = \langle -2, 1, 2\rangle.$$

Apply the distance formula from Equation 12.6.5:

$$\begin{aligned} d &= \frac{\left|\overrightarrow{QP} \cdot \vec{\mathbf{n}}\right|}{\|\vec{\mathbf{n}}\|} \\ &= \frac{|\langle -2, 1, 2\rangle \cdot \langle 1, -2, 1\rangle|}{\sqrt{1^2 + (-2)^2 + 1^2}} \\ &= \frac{|-2 - 2 + 2|}{\sqrt{6}} \\ &= \frac{2}{\sqrt{6}} = \frac{\sqrt{6}}{3} \text{ units.} \end{aligned}$$

### Exercise 12.6.7

Find the distance between point $P = (5, -1, 0)$ and the plane given by $4x + 2y - z = 3$.

**Hint**

Point $(0, 0, -3)$ lies on the plane.

**Answer**

$$\frac{15}{\sqrt{21}} = \frac{5\sqrt{21}}{7} \text{ units}$$

## Parallel and Intersecting Planes

We have discussed the various possible relationships between two lines in two dimensions and three dimensions. When we describe the relationship between two planes in space, we have only two possibilities: the two distinct planes are parallel or they intersect. When two planes are parallel, their normal vectors are parallel. When two planes intersect, the intersection is a line (Figure **12.6.9**).

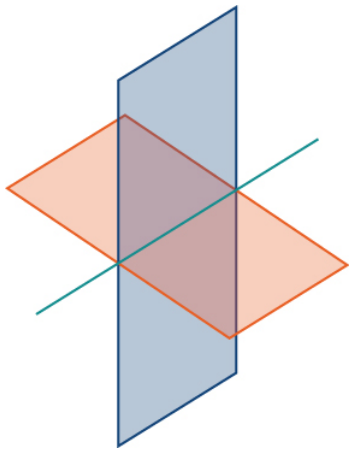


Figure **12.6.9**: The intersection of two nonparallel planes is always a line.

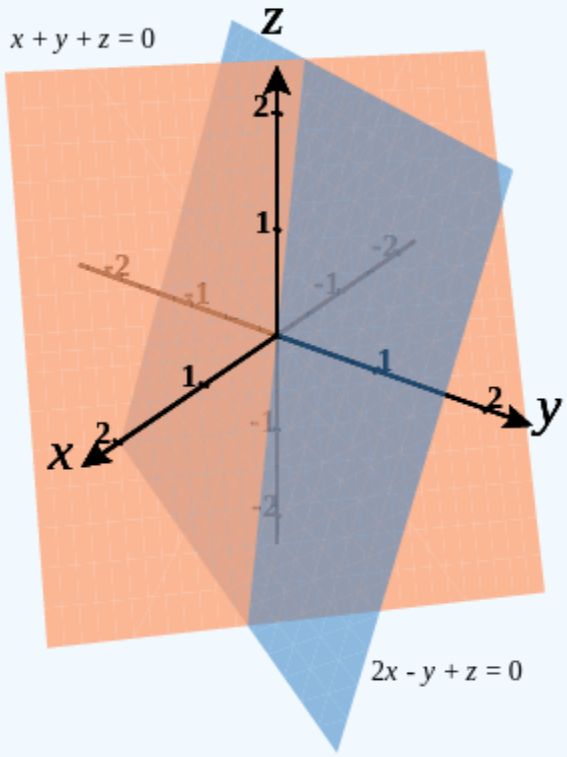
We can use the equations of the two planes to find parametric equations for the line of intersection.

### Example 12.6.8: Finding the Line of Intersection for Two Planes

Find parametric and symmetric equations for the line formed by the intersection of the planes given by $x + y + z = 0$ and $2x - y + z = 0$ (see the following figure).



**Solution**

Note that the two planes have nonparallel normals, so the planes intersect. Further, the origin satisfies each equation, so we know the line of intersection passes through the origin. Add the plane equations so we can eliminate one of the variables, in this case, $y$:

$$x+y+z=0$$
$$2x-y+z=0$$
$$_____$$
$$3x+2z=0.$$

This gives us $x=-\frac{2}{3}z$. We substitute this value into the first equation to express $y$ in terms of $z$:

$$x+y+z=0$$
$$-\frac{2}{3}z+y+z=0$$
$$y+\frac{1}{3}z=0$$
$$y=-\frac{1}{3}z$$

We now have the first two variables, $x$ and $y$, in terms of the third variable, $z$. Now we define $z$ in terms of $t$. To eliminate the need for fractions, we choose to define the parameter $t$ as $t=-\frac{1}{3}z$. Then, $z=-3t$. Substituting the parametric representation of

$z$ back into the other two equations, we see that the parametric equations for the line of intersection are $x = 2t,\ y = t,\ z = -3t$. The symmetric equations for the line are $\frac{x}{2} = y = \frac{z}{-3}$.

**Exercise 12.6.8**

Find parametric equations for the line formed by the intersection of planes $x + y - z = 3$ and $3x - y + 3z = 5$.

**Hint**

Add the two equations, then express $z$ in terms of $x$. Then, express $y$ in terms of $x$.

**Answer**

$x = t,\ y = 7 - 3t,\ z = 4 - 2t$

In addition to finding the equation of the line of intersection between two planes, we may need to find the angle formed by the intersection of two planes. For example, builders constructing a house need to know the angle where different sections of the roof meet to know whether the roof will look good and drain properly. We can use normal vectors to calculate the angle between the two planes. We can do this because the angle between the normal vectors is the same as the angle between the planes. Figure 12.6.10 shows why this is true.

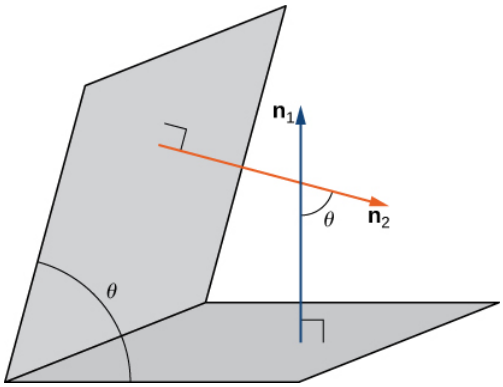


Figure 12.6.10: The angle between two planes has the same measure as the angle between the normal vectors for the planes.

We can find the measure of the angle $\theta$ between two intersecting planes by first finding the cosine of the angle, using the following equation:

$$\cos\theta = \frac{|\vec{\mathbf{n}}_1 \cdot \vec{\mathbf{n}}_2|}{\|\vec{\mathbf{n}}_1\|\|\vec{\mathbf{n}}_2\|}.$$

We can then use the angle to determine whether two planes are parallel or orthogonal or if they intersect at some other angle.

**Example 12.6.9: Finding the Angle between Two Planes**

Determine whether each pair of planes is parallel, orthogonal, or neither. If the planes are intersecting, but not orthogonal, find the measure of the angle between them. Give the answer in radians and round to two decimal places.

a. $x + 2y - z = 8$ and $2x + 4y - 2z = 10$
b. $2x - 3y + 2z = 3$ and $6x + 2y - 3z = 1$
c. $x + y + z = 4$ and $x - 3y + 5z = 1$

**Solution**:

a. The normal vectors for these planes are $\vec{\mathbf{n}}_1 = \langle 1, 2, -1\rangle$ and $\vec{\mathbf{n}}_2 = \langle 2, 4, -2\rangle$. These two vectors are scalar multiples of each other. The normal vectors are parallel, so the planes are parallel.
b. The normal vectors for these planes are $\vec{\mathbf{n}}_1 = \langle 2, -3, 2\rangle$ and $\vec{\mathbf{n}}_2 = \langle 6, 2, -3\rangle$. Taking the dot product of these vectors, we have

$$\begin{aligned}\vec{\mathbf{n}}_1 \cdot \vec{\mathbf{n}}_2 &= \langle 2,-3,2\rangle \cdot \langle 6,2,-3\rangle \\ &= 2(6) - 3(2) + 2(-3) = 0.\end{aligned}$$

The normal vectors are orthogonal, so the corresponding planes are orthogonal as well.

c. The normal vectors for these planes are $\vec{\mathbf{n}}_1 = \langle 1,1,1\rangle$ and $\vec{\mathbf{n}}_2 = \langle 1,-3,5\rangle$:

$$\begin{aligned}\cos\theta &= \frac{|\vec{\mathbf{n}}_1 \cdot \vec{\mathbf{n}}_2|}{\|\vec{\mathbf{n}}_1\|\|\vec{\mathbf{n}}_2\|} \\ &= \frac{|\langle 1,1,1\rangle \cdot \langle 1,-3,5\rangle|}{\sqrt{1^2+1^2+1^2}\sqrt{1^2+(-3)^2+5^2}} \\ &= \frac{3}{\sqrt{105}}\end{aligned}$$

Then $\theta = \arccos\frac{3}{\sqrt{105}} \approx 1.27$ rad.

Thus the angle between the two planes is about $1.27$ rad, or approximately $73°$.

## Exercise 12.6.9

Find the measure of the angle between planes $x + y - z = 3$ and $3x - y + 3z = 5$. Give the answer in radians and round to two decimal places.

**Hint**

Use the coefficients of the variables in each equation to find a normal vector for each plane.

**Answer**

$1.44$ rad

When we find that two planes are parallel, we may need to find the distance between them. To find this distance, we simply select a point in one of the planes. The distance from this point to the other plane is the distance between the planes.

Previously, we introduced the formula for calculating this distance in Equation 12.6.5:

$$d = \frac{\overrightarrow{QP} \cdot \vec{\mathbf{n}}}{\|\vec{\mathbf{n}}\|},$$

where $Q$ is a point on the plane, $P$ is a point not on the plane, and $\vec{n}$ is the normal vector that passes through point $Q$. Consider the distance from point $(x_0, y_0, z_0)$ to plane $ax + by + cz + k = 0$. Let $(x_1, y_1, z_1)$ be any point in the plane. Substituting into the formula yields

$$\begin{aligned}d &= \frac{|a(x_0 - x_1) + b(y_0 - y_1) + c(z_0 - z_1)|}{\sqrt{a^2+b^2+c^2}} \\ &= \frac{|ax_0 + by_0 + cz_0 + k|}{\sqrt{a^2+b^2+c^2}}.\end{aligned}$$

We state this result formally in the following theorem.

### Distance from a Point to a Plane

Let $P(x_0, y_0, z_0)$ be a point. The distance from $P$ to plane $ax + by + cz + k = 0$ is given by

$$d = \frac{|ax_0 + by_0 + cz_0 + k|}{\sqrt{a^2+b^2+c^2}}.$$

### Example 12.6.10: Finding the Distance between Parallel Planes

Find the distance between the two parallel planes given by $2x + y - z = 2$ and $2x + y - z = 8$.

**Solution**

Point $(1, 0, 0)$ lies in the first plane. The desired distance, then, is

$$\begin{aligned} d &= \frac{|ax_0 + by_0 + cz_0 + k|}{\sqrt{a^2 + b^2 + c^2}} \\ &= \frac{|2(1) + 1(0) + (-1)(0) + (-8)|}{\sqrt{2^2 + 1^2 + (-1)^2}} \\ &= \frac{6}{\sqrt{6}} = \sqrt{6} \text{ units} \end{aligned}$$

### Exercise 12.6.10:

Find the distance between parallel planes $5x - 2y + z = 6$ and $5x - 2y + z = -3$.

**Hint**

Set $x = y = 0$ to find a point on the first plane.

**Answer**

$$\frac{9}{\sqrt{30}} = \frac{3\sqrt{30}}{10} \text{ units}$$

### Distance between Two Skew Lines

Finding the distance from a point to a line or from a line to a plane seems like a pretty abstract procedure. But, if the lines represent pipes in a chemical plant or tubes in an oil refinery or roads at an intersection of highways, confirming that the distance between them meets specifications can be both important and awkward to measure. One way is to model the two pipes as lines, using the techniques in this chapter, and then calculate the distance between them. The calculation involves forming vectors along the directions of the lines and using both the cross product and the dot product.

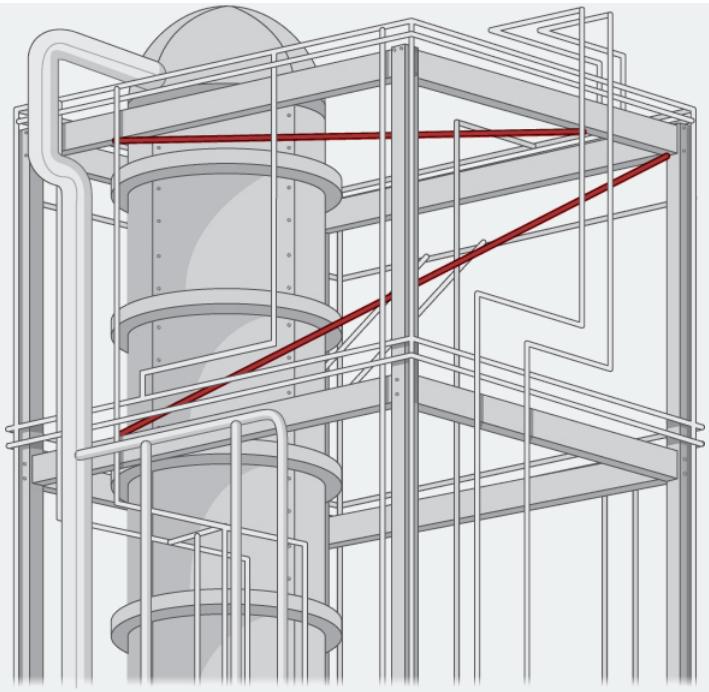

Figure 12.6.11: Industrial pipe installations often feature pipes running in different directions. How can we find the distance between two skew pipes?

The symmetric forms of two lines, $L_1$ and $L_2$, are

$$L_1 : \frac{x-x_1}{a_1} = \frac{y-y_1}{b_1} = \frac{z-z_1}{c_1}$$

$$L_2 : \frac{x-x_2}{a_2} = \frac{y-y_2}{b_2} = \frac{z-z_2}{c_2}.$$

You are to develop a formula for the distance $d$ between these two lines, in terms of the values $a_1, b_1, c_1; a_2, b_2, c_2; x_1, y_1, z_1$; and $x_2, y_2, z_2$. The distance between two lines is usually taken to mean the minimum distance, so this is the length of a line segment or the length of a vector that is perpendicular to both lines and intersects both lines.

1. First, write down two vectors, $\vec{\mathbf{v}}_1$ and $\vec{\mathbf{v}}_2$, that lie along $L_1$ and $L_2$, respectively.

2. Find the cross product of these two vectors and call it $\vec{\mathbf{N}}$. This vector is perpendicular to $\vec{\mathbf{v}}_1$ and $\vec{\mathbf{v}}_2$, and hence is perpendicular to both lines.

3. From vector $\vec{\mathbf{N}}$, form a unit vector $\vec{\mathbf{n}}$ in the same direction.

4. Use symmetric equations to find a convenient vector $\vec{\mathbf{v}}_{12}$ that lies between any two points, one on each line. Again, this can be done directly from the symmetric equations.

5. The dot product of two vectors is the magnitude of the projection of one vector onto the other—that is, $\vec{\mathbf{A}} \cdot \vec{\mathbf{B}} = \|\vec{\mathbf{A}}\|\|\vec{\mathbf{B}}\| \cos\theta$, where $\theta$ is the angle between the vectors. Using the dot product, find the projection of vector $\vec{\mathbf{v}}_{12}$ found in step 4 onto unit vector $\vec{\mathbf{n}}$ found in step 3. This projection is perpendicular to both lines, and hence its length must be the perpendicular distance d between them. Note that the value of $d$ may be negative, depending on your choice of vector $\vec{\mathbf{v}}_{12}$ or the order of the cross product, so use absolute value signs around the numerator.

6. Check that your formula gives the correct distance of $|-25|/\sqrt{198} \approx 1.78$ between the following two lines:

$$L_1 : \frac{x-5}{2} = \frac{y-3}{4} = \frac{z-1}{3}$$

$$L_2 : \frac{x-6}{3} = \frac{y-1}{5} = \frac{z}{7}.$$

7. Is your general expression valid when the lines are parallel? If not, why not? (Hint: What do you know about the value of the cross product of two parallel vectors? Where would that result show up in your expression for $d$?)

8. Demonstrate that your expression for the distance is zero when the lines intersect. Recall that two lines intersect if they are not parallel and they are in the same plane. Hence, consider the direction of $\vec{\mathbf{n}}$ and $\vec{\mathbf{v}}_{12}$. What is the result of their dot product?

9. Consider the following application. Engineers at a refinery have determined they need to install support struts between many of the gas pipes to reduce damaging vibrations. To minimize cost, they plan to install these struts at the closest points between adjacent skewed pipes. Because they have detailed schematics of the structure, they are able to determine the correct lengths of the struts needed, and hence manufacture and distribute them to the installation crews without spending valuable time making measurements.

The rectangular frame structure has the dimensions $4.0 \times 15.0 \times 10.0\,\text{m}$ (height, width, and depth). One sector has a pipe entering the lower corner of the standard frame unit and exiting at the diametrically opposed corner (the one farthest away at the top); call this $L_1$. A second pipe enters and exits at the two different opposite lower corners; call this $L_2$ (Figure 12.6.12).

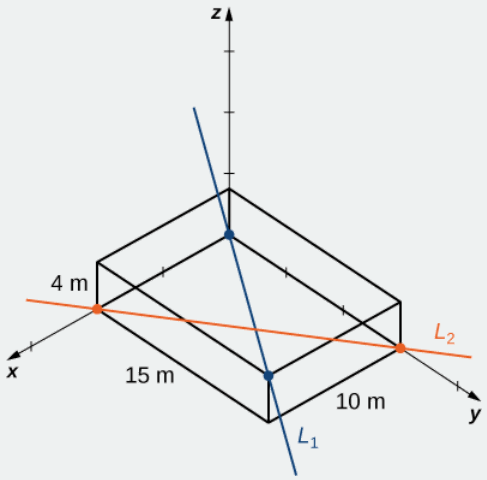

Figure 12.6.12: Two pipes cross through a standard frame unit.

Write down the vectors along the lines representing those pipes, find the cross product between them from which to create the unit vector $\vec{\mathbf{n}}$, define a vector that spans two points on each line, and finally determine the minimum distance between the lines. (Take the origin to be at the lower corner of the first pipe.) Similarly, you may also develop the symmetric equations for each line and substitute directly into your formula.

## Key Concepts

- In three dimensions, the direction of a line is described by a direction vector. The vector equation of a line with direction vector $\vec{\mathbf{v}} = \langle a, b, c \rangle$ passing through point $P = (x_0, y_0, z_0)$ is $\vec{\mathbf{r}} = \vec{\mathbf{r}}_0 + t\vec{\mathbf{v}}$, where $\vec{\mathbf{r}}_0 = \langle x_0, y_0, z_0 \rangle$ is the position vector of point $P$. This equation can be rewritten to form the parametric equations of the line: $x = x_0 + ta, y = y_0 + tb$, and $z = z_0 + tc$. The line can also be described with the symmetric equations $\frac{x - x_0}{a} = \frac{y - y_0}{b} = \frac{z - z_0}{c}$.
- Let $L$ be a line in space passing through point $P$ with direction vector $\vec{\mathbf{v}}$. If $Q$ is any point not on $L$, then the distance from $Q$ to $L$ is $d = \frac{\|\overrightarrow{PQ} \times \vec{\mathbf{v}}\|}{\|\vec{\mathbf{v}}\|}$.
- In three dimensions, two lines may be parallel but not equal, equal, intersecting, or skew.
- Given a point $P$ and vector $\vec{\mathbf{n}}$, the set of all points $Q$ satisfying equation $\vec{\mathbf{n}} \cdot \overrightarrow{PQ} = 0$ forms a plane. Equation $\vec{\mathbf{n}} \cdot \overrightarrow{PQ} = 0$ is known as the *vector equation of a plane*.
- The scalar equation of a plane containing point $P = (x_0, y_0, z_0)$ with normal vector $\vec{\mathbf{n}} = \langle a, b, c \rangle$ is $a(x - x_0) + b(y - y_0) + c(z - z_0) = 0$. This equation can be expressed as $ax + by + cz + d = 0$, where $d = -ax_0 - by_0 - cz_0$. This form of the equation is sometimes called the general *form of the equation of a plane*.

- Suppose a plane with normal vector $n$ passes through point $Q$. The distance $D$ from the plane to point $P$ not in the plane is given by

$$D = \|\text{proj}_{\vec{\mathbf{n}}}\overrightarrow{QP}\| = |\text{ comp}_{\vec{\mathbf{n}}}\vec{QP}| = \frac{|\vec{QP}\cdot\vec{\mathbf{n}}|}{\|\vec{\mathbf{n}}\|}.$$

- The normal vectors of parallel planes are parallel. When two planes intersect, they form a line.
- The measure of the angle $\theta$ between two intersecting planes can be found using the equation: $\cos\theta = \frac{|\vec{\mathbf{n}}_1\cdot\vec{\mathbf{n}}_2|}{\|\vec{\mathbf{n}}_1\|\|\vec{\mathbf{n}}_2\|}$, where $\vec{\mathbf{n}}_1$ and $\vec{\mathbf{n}}_2$ are normal vectors to the planes.
- The distance $D$ from point $(x_0, y_0, z_0)$ to plane $ax + by + cz + d = 0$ is given by

$$D = \frac{|a(x_0 - x_1) + b(y_0 - y_1) + c(z_0 - z_1)|}{\sqrt{a^2 + b^2 + c^2}} = \frac{|ax_0 + by_0 + cz_0 + d|}{\sqrt{a^2 + b^2 + c^2}}$$

.

## Key Equations

- **Vector Equation of a Line**

  $\vec{\mathbf{r}} = \vec{\mathbf{r}}_0 + t\vec{\mathbf{v}}$

- **Parametric Equations of a Line**

  $x = x_0 + ta,\ y = y_0 + tb$, and $z = z_0 + tc$

- **Symmetric Equations of a Line**

  $\frac{x - x_0}{a} = \frac{y - y_0}{b} = \frac{z - z_0}{c}$

- **Vector Equation of a Plane**

  $\vec{\mathbf{n}}\cdot\overrightarrow{PQ} = 0$

- **Scalar Equation of a Plane**

  $a(x - x_0) + b(y - y_0) + c(z - z_0) = 0$

- **Distance between a Plane and a Point**

  $d = \|\text{proj}_{\vec{\mathbf{n}}}\overrightarrow{QP}\| = |\text{ comp}_{\vec{\mathbf{n}}}\overrightarrow{QP}| = \frac{|\overrightarrow{QP}\cdot\vec{\mathbf{n}}|}{\|\vec{\mathbf{n}}\|}$

## Glossary

**direction vector**

a vector parallel to a line that is used to describe the direction, or orientation, of the line in space

**general form of the equation of a plane**

an equation in the form $ax + by + cz + d = 0$, where $\vec{\mathbf{n}} = \langle a, b, c\rangle$ is a normal vector of the plane, $P = (x_0, y_0, z_0)$ is a point on the plane, and $d = -ax_0 - by_0 - cz_0$

**normal vector**

a vector perpendicular to a plane

**parametric equations of a line**

the set of equations $x = x_0 + ta, y = y_0 + tb$, and $z = z_0 + tc$ describing the line with direction vector $v = \langle a, b, c\rangle$ passing through point $(x_0, y_0, z_0)$

**scalar equation of a plane**

the equation $a(x-x_0)+b(y-y_0)+c(z-z_0)=0$ used to describe a plane containing point $P=(x_0,y_0,z_0)$ with normal vector $n=\langle a,b,c\rangle$ or its alternate form $ax+by+cz+d=0$, where $d=-ax_0-by_0-cz_0$

**skew lines**

two lines that are not parallel but do not intersect

**symmetric equations of a line**

the equations $\frac{x-x_0}{a}=\frac{y-y_0}{b}=\frac{z-z_0}{c}$ describing the line with direction vector $v=\langle a,b,c\rangle$ passing through point $(x_0,y_0,z_0)$

**vector equation of a line**

the equation $\vec{\mathbf{r}}=\vec{\mathbf{r}}_0+t\vec{\mathbf{v}}$ used to describe a line with direction vector $\vec{\mathbf{v}}=\langle a,b,c\rangle$ passing through point $P=(x_0,y_0,z_0)$, where $\vec{\mathbf{r}}_0=\langle x_0,y_0,z_0\rangle$, is the position vector of point $P$

**vector equation of a plane**

the equation $\vec{\mathbf{n}}\cdot\overrightarrow{PQ}=0$, where $P$ is a given point in the plane, $Q$ is any point in the plane, and $\vec{\mathbf{n}}$ is a normal vector of the plane

# 12.6E: Exercises for Section 12.5

**In exercises 1 - 4, points $P$ and $Q$ are given. Let $L$ be the line passing through points $P$ and $Q$.**

**a. Find the vector equation of line $L$.**

**b. Find parametric equations of line $L$.**

**c. Find symmetric equations of line $L$.**

**d. Find parametric equations of the line segment determined by $P$ and $Q$.**

1) $P(-3,5,9), \quad Q(4,-7,2)$

**Answer**

a. $\vec{\mathbf{r}} = \langle -3,5,9\rangle + t\langle 7,-12,-7\rangle, \quad t \in R;$
b. $x = -3+7t, \quad y = 5-12t, \quad z = 9-7t, \quad t \in R;$
c. $\dfrac{x+3}{7} = \dfrac{y-5}{-12} = \dfrac{z-9}{-7};$
d. $x = -3+7t, \quad y = 5-12t, \quad z = 9-7t, \quad 0 \le t \le 1$

2) $P(4,0,5), \quad Q(2,3,1)$

3) $P(-1,0,5), \quad Q(4,0,3)$

**Answer**

a. $\vec{\mathbf{r}} = \langle -1,0,5\rangle + t\langle 5,0,-2\rangle, \quad t \in R;$
b. $x = -1+5t, y = 0, z = 5-2t, \quad t \in R;$
c. $\dfrac{x+1}{5} = \dfrac{z-5}{-2}, \quad y = 0;$
d. $x = -1+5t, \quad y = 0, \quad z = 5-2t, \quad t \in [0,1]$

4) $P(7,-2,6), \quad Q(-3,0,6)$

**For exercises 5 - 8, point $P$ and vector $\vec{\mathbf{v}}$ are given. Let $L$ be the line passing through point $P$ with direction $\vec{\mathbf{v}}$.**

**a. Find parametric equations of line $L$.**

**b. Find symmetric equations of line $L$.**

**c. Find the intersection of the line with the $xy$-plane.**

5) $P(1,-2,3), \ \vec{\mathbf{v}} = \langle 1,2,3\rangle$

**Answer**

a. $x = 1+t, \quad y = -2+2t, \quad z = 3+3t, \quad t \in R;$
b. $\dfrac{x-1}{1} = \dfrac{y+2}{2} = \dfrac{z-3}{3};$
c. $(0,-4,0)$

6) $P(3,1,5), \ \vec{\mathbf{v}} = \langle 1,1,1\rangle$

7) $P(3,1,5), \ \vec{\mathbf{v}} = \overrightarrow{QR}$, where $Q(2,2,3)$ and $R(3,2,3)$

**Answer**

a. $x = 3+t, \quad y = 1, \quad z = 5, \quad t \in R;$
b. $y = 1, \quad z = 5;$
c. The line does not intersect the $xy$-plane.

8) $P(2,3,0), \ \vec{\mathbf{v}} = \overrightarrow{QR}$, where $Q(0,4,5)$ and $R(0,4,6)$

**For exercises 9 and 10, line $L$ is given.**

**a. Find a point $P$ that belongs to the line and a direction vector $\vec{\mathbf{v}}$ of the line. Express $\vec{\mathbf{v}}$ in component form.**

**b. Find the distance from the origin to line $L$.**

9) $x = 1 + t, \quad y = 3 + t, \quad z = 5 + 4t, \quad t \in R$

**Answer**

a. A possible point and direction vector are $P(1, 3, 5)$ and $\vec{\mathbf{v}} = \langle 1, 1, 4 \rangle$, but these answers are not unique.
b. $\sqrt{3}$ units

10) $-x = y + 1, \quad z = 2$

11) Find the distance between point $A(-3, 1, 1)$ and the line of symmetric equations

$x = -y = -z.$

**Answer**

$\frac{2\sqrt{2}}{\sqrt{3}} = \frac{2\sqrt{6}}{3}$ units

12) Find the distance between point $A(4, 2, 5)$ and the line of parametric equations

$x = -1 - t, \ y = -t, \ z = 2, \ t \in R.$

**For exercises 13 - 14, lines $L_1$ and $L_2$ are given.**

**a. Verify whether lines $L_1$ and $L_2$ are parallel.**

**b. If the lines $L_1$ and $L_2$ are parallel, then find the distance between them.**

13) $L_1 : x = 1 + t, \quad y = t, \quad z = 2 + t, \quad t \in R$ and $L_2 : x - 3 = y - 1 = z - 3$

**Answer**

a. Parallel;
b. $\frac{\sqrt{2}}{\sqrt{3}} = \frac{\sqrt{6}}{3}$ units

14) $L_1 : x = 2, \quad y = 1, \quad z = t, \quad t \in R$ and $L_2 : x = 1, \quad y = 1, \quad z = 2 - 3t, \quad t \in R$

15) Show that the line passing through points $P(3, 1, 0)$ and $Q(1, 4, -3)$ is perpendicular to the line with equation $x = 3t, \quad y = -32 + 8t, \quad z = -9 + 6t, \quad t \in R.$

**Answer**

$\overrightarrow{PQ} = \langle -2, 3, -3 \rangle$ is the direction vector of the line through points $P$ and $Q$, and the direction vector of the line defined by the parametric equations above is $\vec{\mathbf{v}} = \langle 3, 8, 6 \rangle$.
Since $\vec{\mathbf{v}} \cdot \overrightarrow{PQ} = -6 + 24 - 18 = 0$, the two direction vectors are orthogonal.
Now all we need to show is that the two lines intersect.
The line through points $P(3, 1, 0)$ and $Q(1, 4, -3)$ has parametric equations: $x = 3 - 2u$, $y = 1 + 3u$, and $z = -3u$.
Setting the $x$- and $z$-coordinates of the two lines equal, we obtain the system of equations:

$$3t = 3 - 2u \quad \text{and} \quad -9 + 6t = -3u$$

Solving this system using substitution gives us, $u = -3$ and $t = 3$. Plugging these values of $t$ and $u$ back into the parametric equations of these two lines gives us the intersection point with coordinates $(9, -8, 9)$ on both lines.
Therefore the lines intersect and the line through points $P$ and $Q$ with direction vector $\overrightarrow{PQ}$ is perpendicular to the other line.

16) Are the lines of equations $x = -2 + 2t, \quad y = -6, \quad z = 2 + 6t, \quad t \in R$ and $x = -1 + t, \quad y = 1 + t, \quad z = t, \quad t \in R$, perpendicular to each other?

17) Find the point of intersection of the lines of equations $x = -2y = 3z$ and $x = -5 - t, \quad y = -1 + t, \quad z = t - 11, \quad t \in R.$

**Answer**

$(-12, 6, -4)$

18) Find the intersection point of the $x$-axis with the line of parametric equations $x = 10 + t, \quad y = 2 - 2t, \quad z = -3 + 3t, \quad t \in R.$

**For exercises 19 - 22, lines $L_1$ and $L_2$ are given. Determine whether the lines are *equal, parallel but not equal, skew,* or *intersecting*.**

19) $L_1 : x = y - 1 = -z$ and $L_2 : x - 2 = -y = \frac{z}{2}$

**Answer**

The lines are skew.

20) $L_1 : x = 2t, \quad y = 0, \quad z = 3, \quad t \in R$ and $L_2 : x = 0, \quad y = 8 + s, \quad z = 7 + s, \quad s \in R$

21) $L_1 : x = -1 + 2t, \quad y = 1 + 3t, \quad z = 7t, \quad t \in R$ and $L_2 : x - 1 = \frac{2}{3}(y - 4) = \frac{2}{7}z - 2$

**Answer**

The lines are equal.

22) $L_1 : 3x = y + 1 = 2z$ and $L_2 : x = 6 + 2t, \quad y = 17 + 6t, \quad z = 9 + 3t, \quad t \in R$

23) Consider line $L$ of symmetric equations $x - 2 = -y = \frac{z}{2}$ and point $A(1, 1, 1)$.

a. Find parametric equations for a line parallel to $L$ that passes through point $A$.

b. Find symmetric equations of a line skew to $L$ and that passes through point $A$.

c. Find symmetric equations of a line that intersects $L$ and passes through point $A$.

**Answer**

a. $x = 1 + t, \quad y = 1 - t, \quad z = 1 + 2t, \quad t \in R$

b. For instance, the line passing through $A$ with direction vector $j : x = 1, z = 1$

c. For instance, the line passing through $A$ and point $(2, 0, 0)$ that belongs to $L$ is a line that intersects; $L : \frac{x-1}{-1} = y - 1 = z - 1$

24) Consider line $L$ of parametric equations $x = t, \quad y = 2t, \quad z = 3, \quad t \in R.$

a. Find parametric equations for a line parallel to $L$ that passes through the origin.

b. Find parametric equations of a line skew to $L$ that passes through the origin.

c. Find symmetric equations of a line that intersects $L$ and passes through the origin.

**For exercises 25 - 28, point $P$ and vector $\vec{n}$ are given.**

**a. Find the scalar equation of the plane that passes through $P$ and has normal vector $\vec{n}$.**

**b. Find the general form of the equation of the plane that passes through $P$ and has normal vector $\vec{n}$.**

25) $P(0, 0, 0), \quad \vec{n} = 3\hat{i} - 2\hat{j} + 4\hat{k}$

**Answer**

a. $3x - 2y + 4z = 0$

b. $3x - 2y + 4z = 0$

26) $P(3, 2, 2), \quad \vec{n} = 2\hat{i} + 3\hat{j} - \hat{k}$

27) $P(1, 2, 3), \quad \vec{n} = \langle 1, 2, 3 \rangle$

**Answer**

a. $(x-1)+2(y-2)+3(z-3)=0$

b. $x+2y+3z-14=0$

28) $P(0,0,0)$, $\vec{\mathbf{n}}=\langle -3,2,-1\rangle$

**For exercises 29 - 32, the equation of a plane is given.**

**a. Find normal vector $\vec{\mathbf{n}}$ to the plane. Express $\vec{\mathbf{n}}$ using standard unit vectors.**

**b. Find the intersections of the plane with each of the coordinate axes (its intercepts).**

**c. Sketch the plane.**

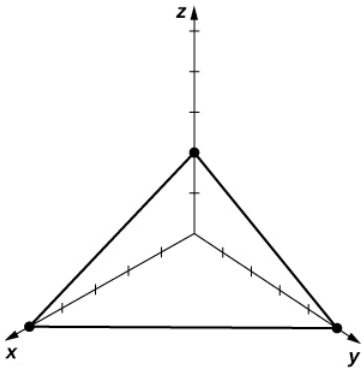
29) [T] $4x+5y+10z-20=0$

**Answer**

a. $\vec{\mathbf{n}}=4\hat{\mathbf{i}}+5\hat{\mathbf{j}}+10\hat{\mathbf{k}}$

b. $(5,0,0)$, $(0,4,0)$, and $(0,0,2)$

c.



30) $3x+4y-12=0$

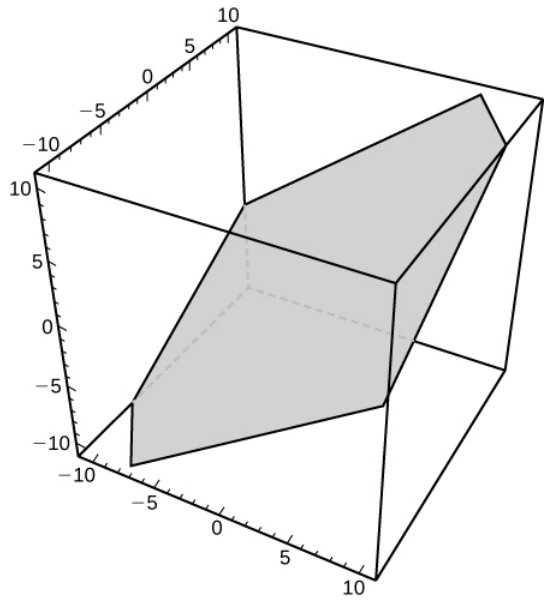
31) $3x-2y+4z=0$

**Answer**

a. $\vec{\mathbf{n}}=3\hat{\mathbf{i}}-2\hat{\mathbf{j}}+4\hat{\mathbf{k}}$

b. $(0,0,0)$

c.



32) $x + z = 0$

33) Given point $P(1, 2, 3)$ and vector $\vec{\mathbf{n}} = \hat{\mathbf{i}} + \hat{\mathbf{j}}$, find point $Q$ on the $x$-axis such that $\overrightarrow{PQ}$ and $\vec{\mathbf{n}}$ are orthogonal.

**Answer**

$(3, 0, 0)$

34) Show there is no plane perpendicular to $\vec{\mathbf{n}} = \hat{\mathbf{i}} + \hat{\mathbf{j}}$ that passes through points $P(1, 2, 3)$ and $Q(2, 3, 4)$.

35) Find parametric equations of the line passing through point $P(-2, 1, 3)$ that is perpendicular to the plane of equation $2x - 3y + z = 7$.

**Answer**

$x = -2 + 2t, \quad y = 1 - 3t, \quad z = 3 + t, \quad t \in R$

36) Find symmetric equations of the line passing through point $P(2, 5, 4)$ that is perpendicular to the plane of equation $2x + 3y - 5z = 0$.

37) Show that line $\frac{x-1}{2} = \frac{y+1}{3} = \frac{z-2}{4}$ is parallel to plane $x - 2y + z = 6$.

38) Find the real number $\alpha$ such that the line of parametric equations $x = t, \quad y = 2 - t, \quad z = 3 + t, \quad t \in R$ is parallel to the plane of equation $\alpha x + 5y + z - 10 = 0$.

**For exercises 39 - 42, the equations of two planes are given.**

**a. Determine whether the planes are *parallel*, *orthogonal*, or *neither*.**

**b. If the planes are neither parallel nor orthogonal, then find the measure of the angle between the planes. Express the answer in degrees rounded to the nearest integer.**

**c. If the planes intersect, find the line of intersection of the planes, providing the parametric equations of this line.**

39) [T] $x + y + z = 0, \quad 2x - y + z - 7 = 0$

**Answer**

a. The planes are neither parallel nor orthogonal.

b. $62°$

c. $x = -1 + 2t$

$y = -4 + t$
$z = 5 - 3t$

40) $5x - 3y + z = 4, \quad x + 4y + 7z = 1$

41) $x - 5y - z = 1, \quad 5x - 25y - 5z = -3$

**Answer**

a. The planes are parallel.

42) [T] $x - 3y + 6z = 4, \quad 5x + y - z = 4$

**For exercises 43 - 46, determine whether the given line intersects with the given plane. If they do intersect, state the point of intersection.**

43) Plane: $2x + y - z = 11$ Line: $x = 1 + t, \quad y = 3 - 2t, \quad z = 2 + 4t$

**Answer**

They intersect at point $(-1, 7, -6)$.

44) Plane: $-x + 2y + z = 2$ Line: $x = 1 + 2t, \quad y = -2 + t, \quad z = 5 - 3t$

**Answer**

They intersect at point $\left(-\frac{1}{3}, -\frac{8}{3}, 7\right)$.

45) Plane: $x - 3y + 2z = 4$ Line: $x = 2 - t, \quad y = t, \quad z = 4 + 2t$

**Answer**

The line does not intersect with this plane.

46) Plane: $x - 3y + 2z = 10$ Line: $x = 2 - t, \quad y = t, \quad z = 4 + 2t$

**Answer**

The line is actually fully contained in this plane, so every point on the line is on the plane. For example, when $t = 0$ we have the point, $(2, 0, 4)$.

47) Show that the lines of equations $x = t, \quad y = 1 + t, \quad z = 2 + t, \quad t \in R$, and $\frac{x}{2} = \frac{y - 1}{3} = z - 3$ are skew, and find the distance between them.

**Answer**

$\frac{1}{\sqrt{6}} = \frac{\sqrt{6}}{6}$ units

48) Show that the lines of equations $x = -1 + t, \quad y = -2 + t, \quad z = 3t, \quad t \in R$, and $x = 5 + s, \quad y = -8 + 2s, \quad z = 7s, \quad s \in R$ are skew, and find the distance between them.

49) Consider point $C(-3, 2, 4)$ and the plane of equation $2x + 4y - 3z = 8$.

a. Find the radius of the sphere with center $C$ tangent to the given plane.

b. Find point $P$ of tangency.

**Answer**

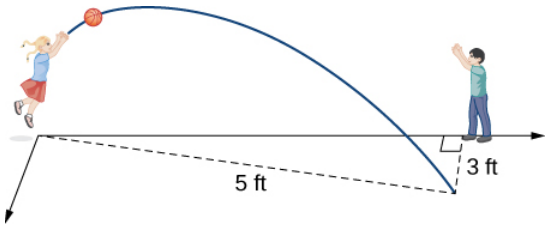
a. $r = \frac{18}{\sqrt{29}} = \frac{18\sqrt{29}}{29}$
b. $P\left(-\frac{51}{29}, \frac{130}{29}, \frac{62}{29}\right)$

50) Consider the plane of equation $x - y - z - 8 = 0$.

a. Find the equation of the sphere with center $C$ at the origin that is tangent to the given plane.

b. Find parametric equations of the line passing through the origin and the point of tangency.

51) Two children are playing with a ball. The girl throws the ball to the boy. The ball travels in the air, curves $3$ ft to the right, and falls $5$ ft away from the girl (see the following figure). If the plane that contains the trajectory of the ball is perpendicular to the ground, find its equation.



**Answer**

$4x - 3y = 0$

52) [T] John allocates $d$ dollars to consume monthly three goods of prices $a, b$, and $c$. In this context, the budget equation is defined as $ax + by + cz = d$, where $x \geq 0,\ y \geq 0$, and $z \geq 0$ represent the number of items bought from each of the goods. The budget set is given by $\{(x, y, z) \mid ax + by + cz \leq d,\ x \geq 0,\ y \geq 0,\ z \geq 0\}$, and the budget plane is the part of the plane of equation $ax + by + cz = d$ for which $x \geq 0,\ y \geq 0$, and $z \geq 0$. Consider $a = \$8,\ b = \$5,\ c = \$10$, and $d = \$500$.

a. Use a CAS to graph the budget set and budget plane.

b. For $z = 25$, find the new budget equation and graph the budget set in the same system of coordinates.

53) [T] Consider $\vec{\mathbf{r}}(t) = \langle \sin t, \cos t, 2t \rangle$ the position vector of a particle at time $t \in [0, 3]$, where the components of $\vec{\mathbf{r}}$ are expressed in centimeters and time is measured in seconds. Let $\overrightarrow{OP}$ be the position vector of the particle after $1$ sec.

a. Determine the velocity vector $\vec{\mathbf{v}}(1)$ of the particle after $1$ sec.

b. Find the scalar equation of the plane that is perpendicular to $v(1)$ and passes through point $P$. This plane is called the normal plane to the path of the particle at point $P$.

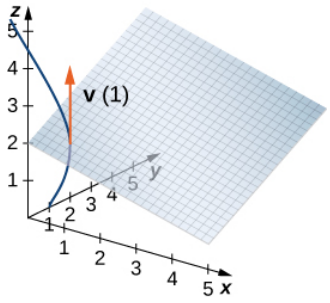
c. Use a CAS to visualize the path of the particle along with the velocity vector and normal plane at point $P$.

**Answer**

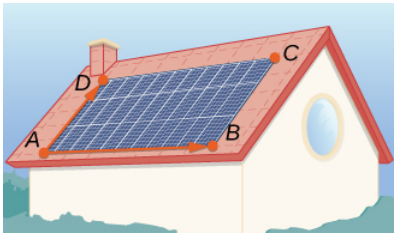
a. $\vec{\mathbf{v}}(1) = \langle \cos 1, -\sin 1, 2 \rangle$

b. $(\cos 1)(x - \sin 1) - (\sin 1)(y - \cos 1) + 2(z - 2) = 0$

c.



54) [T] A solar panel is mounted on the roof of a house. The panel may be regarded as positioned at the points of coordinates (in meters) $A(8, 0, 0),\ B(8, 18, 0),\ C(0, 18, 8)$, and $D(0, 0, 8)$ (see the following figure).



a. Find the general form of the equation of the plane that contains the solar panel by using points $A$, $B$, and $C$, and show that its normal vector is equivalent to $\overrightarrow{AB} \times \overrightarrow{AD}$.

b. Find parametric equations of line $L_1$ that passes through the center of the solar panel and has direction vector $\vec{s} = \frac{1}{\sqrt{3}}\hat{\mathbf{i}} + \frac{1}{\sqrt{3}}\hat{\mathbf{j}} + \frac{1}{\sqrt{3}}\hat{\mathbf{k}}$, which points toward the position of the Sun at a particular time of day.

c. Find symmetric equations of line $L_2$ that passes through the center of the solar panel and is perpendicular to it.

d. Determine the angle of elevation of the Sun above the solar panel by using the angle between lines $L_1$ and $L_2$.

# 12.7: Quadric Surfaces

**Learning Objectives**

- Identify a cylinder as a type of three-dimensional surface.
- Recognize the main features of ellipsoids, paraboloids, and hyperboloids.
- Use traces to draw the intersections of quadric surfaces with the coordinate planes.

We have been exploring vectors and vector operations in three-dimensional space, and we have developed equations to describe lines, planes, and spheres. In this section, we use our knowledge of planes and spheres, which are examples of three-dimensional figures called *surfaces*, to explore a variety of other surfaces that can be graphed in a three-dimensional coordinate system.

## Identifying Cylinders

The first surface we'll examine is the cylinder. Although most people immediately think of a hollow pipe or a soda straw when they hear the word cylinder, here we use the broad mathematical meaning of the term. As we have seen, cylindrical surfaces don't have to be circular. A rectangular heating duct is a cylinder, as is a rolled-up yoga mat, the cross-section of which is a spiral shape.

In the two-dimensional coordinate plane, the equation $x^2 + y^2 = 9$ describes a circle centered at the origin with radius $3$. In three-dimensional space, this same equation represents a surface. Imagine copies of a circle stacked on top of each other centered on the $z$-axis (Figure 12.7.1), forming a hollow tube. We can then construct a cylinder from the set of lines parallel to the $z$-axis passing through the circle $x^2 + y^2 = 9$ in the $xy$-plane, as shown in the figure. In this way, any curve in one of the coordinate planes can be extended to become a surface.

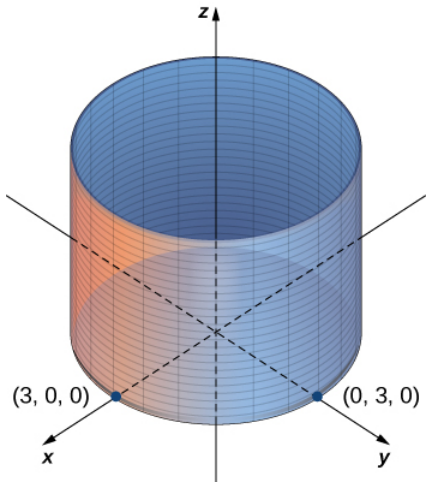

Figure 12.7.1: In three-dimensional space, the graph of equation $x^2 + y^2 = 9$ is a cylinder with radius $3$ centered on the $z$-axis. It continues indefinitely in the positive and negative directions.

**Definition: cylinders and rulings**

A set of lines parallel to a given line passing through a given curve is known as a cylindrical surface, or *cylinder*. The parallel lines are called rulings.

From this definition, we can see that we still have a cylinder in three-dimensional space, even if the curve is not a circle. Any curve can form a cylinder, and the rulings that compose the cylinder may be parallel to any given line (Figure 12.7.2).

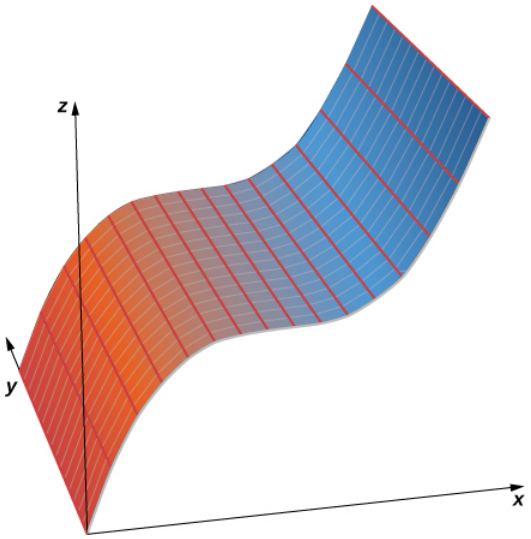

Figure 12.7.2: In three-dimensional space, the graph of equation $z = x^3$ is a cylinder, or a cylindrical surface with rulings parallel to the $y$-axis.

## Example 12.7.1: Graphing Cylindrical Surfaces

Sketch the graphs of the following cylindrical surfaces.

a. $x^2 + z^2 = 25$
b. $z = 2x^2 - y$
c. $y = \sin x$

### Solution

a. The variable $y$ can take on any value without limit. Therefore, the lines ruling this surface are parallel to the $y$-axis. The intersection of this surface with the $xz$-plane forms a circle centered at the origin with radius 5 (see Figure 12.7.3).

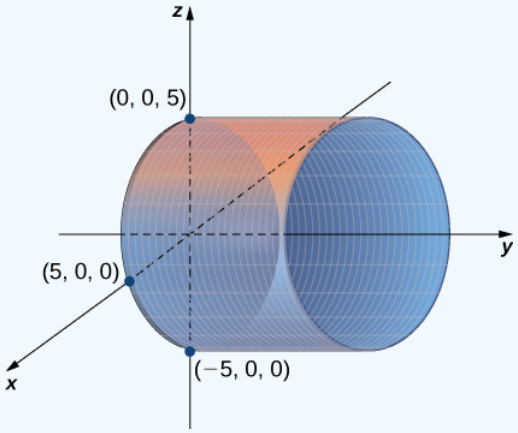

Figure 12.7.3: The graph of equation $x^2 + z^2 = 25$ is a cylinder with radius 5 centered on the $y$-axis.

b. In this case, the equation contains all three variables —$x, y,$ and $z$— so none of the variables can vary arbitrarily. The easiest way to visualize this surface is to use a computer graphing utility (Figure 12.7.4).

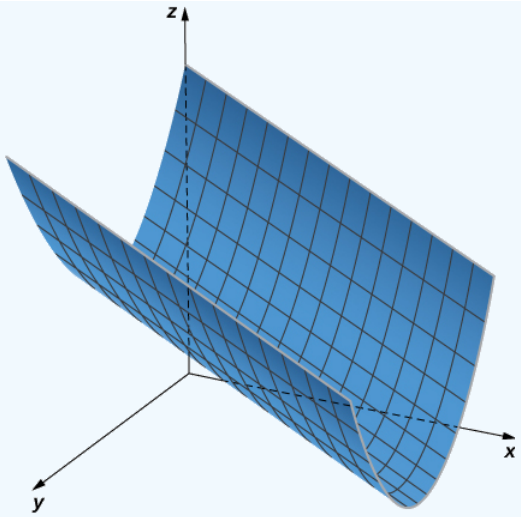

Figure 12.7.4

c. In this equation, the variable $z$ can take on any value without limit. Therefore, the lines composing this surface are parallel to the $z$-axis. The intersection of this surface with the $xy$-plane outlines curve $y = \sin x$ (Figure 12.7.5).

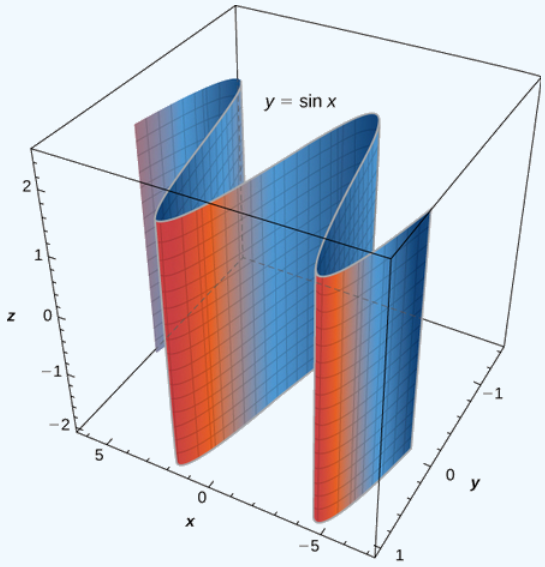

Figure 12.7.5: The graph of equation $y = \sin x$ is formed by a set of lines parallel to the $z$-axis passing through curve $y = \sin x$ in the $xy$-plane.

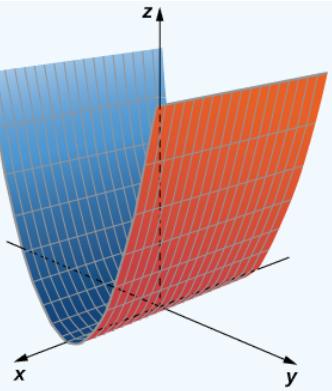
**? Exercise 12.7.1:**

Sketch or use a graphing tool to view the graph of the cylindrical surface defined by equation $z = y^2$.

**Hint**

The variable $x$ can take on any value without limit.

**Answer**



When sketching surfaces, we have seen that it is useful to sketch the intersection of the surface with a plane parallel to one of the coordinate planes. These curves are called traces. We can see them in the plot of the cylinder in Figure 12.7.6.

**Definition: traces**

The *traces* of a surface are the cross-sections created when the surface intersects a plane parallel to one of the coordinate planes.

Traces are useful in sketching cylindrical surfaces. For a cylinder in three dimensions, though, only one set of traces is useful. Notice, in Figure 12.7.6, that the trace of the graph of $z = \sin x$ in the $xz$-plane is useful in constructing the graph. The trace in the $xy$-plane, though, is just a series of parallel lines, and the trace in the $yz$-plane is simply one line.

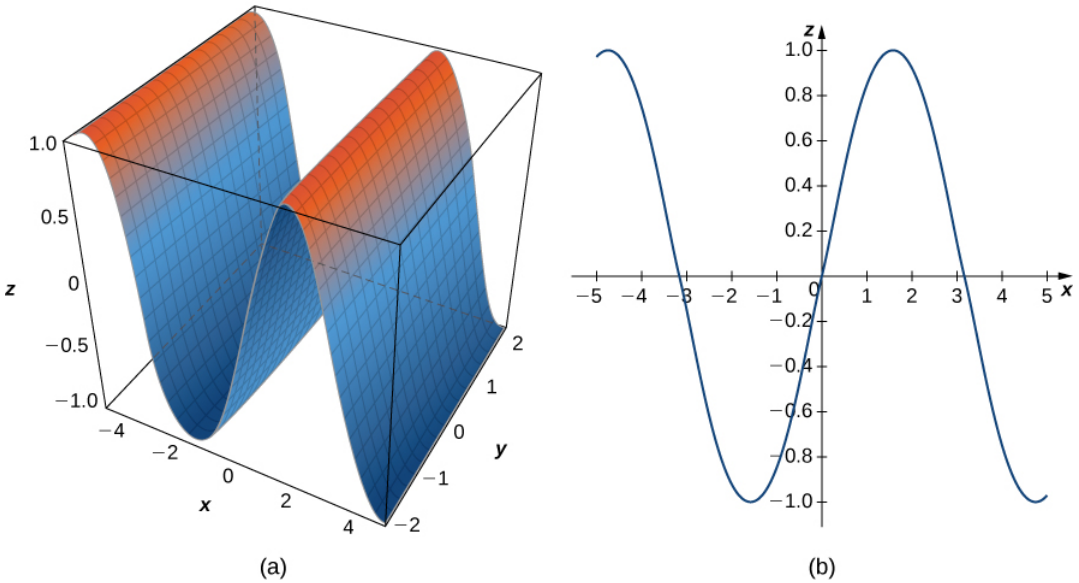


Figure 12.7.6: (a) This is one view of the graph of equation $z = \sin x$. (b) To find the trace of the graph in the $xz$-plane, set $y = 0$. The trace is simply a two-dimensional sine wave.

Cylindrical surfaces are formed by a set of parallel lines. Not all surfaces in three dimensions are constructed so simply, however. We now explore more complex surfaces, and traces are an important tool in this investigation.

## Quadric Surfaces

We have learned about surfaces in three dimensions described by first-order equations; these are planes. Some other common types of surfaces can be described by second-order equations. We can view these surfaces as three-dimensional extensions of the conic sections we discussed earlier: the ellipse, the parabola, and the hyperbola. We call these graphs quadric surfaces

**Definition: Quadric surfaces and conic sections**

*Quadric surfaces* are the graphs of equations that can be expressed in the form

$$Ax^2 + By^2 + Cz^2 + Dxy + Exz + Fyz + Gx + Hy + Jz + K = 0.$$

When a quadric surface intersects a coordinate plane, the trace is a conic section.

An *ellipsoid* is a surface described by an equation of the form $\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$. Set $x = 0$ to see the trace of the ellipsoid in the $yz$-plane. To see the traces in the $xy$- and $xz$-planes, set $z = 0$ and $y = 0$, respectively. Notice that, if $a = b$, the trace in the $xy$-plane is a circle. Similarly, if $a = c$, the trace in the $xz$-plane is a circle and, if $b = c$, then the trace in the $yz$-plane is a circle. A sphere, then, is an ellipsoid with $a = b = c$.

**Example 12.7.2: Sketching an Ellipsoid**

Sketch the ellipsoid

$$\frac{x^2}{2^2} + \frac{y^2}{3^2} + \frac{z^2}{5^2} = 1.$$

**Solution**

Start by sketching the traces. To find the trace in the $xy$-plane, set $z = 0$ : $\frac{x^2}{2^2} + \frac{y^2}{3^2} = 1$ (Figure 12.7.7). To find the other traces, first set $y = 0$ and then set $x = 0$.

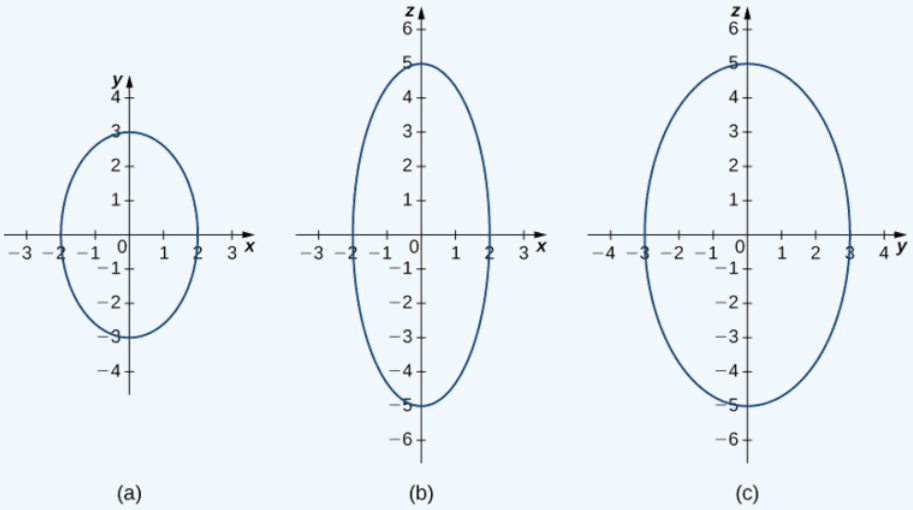

Figure 12.7.7: (a) This graph represents the trace of equation $\frac{x^2}{2^2} + \frac{y^2}{3^2} + \frac{z^2}{5^2} = 1$ in the $xy$-plane, when we set $z = 0$. (b) When we set $y = 0$, we get the trace of the ellipsoid in the $xz$-plane, which is an ellipse. (c) When we set $x = 0$, we get the trace of the ellipsoid in the $yz$-plane, which is also an ellipse.

Now that we know what traces of this solid look like, we can sketch the surface in three dimensions (Figure 12.7.8).

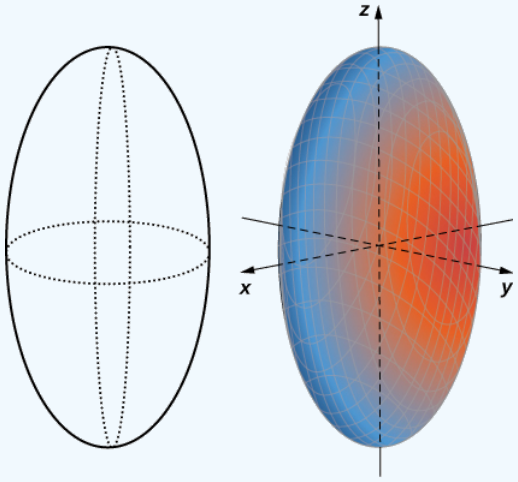

Figure 12.7.8: (a) The traces provide a framework for the surface. (b) The center of this ellipsoid is the origin.

The trace of an ellipsoid is an ellipse in each of the coordinate planes. However, this does not have to be the case for all quadric surfaces. Many quadric surfaces have traces that are different kinds of conic sections, and this is usually indicated by the name of the surface. For example, if a surface can be described by an equation of the form

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}=\frac{z}{c}$$

then we call that surface an **elliptic paraboloid**. The trace in the *xy*-plane is an ellipse, but the traces in the $xz$-plane and $yz$-plane are parabolas (Figure 12.7.9). Other elliptic paraboloids can have other orientations simply by interchanging the variables to give us a different variable in the linear term of the equation $\frac{x^2}{a^2}+\frac{z^2}{c^2}=\frac{y}{b}$ or $\frac{y^2}{b^2}+\frac{z^2}{c^2}=\frac{x}{a}$.

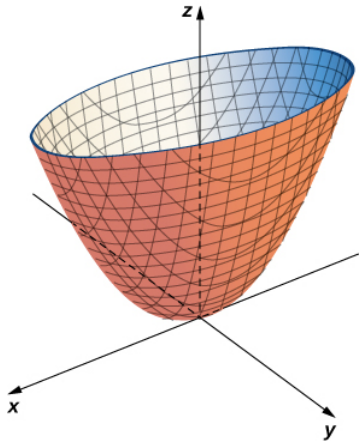

Figure 12.7.9: This quadric surface is called an elliptic paraboloid.

### Example 12.7.3: Identifying Traces of Quadric Surfaces

Describe the traces of the elliptic paraboloid $x^2+\frac{y^2}{2^2}=\frac{z}{5}$.

**Solution**

To find the trace in the $xy$-plane, set $z=0: x^2+\frac{y^2}{2^2}=0$. The trace in the plane $z=0$ is simply one point, the origin. Since a single point does not tell us what the shape is, we can move up the $z$-axis to an arbitrary plane to find the shape of other traces of the figure.

The trace in plane $z = 5$ is the graph of equation $x^2 + \frac{y^2}{2^2} = 1$, which is an ellipse. In the $xz$-plane, the equation becomes $z = 5x^2$. The trace is a parabola in this plane and in any plane with the equation $y = b$.

In planes parallel to the $yz$-plane, the traces are also parabolas, as we can see in Figure 12.7.10.

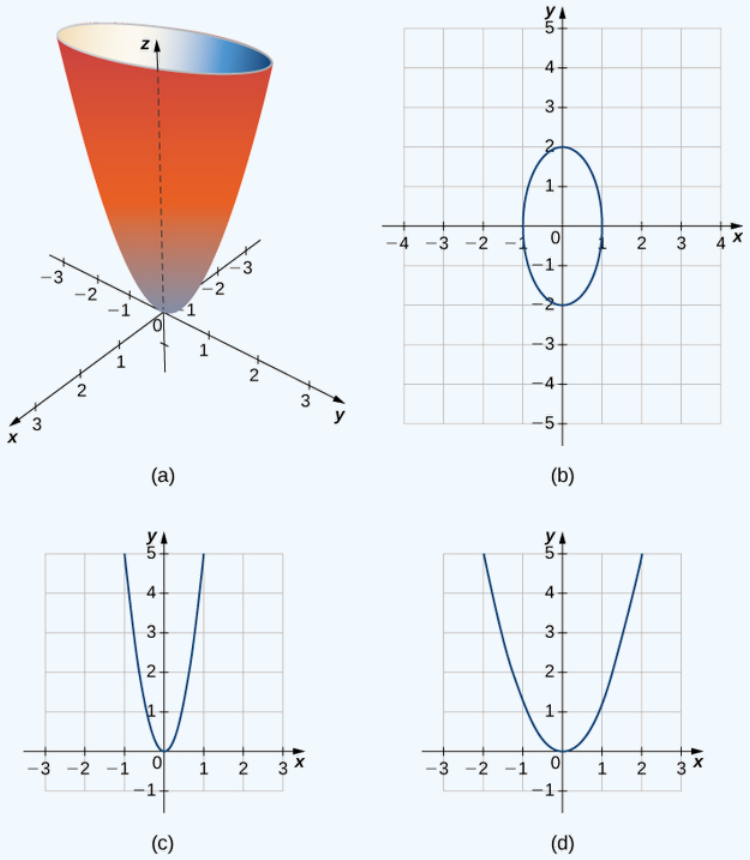

Figure 12.7.10: (a) The paraboloid $x^2 + \frac{y^2}{2^2} = \frac{z}{5}$. (b) The trace in plane $z = 5$. (c) The trace in the $xz$-plane. (d) The trace in the $yz$-plane.

## Exercise 12.7.2:

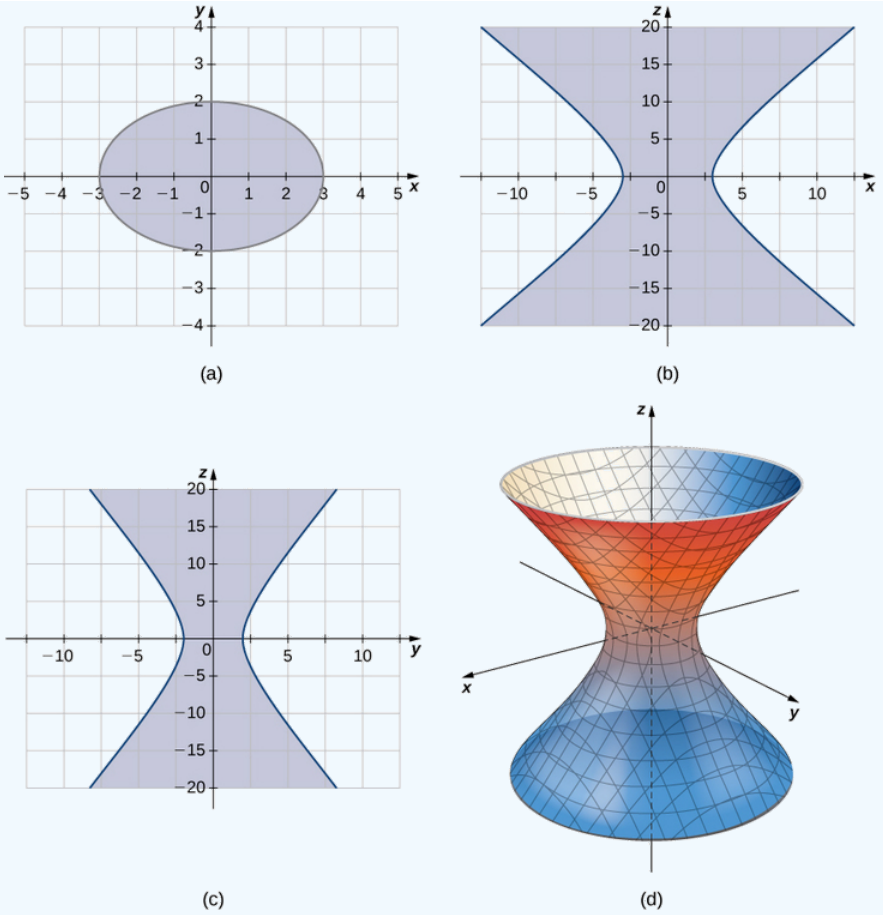
A hyperboloid of one sheet is any surface that can be described with an equation of the form $\frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{z^2}{c^2} = 1$. Describe the traces of the hyperboloid of one sheet given by equation $\frac{x^2}{3^2} + \frac{y^2}{2^2} - \frac{z^2}{5^2} = 1$.

**Hint**

To find the traces in the coordinate planes, set each variable to zero individually.

**Answer**

The traces parallel to the $xy$-plane are ellipses and the traces parallel to the $xz$- and $yz$-planes are hyperbolas. Specifically, the trace in the $xy$-plane is ellipse $\frac{x^2}{3^2} + \frac{y^2}{2^2} = 1$, the trace in the $xz$-plane is hyperbola $\frac{x^2}{3^2} - \frac{z^2}{5^2} = 1$, and the trace in the $yz$-plane is hyperbola $\frac{y^2}{2^2} - \frac{z^2}{5^2} = 1$ (see the following figure).



Hyperboloids of one sheet have some fascinating properties. For example, they can be constructed using straight lines, such as in the sculpture in Figure 12.7.11*a*. In fact, cooling towers for nuclear power plants are often constructed in the shape of a hyperboloid. The builders are able to use straight steel beams in the construction, which makes the towers very strong while using relatively little material (Figure 12.7.11*b*).

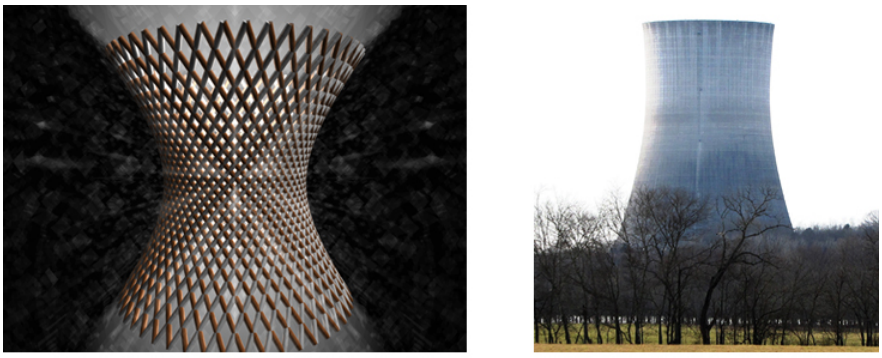


Figure 12.7.11: (a) A sculpture in the shape of a hyperboloid can be constructed of straight lines. (b) Cooling towers for nuclear power plants are often built in the shape of a hyperboloid.

### Example 12.7.4: Chapter Opener: Finding the Focus of a Parabolic Reflector

Energy hitting the surface of a parabolic reflector is concentrated at the focal point of the reflector (Figure 12.7.12). If the surface of a parabolic reflector is described by equation $\frac{x^2}{100}+\frac{y^2}{100}=\frac{z}{4}$, where is the focal point of the reflector?

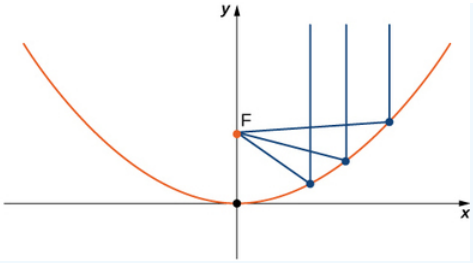

Figure 12.7.12: Energy reflects off of the parabolic reflector and is collected at the focal point. (credit: modification of CGP Grey, Wikimedia Commons)

**Solution**

Since $z$ is the first-power variable, the axis of the reflector corresponds to the $z$-axis. The coefficients of $x^2$ and $y^2$ are equal, so the cross-section of the paraboloid perpendicular to the $z$-axis is a circle. We can consider a trace in the $xz$-plane or the $yz$-plane; the result is the same. Setting $y = 0$, the trace is a parabola opening up along the $z$-axis, with standard equation $x^2 = 4pz$, where $p$ is the focal length of the parabola. In this case, this equation becomes $x^2 = 100 \cdot \frac{z}{4} = 4pz$ or $25 = 4p$. So $p$ is $6.25$ m, which tells us that the focus of the paraboloid is $6.25$ m up the axis from the vertex. Because the vertex of this surface is the origin, the focal point is $(0, 0, 6.25)$.

Seventeen standard quadric surfaces can be derived from the general equation

$$Ax^2 + By^2 + Cz^2 + Dxy + Exz + Fyz + Gx + Hy + Jz + K = 0.$$

The following figures summarize the most important ones.

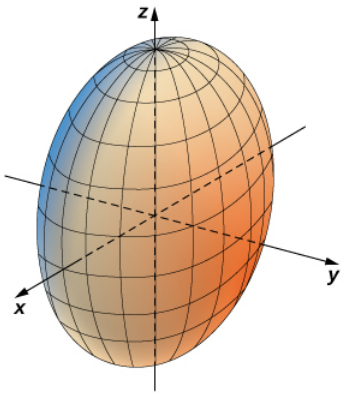
Characteristics of Common Quadric Surfaces

**Ellipsoid**

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$$

*Traces*
In plane $z = p$: an ellipse
In plane $y = q$: an ellipse
In plane $x = r$: an ellipse

If $a = b = c$, then this surface is a sphere.

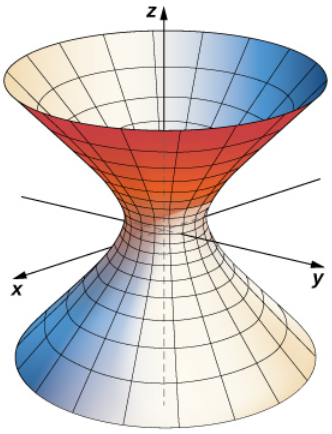


**Hyperboloid of One Sheet**

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{z^2}{c^2} = 1$$

*Traces*
In plane $z = p$: an ellipse
In plane $y = q$: a hyperbola
In plane $x = r$: a hyperbola

In the equation for this surface, two of the variables have positive coefficients and one has a negative coefficient. The axis of the surface corresponds to the variable with the negative coefficient.



**Hyperboloid of Two Sheets**

$$\frac{z^2}{c^2} - \frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$$

*Traces*
In plane $z = p$: an ellipse or the empty set (no trace)
In plane $y = q$: a hyperbola
In plane $x = r$: a hyperbola

In the equation for this surface, two of the variables have negative coefficients and one has a positive coefficient. The axis of the surface corresponds to the variable with a positive coefficient. The surface does not intersect the coordinate plane perpendicular to the axis.

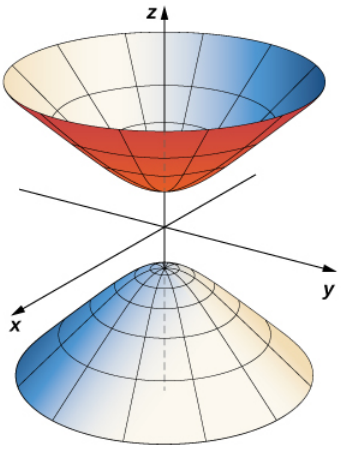


Figure **12.7.13**: Characteristics of Common Quadric Surfaces: Ellipsoid, Hyperboloid of One Sheet, Hyperboloid of Two Sheets.

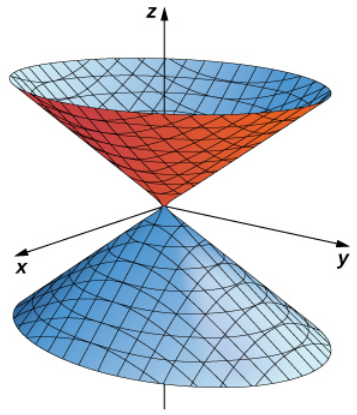
Characteristics of Common Quadric Surfaces

**Elliptic Cone**

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{z^2}{c^2} = 0$$

*Traces*
In plane $z = p$: an ellipse
In plane $y = q$: a hyperbola
In plane $x = r$: a hyperbola
In the $xz$ – plane: a pair of lines that intersect at the origin
In the $yz$ – plane: a pair of lines that intersect at the origin

The axis of the surface corresponds to the variable with a negative coefficient. The traces in the coordinate planes parallel to the axis are intersecting lines.

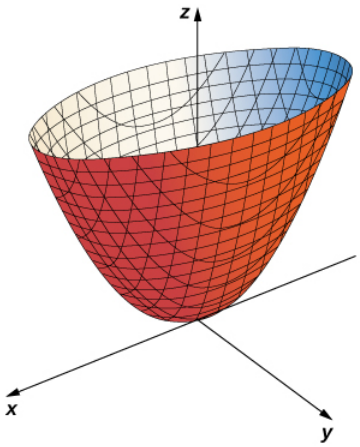


**Elliptic Paraboloid**

$$z = \frac{x^2}{a^2} + \frac{y^2}{b^2}$$

*Traces*
In plane $z = p$: an ellipse
In plane $y = q$: a parabola
In plane $x = r$: a parabola

The axis of the surface corresponds to the linear variable.



**Hyperbolic Paraboloid**

$$z = \frac{x^2}{a^2} - \frac{y^2}{b^2}$$

*Traces*
In plane $z = p$: a hyperbola
In plane $y = q$: a parabola
In plane $x = r$: a parabola

The axis of the surface corresponds to the linear variable.

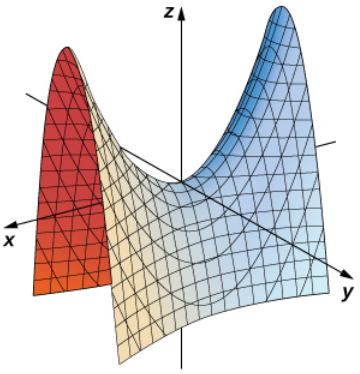


Figure 12.7.14: Characteristics of Common Quadric Surfaces: Elliptic Cone, Elliptic Paraboloid, Hyperbolic Paraboloid.

### Example 12.7.5: Identifying Equations of Quadric Surfaces

Identify the surfaces represented by the given equations.

a. $16x^2 + 9y^2 + 16z^2 = 144$
b. $9x^2 - 18x + 4y^2 + 16y - 36z + 25 = 0$

**Solution**

a. The $x, y,$ and $z$ terms are all squared, and are all positive, so this is probably an ellipsoid. However, let's put the equation into the standard form for an ellipsoid just to be sure. We have

$$16x^2 + 9y^2 + 16z^2 = 144.$$

Dividing through by 144 gives

$$\frac{x^2}{9} + \frac{y^2}{16} + \frac{z^2}{9} = 1.$$

So, this is, in fact, an ellipsoid, centered at the origin.

b. We first notice that the $z$ term is raised only to the first power, so this is either an elliptic paraboloid or a hyperbolic paraboloid. We also note there are $x$ terms and $y$ terms that are not squared, so this quadric surface is not centered at the origin. We need to complete the square to put this equation in one of the standard forms. We have

$$\begin{aligned} 9x^2 - 18x + 4y^2 + 16y - 36z + 25 &= 0 \\ 9x^2 - 18x + 4y^2 + 16y + 25 &= 36z \\ 9(x^2 - 2x) + 4(y^2 + 4y) + 25 &= 36z \\ 9(x^2 - 2x + 1 - 1) + 4(y^2 + 4y + 4 - 4) + 25 &= 36z \\ 9(x-1)^2 - 9 + 4(y+2)^2 - 16 + 25 &= 36z \\ 9(x-1)^2 + 4(y+2)^2 &= 36z \\ \frac{(x-1)^2}{4} + \frac{(y+2)^2}{9} &= z. \end{aligned}$$

This is an elliptic paraboloid centered at $(1, -2, 0)$.

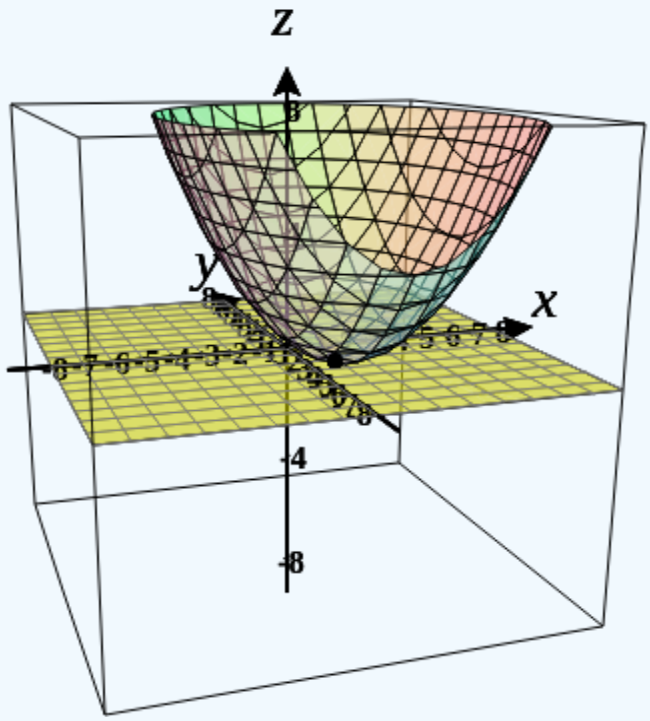

Figure 12.7.15: Plot of $z = \frac{(x-1)^2}{4} + \frac{(y+2)^2}{9}$ in CalcPlot3D.

**? Exercise 12.7.3**

Identify the surface represented by equation $9x^2 + y^2 - z^2 + 2z - 10 = 0$.

**Hint**

Look at the signs and powers of the $x, y$, and $z$ terms

**Answer**

Hyperboloid of one sheet, centered at $(0, 0, 1)$.

## Key Concepts

- A set of lines parallel to a given line passing through a given curve is called a *cylinder*, or a cylindrical surface. The parallel lines are called *rulings*.
- The intersection of a three-dimensional surface and a plane is called a trace. To find the trace in the $xy$-, $yz$-, or $xz$-planes, set $z = 0$, $x = 0$, or $y = 0$, respectively.
- Quadric surfaces are three-dimensional surfaces with traces composed of conic sections. Every quadric surface can be expressed with an equation of the form

$$Ax^2 + By^2 + Cz^2 + Dxy + Exz + Fyz + Gx + Hy + Jz + K = 0.$$

- To sketch the graph of a quadric surface, start by sketching the traces to understand the framework of the surface.
- Important quadric surfaces are summarized in Figures 12.7.13 and 12.7.14.

## Glossary

**cylinder**
a set of lines parallel to a given line passing through a given curve

**ellipsoid**
a three-dimensional surface described by an equation of the form $\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$; all traces of this surface are ellipses

**elliptic cone**
a three-dimensional surface described by an equation of the form $\frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{z^2}{c^2} = 0$; traces of this surface include ellipses and intersecting lines

**elliptic paraboloid**
a three-dimensional surface described by an equation of the form $z = \frac{x^2}{a^2} + \frac{y^2}{b^2}$; traces of this surface include ellipses and parabolas

**hyperboloid of one sheet**
a three-dimensional surface described by an equation of the form $\frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{z^2}{c^2} = 1$; traces of this surface include ellipses and hyperbolas

**hyperboloid of two sheets**
a three-dimensional surface described by an equation of the form $\frac{z^2}{c^2} - \frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$; traces of this surface include ellipses and hyperbolas

**quadric surfaces**
surfaces in three dimensions having the property that the traces of the surface are conic sections (ellipses, hyperbolas, and parabolas)

**rulings**

parallel lines that make up a cylindrical surface

**trace**

the intersection of a three-dimensional surface with a coordinate plane

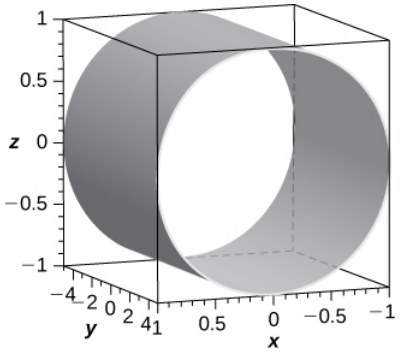
# 12.7E: Exercises for Section 12.6

**For exercises 1 - 6, sketch and describe the cylindrical surface of the given equation.**

1) [T] $x^2 + z^2 = 1$

**Answer**

The surface is a cylinder with the rulings parallel to the $y$-axis.

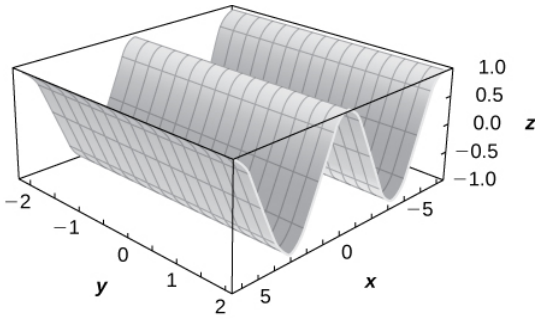


2) [T] $x^2 + y^2 = 9$

3) [T] $z = \cos\left(\frac{\pi}{2} + x\right)$

**Answer**

The surface is a cylinder with rulings parallel to the $y$-axis.

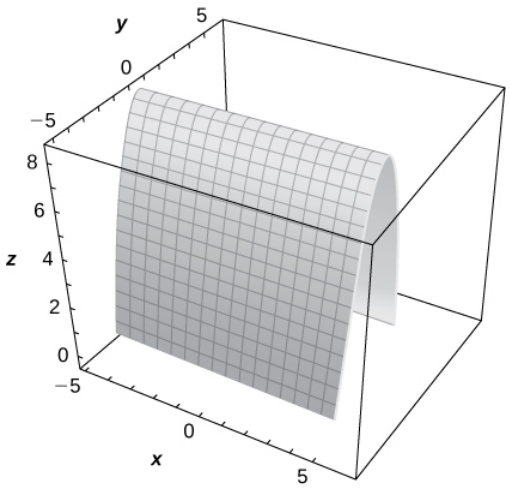


4) [T] $z = e^x$

5) [T] $z = 9 - y^2$

**Answer**

The surface is a cylinder with rulings parallel to the $x$-axis.



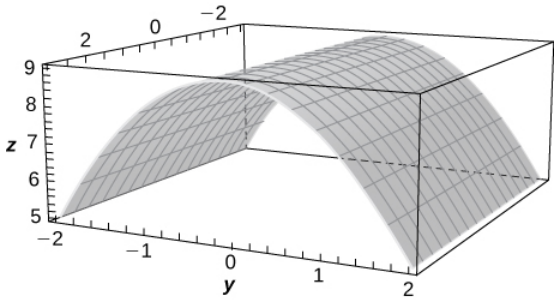
6) [T] $z = \ln x$

**For exercises 7 - 10, the graph of a quadric surface is given.**

**a. Specify the name of the quadric surface.**

**b. Determine the axis of symmetry of the quadric surface.**

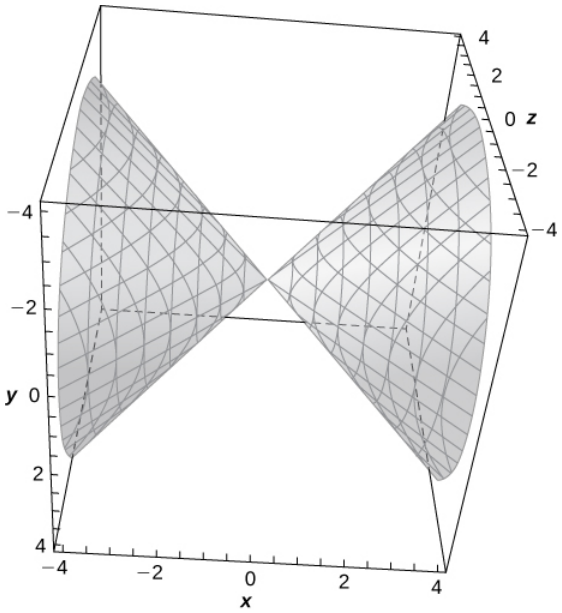
7)



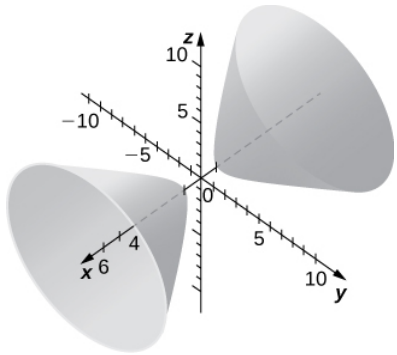
**Answer**

a. Cylinder; b. The $x$-axis

8)



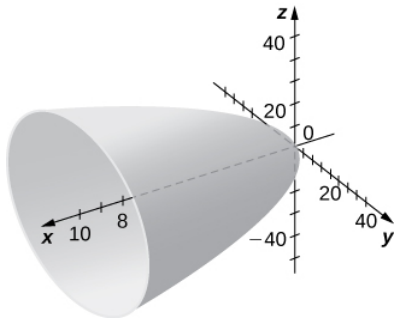
9)



**Answer**

a. Hyperboloid of two sheets; b. The $x$-axis

10)



**For exercises 11 - 16, match the given quadric surface with its corresponding equation in standard form.**

a. $\frac{x^2}{4}+\frac{y^2}{9}-\frac{z^2}{12}=1$

b. $\frac{x^2}{4}-\frac{y^2}{9}-\frac{z^2}{12}=1$

c. $\frac{x^2}{4}+\frac{y^2}{9}+\frac{z^2}{12}=1$

d. $z = 4x^2 + 3y^2$

e. $z = 4x^2 - y^2$

f. $4x^2 + y^2 - z^2 = 0$

11) Hyperboloid of two sheets

**Answer**

b.

12) Ellipsoid

13) Elliptic paraboloid

**Answer**

d.

14) Hyperbolic paraboloid

15) Hyperboloid of one sheet

**Answer**

a.

16) Elliptic cone

**For exercises 17 - 28, rewrite the given equation of the quadric surface in standard form. Identify the surface.**

17) $-x^2 + 36y^2 + 36z^2 = 9$

**Answer**

$-\frac{x^2}{9} + \frac{y^2}{\frac{1}{4}} + \frac{z^2}{\frac{1}{4}} = 1$, hyperboloid of one sheet with the $x$-axis as its axis of symmetry

18) $-4x^2 + 25y^2 + z^2 = 100$

19) $-3x^2 + 5y^2 - z^2 = 10$

**Answer**

$-\frac{x^2}{\frac{10}{3}} + \frac{y^2}{2} - \frac{z^2}{10} = 1$, hyperboloid of two sheets with the $y$-axis as its axis of symmetry

20) $3x^2 - y^2 - 6z^2 = 18$

21) $5y = x^2 - z^2$

**Answer**

$y = -\frac{z^2}{5} + \frac{x^2}{5}$, hyperbolic paraboloid with the $y$-axis as its axis of symmetry

22) $8x^2 - 5y^2 - 10z = 0$

23) $x^2 + 5y^2 + 3z^2 - 15 = 0$

**Answer**

$\frac{x^2}{15} + \frac{y^2}{3} + \frac{z^2}{5} = 1$, ellipsoid

24) $63x^2 + 7y^2 + 9z^2 - 63 = 0$

25) $x^2 + 5y^2 - 8z^2 = 0$

**Answer**

$\frac{x^2}{40}+\frac{y^2}{8}-\frac{z^2}{5}=0$, elliptic cone with the $z$-axis as its axis of symmetry

26) $5x^2-4y^2+20z^2=0$

27) $6x=3y^2+2z^2$

**Answer**

$x=\frac{y^2}{2}+\frac{z^2}{3}$, elliptic paraboloid with the $x$-axis as its axis of symmetry

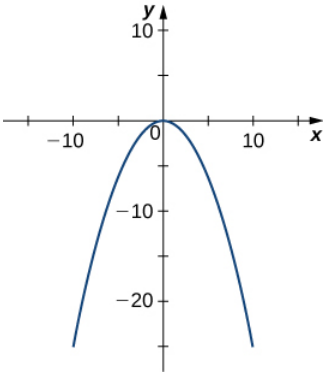
28) $49y=x^2+7z^2$

**For exercises 29 - 34, find the trace of the given quadric surface in the specified plane of coordinates and sketch it.**

29) [T] $x^2+z^2+4y=0, \quad z=0$

**Answer**

Parabola $y=-\frac{x^2}{4}$,

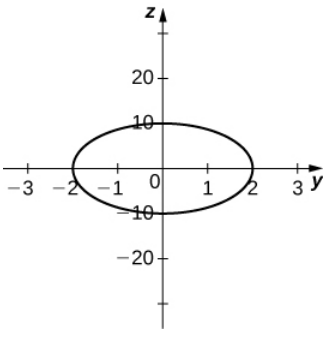


30) [T] $x^2+z^2+4y=0, \quad x=0$

31) [T] $-4x^2+25y^2+z^2=100, \quad x=0$

**Answer**

Ellipse $\frac{y^2}{4}+\frac{z^2}{100}=1$,

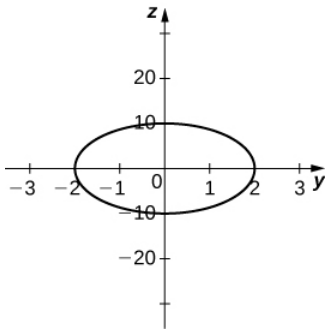


32) [T] $-4x^2+25y^2+z^2=100, \quad y=0$

33) [T] $x^2+\frac{y^2}{4}+\frac{z^2}{100}=1, \quad x=0$

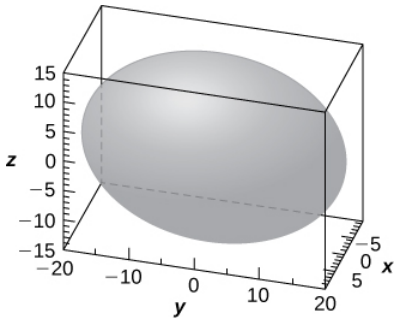
**Answer**

Ellipse $\frac{y^2}{4}+\frac{z^2}{100}=1$,



34) [T] $x^2 - y - z^2 = 1, \quad y = 0$

35) Use the graph of the given quadric surface to answer the questions.



a. Specify the name of the quadric surface.

b. Which of the equations—$16x^2 + 9y^2 + 36z^2 = 3600$, $9x^2 + 36y^2 + 16z^2 = 3600$, or $36x^2 + 9y^2 + 16z^2 = 3600$—corresponds to the graph?

c. Use b. to write the equation of the quadric surface in standard form.

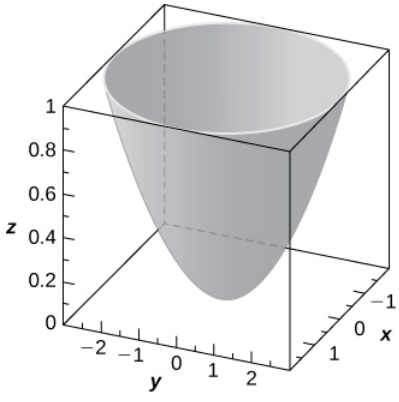
**Answer**

a. Ellipsoid

b. The third equation

c. $\frac{x^2}{100} + \frac{y^2}{400} + \frac{z^2}{225} = 1$

36) Use the graph of the given quadric surface to answer the questions.



a. Specify the name of the quadric surface.

b. Which of the equations—$36z = 9x^2 + y^2$, $9x^2 + 4y^2 = 36z$, or $-36z = -81x^2 + 4y^2$—corresponds to the graph above?

c. Use b. to write the equation of the quadric surface in standard form.

**For exercises 37 - 42, the equation of a quadric surface is given.**

**a. Use the method of completing the square to write the equation in standard form.**

**b. Identify the surface.**

37) $x^2+2z^2+6x-8z+1=0$

**Answer**

a. $\dfrac{(x+3)^2}{16}+\dfrac{(z-2)^2}{8}=1$

b. Cylinder centered at $(-3,2)$ with rulings parallel to the $y$-axis

38) $4x^2-y^2+z^2-8x+2y+2z+3=0$

39) $x^2+4y^2-4z^2-6x-16y-16z+5=0$

**Answer**

a. $\dfrac{(x-3)^2}{4}+(y-2)^2-(z+2)^2=1$

b. Hyperboloid of one sheet centered at $(3,2,-2)$, with the $z$-axis as its axis of symmetry

40) $x^2+z^2-4y+4=0$

41) $x^2+\dfrac{y^2}{4}-\dfrac{z^2}{3}+6x+9=0$

**Answer**

a. $(x+3)^2+\dfrac{y^2}{4}-\dfrac{z^2}{3}=0$

b. Elliptic cone centered at $(-3,0,0)$, with the $z$-axis as its axis of symmetry

42) $x^2-y^2+z^2-12z+2x+37=0$

43) Write the standard form of the equation of the ellipsoid centered at the origin that passes through points $A(2,0,0)$, $B(0,0,1)$, and $C\left(12,\sqrt{11},\frac{1}{2}\right)$.

**Answer**

$\dfrac{x^2}{4}+\dfrac{y^2}{16}+z^2=1$

44) Write the standard form of the equation of the ellipsoid centered at point $P(1,1,0)$ that passes through points $A(6,1,0)$, $B(4,2,0)$ and $C(1,2,1)$.

45) Determine the intersection points of elliptic cone $x^2-y^2-z^2=0$ with the line of symmetric equations $\dfrac{x-1}{2}=\dfrac{y+1}{3}=z$.

**Answer**

$(1,-1,0)$ and $\left(\frac{13}{3},4,\frac{5}{3}\right)$

46) Determine the intersection points of parabolic hyperboloid $z=3x^2-2y^2$ with the line of parametric equations $x=3t$, $y=2t$, $z=19t$, where $t\in R$.

47) Find the equation of the quadric surface with points $P(x,y,z)$ that are equidistant from point $Q(0,-1,0)$ and plane of equation $y=1$. Identify the surface.

**Answer**

$x^2+z^2+4y=0$, elliptic paraboloid

48) Find the equation of the quadric surface with points $P(x,y,z)$ that are equidistant from point $Q(0,2,0)$ and plane of equation $y=-2$. Identify the surface.

49) If the surface of a parabolic reflector is described by equation $400z = x^2 + y^2$, find the focal point of the reflector.

**Answer**

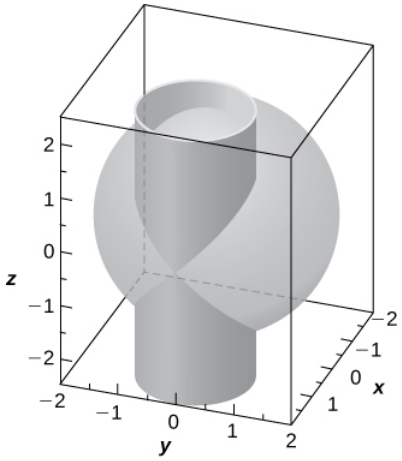
$(0, 0, 100)$

50) Consider the parabolic reflector described by equation $z = 20x^2 + 20y^2$. Find its focal point.

51) Show that quadric surface $x^2 + y^2 + z^2 + 2xy + 2xz + 2yz + x + y + z = 0$ reduces to two parallel planes.

52) Show that quadric surface $x^2 + y^2 + z^2 - 2xy - 2xz + 2yz - 1 = 0$ reduces to two parallel planes passing.

53) [T] The intersection between cylinder $(x-1)^2 + y^2 = 1$ and sphere $x^2 + y^2 + z^2 = 4$ is called a *Viviani curve*.



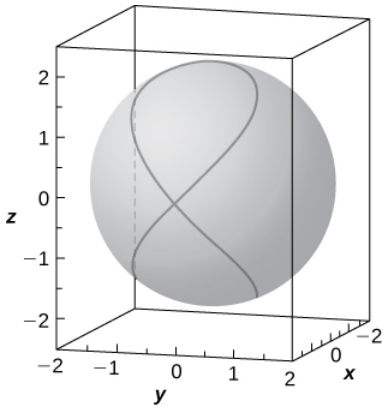
a. Solve the system consisting of the equations of the surfaces to find the equation of the intersection curve. (Hint: Find $x$ and $y$ in terms of $z$.)

b. Use a computer algebra system (CAS) or CalcPlot3D to visualize the intersection curve on sphere $x^2 + y^2 + z^2 = 4$.

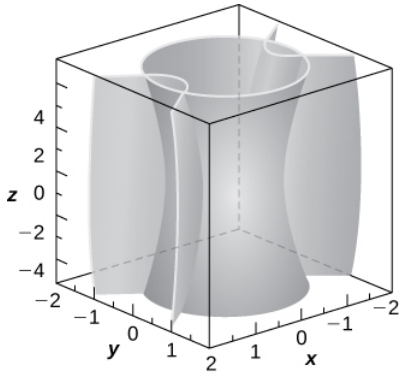
**Answer**

a. $x = 2 - \frac{z^2}{2}, \quad y = \pm\frac{z}{2}\sqrt{4 - z^2}$, where $z \in [-2, 2]$;

b.



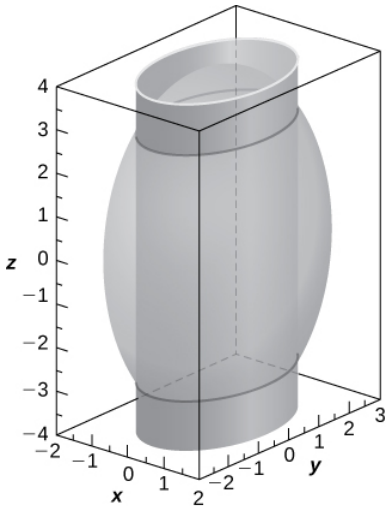
54) Hyperboloid of one sheet $25x^2 + 25y^2 - z^2 = 25$ and elliptic cone $-25x^2 + 75y^2 + z^2 = 0$ are represented in the following figure along with their intersection curves. Identify the intersection curves and find their equations (Hint: Find y from the system consisting of the equations of the surfaces.)



55) [T] Use a CAS or CalcPlot3D to create the intersection between cylinder $9x^2 + 4y^2 = 18$ and ellipsoid $36x^2 + 16y^2 + 9z^2 = 144$, and find the equations of the intersection curves.

**Answer**

two ellipses of equations $\frac{x^2}{2} + \frac{y^2}{\frac{9}{2}} = 1$ in planes $z = \pm 2\sqrt{2}$



56) [T] A spheroid is an ellipsoid with two equal semiaxes. For instance, the equation of a spheroid with the z-axis as its axis of symmetry is given by $\frac{x^2}{a^2} + \frac{y^2}{a^2} + \frac{z^2}{c^2} = 1$, where $a$ and $c$ are positive real numbers. The spheroid is called oblate if $c < a$, and prolate for $c > a$.

a. The eye cornea is approximated as a prolate spheroid with an axis that is the eye, where $a = 8.7mm$ and $c = 9.6mm$.Write the equation of the spheroid that models the cornea and sketch the surface.

b. Give two examples of objects with prolate spheroid shapes.

57) [T] In cartography, Earth is approximated by an oblate spheroid rather than a sphere. The radii at the equator and poles are approximately $3963$mi and $3950$mi, respectively.

a. Write the equation in standard form of the ellipsoid that represents the shape of Earth. Assume the center of Earth is at the origin and that the trace formed by plane $z = 0$ corresponds to the equator.

b. Sketch the graph.

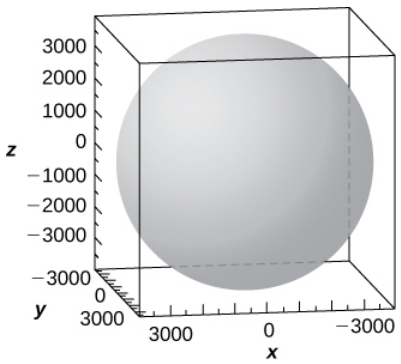
c. Find the equation of the intersection curve of the surface with plane $z = 1000$ that is parallel to the $xy$-plane. The intersection curve is called a *parallel.*

d. Find the equation of the intersection curve of the surface with plane $x + y = 0$ that passes through the $z$-axis. The intersection curve is called a meridian.

**Answer**

a. $\frac{x^2}{3963^2}+\frac{y^2}{3963^2}+\frac{z^2}{3950^2}=1$

b.



c. The intersection curve is the ellipse of equation $\frac{x^2}{3963^2}+\frac{y^2}{3963^2}=\frac{(2950)(4950)}{3950^2}$, and the intersection is an ellipse.

d. The intersection curve is the ellipse of equation $\frac{2y^2}{3963^2}+\frac{z^2}{3950^2}=1$.

58) [T] A set of buzzing stunt magnets (or “rattlesnake eggs”) includes two sparkling, polished, superstrong spheroid-shaped magnets well-known for children’s entertainment. Each magnet is $1.625$ in. long and $0.5$ in. wide at the middle. While tossing them into the air, they create a buzzing sound as they attract each other.

a. Write the equation of the prolate spheroid centered at the origin that describes the shape of one of the magnets.

b. Write the equations of the prolate spheroids that model the shape of the buzzing stunt magnets. Use a CAS or CalcPlot3D to create the graphs.

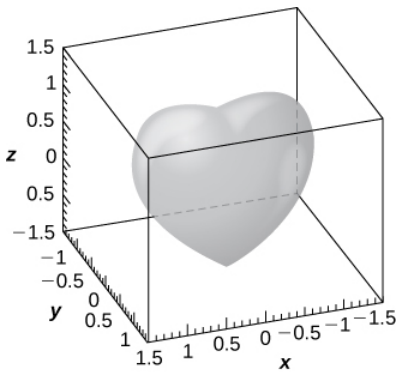
59) [T] A heart-shaped surface is given by equation $(x^2+\frac{9}{4}y^2+z^2-1)^3-x^2z^3-\frac{9}{80}y^2z^3=0$.

a. Use a CAS or CalcPlot3D to graph the surface that models this shape.

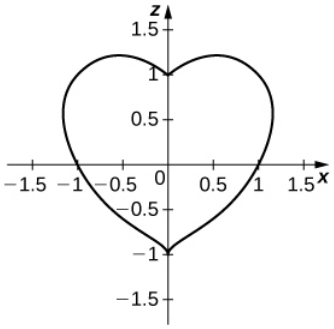
b. Determine and sketch the trace of the heart-shaped surface on the $xz$-plane.

**Answer**

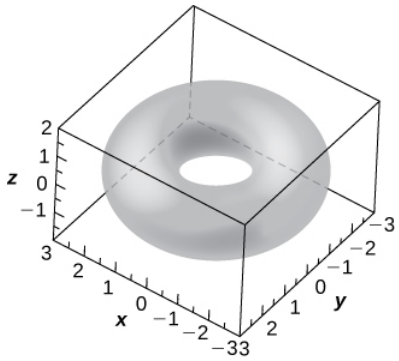
a.



b. The intersection curve is $(x^2+z^2-1)^3-x^2z^3=0$.



60) [T] The ring torus symmetric about the $z$-axis is a special type of surface in topology and its equation is given by $(x^2+y^2+z^2+R^2-r^2)^2 = 4R^2(x^2+y^2)$, where $R > r > 0$. The numbers $R$ and $r$ are called are the major and minor radii, respectively, of the surface. The following figure shows a ring torus for which $R = 2$ and $r = 1$.



a. Write the equation of the ring torus with $R = 2$ and $r = 1$, and use a CAS or CalcPlot3D to graph the surface. Compare the graph with the figure given.

b. Determine the equation and sketch the trace of the ring torus from a. on the $xy$-plane.

c. Give two examples of objects with ring torus shapes.

# 12.8: Cylindrical and Spherical Coordinates

**Learning Objectives**

- Convert from cylindrical to rectangular coordinates.
- Convert from rectangular to cylindrical coordinates.
- Convert from spherical to rectangular coordinates.
- Convert from rectangular to spherical coordinates.

The Cartesian coordinate system provides a straightforward way to describe the location of points in space. Some surfaces, however, can be difficult to model with equations based on the Cartesian system. This is a familiar problem; recall that in two dimensions, polar coordinates often provide a useful alternative system for describing the location of a point in the plane, particularly in cases involving circles. In this section, we look at two different ways of describing the location of points in space, both of them based on extensions of polar coordinates. As the name suggests, cylindrical coordinates are useful for dealing with problems involving cylinders, such as calculating the volume of a round water tank or the amount of oil flowing through a pipe. Similarly, spherical coordinates are useful for dealing with problems involving spheres, such as finding the volume of domed structures.

## Cylindrical Coordinates

When we expanded the traditional Cartesian coordinate system from two dimensions to three, we simply added a new axis to model the third dimension. Starting with polar coordinates, we can follow this same process to create a new three-dimensional coordinate system, called the cylindrical coordinate system. In this way, cylindrical coordinates provide a natural extension of polar coordinates to three dimensions.

**Definition: The Cylindrical Coordinate System**

In the cylindrical coordinate system, a point in space (Figure 12.8.1) is represented by the ordered triple $(r, \theta, z)$, where

- $(r, \theta)$ are the polar coordinates of the point's projection in the $xy$-plane
- $z$ is the usual **$z$-coordinate** in the Cartesian coordinate system

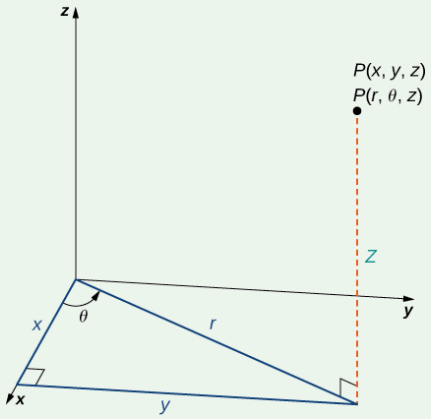

Figure 12.8.1: The right triangle lies in the $xy$-plane. The length of the hypotenuse is $r$ and $\theta$ is the measure of the angle formed by the positive $x$-axis and the hypotenuse. The $z$-coordinate describes the location of the point above or below the $xy$-plane.

In the $xy$-plane, the right triangle shown in Figure 12.8.1 provides the key to transformation between cylindrical and Cartesian, or rectangular, coordinates.

### Conversion between Cylindrical and Cartesian Coordinates

The rectangular coordinates $(x, y, z)$ and the cylindrical coordinates $(r, \theta, z)$ of a point are related as follows:

These equations are used to convert from cylindrical coordinates to rectangular coordinates.

- $x = r\cos\theta$
- $y = r\sin\theta$
- $z = z$

These equations are used to convert from rectangular coordinates to cylindrical coordinates

1. $r^2 = x^2 + y^2$
2. $\tan\theta = \dfrac{y}{x}$
3. $z = z$

As when we discussed conversion from rectangular coordinates to polar coordinates in two dimensions, it should be noted that the equation $\tan\theta = \frac{y}{x}$ has an infinite number of solutions. However, if we restrict $\theta$ to values between $0$ and $2\pi$, then we can find a unique solution based on the quadrant of the $xy$-plane in which original point $(x, y, z)$ is located. Note that if $x = 0$, then the value of $\theta$ is either $\frac{\pi}{2}$, $\frac{3\pi}{2}$, or $0$, depending on the value of $y$.

Notice that these equations are derived from properties of right triangles. To make this easy to see, consider point $P$ in the $xy$-plane with rectangular coordinates $(x, y, 0)$ and with cylindrical coordinates $(r, \theta, 0)$, as shown in Figure 12.8.2.

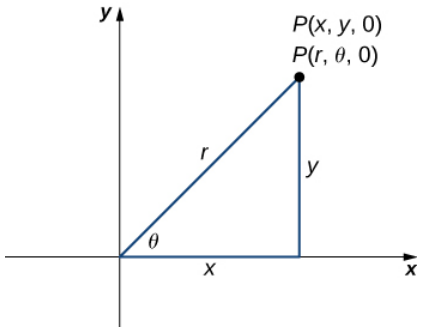

Figure 12.8.2: The Pythagorean theorem provides equation $r^2 = x^2 + y^2$. Right-triangle relationships tell us that $x = r\cos\theta, y = r\sin\theta$, and $\tan\theta = y/x$.

Let's consider the differences between rectangular and cylindrical coordinates by looking at the surfaces generated when each of the coordinates is held constant. If $c$ is a constant, then in rectangular coordinates, surfaces of the form $x = c, y = c$, or $z = c$ are all planes. Planes of these forms are parallel to the $yz$-plane, the $xz$-plane, and the $xy$-plane, respectively. When we convert to cylindrical coordinates, the $z$-coordinate does not change. Therefore, in cylindrical coordinates, surfaces of the form $z = c$ are planes parallel to the $xy$-plane. Now, let's think about surfaces of the form $r = c$. The points on these surfaces are at a fixed distance from the $z$-axis. In other words, these surfaces are vertical circular cylinders. Last, what about $\theta = c$? The points on a surface of the form $\theta = c$ are at a fixed angle from the $x$-axis, which gives us a half-plane that starts at the $z$-axis (Figures 12.8.3 and 12.8.4).

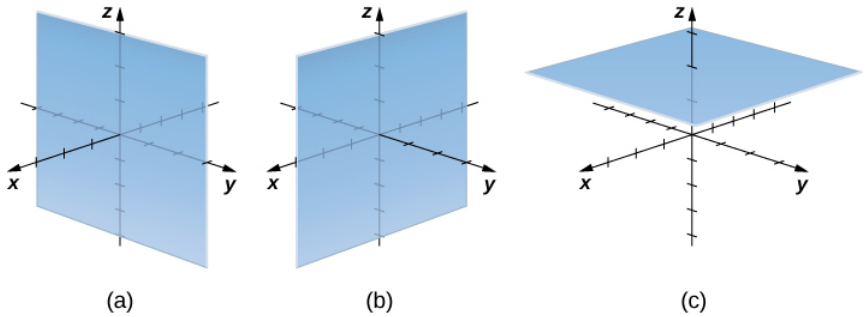

Figure 12.8.3: In rectangular coordinates, (a) surfaces of the form $x = c$ are planes parallel to the $yz$-plane, (b) surfaces of the form $y = c$ are planes parallel to the $xz$-plane, and (c) surfaces of the form $z = c$ are planes parallel to the $xy$-plane.

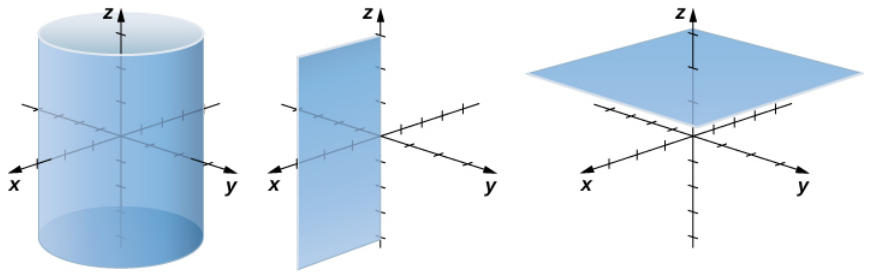

Figure 12.8.4: In cylindrical coordinates, (a) surfaces of the form $r = c$ are vertical cylinders of radius $r$, (b) surfaces of the form $\theta = c$ are half-planes at angle $\theta$ from the $x$-axis, and (c) surfaces of the form $z = c$ are planes parallel to the $xy$-plane.

## Example 12.8.1: Converting from Cylindrical to Rectangular Coordinates

Plot the point with cylindrical coordinates $(4, \frac{2\pi}{3}, -2)$ and express its location in rectangular coordinates.

### Solution

Conversion from cylindrical to rectangular coordinates requires a simple application of the equations listed in Conversion between Cylindrical and Cartesian Coordinates:

$$x = r\cos\theta = 4\cos\frac{2\pi}{3} = -2$$
$$y = r\sin\theta = 4\sin\frac{2\pi}{3} = 2\sqrt{3}.$$
$$z = -2$$

The point with cylindrical coordinates $(4, \frac{2\pi}{3}, -2)$ has rectangular coordinates $(-2, 2\sqrt{3}, -2)$ (Figure 12.8.5).

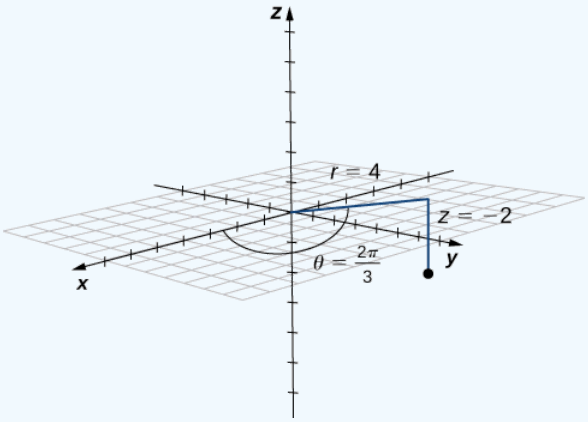

Figure 12.8.5: The projection of the point in the $xy$-plane is 4 units from the origin. The line from the origin to the point's projection forms an angle of $\frac{2\pi}{3}$ with the positive $x$-axis. The point lies 2 units below the $xy$-plane.

## Exercise 12.8.1

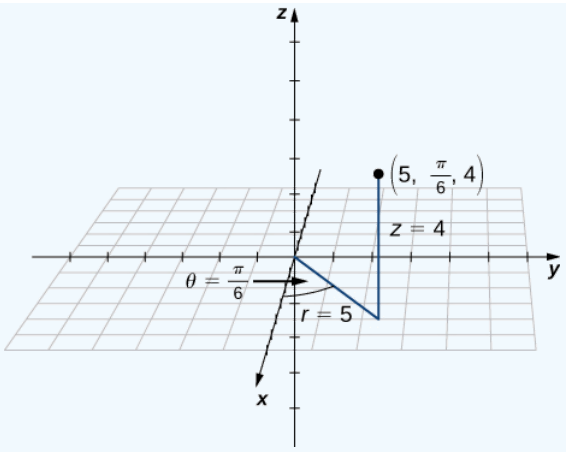
Point $R$ has cylindrical coordinates $(5, \frac{\pi}{6}, 4)$. Plot $R$ and describe its location in space using rectangular, or Cartesian, coordinates.

**Hint**

The first two components match the polar coordinates of the point in the $xy$-plane.

**Answer**

The rectangular coordinates of the point are $(\frac{5\sqrt{3}}{2}, \frac{5}{2}, 4)$.



If this process seems familiar, it is with good reason. This is exactly the same process that we followed in Introduction to Parametric Equations and Polar Coordinates to convert from polar coordinates to two-dimensional rectangular coordinates.

### Example 12.8.2: Converting from Rectangular to Cylindrical Coordinates

Convert the rectangular coordinates $(1, -3, 5)$ to cylindrical coordinates.

**Solution**

Use the second set of equations from Conversion between Cylindrical and Cartesian Coordinates to translate from rectangular to cylindrical coordinates:

$$\begin{aligned} r^2 &= x^2 + y^2 \\ r &= \pm\sqrt{1^2 + (-3)^2} \\ &= \pm\sqrt{10}. \end{aligned}$$

We choose the positive square root, so $r = \sqrt{10}$.Now, we apply the formula to find $\theta$. In this case, $y$ is negative and $x$ is positive, which means we must select the value of $\theta$ between $\frac{3\pi}{2}$ and $2\pi$:

$$\begin{aligned} \tan\theta &= \frac{y}{x} & &= \frac{-3}{1} \\ \theta &= \arctan(-3) & &\approx 5.03\,\text{rad}. \end{aligned}$$

In this case, the $z$-coordinates are the same in both rectangular and cylindrical coordinates:

$$z = 5.$$

The point with rectangular coordinates $(1, -3, 5)$ has cylindrical coordinates approximately equal to $(\sqrt{10}, 5.03, 5)$.

### Exercise 12.8.2

Convert point $(-8, 8, -7)$ from Cartesian coordinates to cylindrical coordinates.

**Hint**

$r^2 = x^2 + y^2$ and $\tan\theta = \frac{y}{x}$

**Answer**

$(8\sqrt{2}, \frac{3\pi}{4}, -7)$

The use of cylindrical coordinates is common in fields such as physics. Physicists studying electrical charges and the capacitors used to store these charges have discovered that these systems sometimes have a cylindrical symmetry. These systems have

complicated modeling equations in the Cartesian coordinate system, which make them difficult to describe and analyze. The equations can often be expressed in more simple terms using cylindrical coordinates. For example, the cylinder described by equation $x^2 + y^2 = 25$ in the Cartesian system can be represented by cylindrical equation $r = 5$.

### Example 12.8.3: Identifying Surfaces in the Cylindrical Coordinate System

Describe the surfaces with the given cylindrical equations.

a. $\theta = \dfrac{\pi}{4}$
b. $r^2 + z^2 = 9$
c. $z = r$

**Solution**

a. When the angle $\theta$ is held constant while $r$ and $z$ are allowed to vary, the result is a half-plane (Figure 12.8.6).

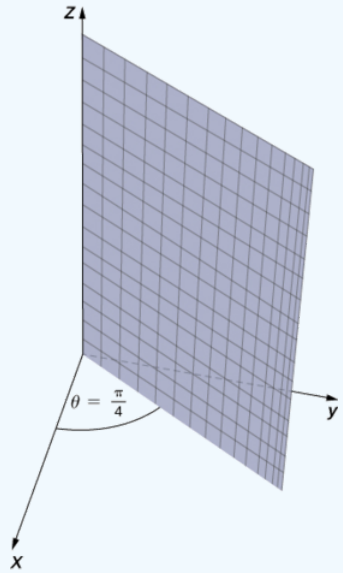


Figure 12.8.6: In polar coordinates, the equation $\theta = \pi/4$ describes the ray extending diagonally through the first quadrant. In three dimensions, this same equation describes a half-plane.

b. Substitute $r^2 = x^2 + y^2$ into equation $r^2 + z^2 = 9$ to express the rectangular form of the equation: $x^2 + y^2 + z^2 = 9$. This equation describes a sphere centered at the origin with radius 3 (Figure 12.8.7).

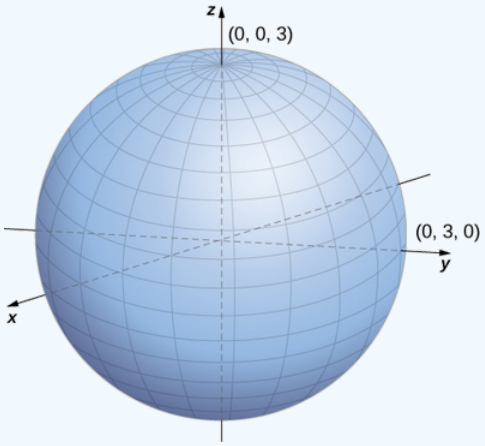

Figure 12.8.7: The sphere centered at the origin with radius 3 can be described by the cylindrical equation $r^2 + z^2 = 9$.

c. To describe the surface defined by equation $z = r$, is it useful to examine traces parallel to the $xy$-plane. For example, the trace in plane $z = 1$ is circle $r = 1$, the trace in plane $z = 3$ is circle $r = 3$, and so on. Each trace is a circle. As the value of $z$ increases, the radius of the circle also increases. The resulting surface is a cone (Figure 12.8.8).

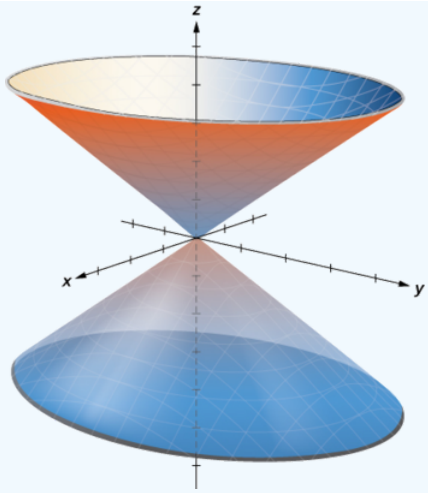

Figure 12.8.8: The traces in planes parallel to the $xy$-plane are circles. The radius of the circles increases as $z$ increases.

## Exercise 12.8.3

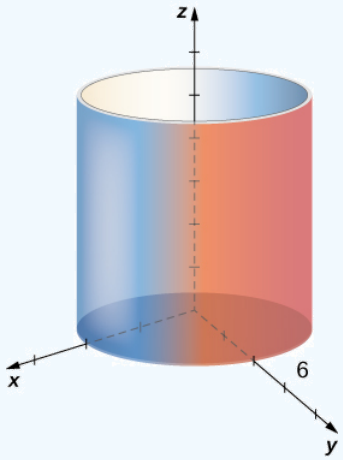
Describe the surface with cylindrical equation $r = 6$.

**Hint**

The $\theta$ and $z$ components of points on the surface can take any value.

**Answer**

This surface is a cylinder with radius 6.



## Spherical Coordinates

In the Cartesian coordinate system, the location of a point in space is described using an ordered triple in which each coordinate represents a distance. In the cylindrical coordinate system, the location of a point in space is described using two distances ($r$ and $z$) and an angle measure ($\theta$). In the spherical coordinate system, we again use an ordered triple to describe the location of a point in space. In this case, the triple describes one distance and two angles. Spherical coordinates make it simple to describe a sphere, just as cylindrical coordinates make it easy to describe a cylinder. Grid lines for spherical coordinates are based on angle measures, like those for polar coordinates.

## Definition: spherical coordinate system

In the *spherical coordinate system*, a point $P$ in space (Figure 12.8.9) is represented by the ordered triple $(\rho, \theta, \varphi)$ where

- $\rho$ (the Greek letter rho) is the distance between $P$ and the origin $(\rho \neq 0)$;
- $\theta$ is the same angle used to describe the location in cylindrical coordinates;
- $\varphi$ (the Greek letter phi) is the angle formed by the positive $z$-axis and line segment $\overline{OP}$, where $O$ is the origin and $0 \leq \varphi \leq \pi$.

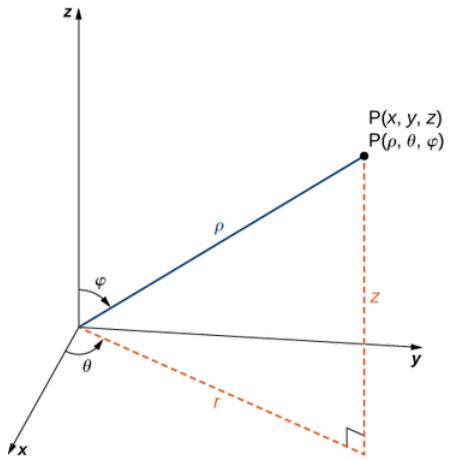


Figure 12.8.9: The relationship among spherical, rectangular, and cylindrical coordinates.

By convention, the origin is represented as $(0, 0, 0)$ in spherical coordinates.

## HOW TO: Converting among Spherical, Cylindrical, and Rectangular Coordinates

Rectangular coordinates $(x, y, z)$, cylindrical coordinates $(r, \theta, z)$, and spherical coordinates $(\rho, \theta, \varphi)$ of a point are related as follows:

**Convert from spherical coordinates to rectangular coordinates**

These equations are used to convert from spherical coordinates to rectangular coordinates.

- $x = \rho \sin \varphi \cos \theta$
- $y = \rho \sin \varphi \sin \theta$
- $z = \rho \cos \varphi$

**Convert from rectangular coordinates to spherical coordinates**

These equations are used to convert from rectangular coordinates to spherical coordinates.

- $\rho^2 = x^2 + y^2 + z^2$
- $\tan \theta = \dfrac{y}{x}$
- $\varphi = \arccos\left(\dfrac{z}{\sqrt{x^2 + y^2 + z^2}}\right)$.

**Convert from spherical coordinates to cylindrical coordinates**

These equations are used to convert from spherical coordinates to cylindrical coordinates.

- $r = \rho \sin \varphi$
- $\theta = \theta$
- $z = \rho \cos \varphi$

**Convert from cylindrical coordinates to spherical coordinates**

These equations are used to convert from cylindrical coordinates to spherical coordinates.

- $\rho = \sqrt{r^2 + z^2}$

- $\theta = \theta$
- $\varphi = \arccos\left(\frac{z}{\sqrt{r^2+z^2}}\right)$

The formulas to convert from spherical coordinates to rectangular coordinates may seem complex, but they are straightforward applications of trigonometry. Looking at Figure 12.8.10, it is easy to see that $r = \rho \sin\varphi$. Then, looking at the triangle in the $xy$-plane with r as its hypotenuse, we have $x = r\cos\theta = \rho\sin\varphi\cos\theta$. The derivation of the formula for $y$ is similar. Figure 12.8.10 also shows that $\rho^2 = r^2 + z^2 = x^2 + y^2 + z^2$ and $z = \rho\cos\varphi$. Solving this last equation for $\varphi$ and then substituting $\rho = \sqrt{r^2+z^2}$ (from the first equation) yields $\varphi = \arccos\left(\frac{z}{\sqrt{r^2+z^2}}\right)$. Also, note that, as before, we must be careful when using the formula $\tan\theta = \frac{y}{x}$ to choose the correct value of $\theta$.

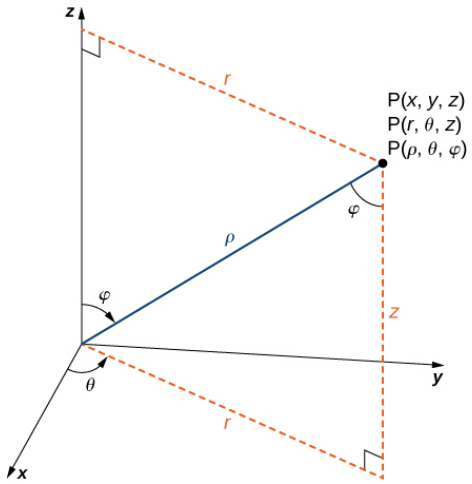

Figure 12.8.10: The equations that convert from one system to another are derived from right-triangle relationships.

As we did with cylindrical coordinates, let's consider the surfaces that are generated when each of the coordinates is held constant. Let $c$ be a constant, and consider surfaces of the form $\rho = c$. Points on these surfaces are at a fixed distance from the origin and form a sphere. The coordinate $\theta$ in the spherical coordinate system is the same as in the cylindrical coordinate system, so surfaces of the form $\theta = c$ are half-planes, as before. Last, consider surfaces of the form $\varphi = c$. The points on these surfaces are at a fixed angle from the $z$-axis and form a half-cone (Figure 12.8.11).

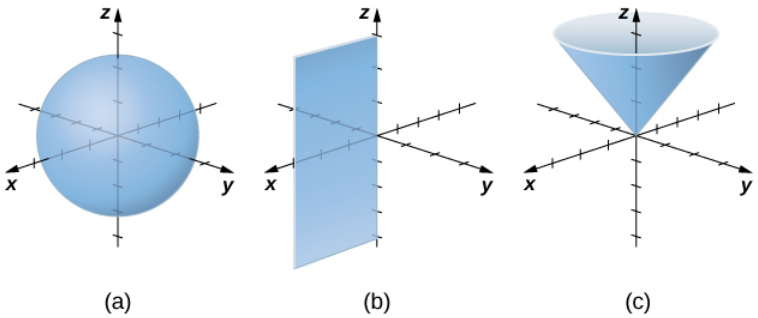

Figure 12.8.11: In spherical coordinates, surfaces of the form $\rho = c$ are spheres of radius $\rho$ (a), surfaces of the form $\theta = c$ are half-planes at an angle $\theta$ from the $x$-axis (b), and surfaces of the form $\phi = c$ are half-cones at an angle $\phi$ from the $z$-axis (c).

### Example 12.8.4: Converting from Spherical Coordinates

Plot the point with spherical coordinates $(8, \frac{\pi}{3}, \frac{\pi}{6})$ and express its location in both rectangular and cylindrical coordinates.

**Solution**

Use the equations in Converting among Spherical, Cylindrical, and Rectangular Coordinates to translate between spherical and cylindrical coordinates (Figure 12.8.12):

$$
\begin{aligned}
x &= \rho \sin\varphi \cos\theta \\
&= 8 \sin\left(\frac{\pi}{6}\right) \cos\left(\frac{\pi}{3}\right) \\
&= 8\left(\frac{1}{2}\right)\frac{1}{2} \\
&= 2 \\
y &= \rho \sin\varphi \sin\theta \\
&= 8 \sin\left(\frac{\pi}{6}\right) \sin\left(\frac{\pi}{3}\right) \\
&= 8\left(\frac{1}{2}\right)\frac{\sqrt{3}}{2} \\
&= 2\sqrt{3} \\
z &= \rho \cos\varphi \\
&= 8 \cos\left(\frac{\pi}{6}\right) \\
&= 8\left(\frac{\sqrt{3}}{2}\right) \\
&= 4\sqrt{3}
\end{aligned}
$$

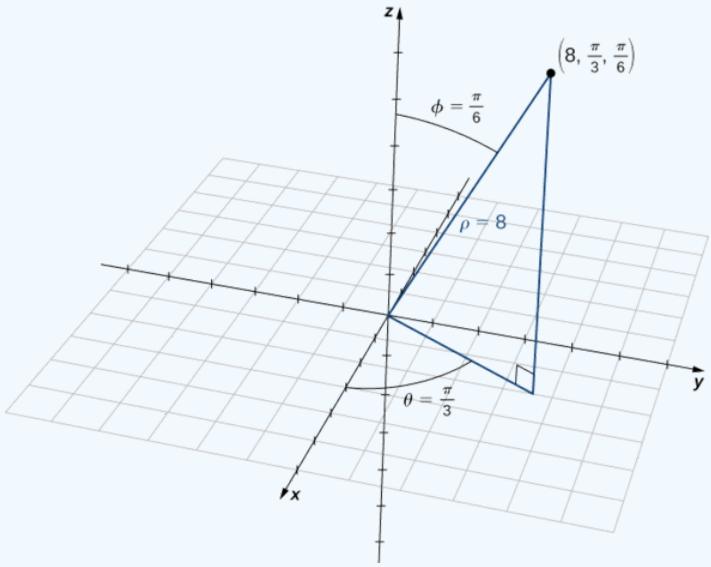

Figure 12.8.12: The projection of the point in the $xy$-plane is $4$ units from the origin. The line from the origin to the point's projection forms an angle of $\pi/3$ with the positive $x$-axis. The point lies $4\sqrt{3}$ units above the $xy$-plane.

The point with spherical coordinates $(8, \frac{\pi}{3}, \frac{\pi}{6})$ has rectangular coordinates $(2, 2\sqrt{3}, 4\sqrt{3})$.

Finding the values in cylindrical coordinates is equally straightforward:

$$
\begin{aligned}
r &= \rho \sin\varphi \\
&= 8 \sin\frac{\pi}{6} \\
&= 4 \\
\theta &= \theta \\
z &= \rho \cos\varphi \\
&= 8 \cos\frac{\pi}{6} \\
&= 4\sqrt{3}.
\end{aligned}
$$

Thus, cylindrical coordinates for the point are $(4, \frac{\pi}{3}, 4\sqrt{3})$.

## Exercise 12.8.4

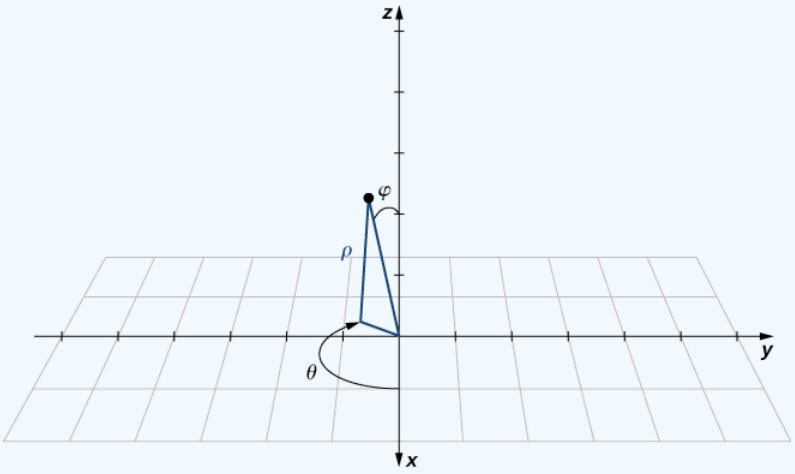
Plot the point with spherical coordinates $(2, -\frac{5\pi}{6}, \frac{\pi}{6})$ and describe its location in both rectangular and cylindrical coordinates.

**Hint**

Converting the coordinates first may help to find the location of the point in space more easily.

**Answer**

Cartesian: $(-\frac{\sqrt{3}}{2}, -\frac{1}{2}, \sqrt{3})$, cylindrical: $(1, -\frac{5\pi}{6}, \sqrt{3})$



## Example 12.8.5: Converting from Rectangular Coordinates

Convert the rectangular coordinates $(-1, 1, \sqrt{6})$ to both spherical and cylindrical coordinates.

### Solution

Start by converting from rectangular to spherical coordinates:

$$\rho^2 = x^2 + y^2 + z^2 = (-1)^2 + 1^2 + (\sqrt{6})^2 = 8$$

$$\tan\theta = \frac{1}{-1}$$

$$\rho = 2\sqrt{2} \text{ and } \theta = \arctan(-1) = \frac{3\pi}{4}.$$

Because $(x, y) = (-1, 1)$, then the correct choice for $\theta$ is $\frac{3\pi}{4}$.

There are actually two ways to identify $\varphi$. We can use the equation $\varphi = \arccos\left(\frac{z}{\sqrt{x^2+y^2+z^2}}\right)$. A more simple approach, however, is to use equation $z = \rho\cos\varphi$. We know that $z = \sqrt{6}$ and $\rho = 2\sqrt{2}$, so

$$\sqrt{6} = 2\sqrt{2}\cos\varphi, \text{ so } \cos\varphi = \frac{\sqrt{6}}{2\sqrt{2}} = \frac{\sqrt{3}}{2}$$

and therefore $\varphi = \frac{\pi}{6}$. The spherical coordinates of the point are $(2\sqrt{2}, \frac{3\pi}{4}, \frac{\pi}{6})$.

To find the cylindrical coordinates for the point, we need only find $r$:

$$r = \rho\sin\varphi = 2\sqrt{2}\sin(\frac{\pi}{6}) = \sqrt{2}.$$

The cylindrical coordinates for the point are $(\sqrt{2}, \frac{3\pi}{4}, \sqrt{6})$.

## Example 12.8.6: Identifying Surfaces in the Spherical Coordinate System

Describe the surfaces with the given spherical equations.

a. $\theta = \frac{\pi}{3}$
b. $\varphi = \frac{5\pi}{6}$
c. $\rho = 6$
d. $\rho = \sin\theta \sin\varphi$

### Solution

a. The variable $\theta$ represents the measure of the same angle in both the cylindrical and spherical coordinate systems. Points with coordinates $(\rho, \frac{\pi}{3}, \varphi)$ lie on the plane that forms angle $\theta = \frac{\pi}{3}$ with the positive $x$-axis. Because $\rho > 0$, the surface described by equation $\theta = \frac{\pi}{3}$ is the half-plane shown in Figure 12.8.13.

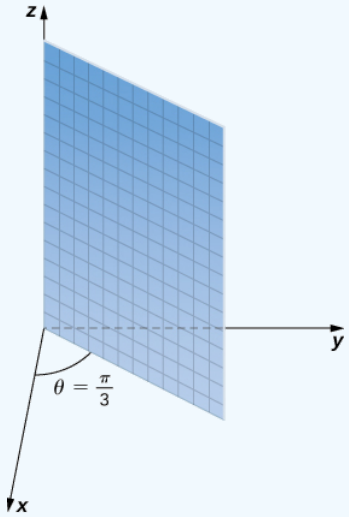


Figure 12.8.13: The surface described by equation $\theta = \frac{\pi}{3}$ is a half-plane.

b. Equation $\varphi = \frac{5\pi}{6}$ describes all points in the spherical coordinate system that lie on a line from the origin forming an angle measuring $\frac{5\pi}{6}$ rad with the positive $z$-axis. These points form a half-cone (Figure 12.8.14). Because there is only one value for $\varphi$ that is measured from the positive $z$-axis, we do not get the full cone (with two pieces).

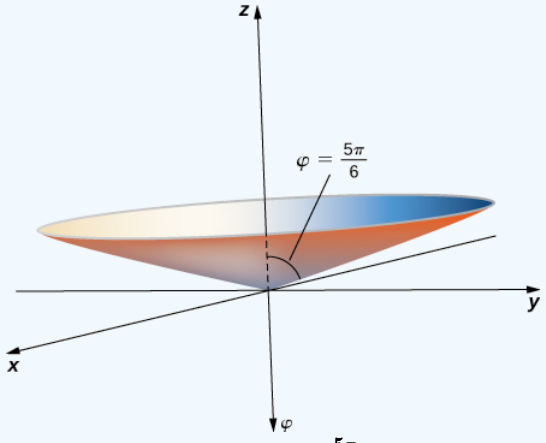

Figure 12.8.14: The equation $\varphi = \frac{5\pi}{6}$ describes a cone.

To find the equation in rectangular coordinates, use equation $\varphi = \arccos\left(\frac{z}{\sqrt{x^2+y^2+z^2}}\right)$.

$$\frac{5\pi}{6} = \arccos\left(\frac{z}{\sqrt{x^2+y^2+z^2}}\right)$$

$$\cos\frac{5\pi}{6} = \frac{z}{\sqrt{x^2+y^2+z^2}}$$

$$-\frac{\sqrt{3}}{2} = \frac{z}{\sqrt{x^2+y^2+z^2}}$$

$$\frac{3}{4} = \frac{z^2}{x^2+y^2+z^2}$$

$$\frac{3x^2}{4} + \frac{3y^2}{4} + \frac{3z^2}{4} = z^2$$

$$\frac{3x^2}{4} + \frac{3y^2}{4} - \frac{z^2}{4} = 0.$$

This is the equation of a cone centered on the $z$-axis.

c. Equation $\rho = 6$ describes the set of all points $6$ units away from the origin—a sphere with radius $6$ (Figure 12.8.15).

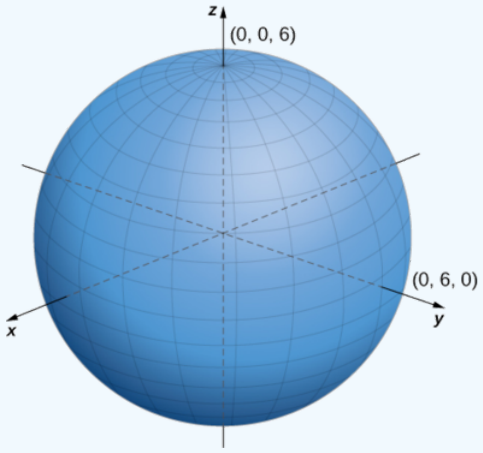

Figure 12.8.15: Equation $\rho = 6$ describes a sphere with radius $6$.

d. To identify this surface, convert the equation from spherical to rectangular coordinates, using equations $y = \rho\sin\varphi\sin\theta$ and $\rho^2 = x^2+y^2+z^2$:

$\rho = \sin\theta\sin\varphi$

$\rho^2 = \rho\sin\theta\sin\varphi$ Multiply both sides of the equation by $\rho$.

$x^2+y^2+z^2 = y$ Substitute rectangular variables using the equations above.

$x^2+y^2-y+z^2 = 0$ Subtract $y$ from both sides of the equation.

$x^2+y^2-y+\frac{1}{4}+z^2 = \frac{1}{4}$ Complete the square.

$x^2+\left(y-\frac{1}{2}\right)^2+z^2 = \frac{1}{4}$. Rewrite the middle terms as a perfect square.

The equation describes a sphere centered at point $(0, \frac{1}{2}, 0)$ with radius $\frac{1}{2}$.

## ? Exercise 12.8.5

Describe the surfaces defined by the following equations.

a. $\rho = 13$

b. $\theta = \frac{2\pi}{3}$

c. $\varphi = \frac{\pi}{4}$

**Hint**

Think about what each component represents and what it means to hold that component constant.

**Answer a**

This is the set of all points $13$ units from the origin. This set forms a sphere with radius $13$.

**Answer b**

This set of points forms a half plane. The angle between the half plane and the positive $x$-axis is $\theta = \frac{2\pi}{3}$.

**Answer c**

Let $P$ be a point on this surface. The position vector of this point forms an angle of $\varphi = \frac{\pi}{4}$ with the positive $z$-axis, which means that points closer to the origin are closer to the axis. These points form a half-cone.

Spherical coordinates are useful in analyzing systems that have some degree of symmetry about a point, such as the volume of the space inside a domed stadium or wind speeds in a planet's atmosphere. A sphere that has Cartesian equation $x^2 + y^2 + z^2 = c^2$ has the simple equation $\rho = c$ in spherical coordinates.

In geography, latitude and longitude are used to describe locations on Earth's surface, as shown in Figure $12.8.16$. Although the shape of Earth is not a perfect sphere, we use spherical coordinates to communicate the locations of points on Earth. Let's assume Earth has the shape of a sphere with radius $4000$ mi. We express angle measures in degrees rather than radians because latitude and longitude are measured in degrees.

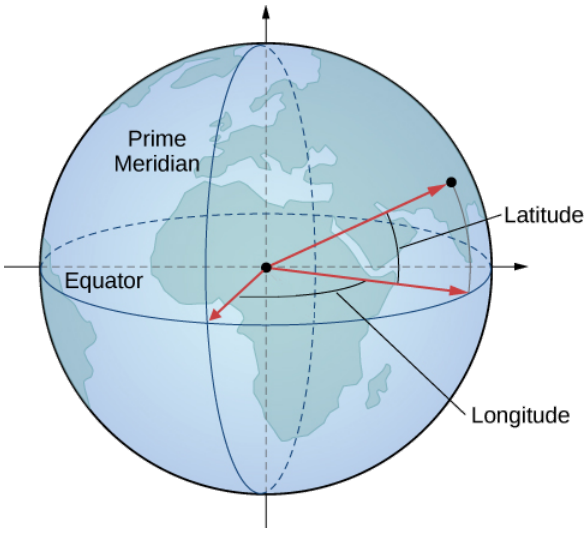

Figure $12.8.16$: In the latitude–longitude system, angles describe the location of a point on Earth relative to the equator and the prime meridian.

Let the center of Earth be the center of the sphere, with the ray from the center through the North Pole representing the positive $z$-axis. The prime meridian represents the trace of the surface as it intersects the $xz$-plane. The equator is the trace of the sphere intersecting the $xy$-plane.

### ✔ Example $12.8.7$: Converting Latitude and Longitude to Spherical Coordinates

The latitude of Columbus, Ohio, is $40°$ N and the longitude is $83°$ W, which means that Columbus is $40°$ north of the equator. Imagine a ray from the center of Earth through Columbus and a ray from the center of Earth through the equator directly south of Columbus. The measure of the angle formed by the rays is $40°$. In the same way, measuring from the prime meridian, Columbus lies $83°$ to the west. Express the location of Columbus in spherical coordinates.

**Solution**

The radius of Earth is $4000$mi, so $\rho = 4000$. The intersection of the prime meridian and the equator lies on the positive $x$-axis. Movement to the west is then described with negative angle measures, which shows that $\theta = -83°$, Because Columbus lies $40°$ north of the equator, it lies $50°$ south of the North Pole, so $\varphi = 50°$. In spherical coordinates, Columbus lies at point $(4000, -83°, 50°)$.

**? Exercise 12.8.6**

Sydney, Australia is at $34°S$ and $151°E$. Express Sydney's location in spherical coordinates.

**Hint**

Because Sydney lies south of the equator, we need to add $90°$ to find the angle measured from the positive $z$-axis.

**Answer**

$(4000, 151°, 124°)$

Cylindrical and spherical coordinates give us the flexibility to select a coordinate system appropriate to the problem at hand. A thoughtful choice of coordinate system can make a problem much easier to solve, whereas a poor choice can lead to unnecessarily complex calculations. In the following example, we examine several different problems and discuss how to select the best coordinate system for each one.

**✓ Example 12.8.8: Choosing the Best Coordinate System**

In each of the following situations, we determine which coordinate system is most appropriate and describe how we would orient the coordinate axes. There could be more than one right answer for how the axes should be oriented, but we select an orientation that makes sense in the context of the problem. Note: There is not enough information to set up or solve these problems; we simply select the coordinate system (Figure 12.8.17).

a. Find the center of gravity of a bowling ball.
b. Determine the velocity of a submarine subjected to an ocean current.
c. Calculate the pressure in a conical water tank.
d. Find the volume of oil flowing through a pipeline.
e. Determine the amount of leather required to make a football.

(a) (b) (c)

(d) (e)

Figure 12.8.17: (credit: (a) modification of work by scl hua, Wikimedia, (b) modification of work by DVIDSHUB, Flickr, (c) modification of work by Michael Malak, Wikimedia, (d) modification of work by Sean Mack, Wikimedia, (e) modification of work by Elvert Barnes, Flickr)

**Solution**

a. Clearly, a bowling ball is a sphere, so spherical coordinates would probably work best here. The origin should be located at the physical center of the ball. There is no obvious choice for how the $x$-, $y$- and $z$-axes should be oriented. Bowling balls normally have a weight block in the center. One possible choice is to align the $z$-axis with the axis of symmetry of the weight block.

b. A submarine generally moves in a straight line. There is no rotational or spherical symmetry that applies in this situation, so rectangular coordinates are a good choice. The $z$-axis should probably point upward. The $x$- and $y$-axes could be aligned to point east and north, respectively. The origin should be some convenient physical location, such as the starting position of the submarine or the location of a particular port.

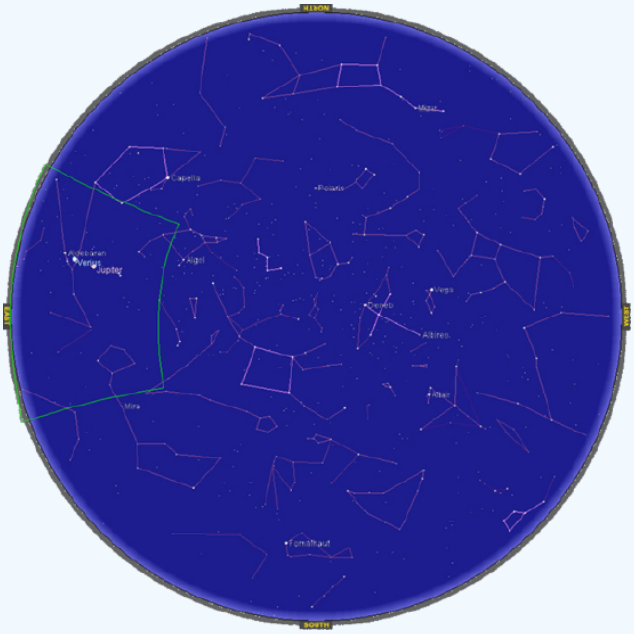
c. A cone has several kinds of symmetry. In cylindrical coordinates, a cone can be represented by equation $z = kr$, where $k$ is a constant. In spherical coordinates, we have seen that surfaces of the form $\varphi = c$ are half-cones. Last, in rectangular coordinates, elliptic cones are quadric surfaces and can be represented by equations of the form $z^2 = \frac{x^2}{a^2} + \frac{y^2}{b^2}$. In this case, we could choose any of the three. However, the equation for the surface is more complicated in rectangular coordinates than in the other two systems, so we might want to avoid that choice. In addition, we are talking about a water tank, and the depth of the water might come into play at some point in our calculations, so it might be nice to have a component that represents height and depth directly. Based on this reasoning, cylindrical coordinates might be the best choice. Choose the $z$-axis to align with the axis of the cone. The orientation of the other two axes is arbitrary. The origin should be the bottom point of the cone.

d. A pipeline is a cylinder, so cylindrical coordinates would be best the best choice. In this case, however, we would likely choose to orient our $z$-axis with the center axis of the pipeline. The $x$-axis could be chosen to point straight downward or to some other logical direction. The origin should be chosen based on the problem statement. Note that this puts the $z$-axis in a horizontal orientation, which is a little different from what we usually do. It may make sense to choose an unusual orientation for the axes if it makes sense for the problem.

e. A football has rotational symmetry about a central axis, so cylindrical coordinates would work best. The $z$-axis should align with the axis of the ball. The origin could be the center of the ball or perhaps one of the ends. The position of the $x$-axis is arbitrary.

**? Exercise 12.8.7**

Which coordinate system is most appropriate for creating a star map, as viewed from Earth (see the following figure)?



How should we orient the coordinate axes?

**Hint**

What kinds of symmetry are present in this situation?

**Answer**

Spherical coordinates with the origin located at the center of the earth, the $z$-axis aligned with the North Pole, and the $x$-axis aligned with the prime meridian

## Key Concepts

- In the cylindrical coordinate system, a point in space is represented by the ordered triple $(r, \theta, z)$, where $(r, \theta)$ represents the polar coordinates of the point's projection in the $xy$-plane and $z$ represents the point's projection onto the $z$-axis.
- To convert a point from cylindrical coordinates to Cartesian coordinates, use equations $x = r\cos\theta, y = r\sin\theta$, and $z = z$.
- To convert a point from Cartesian coordinates to cylindrical coordinates, use equations $r^2 = x^2 + y^2, \tan\theta = \frac{y}{x}$, and $z = z$.
- In the spherical coordinate system, a point $P$ in space is represented by the ordered triple $(\rho, \theta, \varphi)$, where $\rho$ is the distance between $P$ and the origin $(\rho \neq 0), \theta$ is the same angle used to describe the location in cylindrical coordinates, and $\varphi$ is the angle formed by the positive $z$-axis and line segment $\overline{OP}$, where $O$ is the origin and $0 \leq \varphi \leq \pi$.
- To convert a point from spherical coordinates to Cartesian coordinates, use equations $x = \rho\sin\varphi\cos\theta, y = \rho\sin\varphi\sin\theta$, and $z = \rho\cos\varphi$.
- To convert a point from Cartesian coordinates to spherical coordinates, use equations $\rho^2 = x^2 + y^2 + z^2, \tan\theta = \frac{y}{x}$, and $\varphi = \arccos\left(\frac{z}{\sqrt{x^2 + y^2 + z^2}}\right)$.
- To convert a point from spherical coordinates to cylindrical coordinates, use equations $r = \rho\sin\varphi, \theta = \theta$, and $z = \rho\cos\varphi$.
- To convert a point from cylindrical coordinates to spherical coordinates, use equations $\rho = \sqrt{r^2 + z^2}, \theta = \theta$, and $\varphi = \arccos\left(\frac{z}{\sqrt{r^2 + z^2}}\right)$.

## Glossary

**cylindrical coordinate system**

a way to describe a location in space with an ordered triple $(r, \theta, z)$, where $(r, \theta)$ represents the polar coordinates of the point's projection in the $xy$-plane, and $z$ represents the point's projection onto the $z$-axis

**spherical coordinate system**

a way to describe a location in space with an ordered triple $(\rho, \theta, \varphi)$, where $\rho$ is the distance between $P$ and the origin $(\rho \neq 0)$, $\theta$ is the same angle used to describe the location in cylindrical coordinates, and $\varphi$ is the angle formed by the positive $z$-axis and line segment $\bar{OP}$, where $O$ is the origin and $0 \leq \varphi \leq \pi$

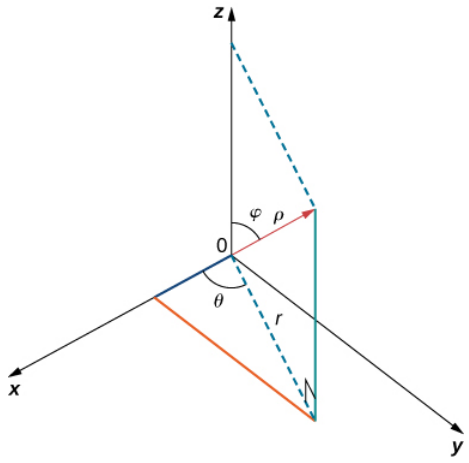
# 12.8E: Exercises for Section 12.7

Use the following figure as an aid in identifying the relationship between the rectangular, cylindrical, and spherical coordinate systems.



**For exercises 1 - 4, the cylindrical coordinates $(r, \theta, z)$ of a point are given. Find the rectangular coordinates $(x, y, z)$ of the point.**

1) $\left(4, \frac{\pi}{6}, 3\right)$

**Answer**

$(2\sqrt{3}, 2, 3)$

2) $\left(3, \frac{\pi}{3}, 5\right)$

3) $\left(4, \frac{7\pi}{6}, 3\right)$

**Answer**

$(-2\sqrt{3}, -2, 3)$

4) $(2, \pi, -4)$

**For exercises 5 - 8, the rectangular coordinates $(x, y, z)$ of a point are given. Find the cylindrical coordinates $(r, \theta, z)$ of the point.**

5) $(1, \sqrt{3}, 2)$

**Answer**

$\left(2, \frac{\pi}{3}, 2\right)$

6) $(1, 1, 5)$

7) $(3, -3, 7)$

**Answer**

$\left(3\sqrt{2}, -\frac{\pi}{4}, 7\right)$

8) $(-2\sqrt{2}, 2\sqrt{2}, 4)$

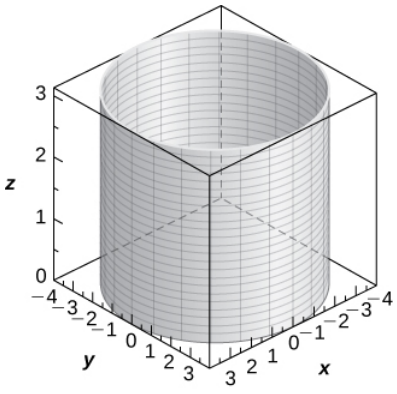
**For exercises 9 - 16, the equation of a surface in cylindrical coordinates is given. Find the equation of the surface in rectangular coordinates. Identify and graph the surface.**

9) [T] $r = 4$

-

**Answer**

A cylinder of equation $x^2 + y^2 = 16$, with its center at the origin and rulings parallel to the $z$-axis,

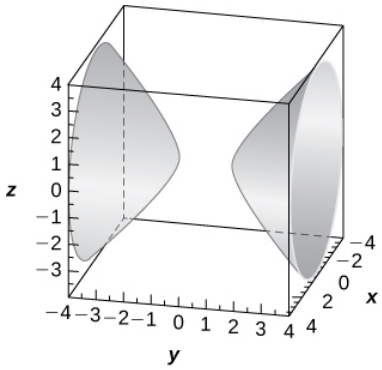


10) [T] $z = r^2 \cos^2 \theta$

11) [T] $r^2 \cos(2\theta) + z^2 + 1 = 0$

**Answer**

Hyperboloid of two sheets of equation $-x^2 + y^2 - z^2 = 1$, with the $y$-axis as the axis of symmetry,

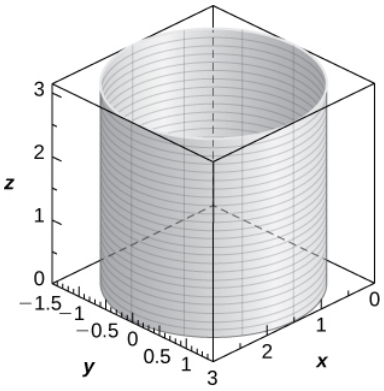


12) [T] $r = 3 \sin \theta$

13) [T] $r = 2 \cos \theta$

**Answer**

Cylinder of equation $x^2 - 2x + y^2 = 0$, with a center at $(1, 0, 0)$ and radius $1$, with rulings parallel to the $z$-axis,

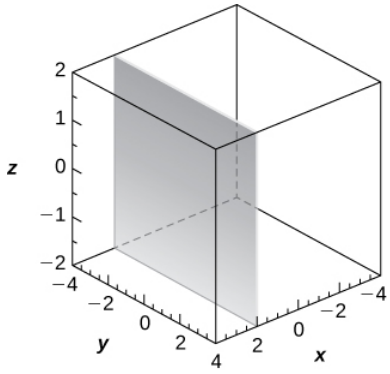


14) [T] $r^2 + z^2 = 5$

15) [T] $r = 2 \sec \theta$

**Answer**

Plane of equation $x = 2$,



16) [T] $r = 3\csc\theta$

**For exercises 17 - 22, the equation of a surface in rectangular coordinates is given. Find the equation of the surface in cylindrical coordinates.**

17) $z = 3$

**Answer**

$z = 3$

18) $x = 6$

19) $x^2 + y^2 + z^2 = 9$

**Answer**

$r^2 + z^2 = 9$

20) $y = 2x^2$

21) $x^2 + y^2 - 16x = 0$

**Answer**

$r = 16\cos\theta, \quad r = 0$

22) $x^2 + y^2 - 3\sqrt{x^2 + y^2} + 2 = 0$

**For exercises 23 - 26, the spherical coordinates $(\rho, \theta, \varphi)$ of a point are given. Find the rectangular coordinates $(x, y, z)$ of the point.**

23) $(3, 0, \pi)$

**Answer**

$(0, 0, -3)$

24) $\left(1, \frac{\pi}{6}, \frac{\pi}{6}\right)$

25) $\left(12, -\frac{\pi}{4}, \frac{\pi}{4}\right)$

**Answer**

$(6, -6, \sqrt{2})$

26) $\left(3, \frac{\pi}{4}, \frac{\pi}{6}\right)$

**For exercises 27 - 30, the rectangular coordinates $(x, y, z)$ of a point are given. Find the spherical coordinates $(\rho, \theta, \varphi)$ of the point. Express the measure of the angles in degrees rounded to the nearest integer.**

27) $(4, 0, 0)$

**Answer**

$(4, 0, 90°)$

28) $(-1, 2, 1)$

29) $(0, 3, 0)$

**Answer**

$(3, 90°, 90°)$

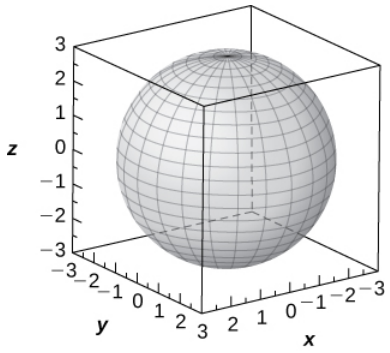
30) $(-2, 2\sqrt{3}, 4)$

**For exercises 31 - 36, the equation of a surface in spherical coordinates is given. Find the equation of the surface in rectangular coordinates. Identify and graph the surface.**

31) [T] $\rho = 3$

**Answer**

Sphere of equation $x^2 + y^2 + z^2 = 9$ centered at the origin with radius $3$,

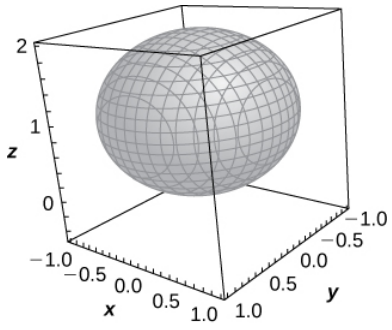


32) [T] $\varphi = \frac{\pi}{3}$

33) [T] $\rho = 2\cos\varphi$

**Answer**

Sphere of equation $x^2 + y^2 + (z-1)^2 = 1$ centered at $(0, 0, 1)$ with radius $1$,

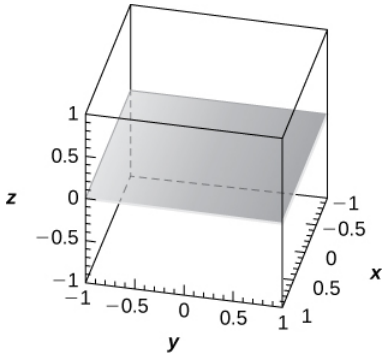


34) [T] $\rho = 4\csc\varphi$

35) [T] $\varphi = \frac{\pi}{2}$

**Answer**

The $xy$-plane of equation $z = 0$,



36) [T] $\rho = 6 \csc \varphi \sec \theta$

**For exercises 37 - 40, the equation of a surface in rectangular coordinates is given. Find the equation of the surface in spherical coordinates. Identify the surface.**

37) $x^2 + y^2 - 3z^2 = 0, \quad z \neq 0$

**Answer**

$\varphi = \frac{\pi}{3}$ or $\varphi = \frac{2\pi}{3}$; Elliptic cone

38) $x^2 + y^2 + z^2 - 4z = 0$

39) $z = 6$

**Answer**

$\rho \cos \varphi = 6$; Plane at $z = 6$

40) $x^2 + y^2 = 9$

**For exercises 41 - 44, the cylindrical coordinates of a point are given. Find its associated spherical coordinates, with the measure of the angle φ in radians rounded to four decimal places.**

41) [T] $(1, \frac{\pi}{4}, 3)$

**Answer**

$\left(\sqrt{10}, \frac{\pi}{4}, 0.3218\right)$

42) [T] $(5, \pi, 12)$

43) $(3, \frac{\pi}{2}, 3)$

**Answer**

$(3\sqrt{2}, \frac{\pi}{2}, \frac{\pi}{4})$

44) $(3, -\frac{\pi}{6}, 3)$

**For exercises 45 - 48, the spherical coordinates of a point are given. Find its associated cylindrical coordinates.**

45) $(2, -\frac{\pi}{4}, \frac{\pi}{2})$

**Answer**

$(2, -\frac{\pi}{4}, 0)$

46) $(4, \frac{\pi}{4}, \frac{\pi}{6})$

47) $\left(8, \frac{\pi}{3}, \frac{\pi}{2}\right)$

**Answer**

$\left(8, \frac{\pi}{3}, 0\right)$

48) $\left(9, -\frac{\pi}{6}, \frac{\pi}{3}\right)$

**For exercises 49 - 52, find the most suitable system of coordinates to describe the solids.**

49) The solid situated in the first octant with a vertex at the origin and enclosed by a cube of edge length $a$, where $a > 0$

**Answer**

Cartesian system, $\{(x, y, z) \mid 0 \le x \le a,\ 0 \le y \le a,\ 0 \le z \le a\}$

50) A spherical shell determined by the region between two concentric spheres centered at the origin, of radii of $a$ and $b$, respectively, where $b > a > 0$

51) A solid inside sphere $x^2 + y^2 + z^2 = 9$ and outside cylinder $\left(x - \frac{3}{2}\right)^2 + y^2 = \frac{9}{4}$

**Answer**

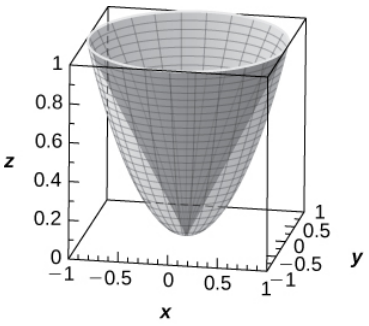
Cylindrical system, $\{(r, \theta, z) \mid r^2 + z^2 \le 9,\ r \ge 3\cos\theta,\ 0 \le \theta \le 2\pi\}$

52) A cylindrical shell of height $10$ determined by the region between two cylinders with the same center, parallel rulings, and radii of $2$ and $5$, respectively

53) [T] Use a CAS or CalcPlot3D to graph in cylindrical coordinates the region between elliptic paraboloid $z = x^2 + y^2$ and cone $x^2 + y^2 - z^2 = 0$.

**Answer**

The region is described by the set of points $\{(r, \theta, z) \mid 0 \le r \le 1,\ 0 \le \theta \le 2\pi,\ r^2 \le z \le r\}$.



54) [T] Use a CAS or CalcPlot3D to graph in spherical coordinates the "ice cream-cone region" situated above the xy-plane between sphere $x^2 + y^2 + z^2 = 4$ and elliptical cone $x^2 + y^2 - z^2 = 0$.

55) Washington, DC, is located at $39°$ N and $77°$ W (see the following figure). Assume the radius of Earth is $4000$ mi. Express the location of Washington, DC, in spherical coordinates.

**Answer**

$(4000, -77°, 51°)$

56) San Francisco is located at $37.78°N$ and $122.42°W$. Assume the radius of Earth is $4000$mi. Express the location of San Francisco in spherical coordinates.

57) Find the latitude and longitude of Rio de Janeiro if its spherical coordinates are $(4000, -43.17°, 102.91°)$.

**Answer**

$43.17°W, 22.91°S$

58) Find the latitude and longitude of Berlin if its spherical coordinates are $(4000, 13.38°, 37.48°)$.

59) [T] Consider the torus of equation $\left(x^2+y^2+z^2+R^2-r^2\right)^2 = 4R^2(x^2+y^2)$, where $R \geq r > 0$.

a. Write the equation of the torus in spherical coordinates.

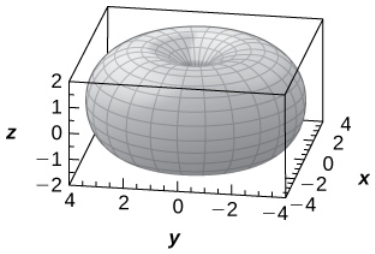
b. If $R = r$, the surface is called a horn torus. Show that the equation of a horn torus in spherical coordinates is $\rho = 2R\sin\varphi$.

c. Use a CAS or CalcPlot3D to graph the horn torus with $R = r = 2$ in spherical coordinates.

**Answer**

a. $\rho = 0, \quad \rho + R^2 - r^2 - 2R\sin\varphi = 0$

c.



60) [T] The "bumpy sphere" with an equation in spherical coordinates is $\rho = a + b\cos(m\theta)\sin(n\varphi)$, with $\theta \in [0, 2\pi]$ and $\varphi \in [0, \pi]$, where $a$ and $b$ are positive numbers and $m$ and $n$ are positive integers, may be used in applied mathematics to model tumor growth.

a. Show that the "bumpy sphere" is contained inside a sphere of equation $\rho = a + b$. Find the values of $\theta$ and $\varphi$ at which the two surfaces intersect.

b. Use a CAS or CalcPlot3D to graph the surface for $a = 14, b = 2, m = 4$, and $n = 6$ along with sphere $\rho = a + b$.

c. Find the equation of the intersection curve of the surface at b. with the cone $\varphi = \frac{\pi}{12}$. Graph the intersection curve in the plane of intersection.

# 12.R: Chapter 12 Review Exercises

**For exercises 1 - 4, determine whether the statement is *true* or *false*. Justify the answer with a proof or a counterexample.**

1) For vectors $\vec{\mathbf{a}}$ and $\vec{\mathbf{b}}$ and any given scalar $c$, $c(\vec{\mathbf{a}} \cdot \vec{\mathbf{b}}) = (c\vec{\mathbf{a}}) \cdot \vec{\mathbf{b}}$.

**Answer**

True; See proof in Section 11.3

2) For vectors $\vec{\mathbf{a}}$ and $\vec{\mathbf{b}}$ and any given scalar $c$, $c(\vec{\mathbf{a}} \times \vec{\mathbf{b}}) = (c\vec{\mathbf{a}}) \times \vec{\mathbf{b}}$.

3) The symmetric equation for the line of intersection between two planes $x + y + z = 2$ and $x + 2y - 4z = 5$ is given by $-\frac{x-1}{6} = \frac{y-1}{5} = z$.

**Answer**

False, Converting the symmetric equations above to the parametric equations of the line, we get:
$x = 1 - 6t$
$y = 1 + 5t$
$z = t$

If this line lies on each plane, we should get an identity (like 5 = 5) when we substitute each expression of $t$ in the each plane's equation.

Substituting into the first plane equation, we get: $(1 - 6t) + (1 + 5t) + t = 2$ ✓

Thus we know that this line does lie on the first plane.

But when we substitute into the second plane equation, we obtain: $(1 - 6t) + 2(1 + 5t) - 4(t) = 1 - 6t + 2 + 10t - 4t = 3 \neq 5$

Since we do not get an identity, we know this line is **not** on the second plane and can therefore not be the line of intersection of the two planes.

4) If $\vec{\mathbf{a}} \cdot \vec{\mathbf{b}} = 0$, then $\vec{\mathbf{a}}$ is perpendicular to $\vec{\mathbf{b}}$.

**Answer**

False, since $\vec{\mathbf{a}}$ or $\vec{\mathbf{b}}$ could also be the zero vector.

**For exercises 5 and 6, use the given vectors to find the quantities.**

5) $\vec{\mathbf{a}} = 9\hat{\mathbf{i}} - 2\hat{\mathbf{j}}, \quad \vec{\mathbf{b}} = -3\hat{\mathbf{i}} + \hat{\mathbf{k}}$

a. $3\vec{\mathbf{a}} + \vec{\mathbf{b}}$

b. $\|\vec{\mathbf{a}}\|$

c. $\vec{\mathbf{a}} \times \|\vec{\mathbf{b}} \times \vec{\mathbf{a}}\|$

d. $\|\vec{\mathbf{b}} \times \vec{\mathbf{a}}\|$

**Answer**

a. $\langle 24, -6, 1 \rangle$
b. $\sqrt{85}$
c. Can't cross a vector with a scalar
d. 11

6) $\vec{\mathbf{a}} = 2\hat{\mathbf{i}} + \hat{\mathbf{j}} - 9\hat{\mathbf{k}}, \quad \vec{\mathbf{b}} = -\hat{\mathbf{i}} + 2\hat{\mathbf{k}}, \quad \vec{\mathbf{c}} = 4\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + \hat{\mathbf{k}}$

a. $2\vec{\mathbf{a}} - \vec{\mathbf{b}}$

b. $\|\vec{\mathbf{b}} \times \vec{\mathbf{c}}\|$

c. $\vec{\mathbf{b}} \times \left(\vec{\mathbf{b}} \times \vec{\mathbf{c}}\right)$

d. $\vec{\mathbf{c}} \times \|\vec{\mathbf{b}} \times \vec{\mathbf{a}}\|$

e. $\text{Proj}_{\vec{\mathbf{a}}} \vec{\mathbf{b}}$

7) Find the values of $a$ such that vectors $\langle 2, 4, a \rangle$ and $\langle 0, -1, a \rangle$ are orthogonal.

**Answer**

$a = \pm 2$

**For exercises 8 and 9, find the unit vectors.**

8) Find the unit vector that has the same direction as vector $\vec{\mathbf{v}}$ that begins at $(0, -3)$ and ends at $(4, 10)$.

9) Find the unit vector that has the same direction as vector $\vec{\mathbf{v}}$ that begins at $(1, 4, 10)$ and ends at $(3, 0, 4)$.

**Answer**

$\langle \frac{1}{\sqrt{14}}, -\frac{2}{\sqrt{14}}, -\frac{3}{\sqrt{14}} \rangle = \langle \frac{\sqrt{14}}{14}, -\frac{\sqrt{14}}{7}, -\frac{3\sqrt{14}}{14} \rangle$

**For exercises 10 and 11, find the area or volume of the given shapes.**

10) The parallelogram spanned by vectors $\vec{\mathbf{a}} = \langle 1, 13 \rangle$ and $\vec{\mathbf{b}} = \langle 3, 21 \rangle$

11) The parallelepiped formed by $\vec{\mathbf{a}} = \langle 1, 4, 1 \rangle$ and $\vec{\mathbf{b}} = \langle 3, 6, 2 \rangle$, and $\vec{\mathbf{c}} = \langle -2, 1, -5 \rangle$

**Answer**

$27$ units$^2$

**For exercises 12 and 13, find the parametric equations and the vector equation of the line with the given properties.**

12) The line that passes through point $(2, -3, 7)$ that is parallel to vector $\langle 1, 3, -2 \rangle$

13) The line that passes through points $(1, 3, 5)$ and $(-2, 6, -3)$

**Answer**

$x = 1 - 3t, y = 3 + 3t, z = 5 - 8t, \quad \vec{\mathbf{r}}(t) = (1 - 3t)\hat{\mathbf{i}} + 3(1 + t)\hat{\mathbf{j}} + (5 - 8t)\hat{\mathbf{k}}$

**For exercises 14 and 15, find the equation of the plane with the given properties.**

14) The plane that passes through point $(4, 7, -1)$ and has normal vector $\vec{\mathbf{n}} = \langle 3, 4, 2 \rangle$

15) The plane that passes through points $(0, 1, 5), (2, -1, 6)$, and $(3, 2, 5)$.

**Answer**

$-x + 3y + 8z = 43$

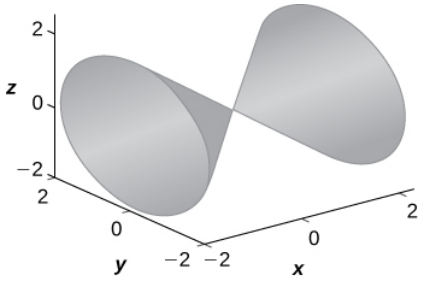
**For exercises 16 and 17, find the traces for the surfaces in planes $x = k$, $y = k$, and $z = k$. Then, describe and draw the surfaces.**

16) $9x^2 + 4y^2 - 16y + 36z^2 = 20$

17) $x^2 = y^2 + z^2$

**Answer**

$x = k$ trace: $k^2 = y^2 + z^2$ is a circle, $y = k$ trace: $x^2 - z^2 = k^2$ is a hyperbola (or a pair of lines if $k = 0$), $z = k$ trace: $x^2 - y^2 = k^2$ is a hyperbola (or a pair of lines if $k = 0$). The surface is a cone.



**For exercises 18 and 19, write the given equation in cylindrical coordinates and spherical coordinates.**

18) $x^2 + y^2 + z^2 = 144$

19) $z = x^2 + y^2 - 1$

**Answer**

Cylindrical: $z = r^2 - 1$, spherical: $\cos\varphi = \rho \sin^2\varphi - \frac{1}{\rho}$

**For exercises 20 and 21, convert the given equations from cylindrical or spherical coordinates to rectangular coordinates. Identify the given surface.**

20) $\rho^2(\sin^2(\varphi) - \cos^2(\varphi)) = 1$

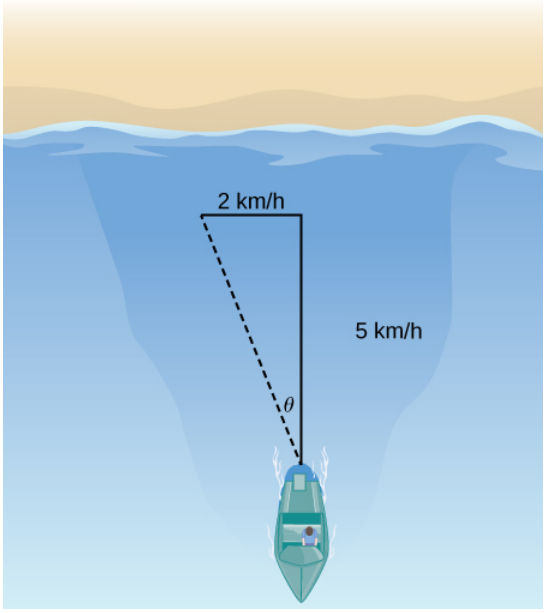
21) $r^2 - 2r\cos(\theta) + z^2 = 1$

**Answer**

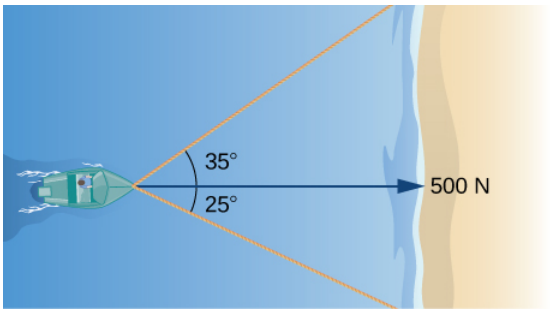
$x^2 - 2x + y^2 + z^2 = 1$, sphere

**For exercises 22 and 23, consider a small boat crossing a river.**

22) If the boat velocity is $5$ km/h due north in still water and the water has a current of $2$ km/h due west (see the following figure), what is the velocity of the boat relative to shore? What is the angle $\theta$ that the boat is actually traveling?



23) When the boat reaches the shore, two ropes are thrown to people to help pull the boat ashore. One rope is at an angle of $25°$ and the other is at $35°$. If the boat must be pulled straight and at a force of $500$ N, find the magnitude of force for each rope (see the following figure).



**Answer**

331 N and 244 N

24) An airplane is flying in the direction of 52° east of north with a speed of 450 mph. A strong wind has a bearing 33° east of north with a speed of 50 mph. What is the resultant ground speed and bearing of the airplane?

25) Calculate the work done by moving a particle from position $(1, 2, 0)$ to $(8, 4, 5)$ along a straight line with a force $\vec{\mathbf{F}} = 2\hat{\mathbf{i}} + 3\hat{\mathbf{j}} - \hat{\mathbf{k}}$.

**Answer**

$15$ J

**In problems 26 and 27, consider your unsuccessful attempt to take the tire off your car using a wrench to loosen the bolts. Assume the wrench is 0.3 m long and you are able to apply a 200-N force.**

26) Because your tire is flat, you are only able to apply your force at a $60°$ angle. What is the torque at the center of the bolt? Assume this force is not enough to loosen the bolt.

27) Someone lends you a tire jack and you are now able to apply a 200-N force at an $80°$ angle. Is your resulting torque going to be more or less? What is the new resulting torque at the center of the bolt? Assume this force is not enough to loosen the bolt.

**Answer**

More, $59.09$ J

# CHAPTER OVERVIEW

## 13: Vector-Valued Functions

A vector-valued function, also referred to as a vector function, is a mathematical function of one or more variables whose range is a set of multidimensional vectors or infinite-dimensional vectors. The input of a vector-valued function could be a scalar or a vector. Vector-valued functions provide a useful method for studying various curves both in the plane and in three-dimensional space. We can apply this concept to calculate the velocity, acceleration, arc length, and curvature of an object's trajectory. In this chapter, we examine these methods and show how they are used.

# 13.1: Prelude to Vector-Valued Functions

In 1705, using Sir Isaac Newton's new laws of motion, the astronomer Edmond Halley made a prediction. He stated that comets that had appeared in 1531, 1607, and 1682 were actually the same comet and that it would reappear in 1758. Halley was proved to be correct, although he did not live to see it. However, the comet was later named in his honor. Halley's Comet follows an elliptical path through the solar system, with the Sun appearing at one focus of the ellipse. This motion is predicted by Johannes Kepler's first law of planetary motion, which we mentioned briefly previously. Kepler's third law of planetary motion can be used with the calculus of vector-valued functions to find the average distance of Halley's Comet from the Sun.

Figure **13.1.1**: Halley's Comet appeared in view of Earth in 1986 and will appear again in 2061.

Vector-valued functions provide a useful method for studying various curves both in the plane and in three-dimensional space. We can apply this concept to calculate the velocity, acceleration, arc length, and curvature of an object's trajectory. In this chapter, we examine these methods and show how they are used.

# 13.2: Vector-Valued Functions and Space Curves

**Learning Objectives**

- Write the general equation of a vector-valued function in component form and unit-vector form.
- Recognize parametric equations for a space curve.
- Describe the shape of a helix and write its equation.
- Define the limit of a vector-valued function.

Our study of vector-valued functions combines ideas from our earlier examination of single-variable calculus with our description of vectors in three dimensions from the preceding chapter. In this section, we extend concepts from earlier chapters and also examine new ideas concerning curves in three-dimensional space. These definitions and theorems support the presentation of material in the rest of this chapter and also in the remaining chapters of the text.

## Definition of a Vector-Valued Function

Our first step in studying the calculus of vector-valued functions is to define what exactly a vector-valued function is. We can then look at graphs of vector-valued functions and see how they define curves in both two and three dimensions.

**Definition: Vector-valued Functions**

A vector-valued function is a function of the form

$$\vec{\mathbf{r}}(t) = f(t)\,\hat{\mathbf{i}} + g(t)\,\hat{\mathbf{j}} \text{ or } \vec{\mathbf{r}}(t) = f(t)\,\hat{\mathbf{i}} + g(t)\,\hat{\mathbf{j}} + h(t)\,\hat{\mathbf{k}},$$

where the component functions $f$, $g$, and $h$, are real-valued functions of the parameter $t$. Vector-valued functions are also written in the form

$$\vec{\mathbf{r}}(t) = \langle f(t), g(t)\rangle \text{ or } \vec{\mathbf{r}}(t) = \langle f(t), g(t), h(t)\rangle.$$

In both cases, the first form of the function defines a two-dimensional vector-valued function; the second form describes a three-dimensional vector-valued function.

The parameter $t$ can lie between two real numbers: $a \le t \le b$. Another possibility is that the value of $t$ might take on all real numbers. Last, the component functions themselves may have domain restrictions that enforce restrictions on the value of $t$. We often use $t$ as a parameter because $t$ can represent time.

**Example 13.2.1: Evaluating Vector-Valued Functions and Determining Domains**

For each of the following vector-valued functions, evaluate $\vec{\mathbf{r}}(0)$, $\vec{\mathbf{r}}(\frac{\pi}{2})$, and $\vec{\mathbf{r}}(\frac{2\pi}{3})$. Do any of these functions have domain restrictions?

a. $\vec{\mathbf{r}}(t) = 4\cos t\,\hat{\mathbf{i}} + 3\sin t\,\hat{\mathbf{j}}$
b. $\vec{\mathbf{r}}(t) = 3\tan t\,\hat{\mathbf{i}} + 4\sec t\,\hat{\mathbf{j}} + 5t\,\hat{\mathbf{k}}$

**Solution**

a. To calculate each of the function values, substitute the appropriate value of $t$ into the function:

$$\begin{aligned}\vec{\mathbf{r}}(0) &= 4\cos(0)\hat{\mathbf{i}} + 3\sin(0)\hat{\mathbf{j}} \\ &= 4\hat{\mathbf{i}} + 0\hat{\mathbf{j}} = 4\hat{\mathbf{i}} \\ \vec{\mathbf{r}}\left(\frac{\pi}{2}\right) &= 4\cos\left(\frac{\pi}{2}\right)\hat{\mathbf{i}} + 3\sin\left(\frac{\pi}{2}\right)\hat{\mathbf{j}} \\ &= 0\hat{\mathbf{i}} + 3\hat{\mathbf{j}} = 3\hat{\mathbf{j}} \\ \vec{\mathbf{r}}\left(\frac{2\pi}{3}\right) &= 4\cos\left(\frac{2\pi}{3}\right)\hat{\mathbf{i}} + 3\sin\left(\frac{2\pi}{3}\right)\hat{\mathbf{j}} \\ &= 4\left(-\tfrac{1}{2}\right)\hat{\mathbf{i}} + 3\left(\tfrac{\sqrt{3}}{2}\right)\hat{\mathbf{j}} = -2\hat{\mathbf{i}} + \tfrac{3\sqrt{3}}{2}\hat{\mathbf{j}}\end{aligned}$$

To determine whether this function has any domain restrictions, consider the component functions separately. The first component function is $f(t) = 4\cos t$ and the second component function is $g(t) = 3\sin t$. Neither of these functions has a domain restriction, so the domain of $\vec{\mathbf{r}}(t) = 4\cos t\,\hat{\mathbf{i}} + 3\sin t\,\hat{\mathbf{j}}$ is all real numbers.

b. To calculate each of the function values, substitute the appropriate value of $t$ into the function:

$$\begin{aligned}\vec{\mathbf{r}}(0) &= 3\tan(0)\hat{\mathbf{i}} + 4\sec(0)\hat{\mathbf{j}} + 5(0)\hat{\mathbf{k}} \\ &= 0\hat{\mathbf{i}} + 4j + 0\hat{\mathbf{k}} = 4\hat{\mathbf{j}} \\ \vec{\mathbf{r}}\left(\frac{\pi}{2}\right) &= 3\tan\left(\frac{\pi}{2}\right)\hat{\mathbf{i}} + 4\sec\left(\frac{\pi}{2}\right)\hat{\mathbf{j}} + 5\left(\frac{\pi}{2}\right)\hat{\mathbf{k}}, \text{ which does not exist} \\ \vec{\mathbf{r}}\left(\frac{2\pi}{3}\right) &= 3\tan\left(\frac{2\pi}{3}\right)\hat{\mathbf{i}} + 4\sec\left(\frac{2\pi}{3}\right)\hat{\mathbf{j}} + 5\left(\frac{2\pi}{3}\right)\hat{\mathbf{k}} \\ &= 3(-\sqrt{3})\hat{\mathbf{i}} + 4(-2)\hat{\mathbf{j}} + \frac{10\pi}{3}\hat{\mathbf{k}} \\ &= (-3\sqrt{3})\hat{\mathbf{i}} - 8\hat{\mathbf{j}} + \frac{10\pi}{3}\hat{\mathbf{k}}\end{aligned}$$

To determine whether this function has any domain restrictions, consider the component functions separately. The first component function is $f(t) = 3\tan t$, the second component function is $g(t) = 4\sec t$, and the third component function is $h(t) = 5t$. The first two functions are not defined for odd multiples of $\frac{\pi}{2}$, so the function is not defined for odd multiples of $\frac{\pi}{2}$. Therefore,

$$\mathrm{D}_{\vec{\mathbf{r}}} = \left\{t \,|\, t \neq \frac{(2n+1)\pi}{2}\right\},$$

where $n$ is any integer.

## ? Exercise 13.2.1

For the vector-valued function $\vec{\mathbf{r}}(t) = (t^2 - 3t)\,\hat{\mathbf{i}} + (4t + 1)\,\hat{\mathbf{j}}$, evaluate $\vec{\mathbf{r}}(0)$, $\vec{\mathbf{r}}(1)$, and $\vec{\mathbf{r}}(-4)$. Does this function have any domain restrictions?

**Hint**

Substitute the appropriate values of $t$ into the function.

**Answer**

$\vec{\mathbf{r}}(0) = \hat{\mathbf{j}}$, $\vec{\mathbf{r}}(1) = -2\hat{\mathbf{i}} + 5\hat{\mathbf{j}}$, $\vec{\mathbf{r}}(-4) = 28\hat{\mathbf{i}} - 15\hat{\mathbf{j}}$

The domain of $\vec{\mathbf{r}}(t) = (t^2 - 3t)\hat{\mathbf{i}} + (4t + 1)\hat{\mathbf{j}}$ is all real numbers.

Example **13.2.1** illustrates an important concept. The domain of a vector-valued function consists of real numbers. The domain can be all real numbers or a subset of the real numbers. The range of a vector-valued function consists of vectors. Each real number in the domain of a vector-valued function is mapped to either a two- or a three-dimensional vector.

## Graphing Vector-Valued Functions

Recall that a plane vector consists of two quantities: direction and magnitude. Given any point in the plane (the *initial point*), if we move in a specific direction for a specific distance, we arrive at a second point. This represents the *terminal point* of the vector. We calculate the components of the vector by subtracting the coordinates of the initial point from the coordinates of the terminal point.

A vector is considered to be in *standard position* if the initial point is located at the origin. When graphing a vector-valued function, we typically graph the vectors in the domain of the function in standard position, because doing so guarantees the uniqueness of the graph. This convention applies to the graphs of three-dimensional vector-valued functions as well. The graph of a vector-valued function of the form

$$\vec{\mathbf{r}}(t) = f(t)\,\hat{\mathbf{i}} + g(t)\,\hat{\mathbf{j}}$$

consists of the set of all points $(f(t),\, g(t))$, and the path it traces is called a **plane curve**. The graph of a vector-valued function of the form

$$\vec{\mathbf{r}}(t) = f(t)\,\hat{\mathbf{i}} + g(t)\,\hat{\mathbf{j}} + h(t)\,\hat{\mathbf{k}}$$

consists of the set of all points $(f(t),\, g(t),\, h(t))$, and the path it traces is called a **space curve**. Any representation of a plane curve or space curve using a vector-valued function is called a **vector parameterization** of the curve.

Each plane curve and space curve has an **orientation**, indicated by arrows drawn in on the curve, that shows the direction of motion along the curve as the value of the parameter $t$ increases.

### Example 13.2.2 : Graphing a Vector-Valued Function

Create a graph of each of the following vector-valued functions:

a. The plane curve represented by $\vec{\mathbf{r}}(t) = 4\cos t\,\hat{\mathbf{i}} + 3\sin t\,\hat{\mathbf{j}},\ 0 \le t \le 2\pi$
b. The plane curve represented by $\vec{\mathbf{r}}(t) = 4\cos(t^3)\,\hat{\mathbf{i}} + 3\sin(t^3)\,\hat{\mathbf{j}},\ 0 \le t \le \sqrt[3]{2\pi}$
c. The space curve represented by $\vec{\mathbf{r}}(t) = 4\cos t\,\hat{\mathbf{i}} + 4\sin t\,\hat{\mathbf{j}} + t\,\hat{\mathbf{k}},\ 0 \le t \le 4\pi$

#### Solution

a. As with any graph, we start with a table of values. We then graph each of the vectors in the second column of the table in standard position and connect the terminal points of each vector to form a curve (Figure 13.2.1). This curve turns out to be an ellipse centered at the origin.

Table 13.2.1: Table of Values for $\vec{\mathbf{r}}(t) = 4\cos t\,\hat{\mathbf{i}} + 3\sin t\,\hat{\mathbf{j}},\ 0 \le t \le 2\pi$

| $t$ | $\vec{\mathbf{r}}(t)$ | $t$ | $\vec{\mathbf{r}}(t)$ |
|---|---|---|---|
| $0$ | $4\hat{\mathbf{i}}$ | $\pi$ | $-4\hat{\mathbf{i}}$ |
| $\frac{\pi}{4}$ | $2\sqrt{2}\hat{\mathbf{i}} + \frac{3\sqrt{2}}{2}\hat{\mathbf{j}}$ | $\frac{5\pi}{4}$ | $-2\sqrt{2}\hat{\mathbf{i}} - \frac{3\sqrt{2}}{2}\hat{\mathbf{j}}$ |
| $\frac{\pi}{2}$ | $3\hat{\mathbf{j}}$ | $\frac{3\pi}{2}$ | $-3\hat{\mathbf{j}}$ |
| $\frac{3\pi}{4}$ | $-2\sqrt{2}\hat{\mathbf{i}} + \frac{3\sqrt{2}}{2}\hat{\mathbf{j}}$ | $\frac{7\pi}{4}$ | $2\sqrt{2}\hat{\mathbf{i}} - \frac{3\sqrt{2}}{2}\hat{\mathbf{j}}$ |
| $2\pi$ | $4\hat{\mathbf{i}}$ | | |

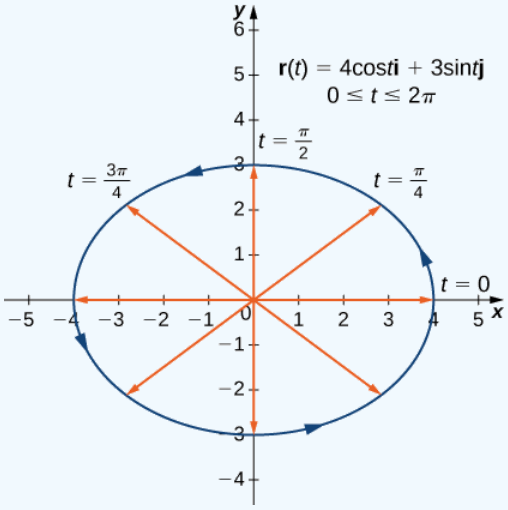

Figure 13.2.1: The graph of the first vector-valued function is an ellipse.

b. The table of values for $\vec{\mathbf{r}}(t) = 4\cos(t^3)\,\hat{\mathbf{i}} + 3\sin(t^3)\,\hat{\mathbf{j}},\ 0 \le t \le \sqrt[3]{2\pi}$ is as follows:

Table of Values for $\vec{\mathbf{r}}(t) = 4\cos(t^3)\,\hat{\mathbf{i}} + 3\sin(t^3)\,\hat{\mathbf{j}},\ 0 \le t \le \sqrt[3]{2\pi}$

| $t$ | $\vec{\mathbf{r}}(t)$ | $t$ | $\vec{\mathbf{r}}(t)$ |
|---|---|---|---|
| $0$ | $4\hat{\mathbf{i}}$ | $\sqrt[3]{\pi}$ | $-4\hat{\mathbf{i}}$ |
| $\sqrt[3]{\frac{\pi}{4}}$ | $2\sqrt{2}\hat{\mathbf{i}} + \frac{3\sqrt{2}}{2}\hat{\mathbf{j}}$ | $\sqrt[3]{\frac{5\pi}{4}}$ | $-2\sqrt{2}\hat{\mathbf{i}} - \frac{3\sqrt{2}}{2}\hat{\mathbf{j}}$ |
| $\sqrt[3]{\frac{\pi}{2}}$ | $3\hat{\mathbf{j}}$ | $\sqrt[3]{\frac{3\pi}{2}}$ | $-3\hat{\mathbf{j}}$ |
| $\sqrt[3]{\frac{3\pi}{4}}$ | $-2\sqrt{2}\hat{\mathbf{i}} + \frac{3\sqrt{2}}{2}\hat{\mathbf{j}}$ | $\sqrt[3]{\frac{7\pi}{4}}$ | $2\sqrt{2}\hat{\mathbf{i}} - \frac{3\sqrt{2}}{2}\hat{\mathbf{j}}$ |
| $\sqrt[3]{2\pi}$ | $4\hat{\mathbf{i}}$ | | |

The graph of this curve is also an ellipse centered at the origin.

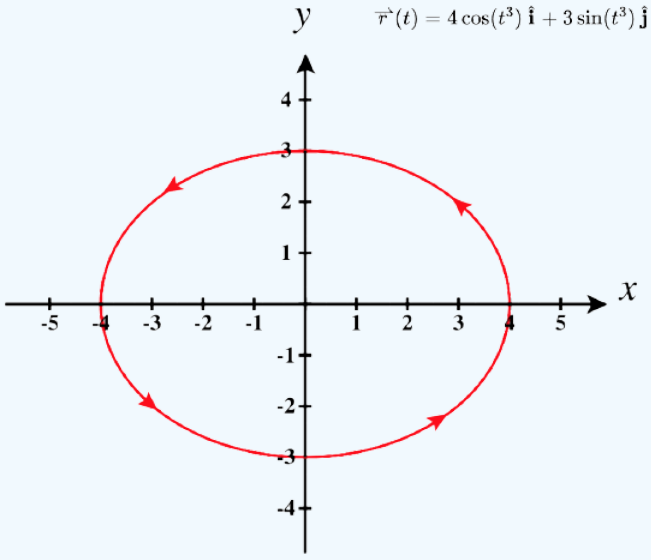

Figure 13.2.2: The graph of the second vector-valued function is also an ellipse.

c. We go through the same procedure for a three-dimensional vector function.

Table of Values for $\mathbf{r}(t) = 4\cos t\hat{\mathbf{i}} + 4\sin t\hat{\mathbf{j}} + t\hat{\mathbf{k}},\ 0 \le t \le 4\pi$

| $t$ | $\vec{\mathbf{r}}(t)$ | $t$ | $\vec{\mathbf{r}}(t)$ |
|---|---|---|---|
| $0$ | $4\hat{\mathbf{i}}$ | $\pi$ | $-4\hat{\mathbf{i}}+\pi\hat{\mathbf{k}}$ |
| $\frac{\pi}{4}$ | $2\sqrt{2}\hat{\mathbf{i}}+2\sqrt{2}\hat{\mathbf{j}}+\frac{\pi}{4}\hat{\mathbf{k}}$ | $\frac{5\pi}{4}$ | $-2\sqrt{2}\hat{\mathbf{i}}-2\sqrt{2}\hat{\mathbf{j}}+\frac{5\pi}{4}\hat{\mathbf{k}}$ |
| $\frac{\pi}{2}$ | $4\hat{\mathbf{j}}+\frac{\pi}{2}\hat{\mathbf{k}}$ | $\frac{3\pi}{2}$ | $-4\hat{\mathbf{j}}+\frac{3\pi}{2}\hat{\mathbf{k}}$ |
| $\frac{3\pi}{4}$ | $-2\sqrt{2}\hat{\mathbf{i}}+2\sqrt{2}\hat{\mathbf{j}}+\frac{3\pi}{4}\hat{\mathbf{k}}$ | $\frac{7\pi}{4}$ | $2\sqrt{2}\hat{\mathbf{i}}-2\sqrt{2}\hat{\mathbf{j}}+\frac{7\pi}{4}\hat{\mathbf{k}}$ |
| $2\pi$ | $4\hat{\mathbf{j}}+2\pi\hat{\mathbf{k}}$ | | |

The values then repeat themselves, except for the fact that the coefficient of $\hat{\mathbf{k}}$ is always increasing ( **13.2.3**). This curve is called a helix. Notice that if the $\hat{\mathbf{k}}$ component is eliminated, then the function becomes $\vec{\mathbf{r}}(t)=4\cos t\hat{\mathbf{i}}+4\sin t\hat{\mathbf{j}}$, which is a circle of radius 4 centered at the origin.

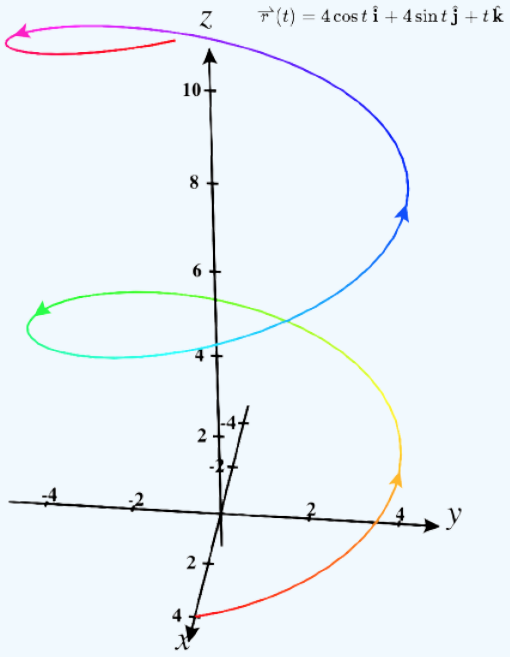

Figure **13.2.3**: The graph of the third vector-valued function is a helix.

You may notice that the graphs in parts a. and b. are identical. This happens because the function describing the curve in part b. is a so-called reparameterization of the function describing the curve in part a. In fact, any curve has an infinite number of reparameterizations; for example, we can replace $t$ with $2t$ in any of the three previous curves without changing the shape of the curve. The interval over which $t$ is defined may change, but that is all. We return to this idea later in this chapter when we study arc-length parameterization. As mentioned, the name of the shape of the curve of the graph in **13.2.3** is a *helix*. The curve resembles a spring, with a circular cross-section looking down along the $z$-axis. It is possible for a helix to be elliptical in cross-section as well. For example, the vector-valued function $\vec{\mathbf{r}}(t)=4\cos t\hat{\mathbf{i}}+3\sin t\hat{\mathbf{j}}+t\hat{\mathbf{k}}$ describes an elliptical helix. The projection of this helix into the $xy$-plane is an ellipse. Last, the arrows in the graph of this helix indicate the orientation of the curve as $t$ progresses from $0$ to $4\pi$.

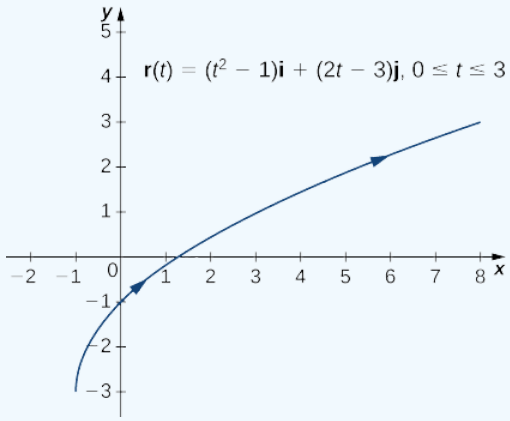
**? Exercise 13.2.2**

Create a graph of the vector-valued function $\vec{\mathbf{r}}(t)=(t^2-1)\hat{\mathbf{i}}+(2t-3)\hat{\mathbf{j}}$, $0\le t\le 3$.

**Hint**

Start by making a table of values, then graph the vectors for each value of $t$.

**Answer**



At this point, you may notice a similarity between vector-valued functions and parameterized curves. Indeed, given a vector-valued function $\vec{\mathbf{r}}(t) = f(t)\hat{\mathbf{i}} + g(t)\hat{\mathbf{j}}$ we can define $x = f(t)$ and $y = g(t)$. If a restriction exists on the values of $t$ (for example, $t$ is restricted to the interval $[a, b]$ for some constants $a < b$, then this restriction is enforced on the parameter. The graph of the parameterized function would then agree with the graph of the vector-valued function, except that the vector-valued graph would represent vectors rather than points. Since we can parameterize a curve defined by a function $y = f(x)$, it is also possible to represent an arbitrary plane curve by a vector-valued function.

## Limits and Continuity of a Vector-Valued Function

We now take a look at the limit of a vector-valued function. This is important to understand to study the calculus of vector-valued functions.

**Definition: limit of a vector-valued function**

A vector-valued function $\vec{\mathbf{r}}$ approaches the limit $\vec{\mathbf{L}}$ as $t$ approaches $a$, written

$$\lim_{t \to a} \vec{\mathbf{r}}(t) = \vec{\mathbf{L}},$$

provided

$$\lim_{t \to a} \|\vec{\mathbf{r}}(t) - \vec{\mathbf{L}}\| = 0.$$

This is a rigorous definition of the limit of a vector-valued function. In practice, we use the following theorem:

**Theorem: Limit of a vector-valued function**

Let $f$, $g$, and $h$ be functions of $t$. Then the limit of the vector-valued function $\vec{\mathbf{r}}(t) = f(t)\hat{\mathbf{i}} + g(t)\hat{\mathbf{j}}$ as $t$ approaches $a$ is given by

$$\lim_{t \to a} \vec{\mathbf{r}}(t) = [\lim_{t \to a} f(t)]\hat{\mathbf{i}} + [\lim_{t \to a} g(t)]\hat{\mathbf{j}}, \tag{13.2.1}$$

provided the limits $\lim_{t \to a} f(t)$ and $\lim_{t \to a} g(t)$ exist.

Similarly, the limit of the vector-valued function $\vec{\mathbf{r}}(t) = f(t)\hat{\mathbf{i}} + g(t)\hat{\mathbf{j}} + h(t)\hat{\mathbf{k}}$ as $t$ approaches $a$ is given by

$$\lim_{t \to a} \vec{\mathbf{r}}(t) = [\lim_{t \to a} f(t)]\hat{\mathbf{i}} + [\lim_{t \to a} g(t)]\hat{\mathbf{j}} + [\lim_{t \to a} h(t)]\hat{\mathbf{k}}, \tag{13.2.2}$$

provided the limits $\lim_{t \to a} f(t)$, $\lim_{t \to a} g(t)$ and $\lim_{t \to a} h(t)$ exist.

In the following example, we show how to calculate the limit of a vector-valued function.

### Example 13.2.3: Evaluating the Limit of a Vector-Valued Function

For each of the following vector-valued functions, calculate $\lim_{t\to 3}\vec{\mathbf{r}}(t)$ for

a. $\vec{\mathbf{r}}(t)=(t^2-3t+4)\hat{\mathbf{i}}+(4t+3)\hat{\mathbf{j}}$
b. $\vec{\mathbf{r}}(t)=\frac{2t-4}{t+1}\hat{\mathbf{i}}+\frac{t}{t^2+1}\hat{\mathbf{j}}+(4t-3)\hat{\mathbf{k}}$

**Solution**

a. Use Equation 13.2.1 and substitute the value $t=3$ into the two component expressions:

$$\begin{aligned}\lim_{t\to 3}\vec{\mathbf{r}}(t) &= \lim_{t\to 3}\left[(t^2-3t+4)\hat{\mathbf{i}}+(4t+3)\hat{\mathbf{j}}\right]\\ &= \left[\lim_{t\to 3}(t^2-3t+4)\right]\hat{\mathbf{i}}+\left[\lim_{t\to 3}(4t+3)\right]\hat{\mathbf{j}}\\ &= 4\hat{\mathbf{i}}+15\hat{\mathbf{j}}\end{aligned}$$

b. Use Equation 13.2.2 and substitute the value $t=3$ into the three component expressions:

$$\begin{aligned}\lim_{t\to 3}\vec{\mathbf{r}}(t) &= \lim_{t\to 3}\left(\frac{2t-4}{t+1}\hat{\mathbf{i}}+\frac{t}{t^2+1}\hat{\mathbf{j}}+(4t-3)\hat{\mathbf{k}}\right)\\ &= \left[\lim_{t\to 3}\left(\frac{2t-4}{t+1}\right)\right]\hat{\mathbf{i}}+\left[\lim_{t\to 3}\left(\frac{t}{t^2+1}\right)\right]\hat{\mathbf{j}}+\left[\lim_{t\to 3}(4t-3)\right]\hat{\mathbf{k}}\\ &= \tfrac{1}{2}\hat{\mathbf{i}}+\tfrac{3}{10}\hat{\mathbf{j}}+9\hat{\mathbf{k}}\end{aligned}$$

### Exercise 13.2.3

Calculate $\lim_{t\to 2}\vec{\mathbf{r}}(t)$ for the function $\vec{\mathbf{r}}(t)=\sqrt{t^2+3t-1}\,\hat{\mathbf{i}}-(4t-3)\hat{\mathbf{j}}-\sin\frac{(t+1)\pi}{2}\hat{\mathbf{k}}$

**Hint**

Use Equation 13.2.2 from the preceding theorem.

**Answer**

$$\lim_{t\to 2}\vec{\mathbf{r}}(t)=3\hat{\mathbf{i}}-5\hat{\mathbf{j}}+\hat{\mathbf{k}}$$

Now that we know how to calculate the limit of a vector-valued function, we can define **continuity at a point** for such a function.

### Definitions

Let $f$, $g$, and $h$ be functions of $t$. Then, the vector-valued function $\vec{\mathbf{r}}(t)=f(t)\hat{\mathbf{i}}+g(t)\hat{\mathbf{j}}$ is **continuous at point** $t=a$ if the following three conditions hold:

1. $\vec{\mathbf{r}}(a)$ exists
2. $\lim_{t\to a}\vec{\mathbf{r}}(t)$ exists
3. $\lim_{t\to a}\vec{\mathbf{r}}(t)=\vec{\mathbf{r}}(a)$

Similarly, the vector-valued function $\vec{\mathbf{r}}(t)=f(t)\hat{\mathbf{i}}+g(t)\hat{\mathbf{j}}+h(t)\hat{\mathbf{k}}$ is **continuous at point** $t=a$ if the following three conditions hold:

1. $\vec{\mathbf{r}}(a)$ exists
2. $\lim_{t\to a}\vec{\mathbf{r}}(t)$ exists
3. $\lim_{t\to a}\vec{\mathbf{r}}(t)=\vec{\mathbf{r}}(a)$

### Summary

- A vector-valued function is a function of the form $\vec{\mathbf{r}}(t)=f(t)\hat{\mathbf{i}}+g(t)\hat{\mathbf{j}}$ or $\vec{\mathbf{r}}(t)=f(t)\hat{\mathbf{i}}+g(t)\hat{\mathbf{j}}+h(t)\hat{\mathbf{k}}$, where the component functions $f$, $g$, and $h$ are real-valued functions of the parameter $t$.

- The graph of a vector-valued function of the form $\vec{\mathbf{r}}(t) = f(t)\hat{\mathbf{i}} + g(t)\hat{\mathbf{j}}$ is called a *plane curve*. The graph of a vector-valued function of the form $\vec{\mathbf{r}}(t) = f(t)\hat{\mathbf{i}} + g(t)\hat{\mathbf{j}} + h(t)\hat{\mathbf{k}}$ is called a *space curve*.
- It is possible to represent an arbitrary plane curve by a vector-valued function.
- To calculate the limit of a vector-valued function, calculate the limits of the component functions separately.

### Key Equations

- **Vector-valued function**
  $\vec{\mathbf{r}}(t) = f(t)\hat{\mathbf{i}} + g(t)\hat{\mathbf{j}}$ or $\vec{\mathbf{r}}(t) = f(t)\hat{\mathbf{i}} + g(t)\hat{\mathbf{j}} + h(t)\hat{\mathbf{k}}$,or $\vec{\mathbf{r}}(t) = \langle f(t), g(t)\rangle$ or $\vec{\mathbf{r}}(t) = \langle f(t), g(t), h(t)\rangle$
- **Limit of a vector-valued function**
  $\lim\limits_{t\to a} \vec{\mathbf{r}}(t) = [\lim\limits_{t\to a} f(t)]\hat{\mathbf{i}} + [\lim\limits_{t\to a} g(t)]\hat{\mathbf{j}}$ or $\lim\limits_{t\to a} \vec{\mathbf{r}}(t) = [\lim\limits_{t\to a} f(t)]\hat{\mathbf{i}} + [\lim\limits_{t\to a} g(t)]\hat{\mathbf{j}} + [\lim\limits_{t\to a} h(t)]\hat{\mathbf{k}}$

## Glossary

**component functions**
the component functions of the vector-valued function $\vec{\mathbf{r}}(t) = f(t)\hat{\mathbf{i}} + g(t)\hat{\mathbf{j}}$ are $f(t)$ and $g(t)$, and the component functions of the vector-valued function $\vec{\mathbf{r}}(t) = f(t)\hat{\mathbf{i}} + g(t)\hat{\mathbf{j}} + h(t)\hat{\mathbf{k}}$ are $f(t)$, $g(t)$ and $h(t)$

**helix**
a three-dimensional curve in the shape of a spiral

**limit of a vector-valued function**
a vector-valued function $\vec{\mathbf{r}}(t)$ has a limit $\vec{\mathbf{L}}$ as $t$ approaches $a$ if $\lim t \to a \left|\vec{\mathbf{r}}(t) - \vec{\mathbf{L}}\right| = 0$

**plane curve**
the set of ordered pairs $(f(t), g(t))$ together with their defining parametric equations $x = f(t)$ and $y = g(t)$

**reparameterization**
an alternative parameterization of a given vector-valued function

**space curve**
the set of ordered triples $(f(t), g(t), h(t))$ together with their defining parametric equations $x = f(t)$, $y = g(t)$ and $z = h(t)$

**vector parameterization**
any representation of a plane or space curve using a vector-valued function

**vector-valued function**
a function of the form $\vec{\mathbf{r}}(t) = f(t)\hat{\mathbf{i}} + g(t)\hat{\mathbf{j}}$ or $\vec{\mathbf{r}}(t) = f(t)\hat{\mathbf{i}} + g(t)\hat{\mathbf{j}} + h(t)\hat{\mathbf{k}}$,where the component functions $f$, $g$, and $h$ are real-valued functions of the parameter $t$.

# 13.2E: EXERCISES FOR SECTION 13.1

## INTRODUCTION TO VECTOR-VALUED FUNCTIONS

**1)** Give the component functions $x = f(t)$ and $y = g(t)$ for the vector-valued function $\vec{\mathbf{r}}(t) = 3\sec t\,\hat{\mathbf{i}} + 2\tan t\,\hat{\mathbf{j}}$.

**2)** Given $\vec{\mathbf{r}}(t) = 3\sec t\hat{\mathbf{i}} + 2\tan t\hat{\mathbf{j}}$, find the following values (if possible).

a. $\vec{\mathbf{r}}\left(\frac{\pi}{4}\right)$
b. $\vec{\mathbf{r}}(\pi)$
c. $\vec{\mathbf{r}}\left(\frac{\pi}{2}\right)$

**3)** Sketch the curve of the vector-valued function $\vec{\mathbf{r}}(t) = 3\sec t\hat{\mathbf{i}} + 2\tan t\hat{\mathbf{j}}$ and give the orientation of the curve. Sketch asymptotes as a guide to the graph.

## LIMITS OF VECTOR-VALUED FUNCTIONS

**4)** Evaluate $\lim\limits_{t\to 0}\left(e^t\hat{\mathbf{i}} + \frac{\sin t}{t}\hat{\mathbf{j}} + e^{-t}\hat{\mathbf{k}}\right)$

**5)** Given the vector-valued function $\vec{\mathbf{r}}(t) = \langle \cos t, \sin t\rangle$ find the following values:

a. $\lim\limits_{t\to\frac{\pi}{4}} \vec{\mathbf{r}}(t)$
b. $\vec{\mathbf{r}}\left(\frac{\pi}{3}\right)$
c. Is $\vec{\mathbf{r}}(t)$ continuous at $t = \frac{\pi}{3}$?
d. Graph $\vec{\mathbf{r}}(t)$.

**6)** Given the vector-valued function $\vec{\mathbf{r}}(t) = \langle t, t^2 + 1\rangle$, find the following values:

a. $\lim\limits_{t\to -3} \vec{\mathbf{r}}(t)$
b. $\vec{\mathbf{r}}(-3)$
c. Is $\vec{\mathbf{r}}(t)$ continuous at $x = -3$?
d. $\vec{\mathbf{r}}(t+2) - \vec{\mathbf{r}}(t)$

**7)** Let $\vec{\mathbf{r}}(t) = e^t\hat{\mathbf{i}} + \sin t\hat{\mathbf{j}} + \ln t\hat{\mathbf{k}}$. Find the following values:

a. $\vec{\mathbf{r}}\left(\frac{\pi}{4}\right)$
b. $\lim\limits_{t\to\frac{\pi}{4}} \vec{\mathbf{r}}(t)$
c. Is $\vec{\mathbf{r}}(t)$ continuous at $t = \frac{\pi}{4}$?

**For exercises 8 - 13, find the limit of the following vector-valued functions at the indicated value of $t$.**

**8)** $\lim\limits_{t\to 4}\langle\sqrt{t-3}, \frac{\sqrt{t}-2}{t-4}, \tan\left(\frac{\pi}{t}\right)\rangle$

**9)** $\lim\limits_{t\to\frac{\pi}{2}} \vec{\mathbf{r}}(t)$ for $\vec{\mathbf{r}}(t) = e^t\hat{\mathbf{i}} + \sin t\hat{\mathbf{j}} + \ln t\hat{\mathbf{k}}$

**10)** $\lim\limits_{t\to\infty}\langle e^{-2t}, \frac{2t+3}{3t-1}, \arctan(2t)\rangle$

**11)** $\lim\limits_{t\to e^2}\langle t\ln(t), \frac{\ln t}{t^2}, \sqrt{\ln(t^2)}\rangle$

**12)** $\lim\limits_{t\to\frac{\pi}{6}}\langle\cos 2t, \sin 2t, 1\rangle$

**13)** $\lim\limits_{t\to\infty} \vec{\mathbf{r}}(t)$ for $\vec{\mathbf{r}}(t) = 2e^{-t}\mathbf{i} + e^{-t}\hat{\mathbf{j}} + \ln(t-1)\hat{\mathbf{k}}$

## DOMAIN OF A VECTOR-VALUED FUNCTION

**For problems 14 - 17, find the domain of the vector-valued functions.**

**14)** Domain: $\vec{\mathbf{r}}(t) = \langle t^2, t, \sin t\rangle$

**15)** Domain: $\vec{\mathbf{r}}(t) = \langle t^2, \tan t, \ln t\rangle$

**16)** Domain: $\vec{\mathbf{r}}(t) = \langle t^2, \sqrt{t-3}, \frac{3}{2t+1}\rangle$

**17)** Domain: $\vec{\mathbf{r}}(t) = \langle \csc(t), \frac{1}{\sqrt{t-3}}, \ln(t-2)\rangle$

**18)** a. Find the domain of $\vec{\mathbf{r}}(t) = 2e^{-t}\hat{\mathbf{i}} + e^{-t}\hat{\mathbf{j}} + \ln(t-1)\hat{\mathbf{k}}$.

b. For what values of $t$ is $\vec{\mathbf{r}}(t) = 2e^{-t}\hat{\mathbf{i}} + e^{-t}\hat{\mathbf{j}} + \ln(t-1)\hat{\mathbf{k}}$ continuous?

**19)** Domain: $\vec{\mathbf{r}}(t) = (\arccos t)\,\hat{\mathbf{i}} + \sqrt{2t-1}\,\hat{\mathbf{j}} + \ln(t)\,\hat{\mathbf{k}}$

## VISUALIZING VECTOR-VALUED FUNCTIONS

**20)** Describe the curve defined by the vector-valued function $\vec{\mathbf{r}}(t) = (1+t)\hat{\mathbf{i}} + (2+5t)\hat{\mathbf{j}} + (-1+6t)\hat{\mathbf{k}}$.

**21)** Let $\vec{\mathbf{r}}(t) = \langle \cos t, t, \sin t \rangle$ and use it to answer the following questions.

a. For what values of $t$ is $\vec{\mathbf{r}}(t)$ continuous?

b. Sketch the graph of $\vec{\mathbf{r}}(t)$.

22) Produce a careful sketch of the graph of $\vec{\mathbf{r}}(t) = t^2\hat{\mathbf{i}} + t\hat{\mathbf{j}}$.

**In questions 23 - 25, use a graphing utility to sketch each of the vector-valued functions:**

23) **[T]** $\vec{\mathbf{r}}(t) = 2\cos^2 t\hat{\mathbf{i}} + (2-\sqrt{t})\hat{\mathbf{j}}$

24) **[T]** $\vec{\mathbf{r}}(t) = \langle e^{\cos(3t)}, e^{-\sin(t)} \rangle$

25) **[T]** $\vec{\mathbf{r}}(t) = \langle 2 - \sin(2t), 3 + 2\cos t \rangle$

## FINDING EQUATIONS IN $x$ AND $y$ FOR THE PATH TRACED OUT BY VECTOR-VALUED FUNCTIONS

**For questions 26-33, eliminate the parameter $t$, write the equation in Cartesian coordinates, then sketch the graph of the vector-valued functions.**

26) $\vec{\mathbf{r}}(t) = 2t\hat{\mathbf{i}} + t^2\hat{\mathbf{j}}$

(*Hint:* Let $x = 2t$ and $y = t^2$. Solve the first equation for $t$ in terms of $x$ and substitute this result into the second equation.)

27) $\vec{\mathbf{r}}(t) = t^3\hat{\mathbf{i}} + 2t\hat{\mathbf{j}}$

28) $\vec{\mathbf{r}}(t) = \sin t\hat{\mathbf{i}} + \cos t\hat{\mathbf{j}}$

29) $\vec{\mathbf{r}}(t) = 3\cos t\hat{\mathbf{i}} + 3\sin t\hat{\mathbf{j}}$

30) $\vec{\mathbf{r}}(t) = \langle \sin t, 4\cos t \rangle$

31) $\vec{\mathbf{r}}(t) = 2\sin t\hat{\mathbf{i}} - 3\cos t\hat{\mathbf{j}}$

32) $\vec{\mathbf{r}}(t) = \tan t\hat{\mathbf{i}} - 2\sec t\hat{\mathbf{j}}$

33) $\vec{\mathbf{r}}(t) = 3\sec t\hat{\mathbf{i}} + 4\tan t\hat{\mathbf{j}}$

## FINDING A VECTOR-VALUED FUNCTION TO TRACE OUT THE GRAPH OF AN EQUATION IN $x$ AND $y$

**For questions 34 - 40, find a vector-valued function that traces out the given curve in the indicated direction.**

34) $4x^2 + 9y^2 = 36$; clockwise and counterclockwise

35) $y = x^2$; from left to right

36) The line through $P$ and $Q$ where $P$ is $(1, 4, -2)$ and $Q$ is $(3, 9, 6)$

37) The circle, $x^2 + y^2 = 36$, oriented clockwise, with position $(-6, 0)$ at time $t = 0$.

38) The ellipse, $x^2 + \dfrac{y^2}{36} = 1$, oriented counterclockwise

39) The hyperbola, $\dfrac{y^2}{36} - x^2 = 1$, top piece is oriented from left-to-right

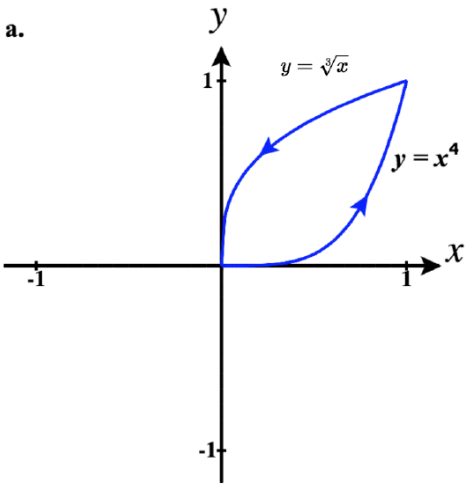
40) The hyperbola, $\dfrac{x^2}{49} - \dfrac{y^2}{64} = 1$, right piece is oriented from bottom-to-top

## PARAMETERIZING A PIECEWISE PATH

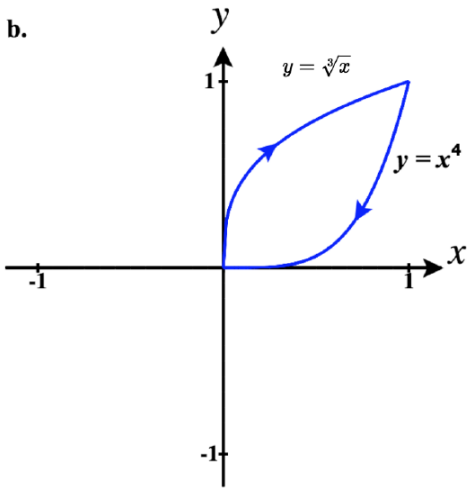
For questions 41 - 44, provide a parameterization for each piecewise path. Try to write a parameterization that starts with $t = 0$ and progresses on through values of $t$ as you move from one piece to another.

41)

a.



b.



42)

## ADDITIONAL VECTOR-VALUED FUNCTION QUESTIONS

**For questions 45 - 48, consider the curve described by the vector-valued function $\vec{\mathbf{r}}(t) = (50e^{-t}\cos t)\hat{\mathbf{i}} + (50e^{-t}\sin t)\hat{\mathbf{j}} + (5 - 5e^{-t})\hat{\mathbf{k}}$.**

45) What is the initial point of the path corresponding to $\vec{\mathbf{r}}(0)$?

46) What is $\lim_{t\to\infty} \vec{\mathbf{r}}(t)$?

47) **[T]** Use technology to sketch the curve.

48) Eliminate the parameter $t$ to show that $z = 5 - \frac{r}{10}$ where $r^2 = x^2 + y^2$.

49) **[T]** Let $\vec{\mathbf{r}}(t) = \cos t\hat{\mathbf{i}} + \sin t\hat{\mathbf{j}} + 0.3\sin(2t)\hat{\mathbf{k}}$. Use technology to graph the curve (called the *roller-coaster curve*) over the interval $[0, 2\pi)$. Choose at least two views to determine the peaks and valleys.

50) **[T]** Use the result of the preceding problem to construct an equation of a roller coaster with a steep drop from the peak and steep incline from the "valley." Then, use technology to graph the equation.

51) Use the results of the preceding two problems to construct an equation of a path of a roller coaster with more than two turning points (peaks and valleys).

52) Complete the following investigation.

a. Graph the curve $\vec{\mathbf{r}}(t) = (4 + \cos(18t))\cos(t)\hat{\mathbf{i}} + (4 + \cos(18t)\sin(t))\hat{\mathbf{j}} + 0.3\sin(18t)\hat{\mathbf{k}}$ using two viewing angles of your choice to see the overall shape of the curve.
b. Does the curve resemble a "slinky"?
c. What changes to the equation should be made to increase the number of coils of the slinky?

# 13.3: Calculus of Vector-Valued Functions

**Learning Objectives**

- Write an expression for the derivative of a vector-valued function.
- Find the tangent vector at a point for a given position vector.
- Find the unit tangent vector at a point for a given position vector and explain its significance.
- Calculate the definite integral of a vector-valued function.

To study the calculus of vector-valued functions, we follow a similar path to the one we took in studying real-valued functions. First, we define the derivative, then we examine applications of the derivative, then we move on to defining integrals. However, we will find some interesting new ideas along the way as a result of the vector nature of these functions and the properties of space curves.

## Derivatives of Vector-Valued Functions

Now that we have seen what a vector-valued function is and how to take its limit, the next step is to learn how to differentiate a vector-valued function. The definition of the derivative of a vector-valued function is nearly identical to the definition of a real-valued function of one variable. However, because the range of a vector-valued function consists of vectors, the same is true for the range of the derivative of a vector-valued function.

**Definition: Derivative of Vector-Valued Functions**

The derivative of a vector-valued function $\vec{\mathbf{r}}(t)$ is

$$\vec{\mathbf{r}}'(t) = \lim_{\Delta t \to 0} \frac{\vec{\mathbf{r}}(t+\Delta t) - \vec{\mathbf{r}}(t)}{\Delta t} \tag{13.3.1}$$

provided the limit exists. If $\vec{\mathbf{r}}'(t)$ exists, then $\vec{\mathbf{r}}(t)$ is differentiable at $t$. If $\vec{\mathbf{r}}'(t)$ exists for all $t$ in an open interval $(a, b)$ then $\vec{\mathbf{r}}(t)$ is differentiable over the interval $(a, b)$. For the function to be differentiable over the closed interval $[a, b]$, the following two limits must exist as well:

$$\vec{\mathbf{r}}'(a) = \lim_{\Delta t \to 0^+} \frac{\vec{\mathbf{r}}(a+\Delta t) - \vec{\mathbf{r}}(a)}{\Delta t}$$

and

$$\vec{\mathbf{r}}'(b) = \lim_{\Delta t \to 0^-} \frac{\vec{\mathbf{r}}(b+\Delta t) - \vec{\mathbf{r}}(b)}{\Delta t}$$

Many of the rules for calculating derivatives of real-valued functions can be applied to calculating the derivatives of vector-valued functions as well. Recall that the derivative of a real-valued function can be interpreted as the slope of a tangent line or the instantaneous rate of change of the function. The derivative of a vector-valued function can be understood to be an instantaneous rate of change as well; for example, when the function represents the position of an object at a given point in time, the derivative represents its velocity at that same point in time.

We now demonstrate taking the derivative of a vector-valued function.

**Example 13.3.1: Finding the Derivative of a Vector-Valued Function**

Use the definition to calculate the derivative of the function

$$\vec{\mathbf{r}}(t) = (3t+4)\,\hat{\mathbf{i}} + (t^2 - 4t + 3)\,\hat{\mathbf{j}}.$$

**Solution**

Let's use Equation 13.3.1:

$$
\begin{aligned}
\vec{\mathbf{r}}'(t) &= \lim_{\Delta t \to 0} \frac{\vec{\mathbf{r}}(t+\Delta t) - \vec{\mathbf{r}}(t)}{\Delta t} \\
&= \lim_{\Delta t \to 0} \frac{[(3(t+\Delta t)+4)\,\hat{\mathbf{i}} + ((t+\Delta t)^2 - 4(t+\Delta t)+3)\,\hat{\mathbf{j}}] - [(3t+4)\,\hat{\mathbf{i}} + (t^2-4t+3)\,\hat{\mathbf{j}}]}{\Delta t} \\
&= \lim_{\Delta t \to 0} \frac{(3t+3\Delta t+4)\,\hat{\mathbf{i}} - (3t+4)\,\hat{\mathbf{i}} + (t^2+2t\Delta t+(\Delta t)^2 - 4t - 4\Delta t + 3)\,\hat{\mathbf{j}} - (t^2-4t+3)\,\hat{\mathbf{j}}}{\Delta t} \\
&= \lim_{\Delta t \to 0} \frac{(3\Delta t)\,\hat{\mathbf{i}} + (2t\Delta t + (\Delta t)^2 - 4\Delta t)\,\hat{\mathbf{j}}}{\Delta t} \\
&= \lim_{\Delta t \to 0} (3\,\hat{\mathbf{i}} + (2t + \Delta t - 4)\,\hat{\mathbf{j}}) \\
&= 3\,\hat{\mathbf{i}} + (2t-4)\,\hat{\mathbf{j}}
\end{aligned}
$$

**? Exercise 13.3.1**

Use the definition to calculate the derivative of the function $\vec{\mathbf{r}}(t) = (2t^2+3)\,\hat{\mathbf{i}} + (5t-6)\,\hat{\mathbf{j}}$.

**Hint**

Use Equation 13.3.1.

**Answer**

$$\vec{\mathbf{r}}'(t) = 4t\,\hat{\mathbf{i}} + 5\,\hat{\mathbf{j}}$$

Notice that in the calculations in Example **13.3.1**, we could also obtain the answer by first calculating the derivative of each component function, then putting these derivatives back into the vector-valued function. This is always true for calculating the derivative of a vector-valued function, whether it is in two or three dimensions. We state this in the following theorem. The proof of this theorem follows directly from the definitions of the limit of a vector-valued function and the derivative of a vector-valued function.

**Theorem 13.3.1: Differentiation of Vector-Valued Functions**

Let $f$, $g$, and $h$ be differentiable functions of $t$.

1. If $\vec{\mathbf{r}}(t) = f(t)\,\hat{\mathbf{i}} + g(t)\,\hat{\mathbf{j}}$ then
$$\vec{\mathbf{r}}'(t) = f'(t)\,\hat{\mathbf{i}} + g'(t)\,\hat{\mathbf{j}}.$$
2. If $\vec{\mathbf{r}}(t) = f(t)\,\hat{\mathbf{i}} + g(t)\,\hat{\mathbf{j}} + h(t)\,\hat{\mathbf{k}}$ then
$$\vec{\mathbf{r}}'(t) = f'(t)\,\hat{\mathbf{i}} + g'(t)\,\hat{\mathbf{j}} + h'(t)\,\hat{\mathbf{k}}.$$

**✓ Example 13.3.2: Calculating the Derivative of Vector-Valued Functions**

Use Theorem **13.3.1** to calculate the derivative of each of the following functions.

a. $\vec{\mathbf{r}}(t) = (6t+8)\,\hat{\mathbf{i}} + (4t^2+2t-3)\,\hat{\mathbf{j}}$
b. $\vec{\mathbf{r}}(t) = 3\cos t\,\hat{\mathbf{i}} + 4\sin t\,\hat{\mathbf{j}}$
c. $\vec{\mathbf{r}}(t) = e^t \sin t\,\hat{\mathbf{i}} + e^t \cos t\,\hat{\mathbf{j}} - e^{2t}\,\hat{\mathbf{k}}$

**Solution**

We use Theorem **13.3.1** and what we know about differentiating functions of one variable.

a. The first component of

$$\vec{\mathbf{r}}(t) = (6t+8)\,\hat{\mathbf{i}} + (4t^2+2t-3)\,\hat{\mathbf{j}}$$

is $f(t) = 6t+8$. The second component is $g(t) = 4t^2+2t-3$. We have $f'(t) = 6$ and $g'(t) = 8t+2$, so the Theorem 13.3.1 gives $\vec{\mathbf{r}}'(t) = 6\,\hat{\mathbf{i}} + (8t+2)\,\hat{\mathbf{j}}$.

b. The first component is $f(t) = 3\cos t$ and the second component is $g(t) = 4\sin t$. We have $f'(t) = -3\sin t$ and $g'(t) = 4\cos t$, so we obtain $\vec{\mathbf{r}}'(t) = -3\sin t\,\hat{\mathbf{i}} + 4\cos t\,\hat{\mathbf{j}}$.

c. The first component of $\vec{\mathbf{r}}(t) = e^t\sin t\,\hat{\mathbf{i}} + e^t\cos t\,\hat{\mathbf{j}} - e^{2t}\hat{\mathbf{k}}$ is $f(t) = e^t\sin t$, the second component is $g(t) = e^t\cos t$, and the third component is $h(t) = -e^{2t}$. We have $f'(t) = e^t(\sin t + \cos t)$, $g'(t) = e^t(\cos t - \sin t)$, and $h'(t) = -2e^{2t}$, so the theorem gives $\vec{\mathbf{r}}'(t) = e^t(\sin t + \cos t)\,\hat{\mathbf{i}} + e^t(\cos t - \sin t)\,\hat{\mathbf{j}} - 2e^{2t}\,\hat{\mathbf{k}}$.

## ? Exercise 13.3.2

Calculate the derivative of the function

$$\vec{\mathbf{r}}(t) = (t\ln t)\,\hat{\mathbf{i}} + (5e^t)\,\hat{\mathbf{j}} + (\cos t - \sin t)\,\hat{\mathbf{k}}.$$

**Hint**

Identify the component functions and use Theorem 13.3.1.

**Answer**

$$\vec{\mathbf{r}}'(t) = (1+\ln t)\,\hat{\mathbf{i}} + 5e^t\,\hat{\mathbf{j}} - (\sin t + \cos t)\,\hat{\mathbf{k}}$$

We can extend to vector-valued functions the properties of the derivative that we presented previously. In particular, the constant multiple rule, the sum and difference rules, the product rule, and the chain rule all extend to vector-valued functions. However, in the case of the product rule, there are actually three extensions:

1. for a real-valued function multiplied by a vector-valued function,
2. for the dot product of two vector-valued functions, and
3. for the cross product of two vector-valued functions.

## Theorem: Properties of the Derivative of Vector-Valued Functions

Let $\vec{\mathbf{r}}$ and $\vec{\mathbf{u}}$ be differentiable vector-valued functions of $t$, let $f$ be a differentiable real-valued function of $t$, and let $c$ be a scalar.

| | | | | |
|---|---|---|---|---|
| i. | $\frac{d}{dt}[c\vec{\mathbf{r}}(t)]$ | $=$ | $c\vec{\mathbf{r}}'(t)$ | Scalar multiple |
| ii. | $\frac{d}{dt}[\vec{\mathbf{r}}(t) \pm \vec{\mathbf{u}}(t)]$ | $=$ | $\vec{\mathbf{r}}'(t) \pm \vec{\mathbf{u}}'(t)$ | Sum and difference |
| iii. | $\frac{d}{dt}[f(t)\vec{\mathbf{u}}(t)]$ | $=$ | $f'(t)\vec{\mathbf{u}}(t) + f(t)\vec{\mathbf{u}}'(t)$ | Scalar product |
| iv. | $\frac{d}{dt}[\vec{\mathbf{r}}(t)\cdot\vec{\mathbf{u}}(t)]$ | $=$ | $\vec{\mathbf{r}}'(t)\cdot\vec{\mathbf{u}}(t) + \vec{\mathbf{r}}(t)\cdot\vec{\mathbf{u}}'(t)$ | Dot product |
| v. | $\frac{d}{dt}[\vec{\mathbf{r}}(t)\times\vec{\mathbf{u}}(t)]$ | $=$ | $\vec{\mathbf{r}}'(t)\times\vec{\mathbf{u}}(t) + \vec{\mathbf{r}}(t)\times\vec{\mathbf{u}}'(t)$ | Cross product |
| vi. | $\frac{d}{dt}[\vec{\mathbf{r}}(f(t))]$ | $=$ | $\vec{\mathbf{r}}'(f(t))\cdot f'(t)$ | Chain rule |
| vii. | If $\vec{\mathbf{r}}(t)\cdot\vec{\mathbf{r}}(t)$ | $=$ | $c$, then $\vec{\mathbf{r}}(t)\cdot\vec{\mathbf{r}}'(t) = 0$. | |

## Proof

The proofs of the first two properties follow directly from the definition of the derivative of a vector-valued function. The third property can be derived from the first two properties, along with the product rule. Let $\vec{\mathbf{u}}(t) = g(t)\,\hat{\mathbf{i}} + h(t)\,\hat{\mathbf{j}}$. Then

$$\begin{aligned}\frac{d}{dt}[f(t)\vec{\mathbf{u}}(t)] &= \frac{d}{dt}[f(t)(g(t)\,\hat{\mathbf{i}} + h(t)\,\hat{\mathbf{j}})] \\ &= \frac{d}{dt}[f(t)g(t)\,\hat{\mathbf{i}} + f(t)h(t)\,\hat{\mathbf{j}}] \\ &= \frac{d}{dt}[f(t)g(t)]\,\hat{\mathbf{i}} + \frac{d}{dt}[f(t)h(t)]\,\hat{\mathbf{j}} \\ &= (f'(t)g(t) + f(t)g'(t))\,\hat{\mathbf{i}} + (f'(t)h(t) + f(t)h'(t))\,\hat{\mathbf{j}} \\ &= f'(t)\vec{\mathbf{u}}(t) + f(t)\vec{\mathbf{u}}'(t).\end{aligned}$$

To prove property iv. let $\vec{\mathbf{r}}(t) = f_1(t)\,\hat{\mathbf{i}} + g_1(t)\,\hat{\mathbf{j}}$ and $\vec{\mathbf{u}}(t) = f_2(t)\,\hat{\mathbf{i}} + g_2(t)\,\hat{\mathbf{j}}$. Then

$$\begin{aligned}\frac{d}{dt}[\vec{\mathbf{r}}(t)\cdot\vec{\mathbf{u}}(t)] &= \frac{d}{dt}[f_1(t)f_2(t) + g_1(t)g_2(t)] \\ &= f_1{}'(t)f_2(t) + f_1(t)f_2{}'(t) + g_1{}'(t)g_2(t) + g_1(t)g_2{}'(t) = f_1{}'(t)f_2(t) + g_1 \\ &\quad {}'(t)g_2(t) + f_1(t)f_2{}'(t) + g_1(t)g_2{}'(t) \\ &= (f_1{}'\,\hat{\mathbf{i}} + g_1{}'\,\hat{\mathbf{j}})\cdot(f_2\,\hat{\mathbf{i}} + g_2\,\hat{\mathbf{j}}) + (f_1\,\hat{\mathbf{i}} + g_1\,\hat{\mathbf{j}})\cdot(f_2{}'\,\hat{\mathbf{i}} + g_2{}'\,\hat{\mathbf{j}}) \\ &= \vec{\mathbf{r}}'(t)\cdot\vec{\mathbf{u}}(t) + \vec{\mathbf{r}}(t)\cdot\vec{\mathbf{u}}'(t).\end{aligned}$$

The proof of property v. is similar to that of property iv. Property vi. can be proved using the chain rule. Last, property vii. follows from property iv:

$$\begin{aligned}\frac{d}{dt}[\vec{\mathbf{r}}(t)\cdot\vec{\mathbf{r}}(t)] &= \frac{d}{dt}[c] \\ \vec{\mathbf{r}}'(t)\cdot\vec{\mathbf{r}}(t) + \vec{\mathbf{r}}(t)\cdot\vec{\mathbf{r}}'(t) &= 0 \\ 2\vec{\mathbf{r}}(t)\cdot\vec{\mathbf{r}}'(t) &= 0 \\ \vec{\mathbf{r}}(t)\cdot\vec{\mathbf{r}}'(t) &= 0\end{aligned}$$

Now for some examples using these properties.

### Example 13.3.3: Using the Properties of Derivatives of Vector-Valued Functions

Given the vector-valued functions

$$\vec{\mathbf{r}}(t) = (6t+8)\,\hat{\mathbf{i}} + (4t^2 + 2t - 3)\,\hat{\mathbf{j}} + 5t\,\hat{\mathbf{k}}$$

and

$$\vec{\mathbf{u}}(t) = (t^2 - 3)\,\hat{\mathbf{i}} + (2t+4)\,\hat{\mathbf{j}} + (t^3 - 3t)\,\hat{\mathbf{k}},$$

calculate each of the following derivatives using the properties of the derivative of vector-valued functions.

a. $\frac{d}{dt}[\vec{\mathbf{r}}(t)\cdot\vec{\mathbf{u}}(t)]$

b. $\frac{d}{dt}[\vec{\mathbf{u}}(t)\times\vec{\mathbf{u}}'(t)]$

**Solution**

We have $\vec{\mathbf{r}}'(t) = 6\,\hat{\mathbf{i}} + (8t+2)\,\hat{\mathbf{j}} + 5\,\hat{\mathbf{k}}$ and $\vec{\mathbf{u}}'(t) = 2t\,\hat{\mathbf{i}} + 2\,\hat{\mathbf{j}} + (3t^2 - 3)\,\hat{\mathbf{k}}$. Therefore, according to **property iv**:

1.
$$\begin{aligned}\frac{d}{dt}[\vec{\mathbf{r}}(t)\cdot\vec{\mathbf{u}}(t)] &= \vec{\mathbf{r}}'(t)\cdot\vec{\mathbf{u}}(t) + \vec{\mathbf{r}}(t)\cdot\vec{\mathbf{u}}'(t) \\ &= (6\,\hat{\mathbf{i}} + (8t+2)\,\hat{\mathbf{j}} + 5\,\hat{\mathbf{k}})\cdot((t^2-3)\,\hat{\mathbf{i}} + (2t+4)\,\hat{\mathbf{j}} + (t^3-3t)\,\hat{\mathbf{k}}) \\ &\quad +((6t+8)\,\hat{\mathbf{i}} + (4t^2+2t-3)\,\hat{\mathbf{j}} + 5t\,\hat{\mathbf{k}})\cdot(2t\,\hat{\mathbf{i}} + 2\,\hat{\mathbf{j}} + (3t^2-3)\,\hat{\mathbf{k}}) \\ &= 6(t^2-3) + (8t+2)(2t+4) + 5(t^3-3t) \\ &\quad +2t(6t+8) + 2(4t^2+2t-3) + 5t(3t^2-3) \\ &= 20t^3 + 42t^2 + 26t - 16.\end{aligned}$$

2. First, we need to adapt **property v** for this problem:

$$\frac{d}{dt}[\vec{\mathbf{u}}(t) \times \vec{\mathbf{u}}'(t)] = \vec{\mathbf{u}}'(t) \times \vec{\mathbf{u}}'(t) + \vec{\mathbf{u}}(t) \times \vec{\mathbf{u}}''(t).$$

Recall that the cross product of any vector with itself is zero. Furthermore, $\vec{\mathbf{u}}''(t)$ represents the second derivative of $\vec{\mathbf{u}}(t)$ :

$$\vec{\mathbf{u}}''(t) = \frac{d}{dt}[\vec{\mathbf{u}}'(t)] = \frac{d}{dt}[2t\,\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + (3t^2 - 3)\,\hat{\mathbf{k}}] = 2\,\hat{\mathbf{i}} + 6t\,\hat{\mathbf{k}}.$$

Therefore,

$$\begin{aligned}\frac{d}{dt}[\vec{\mathbf{u}}(t) \times \vec{\mathbf{u}}'(t)] &= 0 + ((t^2 - 3)\,\hat{\mathbf{i}} + (2t + 4)\,\hat{\mathbf{j}} + (t^3 - 3t)\,\hat{\mathbf{k}}) \times (2\,\hat{\mathbf{i}} + 6t\,\hat{\mathbf{k}}) \\ &= \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ t^2 - 3 & 2t + 4 & t^3 - 3t \\ 2 & 0 & 6t \end{vmatrix} \\ &= 6t(2t + 4)\,\hat{\mathbf{i}} - (6t(t^2 - 3) - 2(t^3 - 3t))\,\hat{\mathbf{j}} - 2(2t + 4)\,\hat{\mathbf{k}} \\ &= (12t^2 + 24t)\,\hat{\mathbf{i}} + (12t - 4t^3)\,\hat{\mathbf{j}} - (4t + 8)\,\hat{\mathbf{k}}.\end{aligned}$$

**? Exercise 13.3.3**

Calculate $\frac{d}{dt}[\vec{\mathbf{r}}(t) \cdot \vec{\mathbf{r}}'(t)]$ and $\frac{d}{dt}[\vec{\mathbf{u}}(t) \times \vec{\mathbf{r}}(t)]$ for the vector-valued functions:

- $\vec{\mathbf{r}}(t) = \cos t\,\hat{\mathbf{i}} + \sin t\,\hat{\mathbf{j}} - e^{2t}\hat{\mathbf{k}}$
- $\vec{\mathbf{u}}(t) = t\,\hat{\mathbf{i}} + \sin t\,\hat{\mathbf{j}} + \cos t\,\hat{\mathbf{k}}$,

**Hint**

Follow the same steps as in Example **13.3.3**.

**Answer**

$$\frac{d}{dt}[\vec{\mathbf{r}}(t) \cdot \vec{\mathbf{r}}'(t)] = 8e^{4t}$$

$$\frac{d}{dt}[\vec{\mathbf{u}}(t) \times \vec{\mathbf{r}}(t)] = -(e^{2t}(\cos t + 2\sin t) + \cos 2t)\,\hat{\mathbf{i}} + (e^{2t}(2t + 1) - \sin 2t)\,\hat{\mathbf{j}} + (t\cos t + \sin t - \cos 2t)\,\hat{\mathbf{k}}$$

## Tangent Vectors and Unit Tangent Vectors

Recall that the derivative at a point can be interpreted as the slope of the tangent line to the graph at that point. In the case of a vector-valued function, the derivative provides a tangent vector to the curve represented by the function. Consider the vector-valued function

$$\vec{\mathbf{r}}(t) = \cos t\,\hat{\mathbf{i}} + \sin t\,\hat{\mathbf{j}} \tag{13.3.2}$$

The derivative of this function is

$$\vec{\mathbf{r}}'(t) = -\sin t\,\hat{\mathbf{i}} + \cos t\,\hat{\mathbf{j}}$$

If we substitute the value $t = \pi/6$ into both functions we get

$$\vec{\mathbf{r}}\left(\frac{\pi}{6}\right) = \frac{\sqrt{3}}{2}\,\hat{\mathbf{i}} + \frac{1}{2}\,\hat{\mathbf{j}}$$

and

$$\vec{\mathbf{r}}'\left(\frac{\pi}{6}\right) = -\frac{1}{2}\,\hat{\mathbf{i}} + \frac{\sqrt{3}}{2}\,\hat{\mathbf{j}}.$$

The graph of this function appears in Figure **13.3.1**, along with the vectors $\vec{\mathbf{r}}\left(\frac{\pi}{6}\right)$ and $\vec{\mathbf{r}}'\left(\frac{\pi}{6}\right)$.

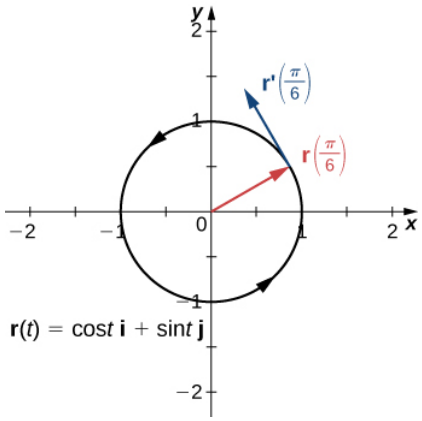

Figure **13.3.1**: The tangent line at a point is calculated from the derivative of the vector-valued function $\vec{\mathbf{r}}(t)$.

Notice that the vector $\vec{\mathbf{r}}'\left(\frac{\pi}{6}\right)$ is tangent to the circle at the point corresponding to $t = \frac{\pi}{6}$. This is an example of a tangent vector to the plane curve defined by Equation **13.3.2**.

### Definition: principal unit tangent vector

Let $C$ be a curve defined by a vector-valued function $\vec{\mathbf{r}}$, and assume that $\vec{\mathbf{r}}'(t)$ exists when $\mathbf{t} = \mathbf{t_0}$ A tangent vector $\vec{\mathbf{r}}$ at $t = t_0$ is any vector such that, when the tail of the vector is placed at point $\vec{\mathbf{r}}(t_0)$ on the graph, vector $\vec{\mathbf{r}}$ is tangent to curve $C$. Vector $\vec{\mathbf{r}}\,'(t_0)$ is an example of a tangent vector at point $t = t_0$. Furthermore, assume that $\vec{\mathbf{r}}'(t) \neq \mathbf{0}$. The principal unit tangent vector at $t$ is defined to be

$$\vec{\mathbf{T}}(t) = \frac{\vec{\mathbf{r}}'(t)}{\|\vec{\mathbf{r}}'(t)\|},$$

provided $\|\vec{\mathbf{r}}'(t)\| \neq 0$.

The unit tangent vector is exactly what it sounds like: a unit vector that is tangent to the curve. To calculate a unit tangent vector, first find the derivative $\vec{\mathbf{r}}\,'(t)$. Second, calculate the magnitude of the derivative. The third step is to divide the derivative by its magnitude.

### Example 13.3.4: Finding a Unit Tangent Vector

Find the unit tangent vector for each of the following vector-valued functions:

a. $\vec{\mathbf{r}}(t) = \cos t\,\hat{\mathbf{i}} + \sin t\,\hat{\mathbf{j}}$

b. $\vec{\mathbf{u}}(t) = (3t^2 + 2t)\,\hat{\mathbf{i}} + (2 - 4t^3)\,\hat{\mathbf{j}} + (6t + 5)\,\hat{\mathbf{k}}$

**Solution**

a.

$$\begin{aligned}
\text{First step:} \quad \vec{\mathbf{r}}'(t) &= -\sin t\,\hat{\mathbf{i}} + \cos t\,\hat{\mathbf{j}} \\
\text{Second step:} \quad \|\vec{\mathbf{r}}'(t)\| &= \sqrt{(-\sin t)^2 + (\cos t)^2} = 1 \\
\text{Third step:} \quad \vec{\mathbf{T}}(t) &= \frac{\vec{\mathbf{r}}'(t)}{\|\vec{\mathbf{r}}'(t)\|} = \frac{-\sin t\,\hat{\mathbf{i}} + \cos t\,\hat{\mathbf{j}}}{1} = -\sin t\,\hat{\mathbf{i}} + \cos t\,\hat{\mathbf{j}}
\end{aligned}$$

b.

$$\begin{aligned}
\text{First step:} \quad \vec{\mathbf{r}}'(t) &= (6t + 2)\,\hat{\mathbf{i}} - 12t^2\,\hat{\mathbf{j}} + 6\,\hat{\mathbf{k}} \\
\text{Second step:} \quad \|\vec{\mathbf{r}}'(t)\| &= \sqrt{(6t + 2)^2 + (-12t^2)^2 + 6^2} \\
&= \sqrt{144t^4 + 36t^2 + 24t + 40} \\
&= 2\sqrt{36t^4 + 9t^2 + 6t + 10} \\
\text{Third step:} \quad \vec{\mathbf{T}}(t) &= \frac{\vec{\mathbf{r}}'(t)}{\|\vec{\mathbf{r}}'(t)\|} = \frac{(6t + 2)\,\hat{\mathbf{i}} - 12t^2\,\hat{\mathbf{j}} + 6\,\hat{\mathbf{k}}}{2\sqrt{36t^4 + 9t^2 + 6t + 10}} \\
&= \frac{3t + 1}{\sqrt{36t^4 + 9t^2 + 6t + 10}}\,\hat{\mathbf{i}} - \frac{6t^2}{\sqrt{36t^4 + 9t^2 + 6t + 10}}\,\hat{\mathbf{j}} + \frac{3}{\sqrt{36t^4 + 9t^2 + 6t + 10}}\,\hat{\mathbf{k}}
\end{aligned}$$

**Exercise 13.3.4**

Find the unit tangent vector for the vector-valued function

$$\vec{\mathbf{r}}(t) = (t^2 - 3)\,\hat{\mathbf{i}} + (2t + 1)\,\hat{\mathbf{j}} + (t - 2)\,\hat{\mathbf{k}}.$$

**Hint**

Follow the same steps as in Example **13.3.4**.

**Answer**

$$\vec{\mathbf{T}}(t) = \frac{2t}{\sqrt{4t^2 + 5}}\,\hat{\mathbf{i}} + \frac{2}{\sqrt{4t^2 + 5}}\,\hat{\mathbf{j}} + \frac{1}{\sqrt{4t^2 + 5}}\,\hat{\mathbf{k}}$$

## Integrals of Vector-Valued Functions

We introduced antiderivatives of real-valued functions in Antiderivatives and definite integrals of real-valued functions in The Definite Integral. Each of these concepts can be extended to vector-valued functions. Also, just as we can calculate the derivative of a vector-valued function by differentiating the component functions separately, we can calculate the antiderivative in the same manner. Furthermore, the Fundamental Theorem of Calculus applies to vector-valued functions as well.

The antiderivative of a vector-valued function appears in applications. For example, if a vector-valued function represents the velocity of an object at time $t$, then its antiderivative represents position. Or, if the function represents the acceleration of the object at a given time, then the antiderivative represents its velocity.

**Definition: Definite and Indefinite Integrals of Vector-Valued Functions**

Let $f$, $g$, and $h$ be integrable real-valued functions over the closed interval $[a, b]$.

1. The indefinite integral of a vector-valued function $\vec{\mathbf{r}}(t) = f(t)\,\hat{\mathbf{i}} + g(t)\,\hat{\mathbf{j}}$ is

$$\int [f(t)\,\hat{\mathbf{i}} + g(t)\,\hat{\mathbf{j}}]\,dt = \left[\int f(t)\,dt\right]\hat{\mathbf{i}} + \left[\int g(t)\,dt\right]\hat{\mathbf{j}}.$$

   The definite integral of a vector-valued function is

$$\int_a^b [f(t)\,\hat{\mathbf{i}} + g(t)\,\hat{\mathbf{j}}]\,dt = \left[\int_a^b f(t)\,dt\right]\hat{\mathbf{i}} + \left[\int_a^b g(t)\,dt\right]\hat{\mathbf{j}}.$$

2. The indefinite integral of a vector-valued function $\vec{\mathbf{r}}(t) = f(t)\,\hat{\mathbf{i}} + g(t)\,\hat{\mathbf{j}} + h(t)\,\hat{\mathbf{k}}$ is

$$\int [f(t)\,\hat{\mathbf{i}} + g(t)\,\hat{\mathbf{j}} + h(t)\,\hat{\mathbf{k}}]\,dt = \left[\int f(t)\,dt\right]\hat{\mathbf{i}} + \left[\int g(t)\,dt\right]\hat{\mathbf{j}} + \left[\int h(t)\,dt\right]\hat{\mathbf{k}}.$$

   The definite integral of the vector-valued function is

$$\int_a^b [f(t)\,\hat{\mathbf{i}} + g(t)\,\hat{\mathbf{j}} + h(t)\,\hat{\mathbf{k}}]\,dt = \left[\int_a^b f(t)\,dt\right]\hat{\mathbf{i}} + \left[\int_a^b g(t)\,dt\right]\hat{\mathbf{j}} + \left[\int_a^b h(t)\,dt\right]\hat{\mathbf{k}}.$$

Since the indefinite integral of a vector-valued function involves indefinite integrals of the component functions, each of these component integrals contains an integration constant. They can all be different. For example, in the two-dimensional case, we can have

$$\int f(t)\,dt = F(t) + C_1 \text{ and } \int g(t)\,dt = G(t) + C_2,$$

where $F$ and $G$ are antiderivatives of $f$ and $g$, respectively. Then

$$\begin{aligned}\int [f(t)\,\hat{\mathbf{i}} + g(t)\,\hat{\mathbf{j}}]\,dt &= \left[\int f(t)\,dt\right]\hat{\mathbf{i}} + \left[\int g(t)\,dt\right]\hat{\mathbf{j}} \\ &= (F(t)+C_1)\,\hat{\mathbf{i}} + (G(t)+C_2)\,\hat{\mathbf{j}} \\ &= F(t)\,\hat{\mathbf{i}} + G(t)\,\hat{\mathbf{j}} + C_1\,\hat{\mathbf{i}} + C_2\,\hat{\mathbf{j}} \\ &= F(t)\,\hat{\mathbf{i}} + G(t)\,\hat{\mathbf{j}} + \vec{\mathbf{C}}\end{aligned}$$

where $\vec{\mathbf{C}} = C_1\,\hat{\mathbf{i}} + C_2\,\hat{\mathbf{j}}$. Therefore, the *integration constants* becomes a *constant vector*.

### Example 13.3.5: Integrating Vector-Valued Functions

Calculate each of the following integrals:

a. $\int [(3t^2+2t)\,\hat{\mathbf{i}} + (3t-6)\,\hat{\mathbf{j}} + (6t^3+5t^2-4)\,\hat{\mathbf{k}}]\,dt$

b. $\int [\langle t, t^2, t^3\rangle \times \langle t^3, t^2, t\rangle]\,dt$

c. $\int_0^{\frac{\pi}{3}} [\sin 2t\,\hat{\mathbf{i}} + \tan t\,\hat{\mathbf{j}} + e^{-2t}\,\hat{\mathbf{k}}]\,dt$

**Solution**

a. We use the first part of the definition of the integral of a space curve:

$$\begin{aligned}\int [(3t^2+2t)\,\hat{\mathbf{i}} + (3t-6)\,\hat{\mathbf{j}} + (6t^3+5t^2-4)\,\hat{\mathbf{k}}]\,dt &= \left[\int 3t^2+2t\,dt\right]\hat{\mathbf{i}} + \left[\int 3t-6\,dt\right]\hat{\mathbf{j}} \\ &\quad + \left[\int 6t^3+5t^2-4\,dt\right]\hat{\mathbf{k}} \\ &= (t^3+t^2)\,\hat{\mathbf{i}} + \left(\frac{3}{2}t^2-6t\right)\hat{\mathbf{j}} \\ &\quad + \left(\frac{3}{2}t^4+\frac{5}{3}t^3-4t\right)\hat{\mathbf{k}} + \vec{\mathbf{C}}.\end{aligned}$$

b.

c. First calculate $\langle t, t^2, t^3\rangle \times \langle t^3, t^2, t\rangle$ :

$$\begin{aligned}\langle t, t^2, t^3\rangle \times \langle t^3, t^2, t\rangle &= \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ t & t^2 & t^3 \\ t^3 & t^2 & t \end{vmatrix} \\ &= (t^2(t) - t^3(t^2))\,\hat{\mathbf{i}} - (t^2 - t^3(t^3))\,\hat{\mathbf{j}} + (t(t^2) - t^2(t^3))\,\hat{\mathbf{k}} \\ &= (t^3 - t^5)\,\hat{\mathbf{i}} + (t^6 - t^2)\,\hat{\mathbf{j}} + (t^3 - t^5)\,\hat{\mathbf{k}}.\end{aligned}$$

Next, substitute this back into the integral and integrate:

$$\begin{aligned}\int [\langle t, t^2, t^3\rangle \times \langle t^3, t^2, t\rangle]\,dt &= \int (t^3 - t^5)\,\hat{\mathbf{i}} + (t^6 - t^2)\,\hat{\mathbf{j}} + (t^3 - t^5)\,\hat{\mathbf{k}}\,dt \\ &= \left(\frac{t^4}{4} - \frac{t^6}{6}\right)\hat{\mathbf{i}} + \left(\frac{t^7}{7} - \frac{t^3}{3}\right)\hat{\mathbf{j}} + \left(\frac{t^4}{4} - \frac{t^6}{6}\right)\hat{\mathbf{k}} + \vec{\mathbf{C}}.\end{aligned}$$

d. Use the second part of the definition of the integral of a space curve:

$$\begin{aligned}\int_0^{\frac{\pi}{3}} [\sin 2t\,\hat{\mathbf{i}} + \tan t\,\hat{\mathbf{j}} + e^{-2t}\,\hat{\mathbf{k}}]\,dt &= \left[\int_0^{\frac{\pi}{3}} \sin 2t\,dt\right]\hat{\mathbf{i}} + \left[\int_0^{\frac{\pi}{3}} \tan t\,dt\right]\hat{\mathbf{j}} + \left[\int_0^{\frac{\pi}{3}} e^{-2t}\,dt\right]\hat{\mathbf{k}} \\ &= \left(-\tfrac{1}{2}\cos 2t\right)\Big|_0^{\pi/3}\hat{\mathbf{i}} - \left(\ln|\cos t|\right)\Big|_0^{\pi/3}\hat{\mathbf{j}} - \left(\tfrac{1}{2}e^{-2t}\right)\Big|_0^{\pi/3}\hat{\mathbf{k}} \\ &= \left(-\tfrac{1}{2}\cos\tfrac{2\pi}{3} + \tfrac{1}{2}\cos 0\right)\hat{\mathbf{i}} - \left(\ln\left(\cos\tfrac{\pi}{3}\right) - \ln(\cos 0)\right)\hat{\mathbf{j}} \\ &\quad - \left(\tfrac{1}{2}e^{-2\pi/3} - \tfrac{1}{2}e^{-2(0)}\right)\hat{\mathbf{k}} \\ &= \left(\tfrac{1}{4} + \tfrac{1}{2}\right)\hat{\mathbf{i}} - (-\ln 2)\,\hat{\mathbf{j}} - \left(\tfrac{1}{2}e^{-2\pi/3} - \tfrac{1}{2}\right)\hat{\mathbf{k}} \\ &= \tfrac{3}{4}\,\hat{\mathbf{i}} + (\ln 2)\,\hat{\mathbf{j}} + \left(\tfrac{1}{2} - \tfrac{1}{2}e^{-2\pi/3}\right)\hat{\mathbf{k}}.\end{aligned}$$

**? Exercise 13.3.5**

Calculate the following integral:

$$\int_1^3 [(2t+4)\,\hat{\mathbf{i}} + (3t^2-4t)\,\hat{\mathbf{j}}]\,dt$$

**Hint**

Use the definition of the definite integral of a plane curve.

**Answer**

$$\int_1^3 [(2t+4)\,\hat{\mathbf{i}} + (3t^2-4t)\,\hat{\mathbf{j}}]\,dt = 16\,\hat{\mathbf{i}} + 10\,\hat{\mathbf{j}}$$

## Summary

- To calculate the derivative of a vector-valued function, calculate the derivatives of the component functions, then put them back into a new vector-valued function.
- Many of the properties of differentiation of scalar functions also apply to vector-valued functions.
- The derivative of a vector-valued function $\vec{\mathbf{r}}(t)$ is also a tangent vector to the curve. The unit tangent vector $\vec{\mathbf{T}}(t)$ is calculated by dividing the derivative of a vector-valued function by its magnitude.
- The antiderivative of a vector-valued function is found by finding the antiderivatives of the component functions, then putting them back together in a vector-valued function.
- The definite integral of a vector-valued function is found by finding the definite integrals of the component functions, then putting them back together in a vector-valued function.

## Key Equations

- **Derivative of a vector-valued function**

$$\vec{\mathbf{r}}'(t) = \lim_{\Delta t \to 0} \frac{\vec{\mathbf{r}}(t+\Delta t) - \vec{\mathbf{r}}(t)}{\Delta t}$$

- **Principal unit tangent vector**

$$\vec{\mathbf{T}}(t) = \frac{\vec{\mathbf{r}}'(t)}{\|\vec{\mathbf{r}}'(t)\|}$$

- **Indefinite integral of a vector-valued function**

$$\int [f(t)\,\hat{\mathbf{i}} + g(t)\,\hat{\mathbf{j}} + h(t)\,\hat{\mathbf{k}}]\,dt = \left[\int f(t)\,dt\right]\hat{\mathbf{i}} + \left[\int g(t)\,dt\right]\hat{\mathbf{j}} + \left[\int h(t)\,dt\right]\hat{\mathbf{k}}$$

- **Definite integral of a vector-valued function**

$$\int_a^b [f(t)\,\hat{\mathbf{i}} + g(t)\,\hat{\mathbf{j}} + h(t)\,\hat{\mathbf{k}}]\,dt = \left[\int_a^b f(t)\,dt\right]\hat{\mathbf{i}} + \left[\int_a^b g(t)\,dt\right]\hat{\mathbf{j}} + \left[\int_a^b h(t)\,dt\right]\hat{\mathbf{k}}$$

## Glossary

**definite integral of a vector-valued function**

the vector obtained by calculating the definite integral of each of the component functions of a given vector-valued function, then using the results as the components of the resulting function

**derivative of a vector-valued function**

the derivative of a vector-valued function $\vec{\mathbf{r}}(t)$ is $\vec{\mathbf{r}}'(t) = \lim_{\Delta t \to 0} \frac{\vec{\mathbf{r}}(t+\Delta t) - \vec{\mathbf{r}}(t)}{\Delta t}$, provided the limit exists

**indefinite integral of a vector-valued function**

a vector-valued function with a derivative that is equal to a given vector-valued function

**principal unit tangent vector**

a unit vector tangent to a curve $C$

**tangent vector**

to $\vec{\mathbf{r}}(t)$ at $t = t_0$ any vector $\vec{\mathbf{v}}$ such that, when the tail of the vector is placed at point $\vec{\mathbf{r}}(t_0)$ on the graph, vector $\vec{\mathbf{v}}$ is tangent to curve $C$

# 13.3E: EXERCISES FOR SECTION 13.2

## TAKING DERIVATIVES OF VECTOR-VALUED FUNCTIONS

**In questions 1 - 10, compute the derivative of each vector-valued function.**

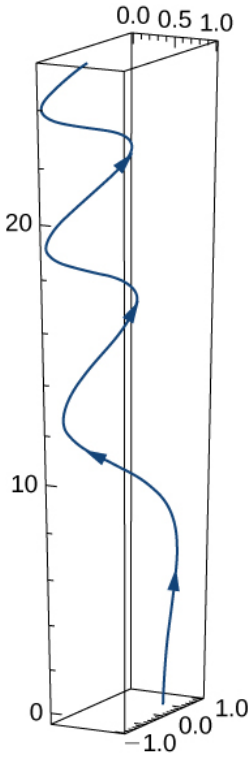
1) $\vec{\mathbf{r}}(t) = t^3\,\hat{\mathbf{i}} + 3t^2\,\hat{\mathbf{j}} + \frac{t^3}{6}\,\hat{\mathbf{k}}$

**Answer**

$\vec{\mathbf{r}}'(t) = 3t^2\,\hat{\mathbf{i}} + 6t\,\hat{\mathbf{j}} + \frac{1}{2}t^2\,\hat{\mathbf{k}}$

2) $\vec{\mathbf{r}}(t) = \sin(t)\,\hat{\mathbf{i}} + \cos(t)\,\hat{\mathbf{j}} + e^t\,\hat{\mathbf{k}}$

3) $\vec{\mathbf{r}}(t) = e^{-t}\,\hat{\mathbf{i}} + \sin(3t)\,\hat{\mathbf{j}} + 10\sqrt{t}\,\hat{\mathbf{k}}$. A sketch of the graph is shown here. Notice the varying periodic nature of the graph.



**Answer**

$\vec{\mathbf{r}}'(t) = -e^{-t}\,\hat{\mathbf{i}} + 3\cos(3t)\,\hat{\mathbf{j}} + \frac{5}{\sqrt{t}}\,\hat{\mathbf{k}}$

4) $\vec{\mathbf{r}}(t) = e^t\,\hat{\mathbf{i}} + 2e^t\,\hat{\mathbf{j}} + \hat{\mathbf{k}}$

5) $\vec{\mathbf{r}}(t) = \hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}$

**Answer**

$\vec{\mathbf{r}}'(t) = \langle 0, 0, 0\rangle = \vec{\mathbf{0}}$

6) $\vec{\mathbf{r}}(t) = te^t\,\hat{\mathbf{i}} + t\ln(t)\,\hat{\mathbf{j}} + \sin(3t)\,\hat{\mathbf{k}}$

7) $\vec{\mathbf{r}}(t) = \left\langle \frac{1}{t+1}, \arctan(t), \ln t^3 \right\rangle$

**Answer**

$\vec{\mathbf{r}}'(t) = \langle \frac{-1}{(t+1)^2}, \frac{1}{1+t^2}, \frac{3}{t}\rangle$

8) $\vec{\mathbf{r}}(t) = \langle \tan 2t,\ \sec 2t,\ \sin^2 t\rangle$

https://math.libretexts.org/@go/page/175741

9) $\vec{\mathbf{r}}(t) = \langle 3,\ 4\sin(3t),\ t\cos(t)\rangle$

**Answer**

$\vec{\mathbf{r}}'(t) = \langle 0, 12\cos(3t), \cos t - t\sin t\rangle$

10) $\vec{\mathbf{r}}(t) = t^2\,\hat{\mathbf{i}} + te^{-2t}\,\hat{\mathbf{j}} - 5e^{-4t}\,\hat{\mathbf{k}}$

11) a. Describe and sketch the curve represented by the vector-valued function $\vec{\mathbf{r}}(t) = \langle 6t, 6t - t^2\rangle$.

b. Locate the highest point on the curve $\vec{\mathbf{r}}(t) = \langle 6t, 6t - t^2\rangle$ and give the value of the function at this point.

**Answer**

b. $\vec{\mathbf{r}}(t) = \langle 18, 9\rangle$ at $t = 3$

12) Find the parametric equations of the tangent line to the curve $\vec{\mathbf{r}}(t) = \langle t, t^2, t\rangle$ at $t = 2$.

13) Find the parametric equations of the tangent line to the curve $\vec{\mathbf{r}}(t) = \langle e^t, e^{-t}, 0\rangle$ at $t = 0$.

**Answer**

$x = 1 + t, \quad y = 1 - t, \quad z = 0$

14) Compute the first, second, and third derivatives of $\vec{\mathbf{r}}(t) = 3t\,\hat{\mathbf{i}} + 6\ln(t)\,\hat{\mathbf{j}} + 5e^{-3t}\,\hat{\mathbf{k}}$.

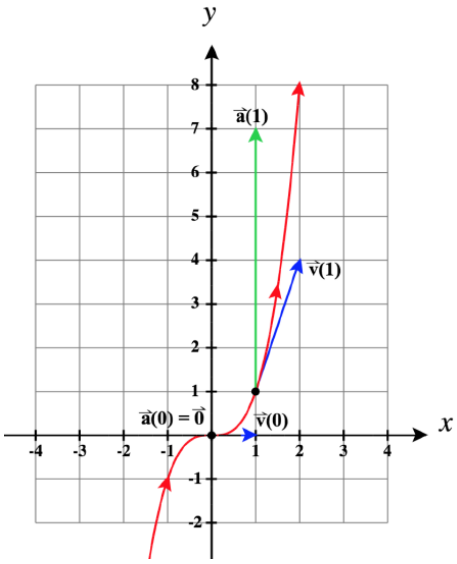
## DESCRIBING MOTION WITH VECTOR-VALUED FUNCTIONS

**In questions 15 - 17, find the velocity and acceleration at the given times, plot the graph of the position function, and draw in the velocity and acceleration vectors at the corresponding locations on the curve.**

15) $\vec{\mathbf{r}}(t) = t\,\hat{\mathbf{i}} + t^3\,\hat{\mathbf{j}}$, at $t = 0$ and at $t = 1$

**Answer**

| | $t = 0$: | $t = 1$: |
|---|---|---|
| $\vec{\mathbf{r}}(t) = t\,\hat{\mathbf{i}} + t^3\,\hat{\mathbf{j}}$, | $\vec{\mathbf{r}}(0) = \vec{\mathbf{0}}$, | $\vec{\mathbf{r}}(1) = \hat{\mathbf{i}} + \hat{\mathbf{j}}$ |
| $\vec{\mathbf{v}}(t) = \hat{\mathbf{i}} + 3t^2\,\hat{\mathbf{j}}$, | $\vec{\mathbf{v}}(0) = \hat{\mathbf{i}}$, | $\vec{\mathbf{v}}(1) = \hat{\mathbf{i}} + 3\,\hat{\mathbf{j}}$ |
| $\vec{\mathbf{a}}(t) = 6t\,\hat{\mathbf{j}}$, | $\vec{\mathbf{a}}(0) = \vec{\mathbf{0}}$, | $\vec{\mathbf{a}}(1) = 6\,\hat{\mathbf{j}}$ |

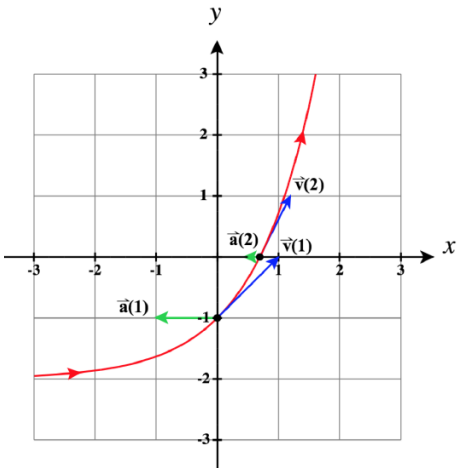


16) $\vec{\mathbf{r}}(t) = \cos t\,\hat{\mathbf{i}} + \sin 3t\,\hat{\mathbf{j}}$, at $t = 0$, at $t = \frac{\pi}{4}$, and at $t = \frac{\pi}{2}$

17) $\vec{\mathbf{r}}(t) = \ln t\,\hat{\mathbf{i}} + (t-2)\,\hat{\mathbf{j}}$, at $t = 1$ and at $t = 2$

**Answer**

| | $t=1:$ | $t=2:$ |
|---|---|---|
| $\vec{\mathbf{r}}(t)=(\ln t)\,\hat{\mathbf{i}}+(t-2)\,\hat{\mathbf{j}},$ | $\vec{\mathbf{r}}(1)=-\hat{\mathbf{j}},$ | $\vec{\mathbf{r}}(2)=(\ln 2)\,\hat{\mathbf{i}}$ |
| $\vec{\mathbf{v}}(t)=\frac{1}{t}\,\hat{\mathbf{i}}+\hat{\mathbf{j}},$ | $\vec{\mathbf{v}}(1)=\hat{\mathbf{i}}+\hat{\mathbf{j}},$ | $\vec{\mathbf{v}}(2)=\frac{1}{2}\hat{\mathbf{i}}+\hat{\mathbf{j}}$ |
| $\vec{\mathbf{a}}(t)=-\frac{1}{t^2}\,\hat{\mathbf{i}},$ | $\vec{\mathbf{a}}(1)=-\hat{\mathbf{i}},$ | $\vec{\mathbf{a}}(2)=-\frac{1}{4}\,\hat{\mathbf{i}}$ |



**In questions 18 - 24, find the velocity, speed, and acceleration of a particle with the given position function. Remember that the speed is the magnitude of the velocity represented by $\|\vec{\mathbf{v}}(t)\|$ or $\|\vec{\mathbf{r}}'(t)\|$.**

18) $\vec{\mathbf{r}}(t)=e^{2t}\,\hat{\mathbf{i}}+\sin t\,\hat{\mathbf{j}}$

19) $\vec{\mathbf{r}}(t)=\cos t^3\,\hat{\mathbf{i}}+\sin t^3\,\hat{\mathbf{j}}$

**Answer**

$\vec{\mathbf{v}}(t)=-3t^2\sin t^3\,\hat{\mathbf{i}}+3t^2\cos t^3\,\hat{\mathbf{j}},\quad \text{speed}(t)=\|\vec{\mathbf{v}}(t)\|=3t^2,\quad \vec{\mathbf{a}}(t)=\left(-6t\sin t^3-9t^4\cos t^3\right)\hat{\mathbf{i}}+\left(6t\cos t^3-9t^4\sin t^3\right)\hat{\mathbf{j}}$

20) $\vec{\mathbf{r}}(t)=\langle e^t,e^{-t},0\rangle$

21) $\vec{\mathbf{r}}(t)=\langle t+\cos t,t-\sin t\rangle$

**Answer**

$\vec{\mathbf{v}}(t)=\langle 1-\sin t,1-\cos t\rangle,\quad \text{speed}(t)=\|\vec{\mathbf{v}}(t)\|=\sqrt{3-2(\sin t+\cos t)},\quad \vec{\mathbf{a}}(t)=\langle-\cos t,\sin t\rangle$

22) $\vec{\mathbf{r}}(t)=\dfrac{2t-1}{2t+1}\,\hat{\mathbf{i}}+\ln(1-4t^2)\,\hat{\mathbf{j}}$

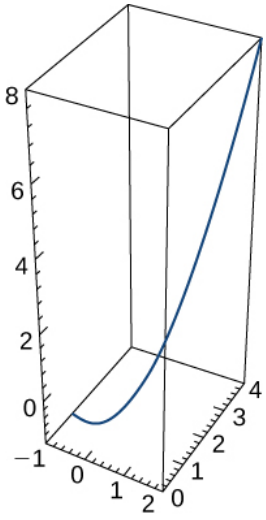
23) $\vec{\mathbf{r}}(t)=\cos 3t\,\hat{\mathbf{i}}+\sin 3t\,\hat{\mathbf{j}}+0.5t\,\hat{\mathbf{k}}$

**Answer**

$\vec{\mathbf{v}}(t)=-3\sin 3t\,\hat{\mathbf{i}}+3\cos 3t\,\hat{\mathbf{j}}+0.5\,\hat{\mathbf{k}},\quad \text{speed}(t)=\|\vec{\mathbf{v}}(t)\|=\sqrt{9.25}\text{ units/sec},\quad \vec{\mathbf{a}}(t)=-9\cos 3t\,\hat{\mathbf{i}}-9\sin 3t\,\hat{\mathbf{j}}$

24) $\vec{\mathbf{r}}(t)=e^{-t}\,\hat{\mathbf{i}}+(\ln t)\,\hat{\mathbf{j}}+(\sin 7t)\,\hat{\mathbf{k}}$

25) Consider the position vector for a particle to be $\vec{\mathbf{r}}(t)=t\,\hat{\mathbf{i}}+t^2\,\hat{\mathbf{j}}+t^3\,\hat{\mathbf{k}}$. The graph is shown here:



a. Find the velocity vector at any time.

b. Find the speed of the particle at time $t = 2$ sec.

c. Find the acceleration at time $t = 2$ sec.

**Answer**

a. $\vec{\mathbf{v}}(t) = \hat{\mathbf{i}} + 2t\hat{\mathbf{j}} + 3t^2\hat{\mathbf{k}}$

b. $\sqrt{161}$ units/sec

Note that $\text{speed}(t) = \|\vec{\mathbf{v}}(t)\| = \sqrt{1^2 + (2t)^2 + (3t^2)^2} = \sqrt{1 + 4t^2 + 9t^4}$.

Hence, $\text{speed}(2) = \sqrt{1 + 16 + 9(16)} = \sqrt{161}$ units/sec.

c. Since $\vec{\mathbf{a}}(t) = 2\hat{\mathbf{j}} + 6t\hat{\mathbf{k}}$, $\vec{\mathbf{a}}(2) = 2\hat{\mathbf{j}} + 12\hat{\mathbf{k}}$

26) A particle travels along the path of an ellipse with the equation $\vec{\mathbf{r}}(t) = \cos t\,\hat{\mathbf{i}} + 2\sin t\,\hat{\mathbf{j}} + 0\hat{\mathbf{k}}$. Find the following:

a. Velocity of the particle

**Answer**

$\vec{\mathbf{v}}(t) = \langle -\sin t, 2\cos t, 0\rangle$

b. Speed of the particle at $t = \frac{\pi}{4}$

c. Acceleration of the particle at $t = \frac{\pi}{4}$

**Answer**

$\vec{\mathbf{a}}(t) = \langle -\frac{\sqrt{2}}{2}, -\sqrt{2}, 0\rangle$

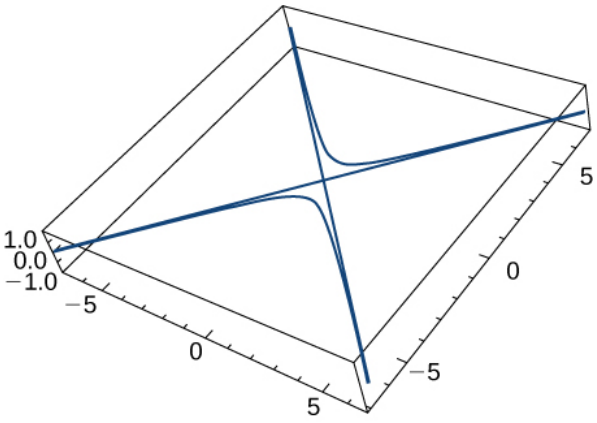
27) Show that if the speed of a particle traveling along a curve represented by a vector-valued function is constant, then the velocity function is always perpendicular to the acceleration function.

**Answer**

$$\begin{aligned} \|\vec{\mathbf{v}}(t)\| &= k \\ \vec{\mathbf{v}}(t)\cdot\vec{\mathbf{v}}(t) &= k^2 \\ \frac{d}{dt}\left(\vec{\mathbf{v}}(t)\cdot\vec{\mathbf{v}}(t)\right) &= \frac{d}{dt}\left(k^2\right) = 0 \\ \vec{\mathbf{v}}(t)\cdot\vec{\mathbf{v}}'(t) + \vec{\mathbf{v}}'(t)\cdot\vec{\mathbf{v}}(t) &= 0 \\ 2\vec{\mathbf{v}}(t)\cdot\vec{\mathbf{v}}'(t) &= 0 \\ \vec{\mathbf{v}}(t)\cdot\vec{\mathbf{v}}'(t) &= 0 \end{aligned}$$

The last statement implies that the velocity and acceleration are perpendicular or orthogonal.

28) Given the vector-valued function $\vec{\mathbf{r}}(t) = \langle \tan t, \sec t, 0\rangle$ (graph is shown here), find the following:



a. Velocity

**Answer**

$\vec{\mathbf{v}}(t) = \langle \sec^2 t,\ \sec t \tan t \rangle$

b. Speed

**Answer**

$\|\vec{\mathbf{v}}(t)\| = \sqrt{\sec^4 t + \sec^2 t \tan^2 t} = \sqrt{(\sec^2 t)(\sec^2 t + \tan^2 t)}$

c. Acceleration

**Answer**

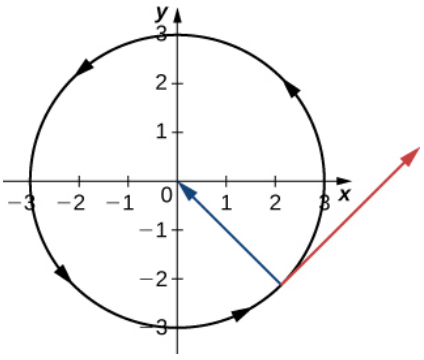
$\vec{\mathbf{a}}(t) = \langle 2\sec^2 t \tan t,\ \sec t \tan^2 t + \sec^3 t \rangle$

29) Find the minimum speed of a particle traveling along the curve $\vec{\mathbf{r}}(t) = \langle t + \cos t, t - \sin t \rangle$, where $t \in [0, 2\pi)$. Then also find its maximum speed on this interval.

**Answer**

Min. speed is $\sqrt{3 - 2\sqrt{2}} \approx 0.41421$ when $t = \frac{\pi}{4}$.
Max. speed is $\sqrt{3 + 2\sqrt{2}} \approx 2.41421$ when $t = \frac{5\pi}{4}$.

**For questions 30 - 31, consider a particle that moves on a circular path of radius $b$ according to the function $\vec{\mathbf{r}}(t) = b\cos(\omega t)\,\hat{\mathbf{i}} + b\sin(\omega t)\,\hat{\mathbf{j}}$, where $\omega$ is the angular velocity, $\frac{d\theta}{dt}$.**



30) Show that the speed of the particle is proportional to the angular velocity.

31) Find the velocity function and show that $\vec{\mathbf{v}}(t)$ is always orthogonal to $\vec{\mathbf{r}}(t)$.

**Answer**

$\vec{\mathbf{r}}'(t) = -b\omega\sin(\omega t)\,\hat{\mathbf{i}} + b\omega\cos(\omega t)\,\hat{\mathbf{j}}$. To show orthogonality, note that $\vec{\mathbf{r}}'(t) \cdot \vec{\mathbf{r}}(t) = 0$.

## SMOOTHNESS OF VECTOR-VALUED FUNCTIONS

**For questions 32 - 40,**

**a. Determine any values of $t$ at which $\vec{\mathbf{r}}$ is not smooth.**

**b. Determine the open intervals on which $\vec{\mathbf{r}}$ is smooth.**

**c. Graph the vector-valued function and describe its behavior at the points where it is not smooth.**

32) $\vec{\mathbf{r}}(t) = \langle 3t, 5t^2 - 1 \rangle$

33) $\vec{\mathbf{r}}(t) = t^3\,\hat{\mathbf{i}} + 5t^2\,\hat{\mathbf{j}}$

**Answer**

a. $\vec{\mathbf{r}}$ is not smooth at $t = 0$, since $\vec{\mathbf{r}}'(0) = \vec{\mathbf{0}}$.
b. $\vec{\mathbf{r}}$ is smooth on the open intervals $(-\infty, 0)$ and $(0, \infty)$.
c. There is a cusp when $t = 0$.

34) $\vec{\mathbf{r}}(t) = \langle 5,\ 2\sin(t),\ \cos(t) \rangle$

35) $\vec{\mathbf{r}}(t) = \langle t^3 - 3t^2, 7 \rangle$

**Answer**

a. $\vec{\mathbf{r}}$ is not smooth at $t = 0$ and $t = 2$, since $\vec{\mathbf{r}}'(0) = \vec{\mathbf{0}}$ and $\vec{\mathbf{r}}'(2) = \vec{\mathbf{0}}$.
b. $\vec{\mathbf{r}}$ is smooth on the open intervals $(-\infty, 0)$, $(0, 2)$, and $(2, \infty)$.
c. The motion on the curve reverses along the same path at both $t = 0$ and $t = 2$.

36) $\vec{\mathbf{r}}(t) = t^2\,\hat{\mathbf{i}} + t^3\,\hat{\mathbf{j}} - 5e^{-4t}\,\hat{\mathbf{k}}$

37) $\vec{\mathbf{r}}(t) = \left\langle \ln(t^2 + 4t + 5),\ \dfrac{t^3}{3} - 4t,\ 5 \right\rangle$

**Answer**

a. $\vec{\mathbf{r}}$ is not smooth at $t = -2$, since $\vec{\mathbf{r}}'(-2) = \vec{\mathbf{0}}$.
Since the domain of $\vec{\mathbf{r}}$ is $(-\infty, \infty)$, this is all we have to remove.
b. $\vec{\mathbf{r}}$ is smooth on the open intervals $(-\infty, -2)$ and $(-2, \infty)$.
c. There is a cusp when $t = -2$.

38) $\vec{\mathbf{r}}(t) = (5\cos t - \cos 5t)\,\hat{\mathbf{i}} + (5\sin t - \sin 5t)\,\hat{\mathbf{j}}$, for $0 \le t \le 2\pi$

39) $\vec{\mathbf{r}}(t) = \sqrt{t^3 + 9t^2}\,\hat{\mathbf{i}} + (t^2 + 12t)\,\hat{\mathbf{j}} + 7\hat{\mathbf{k}}$

**Answer**

a. The domain of $\vec{\mathbf{r}}$ is $[-9, \infty)$.
And $\vec{\mathbf{r}}$ is not smooth at $t = -6$, since $\vec{\mathbf{r}}'(-6) = \vec{\mathbf{0}}$.
The domain of $\vec{\mathbf{r}}'$ is $(-9, \infty)$, since $\vec{\mathbf{r}}'$ is undefined at $t = -9$.
b. $\vec{\mathbf{r}}$ is smooth on the open intervals $(-9, -6)$ and $(-6, \infty)$.
c. There is a cusp when $t = -6$.

40) $\vec{\mathbf{r}}(t) = \cos^3 t\,\hat{\mathbf{i}} + \sin t\,\hat{\mathbf{j}}$, for $0 \le t \le 2\pi$

**Answer**

a. The domain of $\vec{\mathbf{r}}$ is $(-\infty, \infty)$.
$\vec{\mathbf{r}}'(t) = -3(\cos^2 t)(\sin t)\,\hat{\mathbf{i}} + \cos t\,\hat{\mathbf{j}}$. It's domain is also $(-\infty, \infty)$.
But note that both components have a factor of $\cos t$, so both components will be $0$ when $\cos t = 0$.
Therefore, $\vec{\mathbf{r}}$ is not smooth at $t = \frac{\pi}{2}$ and at $t = \frac{3\pi}{2}$, since $\vec{\mathbf{r}}'\left(\frac{\pi}{2}\right) = \vec{\mathbf{0}}$ and $\vec{\mathbf{r}}'\left(\frac{3\pi}{2}\right) = \vec{\mathbf{0}}$. Note then that $\vec{\mathbf{r}}$ is not smooth for any odd multiple of $\frac{\pi}{2}$, that is for $t = \frac{(2n+1)\pi}{2}$, for any integer value $n$.
b. $\vec{\mathbf{r}}$ is smooth on the open intervals $\left(\dfrac{(2n-1)\pi}{2}, \dfrac{(2n+1)\pi}{2}\right)$, for any integer value $n$.
c. There is a cusp when $t = \dfrac{(2n+1)\pi}{2}$, for any integer value $n$.

https://math.libretexts.org/@go/page/175741

## PROPERTIES OF THE DERIVATIVE

**For questions, 41 - 43, evaluate each expression given that $\vec{\mathbf{r}}(t) = t\,\hat{\mathbf{i}} + t^2\,\hat{\mathbf{j}} - t^4\,\hat{\mathbf{k}}$ and $\vec{\mathbf{s}}(t) = \sin(t)\,\hat{\mathbf{i}} + e^t\,\hat{\mathbf{j}} + \cos(t)\,\hat{\mathbf{k}}$**

41) $\frac{d}{dt}\left[\vec{\mathbf{r}}(t^2)\right]$

**Answer**

$\frac{d}{dt}\left[\vec{\mathbf{r}}(t^2)\right] = \langle 2t, 4t^3, -8t^7\rangle$

42) $\frac{d}{dt}\left[t^2 \cdot \vec{\mathbf{s}}(t)\right]$

43) $\frac{d}{dt}\left[\vec{\mathbf{r}}(t) \cdot \vec{\mathbf{s}}(t)\right]$

**Answer**

$\frac{d}{dt}\left[\vec{\mathbf{r}}(t) \cdot \vec{\mathbf{s}}(t)\right] = \sin t + 2te^t - 4t^3\cos t + t\cos t + t^2e^t + t^4\sin t$

44) Find $\vec{\mathbf{r}}'(t) \cdot \vec{\mathbf{r}}''(t)$ *for* $\vec{\mathbf{r}}(t) = -3t^5\,\hat{\mathbf{i}} + 5t\,\hat{\mathbf{j}} + 2t^2\,\hat{\mathbf{k}}$.

**Answer**

$\vec{\mathbf{r}}'(t) \cdot \vec{\mathbf{r}}''(t) = 900t^7 + 16t$

45) Given $\vec{\mathbf{r}}(t) = t\,\hat{\mathbf{i}} + 3t\,\hat{\mathbf{j}} + t^2\,\hat{\mathbf{k}}$ and $\vec{\mathbf{u}}(t) = 4t\,\hat{\mathbf{i}} + t^2\,\hat{\mathbf{j}} + t^3\,\hat{\mathbf{k}}$, find $\frac{d}{dt}(\vec{\mathbf{r}}(t) \times \vec{\mathbf{u}}(t))$.

46) Evaluate $\frac{d}{dt}\left[\vec{\mathbf{u}}(t) \times \vec{\mathbf{u}}'(t)\right]$ given $\vec{\mathbf{u}}(t) = t^2\,\hat{\mathbf{i}} - 2t\,\hat{\mathbf{j}} + \hat{\mathbf{k}}$.

**Answer**

$\frac{d}{dt}\left[\vec{\mathbf{u}}(t) \times \vec{\mathbf{u}}'(t)\right] = 0\,\hat{\mathbf{i}} + 2\,\hat{\mathbf{j}} + 4t\,\hat{\mathbf{k}}$

47) Given $\vec{\mathbf{r}}(t) = t\,\hat{\mathbf{i}} + 2\sin t\,\hat{\mathbf{j}} + 2\cos t\,\hat{\mathbf{k}}$ and $\vec{\mathbf{u}}(t) = \frac{1}{t}\,\hat{\mathbf{i}} + 2\sin t\,\hat{\mathbf{j}} + 2\cos t\,\hat{\mathbf{k}}$, find the following:

a. $\vec{\mathbf{r}}(t) \times \vec{\mathbf{u}}(t)$

**Answer**

$\vec{\mathbf{r}}(t) \times \vec{\mathbf{u}}(t) = \left\langle 0,\ 2(\cos t)\left(\frac{1}{t} - t\right),\ 2(\sin t)\left(t - \frac{1}{t}\right)\right\rangle$

b. $\frac{d}{dt}\left(\vec{\mathbf{r}}(t) \times \vec{\mathbf{u}}(t)\right)$

**Answer**

$\frac{d}{dt}\left(\vec{\mathbf{r}}(t) \times \vec{\mathbf{u}}(t)\right) = \left\langle 0,\ 2(\sin t)\left(t - \frac{1}{t}\right) - 2(\cos t)\left(1 + \frac{1}{t^2}\right),\ 2(\sin t)\left(1 + \frac{1}{t^2}\right) + 2(\cos t)\left(t - \frac{1}{t}\right)\right\rangle$

c. Now, use the product rule for the derivative of the cross product of two vectors and show this result is the same as the answer for the preceding problem.

## UNIT TANGENT VECTORS

**For questions 48 - 51, find a *unit tangent vector* at the indicated value of $t$.**

48) $\vec{\mathbf{r}}(t) = 3t^3\,\hat{\mathbf{i}} + 2t^2\,\hat{\mathbf{j}} + \frac{1}{t}\,\hat{\mathbf{k}};\quad t = 1$

49) $\vec{\mathbf{r}}(t) = t\,\hat{\mathbf{i}} + \sin(2t)\,\hat{\mathbf{j}} + \cos(3t)\,\hat{\mathbf{k}};\quad t = \frac{\pi}{3}$

**Answer**

$\vec{\mathbf{r}}'\left(\frac{\pi}{3}\right) = \langle 1, -1, 0\rangle$ is a tangent vector, so a unit tangent vector would be:
$\frac{1}{\sqrt{2}}\langle 1, -1, 0\rangle \quad = \quad \left\langle \frac{\sqrt{2}}{2}, -\frac{\sqrt{2}}{2}, 0\right\rangle$

50) $\vec{\mathbf{r}}(t) = \cos(2t)\,\hat{\mathbf{i}} + 2\sin t\,\hat{\mathbf{j}} + t^2\,\hat{\mathbf{k}};\quad t = \frac{\pi}{2}$

51) $\vec{\mathbf{r}}(t) = 3e^t\,\hat{\mathbf{i}} + 2e^{-3t}\,\hat{\mathbf{j}} + 4e^{2t}\,\hat{\mathbf{k}};\quad t = \ln(2)$

**Answer**

$\vec{\mathbf{r}}'(\ln(2)) = \langle 6, -\frac{3}{4}, 32\rangle$ is a tangent vector, so a unit tangent vector would be:

$$\frac{1}{\sqrt{1060.5625}}\langle 6, -\frac{3}{4}, 32\rangle = \left\langle \frac{24\sqrt{16969}}{16969}, -\frac{12\sqrt{16969}}{67876}, \frac{128\sqrt{16969}}{16969}\right\rangle$$

**For questions 52 - 58, find the unit tangent vector $\vec{\mathbf{T}}(t)$ for the following parameterized curves.**

52) $\vec{\mathbf{r}}(t) = t\,\hat{\mathbf{i}} + 3t\,\hat{\mathbf{j}} + t^2\,\hat{\mathbf{k}}$

53) $\vec{\mathbf{r}}(t) = 6\,\hat{\mathbf{i}} + \cos(3t)\,\hat{\mathbf{j}} + 3\sin(4t)\,\hat{\mathbf{k}}, \quad 0 \le t < 2\pi$

**Answer**

$$\vec{\mathbf{T}}(t) = \frac{1}{\sqrt{9\sin^2(3t) + 144\cos^2(4t)}}\langle 0, -3\sin(3t), 12\cos(4t)\rangle$$

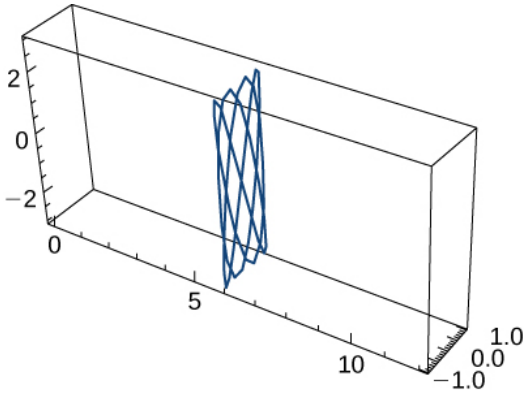
54) $\vec{\mathbf{r}}(t) = \langle t\cos t, t\sin t\rangle$

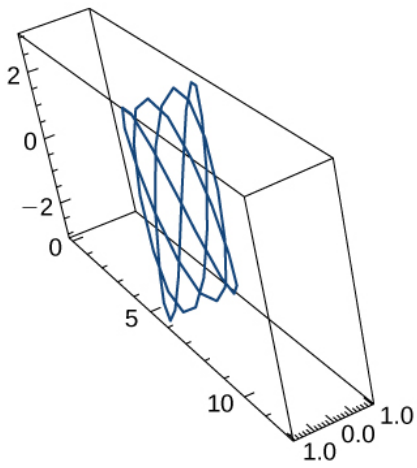
55) $\vec{\mathbf{r}}(t) = \langle t+1, 2t+1, 2t+2\rangle$

**Answer**

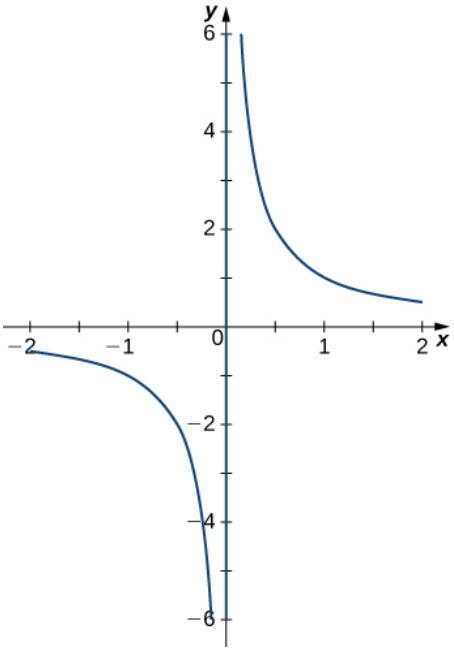
$\vec{\mathbf{T}}(t) = \frac{1}{3}\langle 1, 2, 2\rangle$

56) $\vec{\mathbf{r}}(t) = \cos t\,\hat{\mathbf{i}} + \sin t\,\hat{\mathbf{j}} + \sin t\,\hat{\mathbf{k}}, \quad 0 \le t < 2\pi$. Two views of this curve are presented here:





57) $\vec{\mathbf{r}}(t) = \left\langle t, \frac{1}{t}\right\rangle$. The graph is shown here:



**Answer**

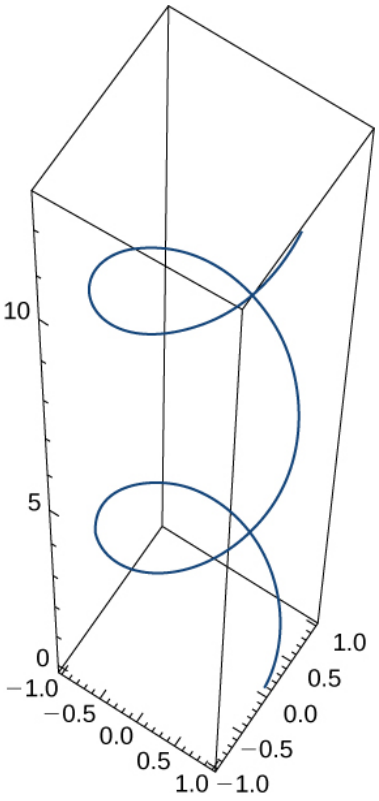
$$\vec{\mathbf{T}}(t) = \left\langle \frac{t^2}{\sqrt{t^4+1}}, \frac{-1}{\sqrt{t^4+1}} \right\rangle$$

58) $\vec{\mathbf{r}}(t) = 3\cos(4t)\,\hat{\mathbf{i}} + 3\sin(4t)\,\hat{\mathbf{j}} + 5t\,\hat{\mathbf{k}}, \quad 1 \le t \le 2$

**Answer**

$$\vec{\mathbf{T}}(t) = -\tfrac{12}{13}\sin(4t)\,\hat{\mathbf{i}} + \tfrac{12}{13}\cos(4t)\,\hat{\mathbf{j}} + \tfrac{5}{13}\,\hat{\mathbf{k}}$$

59) A particle travels along the path of a helix with the equation $\vec{\mathbf{r}}(t) = \cos(t)\,\hat{\mathbf{i}} + \sin(t)\,\hat{\mathbf{j}} + t\,\hat{\mathbf{k}}$. See the graph presented here:



Find the following:

a. Velocity of the particle at any time

**Answer**

$\vec{\mathbf{v}}(t) = \langle -\sin t, \cos t, 1 \rangle$

b. Speed of the particle at any time

c. Acceleration of the particle at any time

**Answer**

$\vec{\mathbf{a}}(t) = -\cos t\,\hat{\mathbf{i}} - \sin t\,\hat{\mathbf{j}} + 0\,\hat{\mathbf{k}}$

d. Find the unit tangent vector for the helix.

## INTEGRATION OF VECTOR-VALUED FUNCTIONS

**Evaluate the following integrals:**

60) $\int \left(e^t\,\hat{\mathbf{i}} + \sin t\,\hat{\mathbf{j}} + \frac{1}{2t-1}\,\hat{\mathbf{k}}\right) dt$

61) $\int_0^1 \vec{\mathbf{r}}(t)\,dt$, where $\vec{\mathbf{r}}(t) = \left\langle \sqrt[3]{t}, \frac{1}{t+1}, e^{-t} \right\rangle$

**Answer**

$\frac{3}{4}\,\hat{\mathbf{i}} + \ln(2)\,\hat{\mathbf{j}} + (1 - \frac{1}{e})\,\hat{\mathbf{k}}$

62) Evaluate $\int_0^3 \|t\,\hat{\mathbf{i}} + t^2\,\hat{\mathbf{j}}\|dt$.

**Answer**

$\frac{1}{3}(10^{\frac{3}{2}} - 1)$

63) The acceleration function, initial velocity, and initial position of a particle are

$$\vec{\mathbf{a}}(t) = -5\cos t\,\hat{\mathbf{i}} - 5\sin t\,\hat{\mathbf{j}},$$
$$\vec{\mathbf{v}}(0) = 9\,\hat{\mathbf{i}} + 2\,\hat{\mathbf{j}}, \quad \text{and}$$
$$\vec{\mathbf{r}}(0) = 5\,\hat{\mathbf{i}}$$

Find $\vec{\mathbf{v}}(t)$ and $\vec{\mathbf{r}}(t)$.

**Answer**

$\vec{\mathbf{v}}(t) = (9 - 5\sin t)\,\hat{\mathbf{i}} + (-3 + 5\cos t)\,\hat{\mathbf{j}}$
$\vec{\mathbf{r}}(t) = (9t + 5\cos t)\,\hat{\mathbf{i}} + (-3t + 5\sin t)\,\hat{\mathbf{j}}$

64) Find the antiderivative of $\vec{\mathbf{r}}'(t) = \cos(2t)\,\hat{\mathbf{i}} - 2\sin t\,\hat{\mathbf{j}} + \frac{1}{1+t^2}\,\hat{\mathbf{k}}$ that satisfies the initial condition $\vec{\mathbf{r}}(0) = 3\,\hat{\mathbf{i}} - 2\,\hat{\mathbf{j}} + \hat{\mathbf{k}}$.

65) An object starts from rest at point $P(1, 2, 0)$ and moves with an acceleration of $\vec{\mathbf{a}}(t) = \hat{\mathbf{j}} + 2\,\hat{\mathbf{k}}$, where $\|\vec{\mathbf{a}}(t)\|$ is measured in feet per second per second. Find the location of the object after $t = 2$ sec.

# 13.4: Arc Length and Curvature

**Learning Objectives**

- Determine the length of a particle's path in space by using the arc-length function.
- Explain the meaning of the curvature of a curve in space and state its formula.
- Describe the meaning of the normal and binormal vectors of a curve in space.

In this section, we study formulas related to curves in both two and three dimensions, and see how they are related to various properties of the same curve. For example, suppose a vector-valued function describes the motion of a particle in space. We would like to determine how far the particle has traveled over a given time interval, which can be described by the arc length of the path it follows. Or, suppose that the vector-valued function describes a road we are building and we want to determine how sharply the road curves at a given point. This is described by the curvature of the function at that point. We explore each of these concepts in this section.

## Arc Length for Vector Functions

We have seen how a vector-valued function describes a curve in either two or three dimensions. Recall that the formula for the arc length of a curve defined by the parametric functions $x = x(t), y = y(t), t_1 \le t \le t_2$ is given by

$$s = \int_{t_1}^{t_2} \sqrt{(x'(t))^2 + (y'(t))^2}\, dt.$$

In a similar fashion, if we define a smooth curve using a vector-valued function $\vec{\mathbf{r}}(t) = f(t)\,\hat{\mathbf{i}} + g(t)\,\hat{\mathbf{j}}$, where $a \le t \le b$, the arc length is given by the formula

$$s = \int_a^b \sqrt{(f'(t))^2 + (g'(t))^2}\, dt.$$

In three dimensions, if the vector-valued function is described by $\vec{\mathbf{r}}(t) = f(t)\,\hat{\mathbf{i}} + g(t)\,\hat{\mathbf{j}} + h(t)\,\hat{\mathbf{k}}$ over the same interval $a \le t \le b$, the arc length is given by

$$s = \int_a^b \sqrt{(f'(t))^2 + (g'(t))^2 + (h'(t))^2}\, dt.$$

**Theorem: Arc-Length Formulas for Plane and Space curves**

*Plane curve*: Given a smooth curve $C$ defined by the function $\vec{\mathbf{r}}(t) = f(t)\,\hat{\mathbf{i}} + g(t)\,\hat{\mathbf{j}}$, where $t$ lies within the interval $[a, b]$, the arc length of $C$ over the interval is

$$s = \int_a^b \sqrt{[f'(t)]^2 + [g'(t)]^2}\, dt \tag{13.4.1}$$

$$= \int_a^b \|\vec{\mathbf{r}}'(t)\|\, dt. \tag{13.4.2}$$

*Space curve*: Given a smooth curve $C$ defined by the function $\vec{\mathbf{r}}(t) = f(t)\,\hat{\mathbf{i}} + g(t)\,\hat{\mathbf{j}} + h(t)\,\hat{\mathbf{k}}$, where $t$ lies within the interval $[a, b]$, the arc length of $C$ over the interval is

$$s = \int_a^b \sqrt{[f'(t)]^2 + [g'(t)]^2 + [h'(t)]^2}\, dt \tag{13.4.3}$$

$$= \int_a^b \|\vec{\mathbf{r}}'(t)\|\, dt. \tag{13.4.4}$$

The two formulas are very similar; they differ only in the fact that a space curve has three component functions instead of two. Note that the formulas are defined for smooth curves: curves where the vector-valued function $\vec{\mathbf{r}}(t)$ is differentiable with a non-zero derivative. The smoothness condition guarantees that the curve has no cusps (or corners) that could make the formula problematic.

## Example 13.4.1: Finding the Arc Length

Calculate the arc length for each of the following vector-valued functions:

a. $\vec{\mathbf{r}}(t) = (3t-2)\,\hat{\mathbf{i}} + (4t+5)\,\hat{\mathbf{j}}, \quad 1 \le t \le 5$

b. $\vec{\mathbf{r}}(t) = \langle t\cos t, t\sin t, 2t\rangle, 0 \le t \le 2\pi$

### Solution

a. Using Equation 13.4.2, $\vec{\mathbf{r}}'(t) = 3\,\hat{\mathbf{i}} + 4\,\hat{\mathbf{j}}$, so

$$\begin{aligned} s &= \int_a^b \|\vec{\mathbf{r}}'(t)\|dt \\ &= \int_1^5 \sqrt{3^2+4^2}dt \\ &= \int_1^5 5dt = 5t\big|_1^5 = 20. \end{aligned}$$

b. Using Equation 13.4.4, $\vec{\mathbf{r}}'(t) = \langle \cos t - t\sin t, \sin t + t\cos t, 2\rangle$, so

$$\begin{aligned} s &= \int_a^b \| \vec{\mathbf{r}}'(t) \| \, dt \\ &= \int_0^{2\pi} \sqrt{(\cos t - t\sin t)^2 + (\sin t + t\cos t)^2 + 2^2}dt \\ &= \int_0^{2\pi} \sqrt{(\cos^2 t - 2t\sin t\cos t + t^2\sin^2 t) + (\sin^2 t + 2t\sin t\cos t + t^2\cos^2 t) + 4}dt \\ &= \int_0^{2\pi} \sqrt{\cos^2 t + \sin^2 t + t^2(\cos^2 t + \sin^2 t) + 4}dt \\ &= \int_0^{2\pi} \sqrt{t^2+5}dt \end{aligned}$$

Here we can use a table integration formula

$$\int \sqrt{u^2+a^2}du = \frac{u}{2}\sqrt{u^2+a^2} + \frac{a^2}{2}\ln\left|u+\sqrt{u^2+a^2}\right| + C,$$

so we obtain

$$\begin{aligned} \int_0^{2\pi} \sqrt{t^2+5}dt &= \frac{1}{2}\left(t\sqrt{t^2+5} + 5\ln\left|t+\sqrt{t^2+5}\right|\right)_0^{2\pi} \\ &= \frac{1}{2}\left(2\pi\sqrt{4\pi^2+5} + 5\ln\left(2\pi+\sqrt{4\pi^2+5}\right)\right) - \frac{5}{2}\ln\sqrt{5} \\ &\approx 25.343 \text{ units}. \end{aligned}$$

## Exercise 13.4.1

Calculate the arc length of the parameterized curve

$$\vec{\mathbf{r}}(t) = \langle 2t^2+1, 2t^2-1, t^3\rangle, \quad 0 \le t \le 3.$$

### Hint

Use Equation 13.4.4.

### Answer

$\vec{\mathbf{r}}'(t) = \langle 4t, 4t, 3t^2\rangle$, so $s = \frac{1}{27}(113^{3/2} - 32^{3/2}) \approx 37.785$ units

We now return to the helix introduced earlier in this chapter. A vector-valued function that describes a helix can be written in the form

$$\vec{\mathbf{r}}(t) = R\cos\left(\frac{2\pi Nt}{h}\right)\hat{\mathbf{i}} + R\sin\left(\frac{2\pi Nt}{h}\right)\hat{\mathbf{j}} + t\hat{\mathbf{k}}, 0 \le t \le h,$$

where $R$ represents the radius of the helix, $h$ represents the height (distance between two consecutive turns), and the helix completes $N$ turns. Let's derive a formula for the arc length of this helix using Equation 13.4.4. First of all,

$$\vec{\mathbf{r}}'(t) = -\frac{2\pi NR}{h}\sin\left(\frac{2\pi Nt}{h}\right)\hat{\mathbf{i}} + \frac{2\pi NR}{h}\cos\left(\frac{2\pi Nt}{h}\right)\hat{\mathbf{j}} + \hat{\mathbf{k}}.$$

Therefore,

$$\begin{aligned} s &= \int_a^b \|\vec{\mathbf{r}}'(t)\|dt \\ &= \int_0^h \sqrt{\left(-\frac{2\pi NR}{h}\sin\left(\frac{2\pi Nt}{h}\right)\right)^2 + \left(\frac{2\pi NR}{h}\cos\left(\frac{2\pi Nt}{h}\right)\right)^2 + 1^2}dt \\ &= \int_0^h \sqrt{\frac{4\pi^2N^2R^2}{h^2}\left(\sin^2\left(\frac{2\pi Nt}{h}\right) + \cos^2\left(\frac{2\pi Nt}{h}\right)\right) + 1}dt \\ &= \int_0^h \sqrt{\frac{4\pi^2N^2R^2}{h^2} + 1}dt \\ &= \left[t\sqrt{\frac{4\pi^2N^2R^2}{h^2} + 1}\right]_0^h \\ &= h\sqrt{\frac{4\pi^2N^2R^2 + h^2}{h^2}} \\ &= \sqrt{4\pi^2N^2R^2 + h^2}. \end{aligned}$$

This gives a formula for the length of a wire needed to form a helix with $N$ turns that has radius $R$ and height $h$.

## Arc-Length Parameterization

We now have a formula for the arc length of a curve defined by a vector-valued function. Let's take this one step further and examine what an **arc-length function** is.

If a vector-valued function represents the position of a particle in space as a function of time, then the arc-length function measures how far that particle travels as a function of time. The formula for the arc-length function follows directly from the formula for arc length:

$$s = \int_a^t \sqrt{(f'(u))^2 + (g'(u))^2 + (h'(u))^2}du. \tag{13.4.5}$$

If the curve is in two dimensions, then only two terms appear under the square root inside the integral. The reason for using the independent variable $u$ is to distinguish between time and the variable of integration. Since $s(t)$ measures distance traveled as a function of time, $s'(t)$ measures the speed of the particle at any given time. Since we have a formula for $s(t)$ in Equation 13.4.5, we can differentiate both sides of the equation:

$$\begin{aligned} s'(t) &= \frac{d}{dt}\left[\int_a^t \sqrt{(f'(u))^2 + (g'(u))^2 + (h'(u))^2}du\right] \\ &= \frac{d}{dt}\left[\int_a^t \|\vec{\mathbf{r}}'(u)\|du\right] \\ &= \|\vec{\mathbf{r}}'(t)\|. \end{aligned}$$

If we assume that $\vec{\mathbf{r}}(t)$ defines a smooth curve, then the arc length is always increasing, so $s'(t) > 0$ for $t > a$. Last, if $\vec{\mathbf{r}}(t)$ is a curve on which $\|\vec{\mathbf{r}}'(t)\| = 1$ for all $t$, then

$$s(t) = \int_a^t \|\vec{\mathbf{r}}'(u)\|\,du = \int_a^t 1\,du = t - a,$$

which means that $t$ represents the arc length as long as $a = 0$.

**Theorem: Arc-Length Function**

Let $\vec{\mathbf{r}}(t)$ describe a smooth curve for $t \geq a$. Then the arc-length function is given by

$$s(t) = \int_a^t \|\vec{\mathbf{r}}'(u)\| \, du$$

Furthermore,

$$\frac{ds}{dt} = \|\vec{\mathbf{r}}'(t)\| > 0.$$

If $\|\vec{\mathbf{r}}'(t)\| = 1$ for all $t \geq a$, then the parameter $t$ represents the arc length from the starting point at $t = a$.

A useful application of this theorem is to find an alternative parameterization of a given curve, called an **arc-length parameterization**. Recall that any vector-valued function can be reparameterized via a change of variables. For example, if we have a function $\vec{\mathbf{r}}(t) = \langle 3\cos t, 3\sin t \rangle, 0 \leq t \leq 2\pi$ that parameterizes a circle of radius 3, we can change the parameter from $t$ to $4t$, obtaining a new parameterization $\vec{\mathbf{r}}(t) = \langle 3\cos 4t, 3\sin 4t \rangle$. The new parameterization still defines a circle of radius 3, but now we need only use the values $0 \leq t \leq \pi/2$ to traverse the circle once.

Suppose that we find the arc-length function $s(t)$ and are able to solve this function for $t$ as a function of $s$. We can then reparameterize the original function $\vec{\mathbf{r}}(t)$ by substituting the expression for $t$ back into $\vec{\mathbf{r}}(t)$. The vector-valued function is now written in terms of the parameter $s$. Since the variable $s$ represents the arc length, we call this an *arc-length parameterization* of the original function $\vec{\mathbf{r}}(t)$. One advantage of finding the arc-length parameterization is that the distance traveled along the curve starting from $s = 0$ is now equal to the parameter $s$. The arc-length parameterization also appears in the context of curvature (which we examine later in this section) and line integrals.

**Example 13.4.2: Finding an Arc-Length Parameterization**

Find the arc-length parameterization for each of the following curves:

a. $\vec{\mathbf{r}}(t) = 4\cos t\,\hat{\mathbf{i}} + 4\sin t\,\hat{\mathbf{j}}, \quad t \geq 0$
b. $\vec{\mathbf{r}}(t) = \langle t+3, 2t-4, 2t \rangle, \quad t \geq 3$

**Solution**

a. First we find the arc-length function using Equation 13.4.5:

$$\begin{aligned} s(t) &= \int_a^t \|\vec{\mathbf{r}}'(u)\| \, du \\ &= \int_0^t \|\langle -4\sin u, 4\cos u \rangle\| \, du \\ &= \int_0^t \sqrt{(-4\sin u)^2 + (4\cos u)^2} \, du \\ &= \int_0^t \sqrt{16\sin^2 u + 16\cos^2 u} \, du \\ &= \int_0^t 4 \, du = 4t, \end{aligned}$$

which gives the relationship between the arc length $s$ and the parameter $t$ as $s = 4t$; so, $t = s/4$. Next we replace the variable $t$ in the original function $\vec{\mathbf{r}}(t) = 4\cos t\,\hat{\mathbf{i}} + 4\sin t\,\hat{\mathbf{j}}$ with the expression $s/4$ to obtain

$$\vec{\mathbf{r}}(s) = 4\cos\left(\frac{s}{4}\right)\hat{\mathbf{i}} + 4\sin\left(\frac{s}{4}\right)\hat{\mathbf{j}}.$$

This is the arc-length parameterization of $\vec{\mathbf{r}}(t)$. Since the original restriction on $t$ was given by $t \geq 0$, the restriction on $s$ becomes $s/4 \geq 0$, or $s \geq 0$.

b. The arc-length function is given by Equation 13.4.5:

$$\begin{aligned} s(t) &= \int_a^t \|\vec{\mathbf{r}}'(u)\|\, du \\ &= \int_3^t \|\langle 1,2,2\rangle\|\, du \\ &= \int_3^t \sqrt{1^2+2^2+2^2}\, du \\ &= \int_3^t 3\, du \\ &= 3t-9. \end{aligned}$$

Therefore, the relationship between the arc length $s$ and the parameter $t$ is $s = 3t-9$, so $t = \frac{s}{3}+3$. Substituting this into the original function $\vec{\mathbf{r}}(t) = \langle t+3, 2t-4, 2t\rangle$ yields

$$\vec{\mathbf{r}}(s) = \langle\left(\frac{s}{3}+3\right)+3,\, 2\left(\frac{s}{3}+3\right)-4,\, 2\left(\frac{s}{3}+3\right)\rangle = \langle\frac{s}{3}+6, \frac{2s}{3}+2, \frac{2s}{3}+6\rangle.$$

This is an arc-length parameterization of $\vec{\mathbf{r}}(t)$. The original restriction on the parameter $t$ was $t \geq 3$, so the restriction on $s$ is $(s/3)+3 \geq 3$, or $s \geq 0$.

**? Exercise 13.4.2**

Find the arc-length function for the helix

$$\vec{\mathbf{r}}(t) = \langle 3\cos t, 3\sin t, 4t\rangle, \quad t \geq 0.$$

Then, use the relationship between the arc length and the parameter $t$ to find an arc-length parameterization of $\vec{\mathbf{r}}(t)$.

**Hint**

Start by finding the arc-length function.

**Answer**

$s = 5t$, or $t = s/5$. Substituting this into $\vec{\mathbf{r}}(t) = \langle 3\cos t, 3\sin t, 4t\rangle$ gives

$$\vec{\mathbf{r}}(s) = \langle 3\cos\left(\frac{s}{5}\right), 3\sin\left(\frac{s}{5}\right), \frac{4s}{5}\rangle, \quad s \geq 0$$

## Curvature

An important topic related to arc length is curvature. The concept of curvature provides a way to measure how sharply a smooth curve turns. A circle has constant curvature. The smaller the radius of the circle, the greater the curvature.

Think of driving down a road. Suppose the road lies on an arc of a large circle. In this case you would barely have to turn the wheel to stay on the road. Now suppose the radius is smaller. In this case you would need to turn more sharply to stay on the road. In the case of a curve other than a circle, it is often useful first to inscribe a circle to the curve at a given point so that it is tangent to the curve at that point and "hugs" the curve as closely as possible in a neighborhood of the point (Figure 13.4.1). The curvature of the graph at that point is then defined to be the same as the curvature of the inscribed circle.

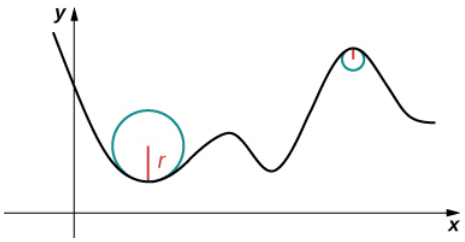

Figure 13.4.1: The graph represents the curvature of a function $y = f(x)$. The sharper the turn in the graph, the greater the curvature, and the smaller the radius of the inscribed circle.

**Definition: Curvature**

Let $C$ be a smooth curve in the plane or in space given by $\vec{\mathbf{r}}(s)$, where $s$ is the arc-length parameter. The curvature $\kappa$ at $s$ is

$$\kappa = \left\| \frac{d\vec{\mathbf{T}}}{ds} \right\| = \|\vec{\mathbf{T}}'(s)\|.$$

Visit this video for more information about the curvature of a space curve.

The formula in the definition of curvature is not very useful in terms of calculation. In particular, recall that $\vec{\mathbf{T}}(t)$ represents the unit tangent vector to a given vector-valued function $\vec{\mathbf{r}}(t)$, and the formula for $\vec{\mathbf{T}}(t)$ is

$$\vec{\mathbf{T}}(t) = \frac{\vec{\mathbf{r}}'(t)}{\| \vec{\mathbf{r}}'(t) \|}.$$

To use the formula for curvature, it is first necessary to express $\vec{\mathbf{r}}(t)$ in terms of the arc-length parameter $s$, then find the unit tangent vector $\vec{\mathbf{T}}(s)$ for the function $\vec{\mathbf{r}}(s)$, then take the derivative of $\vec{\mathbf{T}}(s)$ with respect to $s$. This is a tedious process. Fortunately, there are equivalent formulas for curvature.

**Theorem: Alternate Formulas of Curvature**

If $C$ is a smooth curve given by $\vec{\mathbf{r}}(t)$, then the curvature $\kappa$ of $C$ at $t$ is given by

$$\kappa = \frac{\|\vec{\mathbf{T}}'(t)\|}{\|\vec{\mathbf{r}}'(t)\|}. \tag{13.4.6}$$

If $C$ is a three-dimensional curve, then the curvature can be given by the formula

$$\kappa = \frac{\|\vec{\mathbf{r}}'(t) \times \vec{\mathbf{r}}''(t)\|}{\|\vec{\mathbf{r}}'(t)\|^3}. \tag{13.4.7}$$

If $C$ is the graph of a function $y = f(x)$ and both $y'$ and $y''$ exist, then the curvature $\kappa$ at point $(x, y)$ is given by

$$\kappa = \frac{|y''|}{[1 + (y')^2]^{3/2}}. \tag{13.4.8}$$

**Proof**

The first formula follows directly from the chain rule:

$$\frac{d\vec{\mathbf{T}}}{dt} = \frac{d\vec{\mathbf{T}}}{ds}\frac{ds}{dt},$$

where $s$ is the arc length along the curve $C$. Dividing both sides by $ds/dt$, and taking the magnitude of both sides gives

$$\left\| \frac{d\vec{\mathbf{T}}}{ds} \right\| = \left\| \frac{\vec{\mathbf{T}}'(t)}{\frac{ds}{dt}} \right\|.$$

Since $ds/dt = \|\vec{\mathbf{r}}'(t)\|$, this gives the formula for the curvature $\kappa$ of a curve $C$ in terms of any parameterization of $C$:

$$\kappa = \frac{\|\vec{\mathbf{T}}'(t)\|}{\|\vec{\mathbf{r}}'(t)\|}.$$

In the case of a three-dimensional curve, we start with the formulas $\vec{\mathbf{T}}(t) = (\vec{\mathbf{r}}'(t))/\|\vec{\mathbf{r}}'(t)\|$ and $ds/dt = \|\vec{\mathbf{r}}'(t)\|$. Therefore, $\vec{\mathbf{r}}'(t) = (ds/dt)\vec{\mathbf{T}}(t)$. We can take the derivative of this function using the scalar product formula:

$$\vec{\mathbf{r}}''(t) = \frac{d^2s}{dt^2}\vec{\mathbf{T}}(t) + \frac{ds}{dt}\vec{\mathbf{T}}'(t).$$

Using these last two equations we get

$$\vec{\mathbf{r}}'(t) \times \vec{\mathbf{r}}''(t) = \frac{ds}{dt}\vec{\mathbf{T}}(t) \times \left(\frac{d^2s}{dt^2}\vec{\mathbf{T}}(t) + \frac{ds}{dt}\vec{\mathbf{T}}'(t)\right)$$
$$= \frac{ds}{dt}\frac{d^2s}{dt^2}\vec{\mathbf{T}}(t) \times \vec{\mathbf{T}}(t) + (\frac{ds}{dt})^2\vec{\mathbf{T}}(t) \times \vec{\mathbf{T}}'(t).$$

Since $\vec{\mathbf{T}}(t) \times \vec{\mathbf{T}}(t) = \mathbf{0}$, this reduces to

$$\vec{\mathbf{r}}'(t) \times \vec{\mathbf{r}}''(t) = \left(\frac{ds}{dt}\right)^2 \vec{\mathbf{T}}(t) \times \vec{\mathbf{T}}'(t).$$

Since $\vec{\mathbf{T}}'$ is parallel to $\vec{\mathbf{N}}$, and $\vec{\mathbf{T}}$ is orthogonal to $\vec{\mathbf{N}}$, it follows that $\vec{\mathbf{T}}$ and $\vec{\mathbf{T}}'$ are orthogonal. This means that $\|\vec{\mathbf{T}} \times \vec{\mathbf{T}}'\| = \|\vec{\mathbf{T}}\|\|\vec{\mathbf{T}}'\| \sin(\pi/2) = \|\vec{\mathbf{T}}'\|$, so

$$\|\vec{\mathbf{r}}'(t) \times \vec{\mathbf{r}}''(t)\| = \left(\frac{ds}{dt}\right)^2 \|\vec{\mathbf{T}}'(t)\|.$$

Now we solve this equation for $\|\vec{\mathbf{T}}'(t)\|$ and use the fact that $ds/dt = \|\vec{\mathbf{r}}'(t)\|$:

$$\|\vec{\mathbf{T}}'(t)\| = \frac{\|\vec{\mathbf{r}}'(t) \times \vec{\mathbf{r}}''(t)\|}{\|\vec{\mathbf{r}}'(t)\|^2}.$$

Then, we divide both sides by $\|\vec{\mathbf{r}}'(t)\|$. This gives

$$\kappa = \frac{\|\vec{\mathbf{T}}'(t)\|}{\|\vec{\mathbf{r}}'(t)\|} = \frac{\|\vec{\mathbf{r}}'(t) \times \vec{\mathbf{r}}''(t)\|}{\|\vec{\mathbf{r}}'(t)\|^3}.$$

This proves 13.4.7. To prove 13.4.8, we start with the assumption that curve $C$ is defined by the function $y = f(x)$. Then, we can define $\vec{\mathbf{r}}(t) = x\,\hat{\mathbf{i}} + f(x)\,\hat{\mathbf{j}} + 0\,\hat{\mathbf{k}}$. Using the previous formula for curvature:

$$\vec{\mathbf{r}}'(t) = \hat{\mathbf{i}} + f'(x)\hat{\mathbf{j}}$$
$$\vec{\mathbf{r}}''(t) = f''(x)\hat{\mathbf{j}}$$
$$\vec{\mathbf{r}}'(t) \times \vec{\mathbf{r}}''(t) = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 1 & f'(x) & 0 \\ 0 & f''(x) & 0 \end{vmatrix} = f''(x)\hat{\mathbf{k}}.$$

Therefore,

$$\kappa = \frac{\|\vec{\mathbf{r}}'(t) \times \vec{\mathbf{r}}''(t)\|}{\|\vec{\mathbf{r}}'(t)\|^3} = \frac{|f''(x)|}{(1 + [f'(x)]^2)^{3/2}}$$

## Example 13.4.3: Finding Curvature

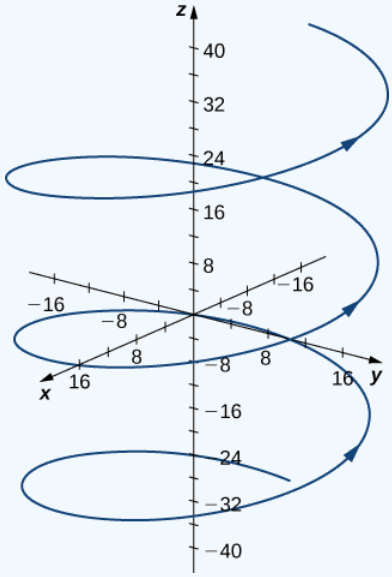
Find the curvature for each of the following curves at the given point:

a. $\vec{\mathbf{r}}(t) = 4\cos t\,\hat{\mathbf{i}} + 4\sin t\,\hat{\mathbf{j}} + 3t\,\hat{\mathbf{k}}, \quad t = \dfrac{4\pi}{3}$

b. $\mathbf{f(x) = \sqrt{4x - x^2}, x = 2}$

### Solution

a. This function describes a helix.



The curvature of the helix at $t = (4\pi)/3$ can be found by using 13.4.6. First, calculate $\vec{\mathbf{T}}(t)$:

$$\begin{aligned}\vec{\mathbf{T}}(t) &= \frac{\vec{\mathbf{r}}'(t)}{\|\vec{\mathbf{r}}'(t)\|} \\ &= \frac{\langle -4\sin t, 4\cos t, 3\rangle}{\sqrt{(-4\sin t)^2 + (4\cos t)^2 + 3^2}} \\ &= \langle -\frac{4}{5}\sin t, \frac{4}{5}\cos t, \frac{3}{5}\rangle.\end{aligned}$$

Next, calculate $\vec{\mathbf{T}}'(t)$ :

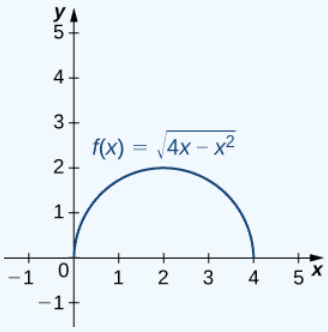
$$\vec{\mathbf{T}}'(t) = \langle -\frac{4}{5}\cos t, -\frac{4}{5}\sin t, 0\rangle.$$

Last, apply 13.4.6 :

$$\begin{aligned}\kappa &= \frac{\|\vec{\mathbf{T}}'(t)\|}{\|\vec{\mathbf{r}}'(t)\|} = \frac{\|\langle -\frac{4}{5}\cos t, -\frac{4}{5}\sin t, 0\rangle\|}{\|\langle -4\sin t, 4\cos t, 3\rangle\|} \\ &= \frac{\sqrt{(-\frac{4}{5}\cos t)^2 + (-\frac{4}{5}\sin t)^2 + 0^2}}{\sqrt{(-4\sin t)^2 + (4\cos t)^2 + 3^2}} \\ &= \frac{4/5}{5} = \frac{4}{25}.\end{aligned}$$

The curvature of this helix is constant at all points on the helix.

2. This function describes a semicircle.



To find the curvature of this graph, we must use 13.4.8. First, we calculate $y'$ and $y''$:

$$\begin{aligned} y &= \sqrt{4x - x^2} = (4x - x^2)^{1/2} \\ y' &= \frac{1}{2}(4x - x^2)^{-1/2}(4 - 2x) = (2 - x)(4x - x^2)^{-1/2} \\ y'' &= -(4x - x^2)^{-1/2} + (2 - x)(-\frac{1}{2})(4x - x^2)^{-3/2}(4 - 2x) \\ &= -\frac{4x - x^2}{(4x - x^2)^{3/2}} - \frac{(2 - x)^2}{(4x - x^2)^{3/2}} \\ &= \frac{x^2 - 4x - (4 - 4x + x^2)}{(4x - x^2)^{3/2}} \\ &= -\frac{4}{(4x - x^2)^{3/2}}. \end{aligned}$$

Then, we apply 13.4.8:

$$\begin{aligned} \kappa &= \frac{|y''|}{[1 + (y')^2]^{3/2}} \\ &= \frac{\left| -\frac{4}{(4x - x^2)^{3/2}} \right|}{\left[1 + ((2 - x)(4x - x^2)^{-1/2})^2\right]^{3/2}} = \frac{\left| \frac{4}{(4x - x^2)^{3/2}} \right|}{\left[1 + \frac{(2 - x)^2}{4x - x^2}\right]^{3/2}} \\ &= \frac{\left| \frac{4}{(4x - x^2)^{3/2}} \right|}{\left[\frac{4x - x^2 + x^2 - 4x + 4}{4x - x^2}\right]^{3/2}} = \left| \frac{4}{(4x - x^2)^{3/2}} \right| \cdot \frac{(4x - x^2)^{3/2}}{8} \\ &= \frac{1}{2}. \end{aligned}$$

The curvature of this circle is equal to the reciprocal of its radius. There is a minor issue with the absolute value in 13.4.8 ; however, a closer look at the calculation reveals that the denominator is positive for any value of $x$.

**? Exercise 13.4.3**

Find the curvature of the curve defined by the function

$$y = 3x^2 - 2x + 4$$

at the point $x = 2$.

**Hint**

Use 13.4.8.

**Answer**

$\kappa = \frac{6}{101^{3/2}} \approx 0.0059$

## The Normal and Binormal Vectors

We have seen that the derivative $\vec{\mathbf{r}}\,'(t)$ of a vector-valued function is a tangent vector to the curve defined by $\vec{\mathbf{r}}(t)$, and the unit tangent vector $\vec{\mathbf{T}}(t)$ can be calculated by dividing $\vec{\mathbf{r}}\,'(t)$ by its magnitude. When studying motion in three dimensions, two other vectors are useful in describing the motion of a particle along a path in space: the principal unit normal vector and the **binormal vector**.

**Definition: Binormal Vectors**

Let $C$ be a three-dimensional **smooth** curve represented by $\vec{\mathbf{r}}$ over an open interval $I$. If $\vec{\mathbf{T}}'(t) \neq \vec{\mathbf{0}}$, then the principal unit normal vector at $t$ is defined to be

$$\vec{\mathbf{N}}(t) = \frac{\vec{\mathbf{T}}'(t)}{\|\vec{\mathbf{T}}'(t)\|}. \tag{13.4.9}$$

The binormal vector at $t$ is defined as

$$\vec{\mathbf{B}}(t) = \vec{\mathbf{T}}(t) \times \vec{\mathbf{N}}(t), \tag{13.4.10}$$

where $\vec{\mathbf{T}}(t)$ is the unit tangent vector.

Note that, by definition, the binormal vector is orthogonal to both the unit tangent vector and the normal vector. Furthermore, $\vec{\mathbf{B}}(t)$ is always a unit vector. This can be shown using the formula for the magnitude of a cross product.

$$\|\vec{\mathbf{B}}(t)\| = \|\vec{\mathbf{T}}(t) \times \vec{\mathbf{N}}(t)\| = \|\vec{\mathbf{T}}(t)\|\|\vec{\mathbf{N}}(t)\| \sin\theta,$$

where $\theta$ is the angle between $\vec{\mathbf{T}}(t)$ and $\vec{\mathbf{N}}(t)$. Since $\vec{\mathbf{N}}(t)$ is the derivative of a unit vector, property (vii) of the derivative of a vector-valued function tells us that $\vec{\mathbf{T}}(t)$ and $\vec{\mathbf{N}}(t)$ are orthogonal to each other, so $\theta = \pi/2$. Furthermore, they are both unit vectors, so their magnitude is 1. Therefore, $\|\vec{\mathbf{T}}(t)\|\|\vec{\mathbf{N}}(t)\| \sin\theta = (1)(1)\sin(\pi/2) = 1$ and $\vec{\mathbf{B}}(t)$ is a unit vector.

The principal unit normal vector can be challenging to calculate because the unit tangent vector involves a quotient, and this quotient often has a square root in the denominator. In the three-dimensional case, finding the cross product of the unit tangent vector and the unit normal vector can be even more cumbersome. Fortunately, we have alternative formulas for finding these two vectors, and they are presented in Motion in Space.

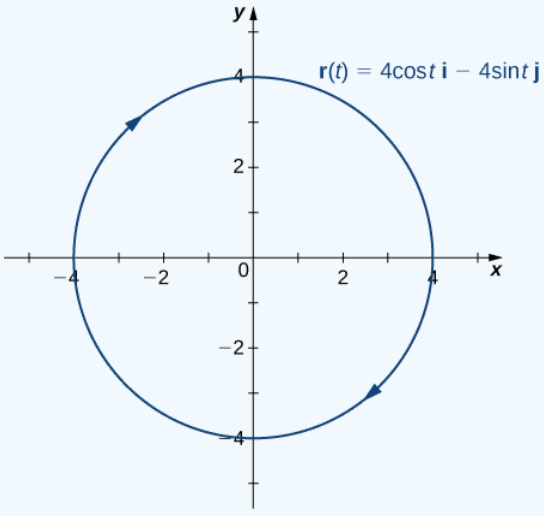
**Example 13.4.4: Finding the Principal Unit Normal Vector and Binormal Vector**

For each of the following vector-valued functions, find the principal unit normal vector. Then, if possible, find the binormal vector.

1. $\vec{\mathbf{r}}(t) = 4\cos t\,\hat{\mathbf{i}} - 4\sin t\,\hat{\mathbf{j}}$
2. $\vec{\mathbf{r}}(t) = (6t+2)\,\hat{\mathbf{i}} + 5t^2\,\hat{\mathbf{j}} - 8t\,\hat{\mathbf{k}}$

**Solution**

1. This function describes a circle.



To find the principal unit normal vector, we first must find the unit tangent vector $\vec{\mathbf{T}}(t)$ :

$$\begin{aligned}\vec{\mathbf{T}}(t) &= \frac{\vec{\mathbf{r}}'(t)}{\|\vec{\mathbf{r}}'(t)\|} \\ &= \frac{-4\sin t\,\hat{\mathbf{i}} - 4\cos t\,\hat{\mathbf{j}}}{\sqrt{(-4\sin t)^2 + (-4\cos t)^2}} \\ &= \frac{-4\sin t\,\hat{\mathbf{i}} - 4\cos t\,\hat{\mathbf{j}}}{\sqrt{16\sin^2 t + 16\cos^2 t}} \\ &= \frac{-4\sin t\,\hat{\mathbf{i}} - 4\cos t\,\hat{\mathbf{j}}}{\sqrt{16(\sin^2 t + \cos^2 t)}} \\ &= \frac{-4\sin t\,\hat{\mathbf{i}} - 4\cos t\,\hat{\mathbf{j}}}{4} \\ &= -\sin t\,\hat{\mathbf{i}} - \cos t\,\hat{\mathbf{j}}.\end{aligned}$$

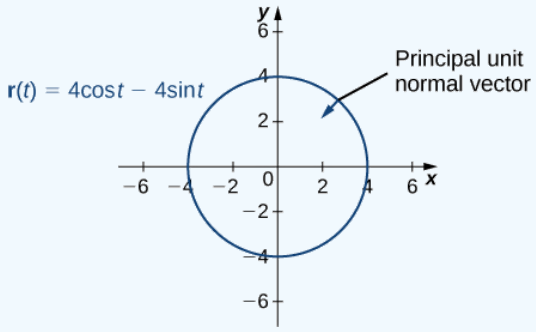
Next, we use 13.4.9 :

$$\begin{aligned}\vec{\mathbf{N}}(t) &= \frac{\vec{\mathbf{T}}'(t)}{\|\vec{\mathbf{T}}'(t)\|} \\ &= \frac{-\cos t\,\hat{\mathbf{i}} + \sin t\,\hat{\mathbf{j}}}{\sqrt{(-\cos t)^2 + (\sin t)^2}} \\ &= \frac{-\cos t\,\hat{\mathbf{i}} + \sin t\,\hat{\mathbf{j}}}{\sqrt{\cos^2 t + \sin^2 t}} \\ &= -\cos t\,\hat{\mathbf{i}} + \sin t\,\hat{\mathbf{j}}.\end{aligned}$$

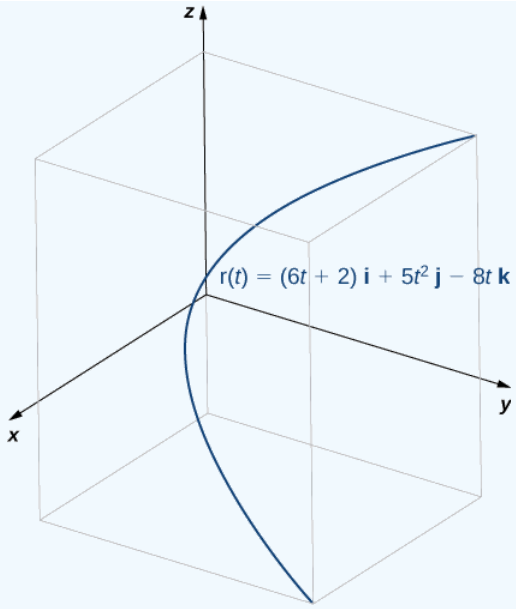
Notice that the unit tangent vector and the principal unit normal vector are orthogonal to each other for all values of $t$:

$$\begin{aligned}\vec{\mathbf{T}}(t) \cdot \vec{\mathbf{N}}(t) &= \langle -\sin t, -\cos t\rangle \cdot \langle -\cos t, \sin t\rangle \\ &= \sin t\cos t - \cos t\sin t \\ &= 0.\end{aligned}$$

Furthermore, the principal unit normal vector points toward the center of the circle from every point on the circle. Since $\vec{\mathbf{r}}(t)$ defines a curve in two dimensions, we cannot calculate the binormal vector.



2. This function looks like this:



To find the principal unit normal vector, we first find the unit tangent vector $\vec{\mathbf{T}}(t)$ :

$$\begin{aligned}\vec{\mathbf{T}}(t) &= \frac{\vec{\mathbf{r}}'(t)}{\|\vec{\mathbf{r}}'(t)\|} \\ &= \frac{6\hat{\mathbf{i}} + 10t\hat{\mathbf{j}} - 8\hat{\mathbf{k}}}{\sqrt{6^2 + (10t)^2 + (-8)^2}} \\ &= \frac{6\hat{\mathbf{i}} + 10t\hat{\mathbf{j}} - 8\hat{\mathbf{k}}}{\sqrt{36 + 100t^2 + 64}} \\ &= \frac{6\hat{\mathbf{i}} + 10t\hat{\mathbf{j}} - 8\hat{\mathbf{k}}}{\sqrt{100(t^2 + 1)}} \\ &= \frac{3\hat{\mathbf{i}} - 5t\hat{\mathbf{j}} - 4\hat{\mathbf{k}}}{5\sqrt{t^2 + 1}} \\ &= \frac{3}{5}(t^2 + 1)^{-1/2}\hat{\mathbf{i}} - t(t^2 + 1)^{-1/2}\hat{\mathbf{j}} - \frac{4}{5}(t^2 + 1)^{-1/2}\hat{\mathbf{k}}.\end{aligned}$$

Next, we calculate $\vec{\mathbf{T}}'(t)$ and $\|\vec{\mathbf{T}}'(t)\|$:

$$\begin{aligned}\vec{\mathbf{T}}'(t) &= \frac{3}{5}(-\frac{1}{2})(t^2 + 1)^{-3/2}(2t)\hat{\mathbf{i}} - ((t^2 + 1)^{-1/2} - t(\frac{1}{2})(t^2 + 1)^{-3/2}(2t))\hat{\mathbf{j}} \\ &\quad - \frac{4}{5}(-\frac{1}{2})(t^2 + 1)^{-3/2}(2t)\hat{\mathbf{k}} \\ &= -\frac{3t}{5(t^2 + 1)^{3/2}}\hat{\mathbf{i}} - \frac{1}{(t^2 + 1)^{3/2}}\hat{\mathbf{j}} + \frac{4t}{5(t^2 + 1)^{3/2}}\hat{\mathbf{k}} \\ \|\vec{\mathbf{T}}'(t)\| &= \sqrt{\left(-\frac{3t}{5(t^2 + 1)^{3/2}}\right)^2 + \left(-\frac{1}{(t^2 + 1)^{3/2}}\right)^2 + \left(\frac{4t}{5(t^2 + 1)^{3/2}}\right)^2} \\ &= \sqrt{\frac{9t^2}{25(t^2 + 1)^3} + \frac{1}{(t^2 + 1)^3} + \frac{16t^2}{25(t^2 + 1)^3}} \\ &= \sqrt{\frac{25t^2 + 25}{25(t^2 + 1)^3}} \\ &= \sqrt{\frac{1}{(t^2 + 1)^2}} \\ &= \frac{1}{t^2 + 1}.\end{aligned}$$

Therefore, according to 13.4.9 :

$$\begin{aligned}\vec{\mathbf{N}}(t) &= \frac{\vec{\mathbf{T}}'(t)}{\|\vec{\mathbf{T}}'(t)\|} \\ &= \left(-\frac{3t}{5(t^2+1)^{3/2}}\,\hat{\mathbf{i}} - \frac{1}{(t^2+1)^{3/2}}\,\hat{\mathbf{j}} + \frac{4t}{5(t^2+1)^{3/2}}\,\hat{\mathbf{k}}\right)(t^2+1) \\ &= -\frac{3t}{5(t^2+1)^{1/2}}\,\hat{\mathbf{i}} - \frac{5}{5(t^2+1)^{1/2}}\,\hat{\mathbf{j}} + \frac{4t}{5(t^2+1)^{1/2}}\,\hat{\mathbf{k}} \\ &= -\frac{3t\,\hat{\mathbf{i}} + 5\,\hat{\mathbf{j}} - 4t\,\hat{\mathbf{k}}}{5\sqrt{t^2+1}}.\end{aligned}$$

Once again, the unit tangent vector and the principal unit normal vector are orthogonal to each other for all values of $t$:

$$\begin{aligned}\vec{\mathbf{T}}(t)\cdot\vec{\mathbf{N}}(t) &= \left(\frac{3\,\hat{\mathbf{i}} - 5t\,\hat{\mathbf{j}} - 4\,\hat{\mathbf{k}}}{5\sqrt{t^2+1}}\right)\cdot\left(-\frac{3t\,\hat{\mathbf{i}} + 5\,\hat{\mathbf{j}} - 4t\,\hat{\mathbf{k}}}{5\sqrt{t^2+1}}\right) \\ &= \frac{3(-3t) - 5t(-5) - 4(4t)}{25(t^2+1)} \\ &= \frac{-9t + 25t - 16t}{25(t^2+1)} \\ &= 0.\end{aligned}$$

Last, since $\vec{\mathbf{r}}(t)$ represents a three-dimensional curve, we can calculate the binormal vector using 13.4.10 :

$$\begin{aligned}\vec{\mathbf{B}}(t) &= \vec{\mathbf{T}}(t)\times\vec{\mathbf{N}}(t) \\ &= \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ \dfrac{3}{5\sqrt{t^2+1}} & -\dfrac{5t}{5\sqrt{t^2+1}} & -\dfrac{4}{5\sqrt{t^2+1}} \\ -\dfrac{3t}{5\sqrt{t^2+1}} & -\dfrac{5}{5\sqrt{t^2+1}} & \dfrac{4t}{5\sqrt{t^2+1}} \end{vmatrix} \\ &= \left(\left(-\frac{5t}{5\sqrt{t^2+1}}\right)\left(\frac{4t}{5\sqrt{t^2+1}}\right) - \left(-\frac{4}{5\sqrt{t^2+1}}\right)\left(-\frac{5}{5\sqrt{t^2+1}}\right)\right)\hat{\mathbf{i}} \\ &- \left(\left(\frac{3}{5\sqrt{t^2+1}}\right)\left(\frac{4t}{5\sqrt{t^2+1}}\right) - \left(-\frac{4}{5\sqrt{t^2+1}}\right)\left(-\frac{3t}{5\sqrt{t^2+1}}\right)\right)\hat{\mathbf{j}} \\ &+ \left(\left(\frac{3}{5\sqrt{t^2+1}}\right)\left(-\frac{5}{5\sqrt{t^2+1}}\right) - \left(-\frac{5t}{5\sqrt{t^2+1}}\right)\left(-\frac{3t}{5\sqrt{t^2+1}}\right)\right)\hat{\mathbf{k}} \\ &= \left(\frac{-20t^2-20}{25(t^2+1)}\right)\hat{\mathbf{i}} + \left(\frac{-15-15t^2}{25(t^2+1)}\right)\hat{\mathbf{k}} \\ &= -20\left(\frac{t^2+1}{25(t^2+1)}\right)\hat{\mathbf{i}} - 15\left(\frac{t^2+1}{25(t^2+1)}\right)\hat{\mathbf{k}} \\ &= -\frac{4}{5}\,\hat{\mathbf{i}} - \frac{3}{5}\,\hat{\mathbf{k}}.\end{aligned}$$

## ? Exercise 13.4.4

Find the unit normal vector for the vector-valued function $\vec{\mathbf{r}}(t) = (t^2-3t)\,\hat{\mathbf{i}} + (4t+1)\,\hat{\mathbf{j}}$ and evaluate it at $t=2$.

**Hint**

First, find $\vec{\mathbf{T}}(t)$, then use 13.4.9.

**Answer**

$$\vec{\mathbf{N}}(2) = \frac{\sqrt{2}}{2}(\hat{\mathbf{i}} - \hat{\mathbf{j}})$$

For any smooth curve in three dimensions that is defined by a vector-valued function, we now have formulas for the unit tangent vector $\vec{\mathbf{T}}$, the unit normal vector $\vec{\mathbf{N}}$, and the binormal vector $\vec{\mathbf{B}}$. The unit normal vector and the binormal vector form a plane that is perpendicular to the curve at any point on the curve, called the normal plane. In addition, these three vectors form a frame of reference in three-dimensional space called the *Frenet frame of reference* (also called the **TNB** frame) (Figure **13.4.2**). Last, the plane determined by the vectors $\vec{\mathbf{T}}$ and $\vec{\mathbf{N}}$ forms the osculating plane of $C$ at any point $P$ on the curve.

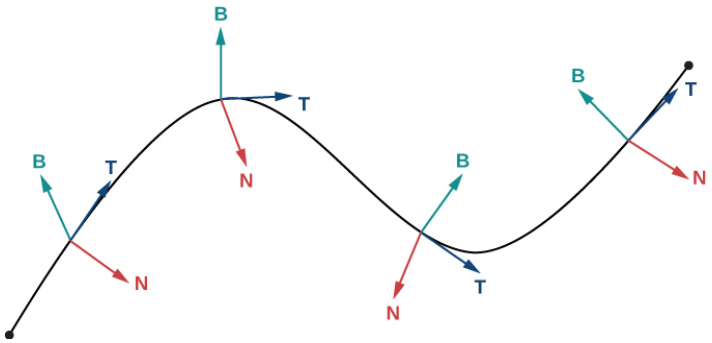


Figure **13.4.2**: This figure depicts a Frenet frame of reference. At every point $P$ *on a three-dimensional curve, the unit tangent, unit normal, and binormal vectors form a three-dimensional frame of reference.*

Suppose we form a circle in the osculating plane of $C$ at point $P$ on the curve. Assume that the circle has the same curvature as the curve does at point $P$ and let the circle have radius $r$. Then, the curvature of the circle is given by $\frac{1}{r}$. We call $r$ the radius of curvature of the curve, and it is equal to the reciprocal of the curvature. If this circle lies on the concave side of the curve and is tangent to the curve at point $P$, then this circle is called the *osculating circle* of $C$ at $P$, as shown in Figure **13.4.3**.

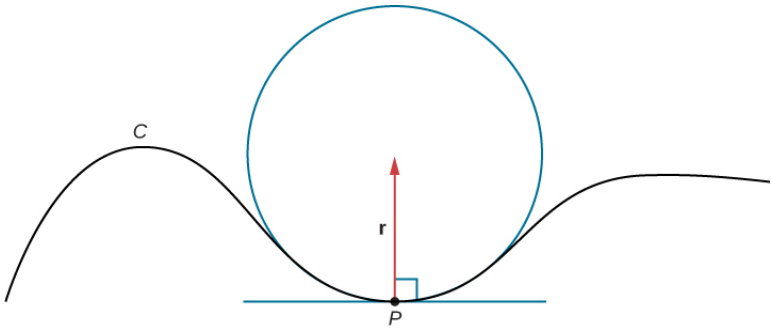

Figure **13.4.3**: In this osculating circle, the circle is tangent to curve $C$ at point $P$ *and shares the same curvature.*

For more information on osculating circles, see this demonstration on curvature and torsion, this article on osculating circles, and this discussion of Serret formulas.

To find the equation of an osculating circle in two dimensions, we need find only the center and radius of the circle.

### Example 13.4.5: Finding the Equation of an Osculating Circle

Find the equation of the osculating circle of the curve defined by the function $y = x^3 - 3x + 1$ at $x = 1$.

**Solution**

Figure **13.4.4** shows the graph of $y = x^3 - 3x + 1$.

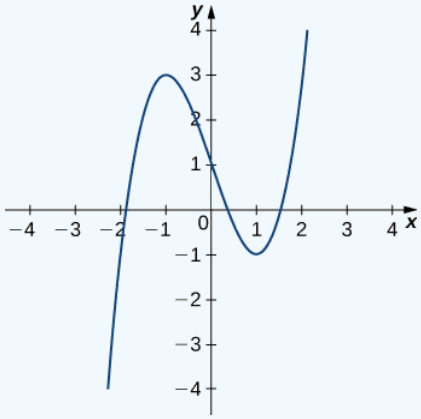

Figure 13.4.4: We want to find the osculating circle of this graph at the point where $x = 1$.

First, let's calculate the curvature at $x = 1$:

$$\kappa = \frac{|f''(x)|}{\left(1 + [f'(x)]^2\right)^{3/2}} = \frac{|6x|}{(1 + [3x^2 - 3]^2)^{3/2}}.$$

This gives $\kappa = 6$. Therefore, the radius of the osculating circle is given by $R = \frac{1}{\kappa} = \frac{1}{6}$. Next, we then calculate the coordinates of the center of the circle. When $x = 1$, the slope of the tangent line is zero. Therefore, the center of the osculating circle is directly above the point on the graph with coordinates $(1, -1)$. The center is located at $(1, -\frac{5}{6})$. The formula for a circle with radius $r$ and center $(h, k)$ is given by $(x - h)^2 + (y - k)^2 = r^2$. Therefore, the equation of the osculating circle is $(x - 1)^2 + (y + \frac{5}{6})^2 = \frac{1}{36}$. The graph and its osculating circle appears in the following graph.

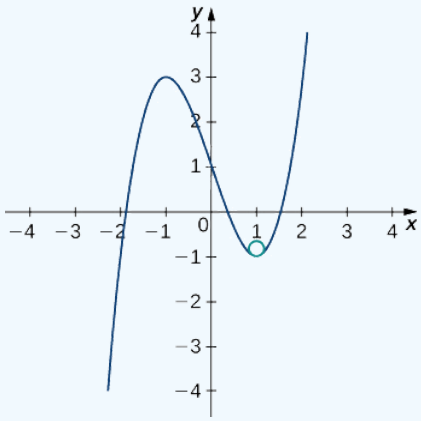

Figure 13.4.5: The osculating circle has radius $R = \frac{1}{6}$.

## ? Exercise 13.4.5

Find the equation of the osculating circle of the curve defined by the vector-valued function $y = 2x^2 - 4x + 5$ at $x = 1$.

**Hint**

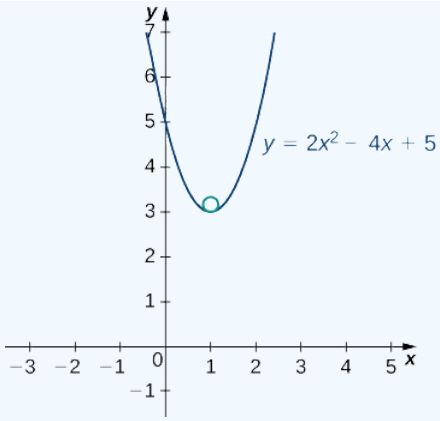
Use 13.4.8 to find the curvature of the graph, then draw a graph of the function around $x = 1$ to help visualize the circle in relation to the graph.

**Answer**

$\kappa = \frac{4}{[1+(4x-4)^2]^{3/2}}$

At the point $x = 1$, the curvature is equal to $4$. Therefore, the radius of the osculating circle is $\frac{1}{4}$.

A graph of this function appears next:



The vertex of this parabola is located at the point $(1, 3)$. Furthermore, the center of the osculating circle is directly above the vertex. Therefore, the coordinates of the center are $(1, \frac{13}{4})$. The equation of the osculating circle is

$(x-1)^2 + (y-\frac{13}{4})^2 = \frac{1}{16}$.

## Key Concepts

- The arc-length function for a vector-valued function is calculated using the integral formula $s(t) = \int_a^b \|\vec{\mathbf{r}}'(t)\|\, dt$. This formula is valid in both two and three dimensions.
- The curvature of a curve at a point in either two or three dimensions is defined to be the curvature of the inscribed circle at that point. The arc-length parameterization is used in the definition of curvature.
- There are several different formulas for curvature. The curvature of a circle is equal to the reciprocal of its radius.
- The principal unit normal vector at $t$ is defined to be

$$\vec{\mathbf{N}}(t) = \frac{\vec{\mathbf{T}}'(t)}{\|\vec{\mathbf{T}}'(t)\|}.$$

- The binormal vector at $t$ is defined as $\vec{\mathbf{B}}(t) = \vec{\mathbf{T}}(t) \times \vec{\mathbf{N}}(t)$, where $\vec{\mathbf{T}}(t)$ is the unit tangent vector.
- The Frenet frame of reference is formed by the unit tangent vector, the principal unit normal vector, and the binormal vector.
- The osculating circle is tangent to a curve at a point and has the same curvature as the tangent curve at that point.

## Key Equations

- **Arc length of space curve**
  $s = \int_a^b \sqrt{[f'(t)]^2 + [g'(t)]^2 + [h'(t)]^2}\, dt = \int_a^b \|\vec{\mathbf{r}}'(t)\|\, dt$
- **Arc-length function**
  $s(t) = \int_a^t \sqrt{f'(u))^2 + (g'(u))^2 + (h'(u))^2}\, du$ *or* $s(t) = \int_a^t \|\vec{\mathbf{r}}'(u)\|\, du$
- $\kappa = \frac{\|\vec{\mathbf{T}}'(t)\|}{\|\vec{\mathbf{r}}'(t)\|}$ *or* $\kappa = \frac{\|\vec{\mathbf{r}}'(t) \times \vec{\mathbf{r}}''(t)\|}{\|\vec{\mathbf{r}}'(t)\|^3}$ *or* $\kappa = \frac{|y''|}{[1+(y')^2]^{3/2}}$
- **Principal unit normal vector**
  $\vec{\mathbf{N}}(t) = \frac{\vec{\mathbf{T}}'(t)}{\|\vec{\mathbf{T}}'(t)\|}$
- **Binormal vector**
  $\vec{\mathbf{B}}(t) = \vec{\mathbf{T}}(t) \times \vec{\mathbf{N}}(t)$

## Glossary

**arc-length function**

a function $s(t)$ that describes the arc length of curve $C$ as a function of $t$

**arc-length parameterization**

a reparameterization of a vector-valued function in which the parameter is equal to the arc length

**binormal vector**

a unit vector orthogonal to the unit tangent vector and the unit normal vector

**curvature**

the derivative of the unit tangent vector with respect to the arc-length parameter

**Frenet frame of reference**

(TNB frame) a frame of reference in three-dimensional space formed by the unit tangent vector, the unit normal vector, and the binormal vector

**normal plane**

a plane that is perpendicular to a curve at any point on the curve

**osculating circle**

a circle that is tangent to a curve $C$ at a point $P$ and that shares the same curvature

**osculating plane**

the plane determined by the unit tangent and the unit normal vector

**principal unit normal vector**

a vector orthogonal to the unit tangent vector, given by the formula $\frac{\vec{\mathbf{T}}'(t)}{\|\vec{\mathbf{T}}'(t)\|}$

**radius of curvature**

the reciprocal of the curvature

**smooth**

curves where the vector-valued function $\vec{\mathbf{r}}(t)$ is differentiable with a non-zero derivative

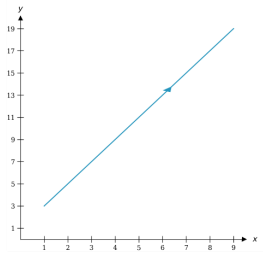
# 13.4E: Exercises for Section 13.3

## Determining Arc Length

**In questions 1 - 5, find the arc length of the curve on the given interval.**

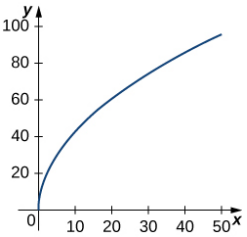
1) $\vec{\mathbf{r}}(t) = t^2\,\hat{\mathbf{i}} + (2t^2+1)\,\hat{\mathbf{j}}, \quad 1 \le t \le 3$. This portion of the graph is shown here:



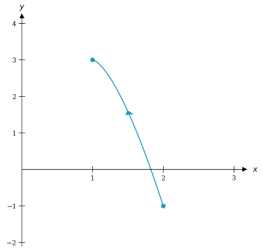
**Answer**

$8\sqrt{5}$ units $\approx 17.9$ units

2) $\vec{\mathbf{r}}(t) = t^2\,\hat{\mathbf{i}} + 14t\,\hat{\mathbf{j}}, \quad 0 \le t \le 7$. This portion of the graph is shown here:



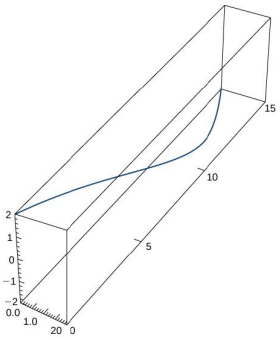
3) $\vec{\mathbf{r}}(t) = \langle t^2+1, 4t^3+3\rangle, \quad -1 \le t \le 0$. This portion of the graph is shown here:



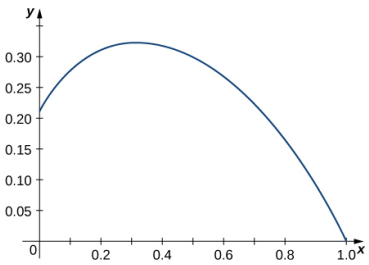
**Answer**

$\frac{1}{54}(37^{3/2}-1)$ units $\approx 4.15$ units

4) $\vec{\mathbf{r}}(t) = \langle 2\sin t, 5t, 2\cos t\rangle, \quad 0 \le t \le \pi$. This portion of the graph is shown here:



5) $\vec{\mathbf{r}}(t) = \langle e^{-t\cos t}, e^{-t\sin t} \rangle$ over the interval $[0, \frac{\pi}{2}]$. Here is the portion of the graph on the indicated interval:



6) Set up an integral to represent the arc length from $t = 0$ to $t = 2$ along the curve traced out by $\vec{\mathbf{r}}(t) = \langle t, t^4 \rangle$. Then use technology to approximate this length to the nearest thousandth of a unit.

7) Find the length of one turn of the helix given by $\vec{\mathbf{r}}(t) = \frac{1}{2}\cos t\,\hat{\mathbf{i}} + \frac{1}{2}\sin t\,\hat{\mathbf{j}} + \frac{\sqrt{3}}{2}t\,\hat{\mathbf{k}}$.

**Answer**

Length $= 2\pi$ units

8) Find the arc length of the vector-valued function $\vec{\mathbf{r}}(t) = -t\,\hat{\mathbf{i}} + 4t\,\hat{\mathbf{j}} + 3t\,\hat{\mathbf{k}}$ over $[0, 1]$.

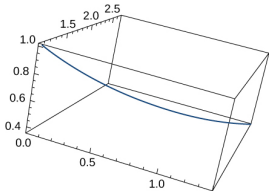
9) A particle travels in a circle with the equation of motion $\vec{\mathbf{r}}(t) = 3\cos t\,\hat{\mathbf{i}} + 3\sin t\,\hat{\mathbf{j}} + 0\,\hat{\mathbf{k}}$. Find the distance traveled around the circle by the particle.

**Answer**

$6\pi$ units

10) Set up an integral to find the circumference of the ellipse with the equation $\vec{\mathbf{r}}(t) = \cos t\,\hat{\mathbf{i}} + 2\sin t\,\hat{\mathbf{j}} + 0\,\hat{\mathbf{k}}$.

11) Find the length of the curve $\vec{\mathbf{r}}(t) = \langle \sqrt{2}t, e^t, e^{-t} \rangle$ over the interval $0 \le t \le 1$. The graph is shown here:



**Answer**

$\left(e - \frac{1}{e}\right)$ units $\approx 2.35$ units

12) Find the length of the curve $\vec{\mathbf{r}}(t) = \langle 2\sin t,\ 5t,\ 2\cos t \rangle$ for $t \in [-10, 10]$.

## Unit Tangent Vectors and Unit Normal Vectors

13) The position function for a particle is $\vec{\mathbf{r}}(t) = a\cos(\omega t)\,\hat{\mathbf{i}} + b\sin(\omega t)\,\hat{\mathbf{j}}$. Find the unit tangent vector and the unit normal vector at $t = 0$.

**Solution:**

$$\vec{\mathbf{r}}'(t) = -a\omega \sin(\omega t)\,\hat{\mathbf{i}} + b\omega \cos(\omega t)\,\hat{\mathbf{j}}$$

$$\|\vec{\mathbf{r}}'(t)\| = \sqrt{a^2\omega^2 \sin^2(\omega t) + b^2\omega^2 \cos^2(\omega t)}$$

$$\vec{\mathbf{T}}(t) = \frac{\vec{\mathbf{r}}'(t)}{\|\vec{\mathbf{r}}'(t)\|} = \frac{-a\omega \sin(\omega t)\,\hat{\mathbf{i}} + b\omega \cos(\omega t)\,\hat{\mathbf{j}}}{\sqrt{a^2\omega^2 \sin^2(\omega t) + b^2\omega^2 \cos^2(\omega t)}}$$

$$\vec{\mathbf{T}}(0) = \frac{b\omega\,\hat{\mathbf{j}}}{\sqrt{(b\omega)^2}} = \frac{b\omega\,\hat{\mathbf{j}}}{|b\omega|}$$

If $b\omega > 0,\ \vec{\mathbf{T}}(0) = \hat{\mathbf{j}}$, and if $b\omega < 0,\ T(0) = -\hat{\mathbf{j}}$

**Answer**

If $b\omega > 0,\ \vec{\mathbf{T}}(0) = \hat{\mathbf{j}}$, and if $b\omega < 0,\ \vec{\mathbf{T}}(0) = -\hat{\mathbf{j}}$

If $a > 0,\ \vec{\mathbf{N}}(0) = -\hat{\mathbf{i}}$, and if $a < 0,\ \vec{\mathbf{N}}(0) = \hat{\mathbf{i}}$

14) Given $\vec{\mathbf{r}}(t) = a\cos(\omega t)\,\hat{\mathbf{i}} + b\sin(\omega t)\,\hat{\mathbf{j}}$, find the binormal vector $\vec{\mathbf{B}}(0)$.

15) Given $\vec{\mathbf{r}}(t) = \langle 2e^t, e^t \cos t, e^t \sin t\rangle$, determine the unit tangent vector $\vec{\mathbf{T}}(t)$.

**Answer**

$$\vec{\mathbf{T}}(t) = \left\langle \frac{2}{\sqrt{6}}, \frac{\cos t - \sin t}{\sqrt{6}}, \frac{\cos t + \sin t}{\sqrt{6}} \right\rangle$$

$$= \left\langle \frac{\sqrt{6}}{3}, \frac{\sqrt{6}}{6}(\cos t - \sin t), \frac{\sqrt{6}}{6}(\cos t + \sin t) \right\rangle$$

16) Given $\vec{\mathbf{r}}(t) = \langle 2e^t,\ e^t \cos t,\ e^t \sin t\rangle$, find the unit tangent vector $\vec{\mathbf{T}}(t)$ evaluated at $t = 0$, $\vec{\mathbf{T}}(0)$.

17) Given $\vec{\mathbf{r}}(t) = \langle 2e^t,\ e^t \cos t,\ e^t \sin t\rangle$, determine the unit normal vector $\vec{\mathbf{N}}(t)$.

**Answer**

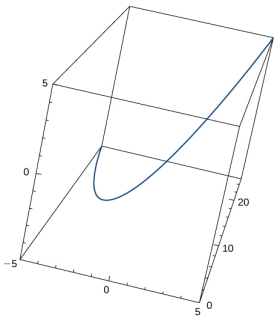
$$\vec{\mathbf{N}}(t) = \langle 0, -\tfrac{\sqrt{2}}{2}(\sin t + \cos t), \tfrac{\sqrt{2}}{2}(\cos t - \sin t)\rangle$$

18) Given $\vec{\mathbf{r}}(t) = \langle 2e^t,\ e^t \cos t,\ e^t \sin t\rangle$, find the unit normal vector $\vec{\mathbf{N}}(t)$ evaluated at $t = 0$, $\vec{\mathbf{N}}(0)$.

**Answer**

$$\vec{\mathbf{N}}(0) = \langle 0,\ -\tfrac{\sqrt{2}}{2},\ \tfrac{\sqrt{2}}{2}\rangle$$

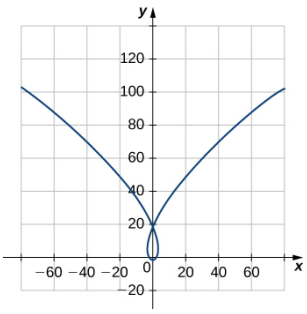
19) Given $\vec{\mathbf{r}}(t) = t\,\hat{\mathbf{i}} + t^2\,\hat{\mathbf{j}} + t\,\hat{\mathbf{k}}$, find the unit tangent vector $\vec{\mathbf{T}}(t)$. The graph is shown here:



**Answer**

$$\vec{\mathbf{T}}(t) = \frac{1}{\sqrt{4t^2 + 2}} < 1, 2t, 1 >$$

20) Find the unit tangent vector $\vec{\mathbf{T}}(t)$ and unit normal vector $\vec{\mathbf{N}}(t)$ at $t = 0$ for the plane curve $\vec{\mathbf{r}}(t) = \langle t^3 - 4t, 5t^2 - 2\rangle$. The graph is shown here:



21) Find the unit tangent vector $\vec{\mathbf{T}}(t)$ for $\vec{\mathbf{r}}(t) = 3t\,\hat{\mathbf{i}} + 5t^2\,\hat{\mathbf{j}} + 2t\,\hat{\mathbf{k}}$.

**Answer**

$$\vec{\mathbf{T}}(t) = \frac{1}{\sqrt{100t^2 + 13}}(3\,\hat{\mathbf{i}} + 10t\,\hat{\mathbf{j}} + 2\,\hat{\mathbf{k}})$$

22) Find the principal normal vector to the curve $\vec{\mathbf{r}}(t) = \langle 6\cos t, 6\sin t\rangle$ at the point determined by $t = \frac{\pi}{3}$.

23) Find $\vec{\mathbf{T}}(t)$ for the curve $\vec{\mathbf{r}}(t) = (t^3 - 4t)\,\hat{\mathbf{i}} + (5t^2 - 2)\,\hat{\mathbf{j}}$.

**Answer**

$$\vec{\mathbf{T}}(t) = \frac{1}{\sqrt{9t^4 + 76t^2 + 16}}\left((3t^2 - 4)\,\hat{\mathbf{i}} + 10t\,\hat{\mathbf{j}}\right)$$

24) Find $\vec{\mathbf{N}}(t)$ for the curve $\vec{\mathbf{r}}(t) = (t^3 - 4t)\,\hat{\mathbf{i}} + (5t^2 - 2)\,\hat{\mathbf{j}}$.

25) Find the unit tangent vector $\vec{\mathbf{T}}(t)$ for $\vec{\mathbf{r}}(t) = \langle 2\sin t,\ 5t,\ 2\cos t\rangle$.

**Answer**

$$\vec{\mathbf{T}}(t) = \langle \tfrac{2\sqrt{29}}{29}\cos t,\ \tfrac{5\sqrt{29}}{29},\ -\tfrac{2\sqrt{29}}{29}\sin t\rangle$$

26) Find the unit normal vector $\vec{\mathbf{N}}(t)$ for $\vec{\mathbf{r}}(t) = \langle 2\sin t,\ 5t,\ 2\cos t\rangle$.

**Answer**

$$\vec{\mathbf{N}}(t) = \langle -\sin t,\ 0,\ -\cos t\rangle$$

## Arc Length Parameterizations

27) Find the arc-length function $\vec{\mathbf{s}}(t)$ for the line segment given by $\vec{\mathbf{r}}(t) = \langle 3 - 3t,\ 4t\rangle$. Then write the arc-length parameterization of $r$ with $s$ as the parameter.

**Answer**

Arc-length function: $s(t) = 5t$; The arc-length parameterization of $\vec{\mathbf{r}}(t)$: $\vec{\mathbf{r}}(s) = \left(3 - \frac{3s}{5}\right)\hat{\mathbf{i}} + \frac{4s}{5}\,\hat{\mathbf{j}}$

28) Parameterize the helix $\vec{\mathbf{r}}(t) = \cos t\,\hat{\mathbf{i}} + \sin t\,\hat{\mathbf{j}} + t\,\hat{\mathbf{k}}$ using the arc-length parameter $s$, from $t = 0$.

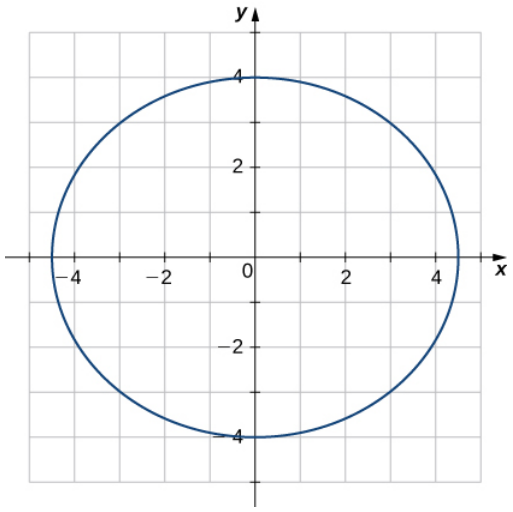
29) Parameterize the curve using the arc-length parameter $s$, at the point at which $t = 0$ for $\vec{\mathbf{r}}(t) = e^t \sin t\,\hat{\mathbf{i}} + e^t \cos t\,\hat{\mathbf{j}}$

**Answer**

$$\vec{\mathbf{r}}(s) = \left(1 + \frac{s}{\sqrt{2}}\right)\sin\left(\ln\left(1 + \frac{s}{\sqrt{2}}\right)\right)\hat{\mathbf{i}} + \left(1 + \frac{s}{\sqrt{2}}\right)\cos\left(\ln\left(1 + \frac{s}{\sqrt{2}}\right)\right)\hat{\mathbf{j}}$$

## Curvature and the Osculating Circle

30) Find the curvature of the curve $\vec{\mathbf{r}}(t) = 5\cos t\,\hat{\mathbf{i}} + 4\sin t\,\hat{\mathbf{j}}$ at $t = \pi/3$. (*Note:* The graph is an ellipse.)



31) Find the $x$-coordinate at which the curvature of the curve $y = 1/x$ is a maximum value.

**Answer**

The maximum value of the curvature occurs at $x = 1$.

32) Find the curvature of the curve $\vec{\mathbf{r}}(t) = 5\cos t\,\hat{\mathbf{i}} + 5\sin t\,\hat{\mathbf{j}}$. Does the curvature depend upon the parameter $t$?

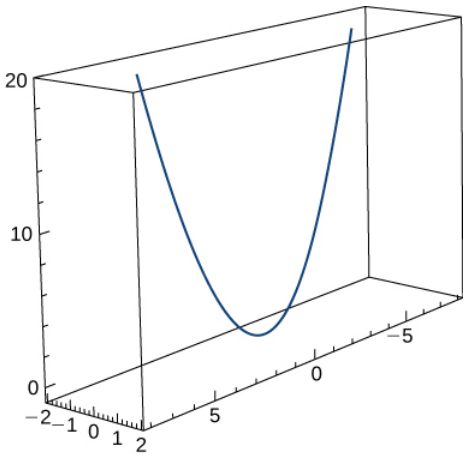
33) Find the curvature $\kappa$ for the curve $y = x - \frac{1}{4}x^2$ at the point $x = 2$.

**Answer**

$\frac{1}{2}$

34) Find the curvature $\kappa$ for the curve $y = \frac{1}{3}x^3$ at the point $x = 1$.

35) Find the curvature $\kappa$ of the curve $\vec{\mathbf{r}}(t) = t\,\hat{\mathbf{i}} + 6t^2\,\hat{\mathbf{j}} + 4t\,\hat{\mathbf{k}}$. The graph is shown here:



**Answer**

$$\kappa \approx \frac{49.477}{(17 + 144t^2)^{3/2}}$$

36) Find the curvature of $\vec{\mathbf{r}}(t) = \langle 2\sin t, 5t, 2\cos t\rangle$.

37) Find the curvature of $\vec{\mathbf{r}}(t) = \sqrt{2}t\,\hat{\mathbf{i}} + e^t\,\hat{\mathbf{j}} + e^{-t}\,\hat{\mathbf{k}}$ at point $P(0, 1, 1)$.

**Answer**

$\frac{1}{2\sqrt{2}}$

38) At what point does the curve $y = e^x$ have maximum curvature?

39) What happens to the curvature as $x \to \infty$ for the curve $y = e^x$?

**Answer**

The curvature approaches zero.

40) Find the point of maximum curvature on the curve $y = \ln x$.

41) Find the equations of the normal plane and the osculating plane of the curve $\vec{\mathbf{r}}(t) = \langle 2\sin(3t), t, 2\cos(3t)\rangle$ at point $(0, \pi, -2)$.

**Answer**

$y = 6x + \pi$ and $x + 6y = 6\pi$

42) Find equations of the osculating circles of the ellipse $4y^2 + 9x^2 = 36$ at the points $(2, 0)$ and $(0, 3)$.

43) Find the equation for the osculating plane at point $t = \pi/4$ on the curve $\vec{\mathbf{r}}(t) = \cos(2t)\,\hat{\mathbf{i}} + \sin(2t)\,\hat{\mathbf{j}} + t\,\hat{\mathbf{k}}$.

**Answer**

$x + 2z = \frac{\pi}{2}$

44) Find the radius of curvature of $6y = x^3$ at the point $(2, \frac{4}{3})$.

45) Find the curvature at each point $(x, y)$ on the hyperbola $\vec{\mathbf{r}}(t) = \langle a\cosh(t), b\sinh(t)\rangle$.

**Answer**

$$\frac{a^4b^4}{(b^4x^2 + a^4y^2)^{3/2}}$$

46) Calculate the curvature of the circular helix $\vec{\mathbf{r}}(t) = r\sin(t)\,\hat{\mathbf{i}} + r\cos(t)\,\hat{\mathbf{j}} + t\,\hat{\mathbf{k}}$.

47) Find the radius of curvature of $y = \ln(x + 1)$ at point $(2, \ln 3)$.

**Answer**

$\frac{10\sqrt{10}}{3}$

48) Find the radius of curvature of the hyperbola $xy = 1$ at point $(1, 1)$.

**A particle moves along the plane curve $C$ described by $\vec{\mathbf{r}}(t) = t\,\hat{\mathbf{i}} + t^2\,\hat{\mathbf{j}}$. Use this parameterization to answer questions 49 - 51.**

49) Find the length of the curve over the interval $[0, 2]$.

**Answer**

$\frac{1}{4}\left[4\sqrt{17} + \ln\left(4 + \sqrt{17}\right)\right]$ units $\approx 4.64678$ units

50) Find the curvature of the plane curve at $t = 0, 1, 2$.

51) Describe the curvature as $t$ increases from $t = 0$ to $t = 2$.

**Answer**

The curvature is decreasing over this interval.

The surface of a large cup is formed by revolving the graph of the function $y = 0.25x^{1.6}$ from $x = 0$ to $x = 5$ about the $y$-axis (measured in centimeters).

52) **[T]** Use technology to graph the surface.

53) Find the curvature $\kappa$ of the generating curve as a function of $x$.

**Answer**

$$\kappa = \frac{30}{x^{2/5}\left(25+4x^{6/5}\right)^{3/2}}$$

Note that initially your answer may be:

$$\frac{6}{25x^{2/5}\left(1+\frac{4}{25}x^{6/5}\right)^{3/2}}$$

We can simplify it as follows:

$$\begin{aligned}\frac{6}{25x^{2/5}\left(1+\frac{4}{25}x^{6/5}\right)^{3/2}} &= \frac{6}{25x^{2/5}\left[\frac{1}{25}\left(25+4x^{6/5}\right)\right]^{3/2}} \\ &= \frac{6}{25x^{2/5}\left(\frac{1}{25}\right)^{3/2}\left[25+4x^{6/5}\right]^{3/2}} \\ &= \frac{6}{\frac{25}{125}x^{2/5}\left[25+4x^{6/5}\right]^{3/2}} \\ &= \frac{30}{x^{2/5}\left(25+4x^{6/5}\right)^{3/2}}\end{aligned}$$

54) **[T]** Use technology to graph the curvature function.

# 13.5: Motion in Space

**Learning Objectives**

- Describe the velocity and acceleration vectors of a particle moving in space.
- Explain the tangential and normal components of acceleration.
- State Kepler's laws of planetary motion.

We have now seen how to describe curves in the plane and in space, and how to determine their properties, such as arc length and curvature. All of this leads to the main goal of this chapter, which is the description of motion along plane curves and space curves. We now have all the tools we need; in this section, we put these ideas together and look at how to use them.

## Motion Vectors in the Plane and in Space

Our starting point is using vector-valued functions to represent the position of an object as a function of time. All of the following material can be applied either to curves in the plane or to space curves. For example, when we look at the orbit of the planets, the curves defining these orbits all lie in a plane because they are elliptical. However, a particle traveling along a helix moves on a curve in three dimensions.

**Definition: Speed, Velocity, and Acceleration**

Let $\vec{\mathbf{r}}(t)$ be a twice-differentiable vector-valued function of the parameter $t$ that represents the position of an object as a function of time.

The velocity vector $\vec{\mathbf{v}}(t)$ of the object is given by

$$\text{Velocity } = \vec{\mathbf{v}}(t) = \vec{\mathbf{r}}\,'(t). \tag{13.5.1}$$

The acceleration vector $\vec{\mathbf{a}}(t)$ is defined to be

$$\text{Acceleration } = \vec{\mathbf{a}}(t) = \vec{\mathbf{v}}\,'(t) = \vec{\mathbf{r}}\,''(t). \tag{13.5.2}$$

The *speed* is defined to be

$$\text{Speed } = v(t) = \|\vec{\mathbf{v}}(t)\| = \|\vec{\mathbf{r}}\,'(t)\| = \frac{ds}{dt}. \tag{13.5.3}$$

Since $\vec{\mathbf{r}}(t)$ can be in either two or three dimensions, these vector-valued functions can have either two or three components. In two dimensions, we define $\vec{\mathbf{r}}(t) = x(t)\hat{\mathbf{i}} + y(t)\hat{\mathbf{j}}$ and in three dimensions $\vec{\mathbf{r}}(t) = x(t)\hat{\mathbf{i}} + y(t)\hat{\mathbf{j}} + z(t)\hat{\mathbf{k}}$. Then the velocity, acceleration, and speed can be written as shown in the following table.

Table **13.5.1**: Formulas for Position, Velocity, Acceleration, and Speed

| Quantity | Two Dimensions | Three Dimensions |
|---|---|---|
| Position | $\vec{\mathbf{r}}(t) = x(t)\hat{\mathbf{i}} + y(t)\hat{\mathbf{j}}$ | $\vec{\mathbf{r}}(t) = x(t)\hat{\mathbf{i}} + y(t)\hat{\mathbf{j}} + z(t)\hat{\mathbf{k}}$ |
| Velocity | $\vec{\mathbf{v}}(t) = x'(t)\hat{\mathbf{i}} + y'(t)\hat{\mathbf{j}}$ | $\vec{\mathbf{v}}(t) = x'(t)\hat{\mathbf{i}} + y'(t)\hat{\mathbf{j}} + z'(t)\hat{\mathbf{k}}$ |
| Acceleration | $\vec{\mathbf{a}}(t) = x''(t)\hat{\mathbf{i}} + y''(t)\hat{\mathbf{j}}$ | $\vec{\mathbf{a}}(t) = x''(t)\hat{\mathbf{i}} + y''(t)\hat{\mathbf{j}} + z''(t)\hat{\mathbf{k}}$ |
| Speed | $\|\vec{\mathbf{v}}(t)\| = \sqrt{(x'(t))^2 + (y'(t))^2}$ | $\|\vec{\mathbf{v}}(t)\| = \sqrt{(x'(t))^2 + (y'(t))^2 + (z'(t))^2}$ |

**Example 13.5.1: Studying Motion Along a Parabola**

A particle moves in a parabolic path defined by the vector-valued function $\vec{\mathbf{r}}(t) = t^2\hat{\mathbf{i}} + \sqrt{5 - t^2}\hat{\mathbf{j}}$, where $t$ measures time in seconds.

1. Find the velocity, acceleration, and speed as functions of time.

2. Sketch the curve along with the velocity vector at time $t = 1$.

**Solution**

1. We use Equations 13.5.1, 13.5.2, and 13.5.3:

$$\vec{\mathbf{v}}(t) = \vec{\mathbf{r}}\,'(t) = 2t\hat{\mathbf{i}} - \frac{t}{\sqrt{5-t^2}}\hat{\mathbf{j}}$$

$$\vec{\mathbf{a}}(t) = \vec{\mathbf{v}}\,'(t) = 2\hat{\mathbf{i}} - 5(5-t^2)^{-\frac{3}{2}}\hat{\mathbf{j}}$$

$$\begin{aligned} ||\vec{\mathbf{v}}(t)|| &= ||\vec{\mathbf{r}}\,'(t)|| \\ &= \sqrt{(2t)^2 + \left(-\frac{t}{\sqrt{5-t^2}}\right)^2} \\ &= \sqrt{4t^2 + \frac{t^2}{5-t^2}} \\ &= \sqrt{\frac{21t^2 - 4t^4}{5-t^2}}. \end{aligned}$$

2. The graph of $\vec{\mathbf{r}}(t) = t^2\hat{\mathbf{i}} + \sqrt{5-t^2}\hat{\mathbf{j}}$ is a portion of a parabola (Figure 13.5.1).

When $t = 1$, $\vec{\mathbf{r}}(1) = (1)^2\hat{\mathbf{i}} + \sqrt{5-(1)^2}\hat{\mathbf{j}} = \hat{\mathbf{i}} + \sqrt{4}\hat{\mathbf{j}} = \hat{\mathbf{i}} + 2\hat{\mathbf{j}}$.

Thus the particle would be located at the point $(1, 2)$ when $t = 1$.

The velocity vector at $t = 1$ is

$$\begin{aligned} \vec{\mathbf{v}}(1) = \vec{\mathbf{r}}\,'(1) &= 2(1)\hat{\mathbf{i}} - \frac{1}{\sqrt{5-1^2}}\hat{\mathbf{j}} \\ &= 2\hat{\mathbf{i}} - \frac{1}{2}\hat{\mathbf{j}} \end{aligned}$$

and the acceleration vector at $t = 1$ is

$$\vec{\mathbf{a}}(1) = \vec{\mathbf{v}}\,'(1) = 2\hat{\mathbf{i}} - 5(5-1^2)^{-3/2}\hat{\mathbf{j}} = 2\hat{\mathbf{i}} - \frac{5}{8}\hat{\mathbf{j}}.$$

Notice that the velocity vector is tangent to the path, as is always the case.

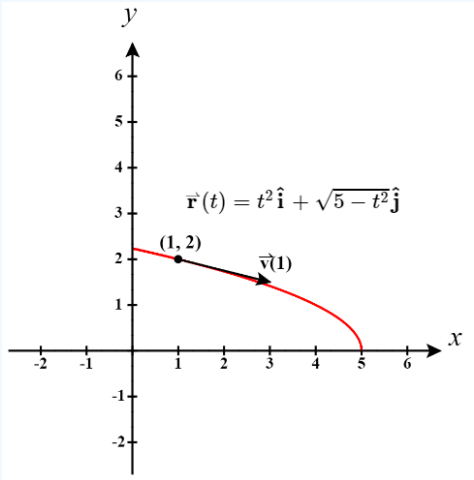

Figure 13.5.1: This graph depicts the velocity vector at time $t = 1$ for a particle moving in a parabolic path.

**? Exercise 13.5.1**

A particle moves in a path defined by the vector-valued function $\vec{\mathbf{r}}(t) = (t^2 - 3t)\,\hat{\mathbf{i}} + (2t - 4)\,\hat{\mathbf{j}} + (t + 2)\,\hat{\mathbf{k}}$, where $t$ measures time in seconds and where distance is measured in feet. Find the velocity, acceleration, and speed as functions of time.

**Hint**

Use Equations 13.5.1, 13.5.2, and 13.5.3.

**Answer**

$$\vec{\mathbf{v}}(t) = \vec{\mathbf{r}}\,'(t) = (2t - 3)\,\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + \hat{\mathbf{k}}$$

$$\vec{\mathbf{a}}(t) = \vec{\mathbf{v}}\,'(t) = 2\hat{\mathbf{i}}$$

$$||\vec{\mathbf{r}}\,'(t)|| = \sqrt{(2t - 3)^2 + 2^2 + 1^2} = \sqrt{4t^2 - 12t + 14}$$

The units for velocity and speed are feet per second, and the units for acceleration are feet per second squared.

To gain a better understanding of the velocity and acceleration vectors, imagine you are driving along a curvy road. If you do not turn the steering wheel, you would continue in a straight line and run off the road. The speed at which you are traveling when you run off the road, coupled with the direction, gives a vector representing your velocity, as illustrated in Figure 13.5.2.

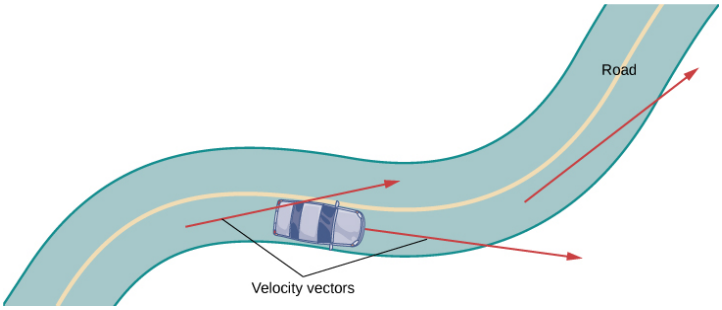

Figure 13.5.2: At each point along a road traveled by a car, the velocity vector of the car is tangent to the path traveled by the car.

However, the fact that you must turn the steering wheel to stay on the road indicates that your velocity is always changing (even if your speed is not) because your *direction* is constantly changing to keep you on the road. As you turn to the right, your acceleration vector also points to the right. As you turn to the left, your acceleration vector points to the left. This indicates that your velocity and acceleration vectors are constantly changing, regardless of whether your actual speed varies (Figure 13.5.3).

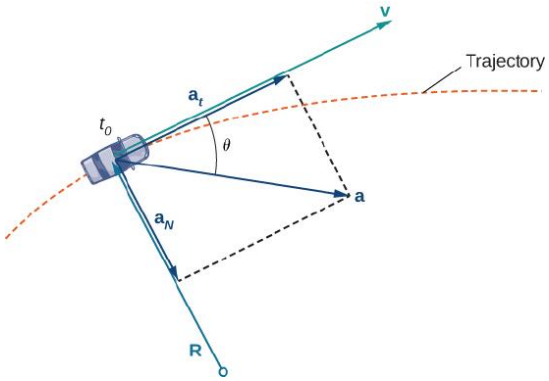

Figure 13.5.3: The dashed line represents the trajectory of an object (a car, for example). The acceleration vector points toward the inside of the turn at all times.

## Components of the Acceleration Vector

We can combine some of the concepts discussed in Arc Length and Curvature with the acceleration vector to gain a deeper understanding of how this vector relates to motion in the plane and in space. Recall that the unit tangent vector $\vec{\mathbf{T}}$ and the unit normal vector $\vec{\mathbf{N}}$ form an osculating plane at any point $P$ on the curve defined by a vector-valued function $\vec{\mathbf{r}}(t)$. The following

theorem shows that the acceleration vector $\vec{\mathbf{a}}(t)$ lies in the osculating plane and can be written as a linear combination of the unit tangent and the unit normal vectors.

**Theorem 13.5.1: The Plane of the Acceleration Vector**

The acceleration vector $\vec{\mathbf{a}}(t)$ of an object moving along a curve traced out by a twice-differentiable function $\vec{\mathbf{r}}(t)$ lies in the plane formed by the unit tangent vector $\vec{\mathbf{T}}(t)$ and the principal unit normal vector $\vec{\mathbf{N}}(t)$ to $C$. Furthermore,

$$\vec{\mathbf{a}}(t) = v'(t)\vec{\mathbf{T}}(t) + [v(t)]^2\kappa\vec{\mathbf{N}}(t)$$

Here, $v(t) = \|\vec{\mathbf{v}}(t)\|$ is the speed of the object and $\kappa$ is the curvature of $C$ traced out by $\vec{\mathbf{r}}(t)$.

**Proof**

Because $\vec{\mathbf{v}}(t) = \vec{\mathbf{r}}\,'(t)$ and $\vec{\mathbf{T}}(t) = \dfrac{\vec{\mathbf{r}}\,'(t)}{\|\vec{\mathbf{r}}\,'(t)\|}$, we have $\vec{\mathbf{v}}(t) = \|\vec{\mathbf{r}}\,'(t)\|\vec{\mathbf{T}}(t) = v(t)\vec{\mathbf{T}}(t)$.

Now we differentiate this equation:

$$\vec{\mathbf{a}}(t) = \vec{\mathbf{v}}\,'(t) = \frac{d}{dt}\left(v(t)\vec{\mathbf{T}}(t)\right) = v'(t)\vec{\mathbf{T}}(t) + v(t)\vec{\mathbf{T}}\,'(t)$$

Since $\vec{\mathbf{N}}(t) = \dfrac{\vec{\mathbf{T}}\,'(t)}{\|\vec{\mathbf{T}}\,'(t)\|}$, we know $\vec{\mathbf{T}}\,'(t) = \|\vec{\mathbf{T}}\,'(t)\|\vec{\mathbf{N}}(t)$, so

$$\vec{\mathbf{a}}(t) = v'(t)\vec{\mathbf{T}}(t) + v(t)\|\vec{\mathbf{T}}\,'(t)\|\vec{\mathbf{N}}(t).$$

A formula for curvature is $\kappa = \dfrac{\|\vec{\mathbf{T}}\,'(t)\|}{\|\vec{\mathbf{r}}\,'(t)\|}$, so $\vec{\mathbf{T}}\,'(t) = \kappa\|\vec{\mathbf{r}}\,'(t)\| = \kappa v(t)$.

This gives $\vec{\mathbf{a}}(t) = v'(t)\vec{\mathbf{T}}(t) + \kappa(v(t))^2\vec{\mathbf{N}}(t)$.

□

The coefficients of $\vec{\mathbf{T}}(t)$ and $\vec{\mathbf{N}}(t)$ are referred to as the **tangential component of acceleration** and the **normal component of acceleration**, respectively. We write $a_{\vec{\mathbf{T}}}$ to denote the tangential component and $a_{\vec{\mathbf{N}}}$ to denote the normal component.

**Theorem 13.5.2: Tangential and Normal Components of Acceleration**

Let $\vec{\mathbf{r}}(t)$ be a vector-valued function that denotes the position of an object as a function of time. Then $\vec{\mathbf{a}}(t) = \vec{\mathbf{r}}\,''(t)$ is the acceleration vector. The tangential and normal components of acceleration $a_{\vec{\mathbf{T}}}$ and $a_{\vec{\mathbf{N}}}$ are given by the formulas

$$a_{\vec{\mathbf{T}}} = \vec{\mathbf{a}} \cdot \vec{\mathbf{T}} = \frac{\vec{\mathbf{v}} \cdot \vec{\mathbf{a}}}{\|\vec{\mathbf{v}}\|} \tag{13.5.4}$$

and

$$a_{\vec{\mathbf{N}}} = \vec{\mathbf{a}} \cdot \vec{\mathbf{N}} = \frac{\|\vec{\mathbf{v}} \times \vec{\mathbf{a}}\|}{\|\vec{\mathbf{v}}\|} = \sqrt{\|\vec{\mathbf{a}}\|^2 - \left(a_{\vec{\mathbf{T}}}\right)^2}. \tag{13.5.5}$$

These components are related by the formula

$$\vec{\mathbf{a}}(t) = a_{\vec{\mathbf{T}}}\vec{\mathbf{T}}(t) + a_{\vec{\mathbf{N}}}\vec{\mathbf{N}}(t). \tag{13.5.6}$$

Here $\vec{\mathbf{T}}(t)$ is the unit tangent vector to the curve defined by $\vec{\mathbf{r}}(t)$, and $\vec{\mathbf{N}}(t)$ is the unit normal vector to the curve defined by $\vec{\mathbf{r}}(t)$.

The normal component of acceleration is also called the *centripetal component of acceleration* or sometimes the *radial component of acceleration*. To understand centripetal acceleration, suppose you are traveling in a car on a circular track at a constant speed. Then, as we saw earlier, the acceleration vector points toward the center of the track at all times. As a rider in the car, you feel a pull toward the *outside* of the track because you are constantly turning. This sensation acts in the opposite direction of centripetal

acceleration. The same holds true for non-circular paths. The reason is that your body tends to travel in a straight line and resists the force resulting from acceleration that push it toward the side. Note that at point $B$ in Figure 13.5.4 the acceleration vector is pointing backward. This is because the car is decelerating as it goes into the curve.

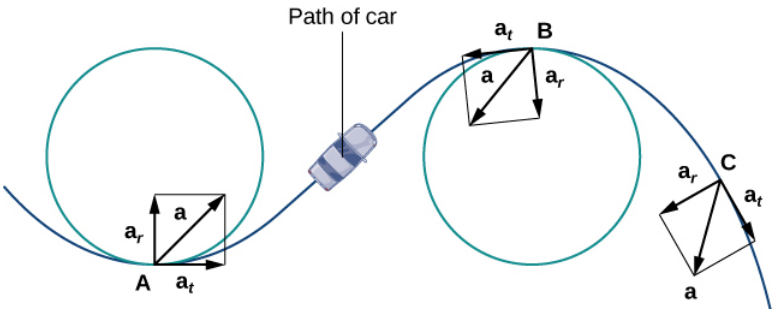

Figure 13.5.4: The tangential and normal components of acceleration can be used to describe the acceleration vector.

The tangential and normal unit vectors at any given point on the curve provide a frame of reference at that point. The tangential and normal components of acceleration are the projections of the acceleration vector onto $\vec{\mathbf{T}}$ and $\vec{\mathbf{N}}$, respectively.

### Example 13.5.2: Finding Components of Acceleration

A particle moves in a path defined by the vector-valued function $\vec{\mathbf{r}}(t) = t^2\,\hat{\mathbf{i}} + (2t-3)\,\hat{\mathbf{j}} + (3t^2 - 3t)\,\hat{\mathbf{k}}$, where $t$ measures time in seconds and distance is measured in feet.

a. Find $a_{\vec{\mathbf{T}}}$ and $a_{\vec{\mathbf{N}}}$ as functions of $t$.
b. Find $a_{\vec{\mathbf{T}}}$ and $a_{\vec{\mathbf{N}}}$ at time $t = 2$.

**Solution**

a. Let's start deriving the velocity and acceleration functions:

$$\begin{aligned}\vec{\mathbf{v}}(t) &= \vec{\mathbf{r}}\,'(t)\\ &= 2t\,\hat{\mathbf{i}} + 2\,\hat{\mathbf{j}} + (6t-3)\,\hat{\mathbf{k}}\\ \vec{\mathbf{a}}(t) &= \vec{\mathbf{v}}\,'(t)\\ &= 2\,\hat{\mathbf{i}} + 6\,\hat{\mathbf{k}}\end{aligned}$$

Now we apply Equation 13.5.4:

$$\begin{aligned}a_{\vec{\mathbf{T}}} &= \frac{\vec{\mathbf{v}}\cdot\vec{\mathbf{a}}}{||\vec{\mathbf{v}}||}\\ &= \frac{(2t\,\hat{\mathbf{i}} + 2\,\hat{\mathbf{j}} + (6t-3)\,\hat{\mathbf{k}})\cdot(2\,\hat{\mathbf{i}} + 6\,\hat{\mathbf{k}})}{||2t\,\hat{\mathbf{i}} + 2\,\hat{\mathbf{j}} + (6t-3)\,\hat{\mathbf{k}}||}\\ &= \frac{4t + 6(6t-3)}{\sqrt{(2t)^2 + 2^2 + (6t-3)^2}}\\ &= \frac{40t - 18}{40t^2 - 36t + 13}\end{aligned}$$

Now we can apply Equation 13.5.5:

$$
\begin{aligned}
a_{\vec{\mathbf{N}}} &= \sqrt{||\vec{\mathbf{a}}||^2 - \left(a_{\vec{\mathbf{T}}}\right)^2} \\
&= \sqrt{||2\hat{\mathbf{i}} + 6\hat{\mathbf{k}}||^2 - \left(\frac{40t - 18}{\sqrt{40t^2 - 36t + 13}}\right)^2} \\
&= \sqrt{4 + 36 - \frac{(40t - 18)^2}{40t^2 - 36t + 13}} \\
&= \sqrt{\frac{40(40t^2 - 36t + 13) - (1600t^2 - 1440t + 324)}{40t^2 - 36t + 13}} \\
&= \sqrt{\frac{196}{40t^2 - 36t + 13}} \\
&= \frac{14}{\sqrt{40t^2 - 36t + 13}}
\end{aligned}
$$

b. We must evaluate each of the answers from part a at $t = 2$:

$$
\begin{aligned}
a_{\vec{\mathbf{T}}}(2) &= \frac{40(2) - 18}{\sqrt{40(2)^2 - 36(2) + 13}} \\
&= \frac{80 - 18}{\sqrt{160 - 72 + 13}} \\
&= \frac{62}{\sqrt{101}} \\
a_{\vec{\mathbf{N}}}(2) &= \frac{14}{\sqrt{40(2)^2 - 36(2) + 13}} \\
&= \frac{14}{\sqrt{160 - 72 + 13}} = \frac{14}{\sqrt{101}}.
\end{aligned}
$$

The units of acceleration are feet per second squared, as are the units of the normal and tangential components of acceleration.

## Exercise 13.5.2

An object moves in a path defined by the vector-valued function $\vec{\mathbf{r}}(t) = 4t\hat{\mathbf{i}} + t^2\hat{\mathbf{j}}$, where $t$ measures time in seconds.

a. Find $a_{\vec{\mathbf{T}}}$ and $a_{\vec{\mathbf{N}}}$ as functions of $t$.
b. Find $a_{\vec{\mathbf{T}}}$ and $a_{\vec{\mathbf{N}}}$ at time $t = -3$.

**Hint**

Use Equations 13.5.4 and 13.5.5

**Answer**

a.

$$
\begin{aligned}
a_{\vec{\mathbf{T}}} = \frac{\vec{\mathbf{v}}(t) \cdot \vec{\mathbf{a}}(t)}{||\vec{\mathbf{v}}(t)||} &= \frac{\vec{\mathbf{r}}\,'(t) \cdot \vec{\mathbf{r}}\,''(t)}{||\vec{\mathbf{r}}\,'(t)||} \\
&= \frac{(4\hat{\mathbf{i}} + 2t\hat{\mathbf{j}}) \cdot (2\hat{\mathbf{j}})}{||4\hat{\mathbf{i}} + 2t\hat{\mathbf{j}}||} \\
&= \frac{4t}{\sqrt{4^2 + (2t)^2}} \\
&= \frac{2t}{\sqrt{2 + t^2}}
\end{aligned}
$$

$$a_{\vec{\mathbf{N}}} = \sqrt{||\vec{\mathbf{a}}||^2 - a_{\vec{\mathbf{T}}}^2}$$
$$= \sqrt{||2\hat{\mathbf{j}}||^2 - \left(\frac{2t}{\sqrt{2+t^2}}\right)^2}$$
$$= \sqrt{4 - \frac{4t^2}{2+t^2}}$$

b.

$$a_{\vec{\mathbf{T}}}(-3) = \frac{2(-3)}{\sqrt{2+(-3)^2}}$$
$$= \frac{-6}{\sqrt{11}}$$

$$a_{\vec{\mathbf{N}}}(-3) = \sqrt{4 - \frac{4(-3)^2}{2+(-3)^2}}$$
$$= \sqrt{4 - \frac{36}{11}}$$
$$= \sqrt{\frac{8}{11}}$$
$$= \frac{2\sqrt{2}}{\sqrt{11}}$$

## Projectile Motion

Now let's look at an application of vector functions. In particular, let's consider the effect of gravity on the motion of an object as it travels through the air, and how it determines the resulting trajectory of that object. In the following, we ignore the effect of air resistance. This situation, with an object moving with an initial velocity but with no forces acting on it other than gravity, is known as projectile motion. It describes the motion of objects from golf balls to baseballs, and from arrows to cannonballs.

First we need to choose a coordinate system. If we are standing at the origin of this coordinate system, then we choose the positive $y$-axis to be up, the negative $y$-axis to be down, and the positive $x$-axis to be forward (i.e., away from the thrower of the object). The effect of gravity is in a downward direction, so Newton's second law tells us that the force on the object resulting from gravity is equal to the mass of the object times the acceleration resulting from gravity, or $\vec{\mathbf{F}}_g = m\vec{\mathbf{a}}$, where $\vec{\mathbf{F}}_g$ represents the force from gravity and $\vec{\mathbf{a}} = -g\,\hat{\mathbf{j}}$ represents the acceleration resulting from gravity at Earth's surface. The value of $g$ in the English system of measurement is approximately 32 ft/sec$^2$ and it is approximately 9.8 m/sec$^2$ in the metric system. This is the only force acting on the object. Since gravity acts in a downward direction, we can write the force resulting from gravity in the form $\vec{\mathbf{F}}_g = -mg\,\hat{\mathbf{j}}$, as shown in Figure 13.5.5.

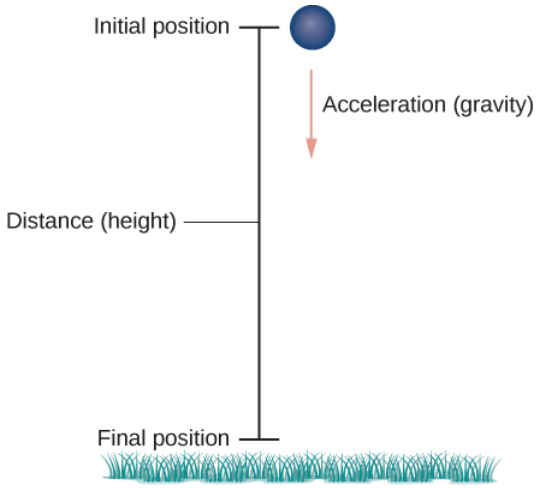

Figure 13.5.5: An object is falling under the influence of gravity.

Newton's second law also tells us that $F = m\vec{\mathbf{a}}$, where $\vec{\mathbf{a}}$ represents the acceleration vector of the object. This force must be equal to the force of gravity at all times, so we therefore know that

$$\begin{aligned} \vec{\mathbf{F}} &= \vec{\mathbf{F}}_g \\ m\vec{\mathbf{a}} &= -mg\hat{\mathbf{j}} \\ \vec{\mathbf{a}} &= -g\hat{\mathbf{j}}. \end{aligned}$$

Now we use the fact that the acceleration vector is the first derivative of the velocity vector. Therefore, we can rewrite the last equation in the form

$$\vec{\mathbf{v}}\,'(t) = -g\hat{\mathbf{j}}$$

By taking the antiderivative of each side of this equation we obtain

$$\vec{\mathbf{v}}(t) = \int -g\hat{\mathbf{j}}\, dt = -gt\hat{\mathbf{j}} + \vec{\mathbf{C}}_1$$

for some constant vector $\vec{\mathbf{C}}_1$. To determine the value of this vector, we can use the velocity of the object at a fixed time, say at time $t = 0$. We call this velocity the *initial velocity*: $\vec{\mathbf{v}}(0) = \vec{\mathbf{v}}_0$. Therefore, $\vec{\mathbf{v}}(0) = -g(0)\,\hat{\mathbf{j}} + \vec{\mathbf{C}}_1 = \vec{\mathbf{v}}_0$ and $\vec{\mathbf{C}}_1 = \vec{\mathbf{v}}_0$. This gives the velocity vector as $\vec{\mathbf{v}}(t) = -gt\hat{\mathbf{j}} + \vec{\mathbf{v}}_0$.

Next we use the fact that velocity $\vec{\mathbf{v}}(t)$ is the derivative of position $\vec{\mathbf{s}}(t)$. This gives the equation

$$\vec{\mathbf{s}}\,'(t) = -gt\hat{\mathbf{j}} + \vec{\mathbf{v}}_0.$$

Taking the antiderivative of both sides of this equation leads to

$$\begin{aligned} \vec{\mathbf{s}}(t) &= \int -gt\hat{\mathbf{j}} + \vec{\mathbf{v}}_0\, dt \\ &= -\frac{1}{2}gt^2\hat{\mathbf{j}} + \vec{\mathbf{v}}_0 t + \vec{\mathbf{C}}_2 \end{aligned}$$

with another unknown constant vector $\vec{\mathbf{C}}_2$. To determine the value of $\vec{\mathbf{C}}_2$, we can use the position of the object at a given time, say at time $t = 0$. We call this position the *initial position*: $\vec{\mathbf{s}}(0) = \vec{\mathbf{s}}_0$. Therefore, $\vec{\mathbf{s}}(0) = -(1/2)g(0)^2\,\hat{\mathbf{j}} + \vec{\mathbf{v}}_0(0) + \vec{\mathbf{C}}_2 = \vec{\mathbf{s}}_0$. This gives the position of the object at any time as

$$\vec{\mathbf{s}}(t) = -\frac{1}{2}gt^2\hat{\mathbf{j}} + \vec{\mathbf{v}}_0 t + \vec{\mathbf{s}}_0.$$

Let's take a closer look at the initial velocity and initial position. In particular, suppose the object is thrown upward from the origin at an angle $\theta$ to the horizontal, with initial speed $\vec{\mathbf{v}}_0$. How can we modify the previous result to reflect this scenario? First, we can assume it is thrown from the origin. If not, then we can move the origin to the point from where it is thrown. Therefore, $\vec{\mathbf{s}}_0 = \vec{\mathbf{0}}$, as shown in Figure 13.5.6.

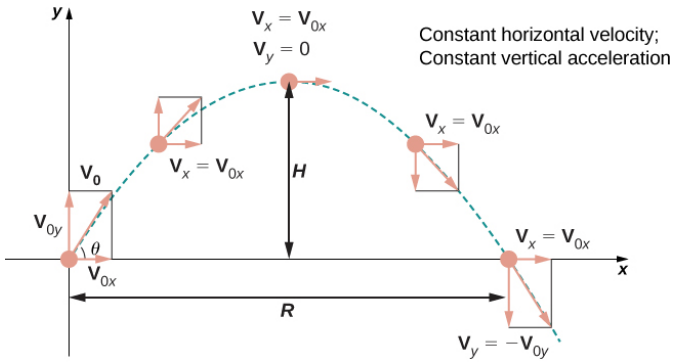

Figure 13.5.6: Projectile motion when the object is thrown upward at an angle θ. The horizontal motion is at constant velocity and the vertical motion is at constant acceleration.

We can rewrite the initial velocity vector in the form $\vec{\mathbf{v}}_0 = v_0\cos\theta\,\hat{\mathbf{i}} + v_0\sin\theta\,\hat{\mathbf{j}}$. Then the equation for the position function $\vec{\mathbf{s}}(t)$ becomes

$$\begin{aligned}\vec{\mathbf{s}}(t) &= -\frac{1}{2}gt^2\hat{\mathbf{j}} + v_0 t\cos\theta\,\hat{\mathbf{i}} + v_0 t\sin\theta\,\hat{\mathbf{j}} \\ &= v_0 t\cos\theta\,\hat{\mathbf{i}} + v_0 t\sin\theta\,\hat{\mathbf{j}} - \frac{1}{2}gt^2\hat{\mathbf{j}} \\ &= v_0 t\cos\theta\,\hat{\mathbf{i}} + \left(v_0 t\sin\theta - \frac{1}{2}gt^2\right)\hat{\mathbf{j}}.\end{aligned}$$

The coefficient of $\hat{\mathbf{i}}$ represents the horizontal component of $\vec{\mathbf{s}}(t)$ and is the horizontal distance of the object from the origin at time $t$. The maximum value of the horizontal distance (measured at the same initial and final altitude) is called the range $R$. The coefficient of $\hat{\mathbf{j}}$ represents the vertical component of $\vec{\mathbf{s}}(t)$ and is the altitude of the object at time $t$. The maximum value of the vertical distance is the height $H$.

### Example 13.5.3: Motion of a Cannonball

During an Independence Day celebration, a cannonball is fired from a cannon on a cliff toward the water. The cannon is aimed at an angle of 30° above horizontal and the initial speed of the cannonball is 600 ft/sec. The cliff is 100 ft above the water (Figure 13.5.7).

a. Find the maximum height of the cannonball.
b. How long will it take for the cannonball to splash into the sea?
c. How far out to sea will the cannonball hit the water?

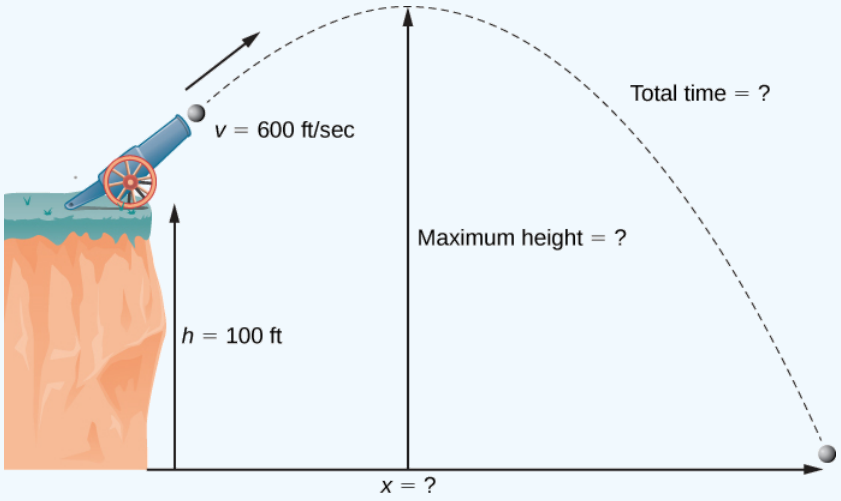

Figure 13.5.7: The flight of a cannonball (ignoring air resistance) is projectile motion.

**Solution**

We use the equation

$$\vec{\mathbf{s}}(t) = v_0 t\cos\theta\,\hat{\mathbf{i}} + \left(v_0 t\sin\theta - \frac{1}{2}gt^2\right)\hat{\mathbf{j}}$$

with $\theta = 30°$, $g = 32\frac{\text{ft}}{\text{sec}^2}$, and $v_0 = 600\frac{\text{ft}}{\text{sec}}$. Then the position equation becomes

$$\begin{aligned}\vec{\mathbf{s}}(t) &= 600t(\cos 30°)\,\hat{\mathbf{i}} + \left(600t\sin 30° - \frac{1}{2}(32)t^2\right)\hat{\mathbf{j}} \\ &= 300t\sqrt{3}\,\hat{\mathbf{i}} + \left(300t - 16t^2\right)\hat{\mathbf{j}}\end{aligned}$$

a. The cannonball reaches its maximum height when the vertical component of its velocity is zero, because the cannonball is neither rising nor falling at that point. The velocity vector is

$$\begin{aligned}\vec{\mathbf{v}}(t) &= \vec{\mathbf{s}}\,'(t) \\ &= 300\sqrt{3}\,\hat{\mathbf{i}} + (300 - 32t)\,\hat{\mathbf{j}}\end{aligned}$$

Therefore, the vertical component of velocity is given by the expression $300 - 32t$. Setting this expression equal to zero and solving for $t$ gives $t = 9.375$ sec. The height of the cannonball at this time is given by the vertical component of the position vector, evaluated at $t = 9.375$.

$$\begin{aligned}\vec{\mathbf{s}}(9.375) &= 300(9.375)\sqrt{3}\,\hat{\mathbf{i}} + (300(9.375) - 16(9.375)^2)\,\hat{\mathbf{j}} \\ &= 4871.39\,\hat{\mathbf{i}} + 1406.25\,\hat{\mathbf{j}}\end{aligned}$$

Therefore, the maximum height of the cannonball is 1406.39 ft above the cannon, or 1506.39 ft above sea level.

b. When the cannonball lands in the water, it is 100 ft below the cannon. Therefore, the vertical component of the position vector is equal to $-100$. Setting the vertical component of $\vec{\mathbf{s}}(t)$ equal to $-100$ and solving, we obtain

$$\begin{aligned}300t - 16t^2 &= -100 \\ 16t^2 - 300t - 100 &= 0 \\ 4t^2 - 75 - 25 &= 0 \\ t &= \frac{75 \pm \sqrt{(-75)^2 - 4(4)(-25)}}{2(4)} \\ &= \frac{75 \pm \sqrt{6025}}{8} \\ &= \frac{75 \pm 5\sqrt{241}}{8}\end{aligned}$$

The positive value of $t$ that solves this equation is approximately 19.08. Therefore, the cannonball hits the water after approximately 19.08 sec.

c. To find the distance out to sea, we simply substitute the answer from part (b) into $\vec{\mathbf{s}}(t)$:

$$\begin{aligned}\vec{\mathbf{s}}(19.08) &= 300(19.08)\sqrt{3}\,\hat{\mathbf{i}} + \left(300(19.08) - 16(19.08)^2\right)\,\hat{\mathbf{j}} \\ &= 9914.26\,\hat{\mathbf{i}} - 100.7424\,\hat{\mathbf{j}}\end{aligned}$$

Therefore, the ball hits the water about 9914.26 ft away from the base of the cliff. Notice that the vertical component of the position vector is very close to −100, which tells us that the ball just hit the water. Note that 9914.26 feet is not the true range of the cannon since the cannonball lands in the ocean at a location below the cannon. The range of the cannon would be determined by finding how far out the cannonball is when its height is 100 ft above the water (the same as the altitude of the cannon).

## ? Exercise 13.5.3

An archer fires an arrow at an angle of 40° above the horizontal with an initial speed of 98 m/sec. The height of the archer is 171.5 cm. Find the horizontal distance the arrow travels before it hits the ground.

**Hint**

The equation for the position vector needs to account for the height of the archer in meters.

**Answer**

967.15 m

One final question remains: In general, what is the maximum distance a projectile can travel, given its initial speed? To determine this distance, we assume the projectile is fired from ground level and we wish it to return to ground level. In other words, we want to determine an equation for the range. In this case, the equation of projectile motion is

$$\vec{\mathbf{s}} = v_0 t\cos\theta\,\hat{\mathbf{i}} + \left(v_0 t\sin\theta - \frac{1}{2}gt^2\right)\,\hat{\mathbf{j}}.$$

Setting the second component equal to zero and solving for $t$ yields

$$v_0 t \sin\theta - \frac{1}{2} g t^2 = 0$$
$$t\left(v_0 \sin\theta - \frac{1}{2} g t\right) = 0$$

Therefore, either $t = 0$ or $t = \dfrac{2v_0 \sin\theta}{g}$. We are interested in the second value of $t$, so we substitute this into $\vec{\mathbf{s}}(t)$, which gives

$$\begin{aligned}\vec{\mathbf{s}}\left(\frac{2v_0 \sin\theta}{g}\right) &= v_0\left(\frac{2v_0 \sin\theta}{g}\right)\cos\theta\,\hat{\mathbf{i}} + \left(v_0\left(\frac{2v_0 \sin\theta}{g}\right)\sin\theta - \frac{1}{2} g\left(\frac{2v_0 \sin\theta}{g}\right)^2\right)\hat{\mathbf{j}} \\ &= \left(\frac{2v_0^2 \sin\theta\cos\theta}{g}\right)\hat{\mathbf{i}} \\ &= \frac{v_0^2 \sin 2\theta}{g}\,\hat{\mathbf{i}}.\end{aligned}$$

Thus, the expression for the range of a projectile fired at an angle $\theta$ is

$$R = \frac{v_0^2 \sin 2\theta}{g}\,\hat{\mathbf{i}}.$$

The only variable in this expression is $\theta$. To maximize the distance traveled, take the derivative of the coefficient of $\hat{\mathbf{i}}$ with respect to $\theta$ and set it equal to zero:

$$\begin{aligned}\frac{d}{d\theta}\left(\frac{v_0^2 \sin 2\theta}{g}\right) &= 0 \\ \frac{2v_0^2 \cos 2\theta}{g} &= 0 \\ \theta &= 45^\circ\end{aligned}$$

This value of $\theta$) is the smallest positive value that makes the derivative equal to zero. Therefore, in the absence of air resistance, the best angle to fire a projectile (to maximize the range) is at a 45° angle. The distance it travels is given by

$$\vec{\mathbf{s}}\left(\frac{2v_0 \sin 45^\circ}{g}\right) = \frac{v_0^2 \sin 90^\circ}{g}\,\hat{\mathbf{i}} = \frac{v_0^2}{g}\,\hat{\mathbf{i}}$$

Therefore, the range for an angle of 45° is $\dfrac{v_0^2}{g}$ units.

## Kepler's Laws

During the early 1600s, Johannes Kepler was able to use the amazingly accurate data from his mentor Tycho Brahe to formulate his three laws of planetary motion, now known as Kepler's laws of planetary motion. These laws also apply to other objects in the solar system in orbit around the Sun, such as comets (e.g., Halley's comet) and asteroids. Variations of these laws apply to satellites in orbit around Earth.

**Theorem 13.5.2: Kepler's Laws of Planetary Motion**

1. The path of any planet about the Sun is elliptical in shape, with the center of the Sun located at one focus of the ellipse (the law of ellipses).
2. A line drawn from the center of the Sun to the center of a planet sweeps out equal areas in equal time intervals (the law of equal areas) (Figure 13.5.8).
3. The ratio of the squares of the periods of any two planets is equal to the ratio of the cubes of the lengths of their semimajor orbital axes (the Law of Harmonies).

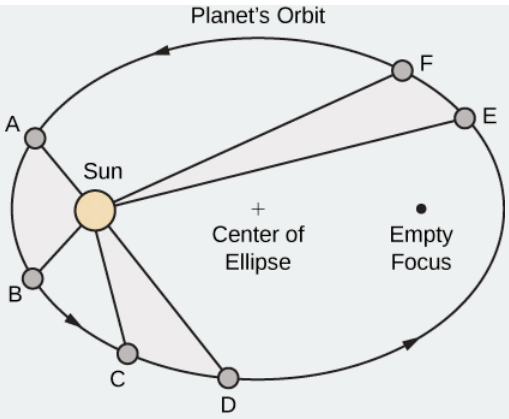

Figure 13.5.8: Kepler's first and second laws are pictured here. The Sun is located at a focus of the elliptical orbit of any planet. Furthermore, the shaded areas are all equal, assuming that the amount of time measured as the planet moves is the same for each region.

Kepler's third law is especially useful when using appropriate units. In particular, *1 astronomical unit* is defined to be the average distance from Earth to the Sun, and is now recognized to be 149,597,870,700 m or, approximately 93,000,000 mi. We therefore write 1 A.U. = 93,000,000 mi. Since the time it takes for Earth to orbit the Sun is 1 year, we use Earth years for units of time. Then, substituting 1 year for the period of Earth and 1 A.U. for the average distance to the Sun, Kepler's third law can be written as

$$T_p^2 = D_p^3$$

for any planet in the solar system, where $T_P$ is the period of that planet measured in Earth years and $D_P$ is the average distance from that planet to the Sun measured in astronomical units. Therefore, if we know the average distance from a planet to the Sun (in astronomical units), we can then calculate the length of its year (in Earth years), and vice versa.

Kepler's laws were formulated based on observations from Brahe; however, they were not proved formally until Sir Isaac Newton was able to apply calculus. Furthermore, Newton was able to generalize Kepler's third law to other orbital systems, such as a moon orbiting around a planet. Kepler's original third law only applies to objects orbiting the Sun.

**Proof**

Let's now prove Kepler's first law using the calculus of vector-valued functions. First we need a coordinate system. Let's place the Sun at the origin of the coordinate system and let the vector-valued function $\vec{\mathbf{r}}(t)$ represent the location of a planet as a function of time. Newton proved Kepler's law using his second law of motion and his law of universal gravitation. Newton's second law of motion can be written as $\vec{\mathbf{F}} = m\vec{\mathbf{a}}$, where $\vec{\mathbf{F}}$ represents the net force acting on the planet. His law of universal gravitation can be written in the form $\vec{\mathbf{F}} = -\dfrac{GmM}{||\vec{\mathbf{r}}||^2} \cdot \dfrac{\vec{\mathbf{r}}}{||\vec{\mathbf{r}}||}$, which indicates that the force resulting from the gravitational attraction of the Sun points back toward the Sun, and has magnitude $\dfrac{GmM}{||\vec{\mathbf{r}}||^2}$ (Figure 13.5.9).

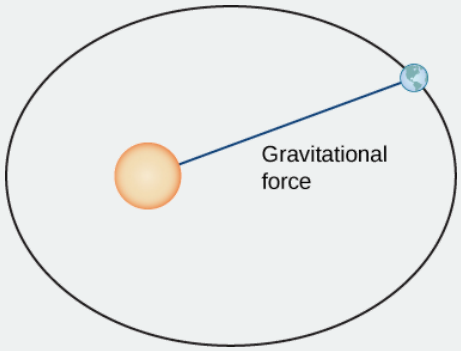

Figure 13.5.9: The gravitational force between Earth and the Sun is equal to the mass of the earth times its acceleration.

Setting these two forces equal to each other, and using the fact that $\vec{\mathbf{a}}(t) = \vec{\mathbf{v}}\,'(t)$, we obtain

$$m\vec{\mathbf{v}}\,'(t) = -\frac{GmM}{\|\vec{\mathbf{r}}\|^2} \cdot \frac{\vec{\mathbf{r}}}{\|\vec{\mathbf{r}}\|},$$

which can be rewritten as

$$\frac{d\vec{\mathbf{v}}}{dt} = -\frac{GM}{||\vec{\mathbf{r}}||^3}\vec{\mathbf{r}}.$$

This equation shows that the vectors $d\vec{\mathbf{v}}/dt$ and $\vec{\mathbf{r}}$ are parallel to each other, so $d\vec{\mathbf{v}}/dt \times \vec{\mathbf{r}} = \vec{\mathbf{0}}$. Next, let's differentiate $\vec{\mathbf{r}} \times \vec{\mathbf{v}}$ with respect to time:

$$\frac{d}{dt}(\vec{\mathbf{r}} \times \vec{\mathbf{v}}) = \frac{d\vec{\mathbf{r}}}{dt} \times \vec{\mathbf{v}} + \vec{\mathbf{r}} \times \frac{d\vec{\mathbf{v}}}{dt} = \vec{\mathbf{v}} \times \vec{\mathbf{v}} + \vec{\mathbf{0}} = \vec{\mathbf{0}}. \tag{13.5.7}$$

This proves that $\vec{\mathbf{r}} \times \vec{\mathbf{v}}$ is a constant vector, which we call $\vec{\mathbf{C}}$. Since $\vec{\mathbf{r}}$ and $\vec{\mathbf{v}}$ are both perpendicular to $\vec{\mathbf{C}}$ for all values of $t$, they must lie in a plane perpendicular to $\vec{\mathbf{C}}$. Therefore, the motion of the planet lies in a plane.

Next we calculate the expression $d\vec{\mathbf{v}}/dt \times \vec{\mathbf{C}}$:

$$\frac{d\vec{\mathbf{v}}}{dt} \times \vec{\mathbf{C}} = -\frac{GM}{||\vec{\mathbf{r}}||^3}\vec{\mathbf{r}} \times (\vec{\mathbf{r}} \times \vec{\mathbf{v}}) = -\frac{GM}{||\vec{\mathbf{r}}||^3}[(\vec{\mathbf{r}} \cdot \vec{\mathbf{v}})\vec{\mathbf{r}} - (\vec{\mathbf{r}} \cdot \vec{\mathbf{r}})\vec{\mathbf{v}}]. \tag{13.5.8}$$

The last equality in Equation 13.5.8 is from the triple cross product formula (see the cross product section in Introduction to Vectors in Space). We need an expression for $\vec{\mathbf{r}} \cdot \vec{\mathbf{v}}$. To calculate this, we differentiate $\vec{\mathbf{r}} \cdot \vec{\mathbf{r}}$ with respect to time:

$$\frac{d}{dt}(\vec{\mathbf{r}} \cdot \vec{\mathbf{r}}) = \frac{d\vec{\mathbf{r}}}{dt} \cdot \vec{\mathbf{r}} + \vec{\mathbf{r}} \cdot \frac{d\vec{\mathbf{r}}}{dt} = 2\vec{\mathbf{r}} \cdot \frac{d\vec{\mathbf{r}}}{dt} = 2\vec{\mathbf{r}} \cdot \vec{\mathbf{v}}. \tag{13.5.9}$$

Since $\vec{\mathbf{r}} \cdot \vec{\mathbf{r}} = ||\vec{\mathbf{r}}||^2$, we also have

$$\frac{d}{dt}(\vec{\mathbf{r}} \cdot \vec{\mathbf{r}}) = \frac{d}{dt}||\vec{\mathbf{r}}||^2 = 2||\vec{\mathbf{r}}||\frac{d}{dt}||\vec{\mathbf{r}}||. \tag{13.5.10}$$

Combining Equation 13.5.9 and Equation 13.5.10, we get

$$\begin{aligned} 2\vec{\mathbf{r}} \cdot \vec{\mathbf{v}} &= 2||\vec{\mathbf{r}}||\frac{d}{dt}||\vec{\mathbf{r}}|| \\ \vec{\mathbf{r}} \cdot \vec{\mathbf{v}} &= ||\vec{\mathbf{r}}||\frac{d}{dt}||\vec{\mathbf{r}}||. \end{aligned}$$

Substituting this into Equation 13.5.8 gives us

$$\begin{aligned} \frac{d\vec{\mathbf{v}}}{dt} \times \vec{\mathbf{C}} &= -\frac{GM}{||\vec{\mathbf{r}}||^3}[(\vec{\mathbf{r}} \cdot \vec{\mathbf{v}})\vec{\mathbf{r}} - (\vec{\mathbf{r}} \cdot \vec{\mathbf{r}})\vec{\mathbf{v}}] \\ &= -\frac{GM}{||\vec{\mathbf{r}}||^3}\left[||\vec{\mathbf{r}}||\left(\frac{d}{dt}||\vec{\mathbf{r}}||\right)\vec{\mathbf{r}} - ||\vec{\mathbf{r}}||^2\vec{\mathbf{v}}\right] \\ &= -GM\left[\frac{1}{||\vec{\mathbf{r}}||^2}\left(\frac{d}{dt}||\vec{\mathbf{r}}||\right)\vec{\mathbf{r}} - \frac{1}{||\vec{\mathbf{r}}||}\vec{\mathbf{v}}\right] \\ &= GM\left[\frac{\vec{\mathbf{v}}}{||\vec{\mathbf{r}}||} - \frac{\vec{\mathbf{r}}}{||\vec{\mathbf{r}}||^2}\left(\frac{d}{dt}||\vec{\mathbf{r}}||\right)\right]. \end{aligned} \tag{13.5.11}$$

However,

$$\begin{aligned} \frac{d}{dt}\frac{\vec{\mathbf{r}}}{||\vec{\mathbf{r}}||} &= \frac{\frac{d}{dt}(\vec{\mathbf{r}})||\vec{\mathbf{r}}|| - \vec{\mathbf{r}}\frac{d}{dt}||\vec{\mathbf{r}}||}{||\vec{\mathbf{r}}||^2} \\ &= \frac{\frac{d\vec{\mathbf{r}}}{dt}}{||\vec{\mathbf{r}}||} - \frac{\vec{\mathbf{r}}}{||\vec{\mathbf{r}}||^2}\frac{d}{dt}||\vec{\mathbf{r}}|| \\ &= \frac{\vec{\mathbf{v}}}{||\vec{\mathbf{r}}||} - \frac{\vec{\mathbf{r}}}{||\vec{\mathbf{r}}||^2}\frac{d}{dt}||\vec{\mathbf{r}}||. \end{aligned}$$

Therefore, Equation 13.5.11 becomes

$$\frac{d\vec{\mathbf{v}}}{dt} \times \vec{\mathbf{C}} = GM\left(\frac{d}{dt}\frac{\vec{\mathbf{r}}}{||\vec{\mathbf{r}}||}\right).$$

Since $\vec{\mathbf{C}}$ is a constant vector, we can integrate both sides and obtain

$$\vec{\mathbf{v}} \times \vec{\mathbf{C}} = GM\frac{\vec{\mathbf{r}}}{||\vec{\mathbf{r}}||} + \vec{\mathbf{D}},$$

where $\vec{\mathbf{D}}$ is a constant vector. Our goal is to solve for $||\vec{\mathbf{r}}||$. Let's start by calculating $\vec{\mathbf{r}} \cdot \left(\vec{\mathbf{v}} \times \vec{\mathbf{C}}\right)$:

$$\vec{\mathbf{r}} \cdot \left(\vec{\mathbf{v}} \times \vec{\mathbf{C}}\right) = GM\frac{||\vec{\mathbf{r}}||^2}{||\vec{\mathbf{r}}||} + \vec{\mathbf{r}} \cdot \vec{\mathbf{D}} = GM||\vec{\mathbf{r}}|| + \vec{\mathbf{r}} \cdot \vec{\mathbf{D}}.$$

However, $\vec{\mathbf{r}} \cdot (\vec{\mathbf{v}} \times \vec{\mathbf{C}}) = (\vec{\mathbf{r}} \times \vec{\mathbf{v}}) \cdot \vec{\mathbf{C}}$, so

$$(\vec{\mathbf{r}} \times \vec{\mathbf{v}}) \cdot \vec{\mathbf{C}} = GM||\vec{\mathbf{r}}|| + \vec{\mathbf{r}} \cdot \vec{\mathbf{D}}.$$

Since $\vec{\mathbf{r}} \times \vec{\mathbf{v}} = \vec{\mathbf{C}}$, we have

$$||\vec{\mathbf{C}}||^2 = GM||\vec{\mathbf{r}}|| + \vec{\mathbf{r}} \cdot \vec{\mathbf{D}}.$$

Note that $\vec{\mathbf{r}} \cdot \vec{\mathbf{D}} = ||\vec{\mathbf{r}}||||\vec{\mathbf{D}}|| \cos\theta$, where $\theta$ is the angle between $\vec{\mathbf{r}}$ and $\vec{\mathbf{D}}$. Therefore,

$$||\vec{\mathbf{C}}||^2 = GM||\vec{\mathbf{r}}|| + ||\vec{\mathbf{r}}||||\vec{\mathbf{D}}|| \cos\theta$$

Solving for $||\vec{\mathbf{r}}||$,

$$||\vec{\mathbf{r}}|| = \frac{||\vec{\mathbf{C}}||^2}{GM + ||\vec{\mathbf{D}}|| \cos\theta} = \frac{||\vec{\mathbf{C}}||^2}{GM}\left(\frac{1}{1 + e\cos\theta}\right).$$

where $e = ||\vec{\mathbf{D}}||/GM$. This is the polar equation of a conic with a focus at the origin, which we set up to be the Sun. It is a hyperbola if $e > 1$, a parabola if $e = 1$, or an ellipse if $e < 1$. Since planets have closed orbits, the only possibility is an ellipse. However, at this point it should be mentioned that hyperbolic comets do exist. These are objects that are merely passing through the solar system at speeds too great to be trapped into orbit around the Sun. As they pass close enough to the Sun, the gravitational field of the Sun deflects the trajectory enough so the path becomes hyperbolic.

□

Kepler's third law of planetary motion can be modified to the case of one object in orbit around an object other than the Sun, such as the Moon around the Earth. In this case, Kepler's third law becomes

$$P^2 = \frac{4\pi^2 a^3}{G(m + M)}, \tag{13.5.12}$$

where $m$ is the mass of the Moon and $M$ is the mass of Earth, $a$ represents the length of the major axis of the elliptical orbit, and $P$ represents the period.

### ✔ Example 13.5.4: Using Kepler's Third Law for Nonheliocentric Orbits

Given that the mass of the Moon is $7.35 \times 10^{22}$ kg, the mass of Earth is $5.97 \times 10^{24}$ kg, $G = 6.67 \times 10^{-11}\text{m/kg} \cdot \text{sec}^2$, and the period of the moon is 27.3 days, let's find the length of the major axis of the orbit of the Moon around Earth.

#### Solution

It is important to be consistent with units. Since the universal gravitational constant contains seconds in the units, we need to use seconds for the period of the Moon as well:

$$27.3 \text{ days} \times \frac{24 \text{ hr}}{1 \text{ day}} \times \frac{3600 \text{ esc}}{1 \text{ hour}} = 2,358,720 \text{ sec}$$

Substitute all the data into Equation 13.5.12 and solve for $a$:

$$
\begin{aligned}
(2,358,720sec)^2 &= \frac{4\pi^2 a^3}{\left(6.67\times10^{-11}\frac{m}{\text{kg}\times\text{sec}^2}\right)(7.35\times10^{22}\text{kg}+5.97\times10^{24}\text{kg})} \\
5.563\times10^{12} &= \frac{4\pi^2 a^3}{(6.67\times10^{-11}\text{m}^3)(6.04\times10^{24})} \\
(5.563\times10^{12})(6.67\times10^{-11}\text{m}^3)(6.04\times10^{24}) &= 4\pi^2 a^3 \\
a^3 &= \frac{2.241\times10^{27}}{4\pi^2}\text{m}^3 \\
a &= 3.84\times10^8\text{m} \\
&\approx 384,000\,\text{km}.
\end{aligned}
$$

### Analysis

According to solarsystem.nasa.gov, the actual average distance from the Moon to Earth is 384,400 km. This is calculated using reflectors left on the Moon by Apollo astronauts back in the 1960s.

## Exercise 13.5.4

Titan is the largest moon of Saturn. The mass of Titan is approximately $1.35\times10^{23}kg$. The mass of Saturn is approximately $5.68\times10^{26}$ kg. Titan takes approximately 16 days to orbit Saturn. Use this information, along with the universal gravitation constant $G=6.67\times10^{-11}\text{m}/\text{kg}\cdot\text{sec}^2$ to estimate the distance from Titan to Saturn.

### Hint

Make sure your units agree, then use Equation 13.5.12.

### Answer

$$a\approx1.224\times10^9\text{m}=1,224,000\text{km}$$

## Example 13.5.5: Halley's Comet

We now return to the chapter opener, which discusses the motion of Halley's comet around the Sun. Kepler's first law states that Halley's comet follows an elliptical path around the Sun, with the Sun as one focus of the ellipse. The period of Halley's comet is approximately 76.1 years, depending on how closely it passes by Jupiter and Saturn as it passes through the outer solar system. Let's use $T=76.1$ years. What is the average distance of Halley's comet from the Sun?

### Solution

Using the equation $T^2=D^3$ with $T=76.1$, we obtain $D^3=5791.21$, so $D\approx17.96$ A.U. This comes out to approximately $1.67\times10^9$ mi.

A natural question to ask is: What are the maximum (aphelion) and minimum (perihelion) distances from Halley's Comet to the Sun? The eccentricity of the orbit of Halley's Comet is 0.967 (Source: http://nssdc.gsfc.nasa.gov/planetary...cometfact.html). Recall that the formula for the eccentricity of an ellipse is $e=c/a$, where $a$ is the length of the semimajor axis and $c$ is the distance from the center to either focus. Therefore, $0.967=c/17.96$ and $c\approx17.37$ A.U. Subtracting this from $a$ gives the perihelion distance $p=a-c=17.96-17.37=0.59$ A.U. According to the

National Space Science Data Center (Source: http://nssdc.gsfc.nasa.gov/planetary...cometfact.html), the perihelion distance for Halley's comet is 0.587 A.U. To calculate the aphelion distance, we add

$$P = a + c = 17.96 + 17.37 = 35.33 \text{ A.U.}$$

This is approximately $3.3 \times 10^9$ mi. The average distance from Pluto to the Sun is 39.5 A.U. (Source: http://www.oarval.org/furthest.htm), so it would appear that Halley's Comet stays just within the orbit of Pluto.

## NAVIGATING A BANKED TURN

How fast can a racecar travel through a circular turn without skidding and hitting the wall? The answer could depend on several factors:

- The weight of the car;
- The friction between the tires and the road;
- The radius of the circle;
- The "steepness" of the turn.

In this project we investigate this question for NASCAR racecars at the Bristol Motor Speedway in Tennessee. Before considering this track in particular, we use vector functions to develop the mathematics and physics necessary for answering questions such as this.

A car of mass $m$ moves with constant angular speed $\omega$ around a circular curve of radius $R$ (Figure 13.5.9). The curve is banked at an angle $\theta$. If the height of the car off the ground is $h$, then the position of the car at time $t$ is given by the function $\vec{\mathbf{r}}(t) =< R\cos(\omega t), R\sin(\omega t), h >$.

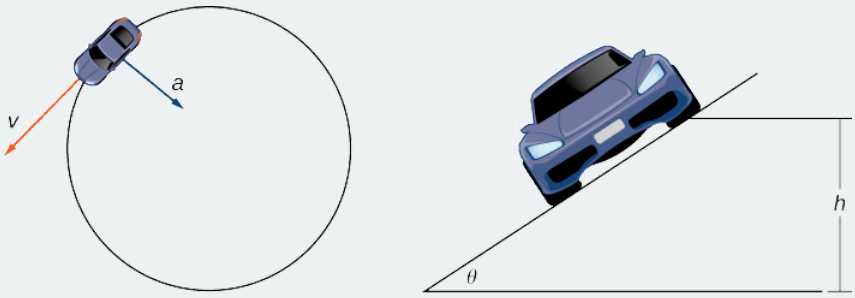

Figure 13.5.9: Views of a race car moving around a track.

1. Find the velocity function $\vec{\mathbf{v}}(t)$ of the car. Show that $\vec{\mathbf{v}}$ is tangent to the circular curve. This means that, without a force to keep the car on the curve, the car will shoot off of it.
2. Show that the speed of the car is $\omega R$. Use this to show that $(2\pi 4)/\|\vec{\mathbf{v}}\| = (2\pi)/\omega$.
3. Find the acceleration $\vec{\mathbf{a}}$. Show that this vector points toward the center of the circle and that $\|\vec{\mathbf{a}}\| = R\omega^2$.
4. The force required to produce this circular motion is called the *centripetal force*, and it is denoted $\vec{\mathbf{F}}_{cent}$. This force points toward the center of the circle (not toward the ground). Show that $\|\vec{\mathbf{F}}_{cent}\| = (m|\vec{\mathbf{v}}|^2)/R$.

As the car moves around the curve, three forces act on it: gravity, the force exerted by the road (this force is perpendicular to the ground), and the friction force (Figure 13.5.10). Because describing the frictional force generated by the tires and the road is complex, we use a standard approximation for the frictional force. Assume that $\vec{\mathbf{f}} = \mu\vec{\mathbf{N}}$ for some positive constant $\mu$. The constant $\mu$ is called the *coefficient of friction*.

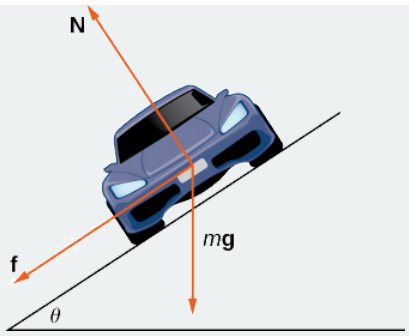

Figure **13.5.10**: The car has three forces acting on it: gravity (denoted by $m\vec{\mathbf{g}}$), *the friction force* $\vec{\mathbf{f}}$, *and the force exerted by the road* $\vec{\mathbf{N}}$.

Let $v_{max}$ denote the maximum speed the car can attain through the curve without skidding. In other words, $v_{max}$ is the fastest speed at which the car can navigate the turn. When the car is traveling at this speed, the magnitude of the centripetal force is

$$\|\vec{\mathbf{F}}_{cent}\| = \frac{m(v_{max})^2}{R}.$$

The next three questions deal with developing a formula that relates the speed $v_{max}$ to the banking angle $\theta$.

5. Show that $\vec{\mathbf{N}}\cos\theta = m\vec{\mathbf{g}} + \vec{\mathbf{f}}\sin\theta$. Conclude that $\vec{\mathbf{N}} = (m\vec{\mathbf{g}})/(\cos\theta - \mu\sin\theta)$.
6. The centripetal force is the sum of the forces in the horizontal direction, since the centripetal force points toward the center of the circular curve. Show that

   $$\vec{\mathbf{F}}_{cent} = \vec{\mathbf{N}}\sin\theta + \vec{\mathbf{f}}\cos\theta.$$

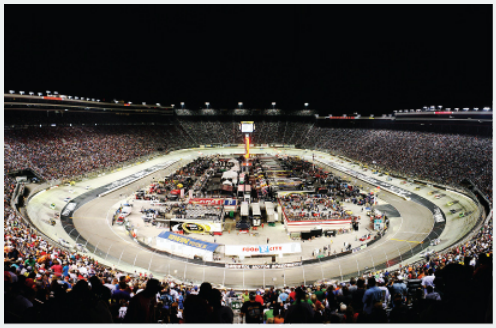
   Conclude that

   $$\vec{\mathbf{F}}_{cent} = \frac{\sin\theta + \mu\cos\theta}{cos\theta - \mu\sin\theta} m\vec{\mathbf{g}}.$$

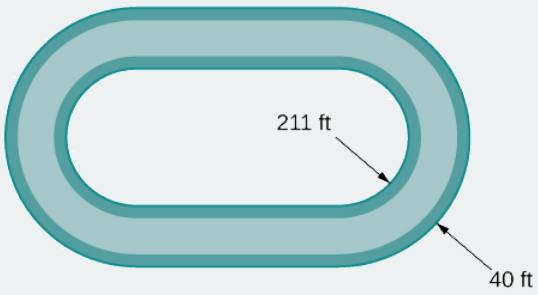
7. Show that $(v_{max})^2 = ((\sin\theta + \mu\, cos\theta)/(\cos\theta - \mu\sin\theta))gR$. Conclude that the maximum speed does not actually depend on the mass of the car.

   Now that we have a formula relating the maximum speed of the car and the banking angle, we are in a position to answer the questions like the one posed at the beginning of the project.

   The Bristol Motor Speedway is a NASCAR short track in Bristol, Tennessee. The track has the approximate shape shown in Figure **13.5.11**. Each end of the track is approximately semicircular, so when cars make turns they are traveling along an approximately circular curve. If a car takes the inside track and speeds along the bottom of turn 1, the car travels along a semicircle of radius approximately 211 ft with a banking angle of 24°. If the car decides to take the outside track and speeds along the top of turn 1, then the car travels along a semicircle with a banking angle of 28°. (The track has variable angle banking.)



(a)



(b)

Figure **13.5.11**: At the Bristol Motor Speedway, Bristol, Tennessee (a), the turns have an inner radius of about 211 ft and a width of 40 ft (b). (credit: part (a) photo by Raniel Diaz, Flickr)

The coefficient of friction for a normal tire in dry conditions is approximately 0.7. Therefore, we assume the coefficient for a NASCAR tire in dry conditions is approximately 0.98.

Before answering the following questions, note that it is easier to do computations in terms of feet and seconds, and then convert the answers to miles per hour as a final step.

8. In dry conditions, how fast can the car travel through the bottom of the turn without skidding?
9. In dry conditions, how fast can the car travel through the top of the turn without skidding?
10. In wet conditions, the coefficient of friction can become as low as 0.1. If this is the case, how fast can the car travel through the bottom of the turn without skidding?
11. Suppose the measured speed of a car going along the outside edge of the turn is 105 mph. Estimate the coefficient of friction for the car's tires.

## Key Concepts

- If $\vec{\mathbf{r}}(t)$ represents the position of an object at time $t$, then $\vec{\mathbf{r}}\,'(t)$ represents the velocity and $\vec{\mathbf{r}}\,''(t)$ represents the acceleration of the object at time $t$. The magnitude of the velocity vector is speed.
- The acceleration vector always points toward the concave side of the curve defined by $\vec{\mathbf{r}}(t)$. The tangential and normal components of acceleration $a_{\vec{\mathbf{T}}}$ and $a_{\vec{\mathbf{N}}}$ are the projections of the acceleration vector onto the unit tangent and unit normal vectors to the curve.
- Kepler's three laws of planetary motion describe the motion of objects in orbit around the Sun. His third law can be modified to describe motion of objects in orbit around other celestial objects as well.
- Newton was able to use his law of universal gravitation in conjunction with his second law of motion and calculus to prove Kepler's three laws.

## Key Equations

- **Velocity**

$$\vec{\mathbf{v}}(t) = \vec{\mathbf{r}}\,'(t)$$

- **Acceleration**

$$\vec{\mathbf{a}}(t) = \vec{\mathbf{v}}\,'(t) = \vec{\mathbf{r}}\,''(t)$$

- **Speed**

$$v(t) = ||\vec{\mathbf{v}}(t)|| = ||\vec{\mathbf{r}}\,'(t)|| = \frac{ds}{dt}$$

- **Tangential component of acceleration**

$$a_{\vec{\mathbf{T}}} = \vec{\mathbf{a}} \cdot \vec{\mathbf{T}} = \frac{\vec{\mathbf{v}} \cdot \vec{\mathbf{a}}}{||\vec{\mathbf{v}}||}$$

- **Normal component of acceleration**

$$a_{\vec{\mathbf{N}}} = \vec{\mathbf{a}} \cdot \vec{\mathbf{N}} = \frac{||\vec{\mathbf{v}} \times \vec{\mathbf{a}}||}{||\vec{\mathbf{v}}||} = \sqrt{||\vec{\mathbf{a}}||^2 - \left(a_{\vec{\mathbf{T}}}\right)^2}$$

## Glossary

**acceleration vector**
the second derivative of the position vector

**Kepler's laws of planetary motion**
three laws governing the motion of planets, asteroids, and comets in orbit around the Sun

**normal component of acceleration**

the coefficient of the unit normal vector $\vec{\mathbf{N}}$ when the acceleration vector is written as a linear combination of $\vec{\mathbf{T}}$ and $\vec{\mathbf{N}}$

**projectile motion**
motion of an object with an initial velocity but no force acting on it other than gravity

**tangential component of acceleration**
the coefficient of the unit tangent vector $\vec{\mathbf{T}}$ when the acceleration vector is written as a linear combination of $\vec{\mathbf{T}}$ and $\vec{\mathbf{N}}$

**velocity vector**
the derivative of the position vector

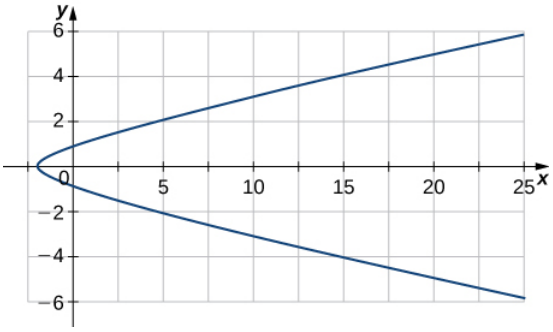
# 13.5E: Exercises for Section 13.4

1) Given $\vec{\mathbf{r}}(t) = (3t^2 - 2)\,\hat{\mathbf{i}} + (2t - \sin t)\,\hat{\mathbf{j}}$,

a. find the velocity of a particle moving along this curve.

b. find the acceleration of a particle moving along this curve.



**Answer**

a. $\vec{\mathbf{v}}(t) = 6t\,\hat{\mathbf{i}} + (2 - \cos t)\,\hat{\mathbf{i}}$

b. $\vec{\mathbf{a}}(t) = 6\,\hat{\mathbf{i}} + \sin t\,\hat{\mathbf{i}}$

**In questions 2 - 5, given the position function, find the velocity, acceleration, and speed in terms of the parameter $t$.**

2) $\vec{\mathbf{r}}(t) = e^{-t}\,\hat{\mathbf{i}} + t^2\,\hat{\mathbf{j}} + \tan t\,\hat{\mathbf{k}}$

3) $\vec{\mathbf{r}}(t) = \langle 3\cos t,\ 3\sin t,\ t^2 \rangle$

**Answer**

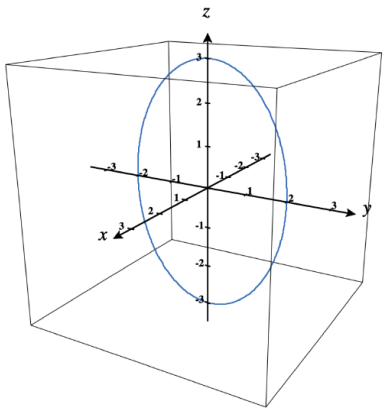
$\vec{\mathbf{v}}(t) = -3\sin t\,\hat{\mathbf{i}} + 3\cos t\,\hat{\mathbf{j}} + 2t\,\hat{\mathbf{k}}$

$\vec{\mathbf{a}}(t) = -3\cos t\,\hat{\mathbf{i}} - 3\sin t\,\hat{\mathbf{j}} + 2\,\hat{\mathbf{k}}$

$\text{Speed}(t) = \|\vec{\mathbf{v}}(t)\| = \sqrt{9 + 4t^2}$

4) $\vec{\mathbf{r}}(t) = t^5\,\hat{\mathbf{i}} + (3t^2 + 2t - 5)\,\hat{\mathbf{j}} + (3t - 1)\,\hat{\mathbf{k}}$

5) $\vec{\mathbf{r}}(t) = 2\cos t\,\hat{\mathbf{j}} + 3\sin t\,\hat{\mathbf{k}}$. The graph is shown here:



**Answer**

$\vec{\mathbf{v}}(t) = -2\sin t\,\hat{\mathbf{j}} + 3\cos t\,\hat{\mathbf{k}}$

$\vec{\mathbf{a}}(t) = -2\cos t\,\hat{\mathbf{j}} - 3\sin t\,\hat{\mathbf{k}}$

$\text{Speed}(t) = \|\vec{\mathbf{v}}(t)\| = \sqrt{4\sin^2 t + 9\cos^2 t} = \sqrt{4 + 5\cos^2 t}$

**In questions 6 - 8, find the velocity, acceleration, and speed of a particle with the given position function.**

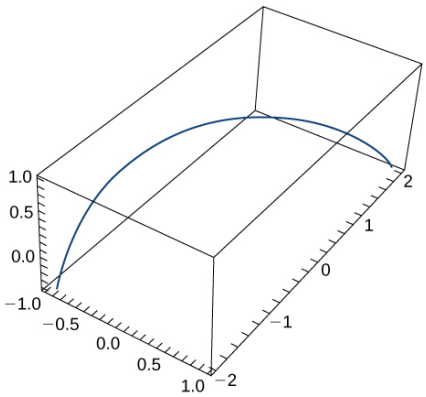
6) $\vec{\mathbf{r}}(t) = \langle t^2 - 1, t \rangle$

7) $\vec{\mathbf{r}}(t) = \langle e^t, e^{-t} \rangle$

**Answer**

$\vec{\mathbf{v}}(t) = \langle e^t, -e^{-t} \rangle,$
$\vec{\mathbf{a}}(t) = \langle e^t, e^{-t} \rangle,$
$\|\vec{\mathbf{v}}(t)\| = \sqrt{e^{2t} + e^{-2t}}$

8) $\vec{\mathbf{r}}(t) = \langle \sin t, t, \cos t \rangle$. The graph is shown here:



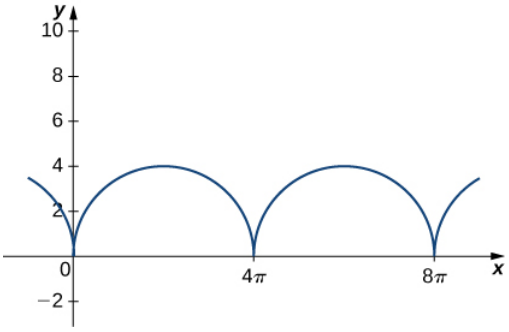
9) The position function of an object is given by $\vec{\mathbf{r}}(t) = \langle t^2, 5t, t^2 - 16t \rangle$. At what time is the speed a minimum?

**Answer**

$t = 4$

10) Let $\vec{\mathbf{r}}(t) = r\cosh(\omega t)\,\hat{\mathbf{i}} + r\sinh(\omega t)\,\hat{\mathbf{j}}$. Find the velocity and acceleration vectors and show that the acceleration is proportional to $\vec{\mathbf{r}}(t)$.

11) Consider the motion of a point on the circumference of a rolling circle. As the circle rolls, it generates the cycloid $\vec{\mathbf{r}}(t) = (\omega t - \sin(\omega t))\,\hat{\mathbf{i}} + (1 - \cos(\omega t))\,\hat{\mathbf{j}}$, where $\omega$ is the angular velocity of the circle and $b$ is the radius of the circle:

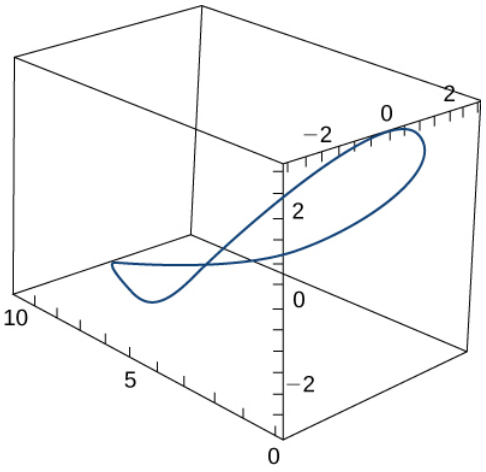


Find the equations for the velocity, acceleration, and speed of the particle at any time.

**Answer**

$\vec{\mathbf{v}}(t) = (\omega - \omega\cos(\omega t))\,\hat{\mathbf{i}} + (\omega\sin(\omega t))\,\hat{\mathbf{j}}$
$\vec{\mathbf{a}}(t) = (\omega^2\sin(\omega t))\,\hat{\mathbf{i}} + (\omega^2\cos(\omega t))\,\hat{\mathbf{j}}$
$\text{speed}(t) = \sqrt{(\omega - \omega\cos(\omega t))^2 + (\omega\sin(\omega t))^2}$
$= \sqrt{\omega^2 - 2\omega^2\cos(\omega t) + \omega^2\cos^2(\omega t) + \omega^2\sin^2(\omega t)}$
$= \sqrt{2\omega^2(1 - \cos(\omega t))}$

12) A person on a hang glider is spiraling upward as a result of the rapidly rising air on a path having position vector $\vec{\mathbf{r}}(t) = (3\cos t)\,\hat{\mathbf{i}} + (3\sin t)\,\hat{\mathbf{j}} + t^2\,\hat{\mathbf{k}}$. The path is similar to that of a helix, although it is not a helix. The graph is shown here:



Find the following quantities:

a. The velocity and acceleration vectors

b. The glider's speed at any time

**Answer**

$\|\vec{\mathbf{v}}(t)\| = \sqrt{9 + 4t^2}$

c. The times, if any, at which the glider's acceleration is orthogonal to its velocity

13) Given that $\vec{\mathbf{r}}(t) = \langle e^{-5t}\sin t,\ e^{-5t}\cos t,\ 4e^{-5t}\rangle$ is the position vector of a moving particle, find the following quantities:

a. The velocity of the particle

**Answer**

$\vec{\mathbf{v}}(t) = \langle e^{-5t}(\cos t - 5\sin t),\ -e^{-5t}(\sin t + 5\cos t),\ -20e^{-5t}\rangle$

b. The speed of the particle

c. The acceleration of the particle

**Answer**

$\vec{\mathbf{a}}(t) = \langle e^{-5t}(-\sin t - 5\cos t) - 5e^{-5t}(\cos t - 5\sin t),\ -e^{-5t}(\cos t - 5\sin t) + 5e^{-5t}(\sin t + 5\cos t),\ 100e^{-5t}\rangle$

14) Find the maximum speed of a point on the circumference of an automobile tire of radius $1$ ft when the automobile is traveling at $55$ mph.

15) Find the position vector-valued function $\vec{\mathbf{r}}(t)$, given that $\vec{\mathbf{a}}(t) = \hat{\mathbf{i}} + e^t\,\hat{\mathbf{j}}$, $\vec{\mathbf{v}}(0) = 2\,\hat{\mathbf{j}}$, and $\vec{\mathbf{r}}(0) = 2\,\hat{\mathbf{i}}$.

16) Find $\vec{\mathbf{r}}(t)$ given that $\vec{\mathbf{a}}(t) = -32\,\hat{\mathbf{j}}$, $\vec{\mathbf{v}}(0) = 600\sqrt{3}\,\hat{\mathbf{i}} + 600\,\hat{\mathbf{j}}$, and $\vec{\mathbf{r}}(0) = \vec{\mathbf{0}}$.

17) The acceleration of an object is given by $\vec{\mathbf{a}}(t) = t\,\hat{\mathbf{j}} + t\,\hat{\mathbf{k}}$. The velocity at $t = 1$ sec is $\vec{\mathbf{v}}(1) = 5\,\hat{\mathbf{j}}$ and the position of the object at $t = 1$ sec is $\vec{\mathbf{r}}(1) = 0\,\hat{\mathbf{i}} + 0\,\hat{\mathbf{j}} + 0\,\hat{\mathbf{k}}$. Find the object's position at any time.

**Answer**

$\vec{\mathbf{r}}(t) = 0\,\hat{\mathbf{i}} + \left(\frac{1}{6}t^3 + 4.5t - \frac{14}{3}\right)\hat{\mathbf{j}} + \left(\frac{1}{6}t^3 - \frac{1}{2}t + \frac{1}{3}\right)\hat{\mathbf{k}}$

## Projectile Motion

18) A projectile is shot in the air from ground level with an initial velocity of $500$ m/sec at an angle of 60° with the horizontal.

a. At what time does the projectile reach maximum height?

**Answer**

$44.185$ sec

b. What is the approximate maximum height of the projectile?

c. At what time is the maximum range of the projectile attained?

**Answer**

$t = 88.37$ sec

d. What is the maximum range?

e. What is the total flight time of the projectile?

**Answer**

$t = 88.37$ sec

19) A projectile is fired at a height of $1.5$ m above the ground with an initial velocity of $100$ m/sec and at an angle of 30° above the horizontal. Use this information to answer the following questions:

a. Determine the maximum height of the projectile.

b. Determine the range of the projectile.

**Answer**

The range is approximately $886.29$ m.

20) A golf ball is hit in a horizontal direction off the top edge of a building that is 100 ft tall. How fast must the ball be launched to land $450$ ft away?

21) A projectile is fired from ground level at an angle of 8° with the horizontal. The projectile is to have a range of $50$ m. Find the minimum velocity (speed) necessary to achieve this range.

**Answer**

$v = 42.16$ m/sec

22) Prove that an object moving in a straight line at a constant speed has an acceleration of zero.

## Finding Components of Acceleration & Kepler's Laws

23) Find the tangential and normal components of acceleration for $\vec{\mathbf{r}}(t) = t^2\,\hat{\mathbf{i}} + 2t\,\hat{\mathbf{j}}$ when $t = 1$.

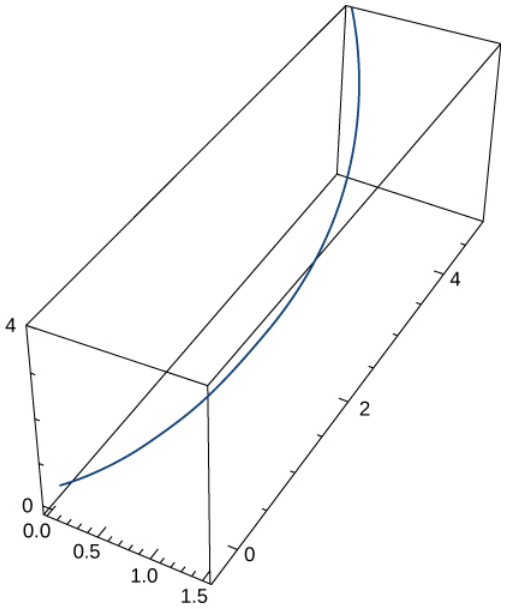
**Answer**

$a_{\vec{\mathbf{T}}} = \sqrt{2}, \quad a_{\vec{\mathbf{N}}} = \sqrt{2}$

**In questions 24 - 30, find the tangential and normal components of acceleration.**

24) $\vec{\mathbf{r}}(t) = \langle \cos(2t),\ \sin(2t),\ 1 \rangle$

25) $\vec{\mathbf{r}}(t) = \langle e^t \cos t,\ e^t \sin t,\ e^t \rangle$. The graph is shown here:



**Answer**

$$a_{\vec{\mathbf{T}}} = \sqrt{3}e^t, \quad a_{\vec{\mathbf{N}}} = \sqrt{2}e^t$$

26) $\vec{\mathbf{r}}(t) = \langle \frac{2}{3}(1+t)^{3/2}, \frac{2}{3}(1-t)^{3/2}, \sqrt{2}t \rangle$

27) $\vec{\mathbf{r}}(t) = \left\langle 2t, t^2, \frac{t^3}{3} \right\rangle$

**Answer**

$$a_{\vec{\mathbf{T}}} = 2t, \quad a_{\vec{\mathbf{N}}} = 2$$

28) $\vec{\mathbf{r}}(t) = t^2\,\hat{\mathbf{i}} + t^2\,\hat{\mathbf{j}} + t^3\,\hat{\mathbf{k}}$

29) $\vec{\mathbf{r}}(t) = \langle 6t, 3t^2, 2t^3 \rangle$

**Answer**

$$a_{\vec{\mathbf{T}}} = \frac{6t + 12t^3}{\sqrt{1 + t^2 + t^4}}, \quad a_{\vec{\mathbf{N}}} = 6\sqrt{\frac{1 + 4t^2 + t^4}{1 + t^2 + t^4}}$$

30) $\vec{\mathbf{r}}(t) = 3\cos(2\pi t)\,\hat{\mathbf{i}} + 3\sin(2\pi t)\,\hat{\mathbf{j}}$

**Answer**

$$a_{\vec{\mathbf{T}}} = 0, \quad a_{\vec{\mathbf{N}}} = 12\pi^2$$

31) Find the tangential and normal components of acceleration for $\vec{\mathbf{r}}(t) = a\cos(\omega t)\,\hat{\mathbf{i}} + b\sin(\omega t)\,\hat{\mathbf{j}}$ at $t = 0$.

**Answer**

$$a_{\vec{\mathbf{T}}} = 0, \quad a_{\vec{\mathbf{N}}} = a\omega^2$$

32) Suppose that the position function for an object in three dimensions is given by the equation $\vec{\mathbf{r}}(t) = t\cos(t)\,\hat{\mathbf{i}} + t\sin(t)\,\hat{\mathbf{j}} + 3t\,\hat{\mathbf{k}}$.

a. Show that the particle moves on a circular cone.

b. Find the angle between the velocity and acceleration vectors when $t = 1.5$.

c. Find the tangential and normal components of acceleration when $t = 1.5$.

**Answer**

c. $a_{\vec{\mathbf{T}}} = 0.43 \text{ m/sec}^2, \quad a_{\vec{\mathbf{N}}} = 2.46 \text{ m/sec}^2$

33) The force on a particle is given by $\vec{\mathbf{f}}(t) = (\cos t)\,\hat{\mathbf{i}} + (\sin t)\,\hat{\mathbf{j}}$. The particle is located at point $(c, 0)$ at $t = 0$. The initial velocity of the particle is given by $\vec{\mathbf{v}}(0) = v_0\,\hat{\mathbf{j}}$. Find the path of the particle of mass $m$. (Recall, $\vec{\mathbf{F}} = m\vec{\mathbf{a}}$.)

**Answer**

$$\vec{\mathbf{r}}(t) = \left(\frac{-\cos t}{m} + c + \frac{1}{m}\right)\hat{\mathbf{i}} + \left(\frac{-\sin t}{m} + \left(v_0 + \frac{1}{m}\right)t\right)\hat{\mathbf{j}}$$

34) An automobile that weighs $2700$ lb makes a turn on a flat road while traveling at $56$ ft/sec. If the radius of the turn is $70$ ft, what is the required frictional force to keep the car from skidding?

35) Using Kepler's laws, it can be shown that $v_0 = \sqrt{\frac{2GM}{r_0}}$ is the minimum speed needed when $\theta = 0$ so that an object will escape from the pull of a central force resulting from mass $M$. Use this result to find the minimum speed when $\theta = 0$ for a space capsule to escape from the gravitational pull of Earth if the probe is at an altitude of $300$ km above Earth's surface.

**Answer**

$10.94$ km/sec

36) Find the time in years it takes the dwarf planet Pluto to make one orbit about the Sun given that $a = 39.5$ A.U.

# 13.R: Chapter 13 Review Exercises

***True or False*? Justify your answer with a proof or a counterexample.**

1. A parametric equation that passes through points $P$ and $Q$ can be given by $\vec{\mathbf{r}}(t) = \langle t^2,\ 3t+1,\ t-2\rangle$, where $P(1,4,-1)$ and $Q(16,11,2)$.

2. $\dfrac{d}{dt}\left[\vec{\mathbf{u}}(t)\times\vec{\mathbf{u}}(t)\right] = 2\vec{\mathbf{u}}'(t)\times\vec{\mathbf{u}}(t)$

**Answer**

False, $\dfrac{d}{dt}\left[\vec{\mathbf{u}}(t)\times\vec{\mathbf{u}}(t)\right] = \vec{\mathbf{0}}$.

3. The curvature of a circle of radius $r$ is constant everywhere. Furthermore, the curvature is equal to $1/r$.

4. The speed of a particle with a position function $\vec{\mathbf{r}}(t)$ is $\dfrac{\vec{\mathbf{r}}'(t)}{\|\vec{\mathbf{r}}'(t)\|}$.

**Answer**

False, it is $\|\vec{\mathbf{r}}'(t)\|$

**Find the domains of the vector-valued functions.**

5. $\vec{\mathbf{r}}(t) = \langle \sin(t),\ \ln(t),\ \sqrt{t}\rangle$

6. $\vec{\mathbf{r}}(t) = \left\langle e^t,\ \dfrac{1}{\sqrt{4-t}},\ \sec t\right\rangle$

**Answer**

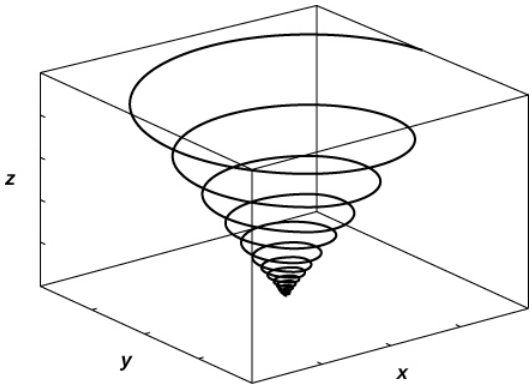
$t<4,\ t\neq\dfrac{n\pi}{2}$

**Sketch the curves for the following vector equations. Use a calculator if needed.**

7. **[T]** $\vec{\mathbf{r}}(t) = \langle t^2, t^3\rangle$

8. **[T]** $\vec{\mathbf{r}}(t) = \langle \sin(20t)e^{-t},\ \cos(20t)e^{-t},\ e^{-t}\rangle$

**Answer**



**Find a vector function that describes the following curves.**

9. Intersection of the cylinder $x^2+y^2=4$ with the plane $x+z=6$

10. Intersection of the cone $z=\sqrt{x^2+y^2}$ and plane $z=y-4$

**Answer**

$\vec{\mathbf{r}}(t) = \left\langle t,\ 2-\frac{t^2}{8},\ -2-\frac{t^2}{8}\right\rangle$

**Find the derivatives of $\vec{\mathbf{u}}(t)$, $\vec{\mathbf{u}}'(t)$, $\vec{\mathbf{u}}'(t) \times \vec{\mathbf{u}}(t)$, $\vec{\mathbf{u}}(t) \times \vec{\mathbf{u}}'(t)$, and $\vec{\mathbf{u}}(t) \cdot \vec{\mathbf{u}}'(t)$. Find the unit tangent vector.**

11. $\vec{\mathbf{u}}(t) = \langle e^t, e^{-t} \rangle$

12. $\vec{\mathbf{u}}(t) = \langle t^2, 2t + 6, 4t^5 - 12 \rangle$

**Answer**

$\vec{\mathbf{u}}'(t) = \langle 2t, 2, 20t^4 \rangle$,
$\vec{\mathbf{u}}''(t) = \langle 2, 0, 80t^3 \rangle$,
$\frac{d}{dt}\left[\vec{\mathbf{u}}'(t) \times \vec{\mathbf{u}}(t)\right] = \langle -480t^3 - 160t^4, 24 + 75t^2, 12 + 4t \rangle$,
$\frac{d}{dt}\left[\vec{\mathbf{u}}(t) \times \vec{\mathbf{u}}'(t)\right] = \langle 480t^3 + 160t^4, -24 - 75t^2, -12 - 4t \rangle$,
$\frac{d}{dt}\left[\vec{\mathbf{u}}(t) \cdot \vec{\mathbf{u}}'(t)\right] = 720t^8 - 9600t^3 + 6t^2 + 4$,
unit tangent vector: $\vec{\mathbf{T}}(t) = \frac{2t}{\sqrt{400t^8 + 4t^2 + 4}}\,\hat{\mathbf{i}} + \frac{2}{\sqrt{400t^8 + 4t^2 + 4}}\,\hat{\mathbf{j}} + \frac{20t^4}{\sqrt{400t^8 + 4t^2 + 4}}\,\hat{\mathbf{k}}$

**Evaluate the following integrals.**

13. $\int \left(\tan(t)\sec(t)\,\hat{\mathbf{i}} - te^{3t}\,\hat{\mathbf{j}}\right)\,dt$

14. $\int_1^4 \vec{\mathbf{u}}(t)\,dt$, with $\vec{\mathbf{u}}(t) = \left\langle \frac{\ln t}{t}, \frac{1}{\sqrt{t}}, \sin\left(\frac{t\pi}{4}\right) \right\rangle$

**Answer**

$\frac{\ln(4^2)}{2}\,\hat{\mathbf{i}} + 2\,\hat{\mathbf{j}} + \frac{2(2+\sqrt{2})}{\pi}\,\hat{\mathbf{k}}$

**Find the length for the following curves.**

15. $\vec{\mathbf{r}}(t) = \langle 3t, 4\cos t, 4\sin t \rangle$ for $1 \le t \le 4$

16. $\vec{\mathbf{r}}(t) = 2\,\hat{\mathbf{i}} + t\,\hat{\mathbf{j}} + 3t^2\,\hat{\mathbf{k}}$ for $0 \le t \le 1$

**Answer**

$\frac{\sqrt{37}}{2} + \frac{1}{12}\sinh^{-1} 6$

**Reparameterize the following functions with respect to their arc length measured from $t = 0$ in direction of increasing $t$.**

17. $\vec{\mathbf{r}}(t) = 2t\,\hat{\mathbf{i}} + (4t - 5)\,\hat{\mathbf{j}} + (1 - 3t)\,\hat{\mathbf{k}}$

18. $\vec{\mathbf{r}}(t) = \cos(2t)\,\hat{\mathbf{i}} + 8t\,\hat{\mathbf{j}} - \sin(2t)\,\hat{\mathbf{k}}$

**Answer**

$\vec{\mathbf{r}}(t(s)) = \cos\left(\frac{2s}{\sqrt{65}}\right)\,\hat{\mathbf{i}} + \frac{8s}{\sqrt{65}}\,\hat{\mathbf{j}} - \sin\left(\frac{2s}{\sqrt{65}}\right)\,\hat{\mathbf{k}}$

**Find the curvature for the following vector functions.**

19. $\vec{\mathbf{r}}(t) = (2\sin t)\,\hat{\mathbf{i}} - 4t\,\hat{\mathbf{j}} + (2\cos t)\,\hat{\mathbf{k}}$

20. $\vec{\mathbf{r}}(t) = \sqrt{2}e^t\,\hat{\mathbf{i}} + \sqrt{2}e^{-t}\,\hat{\mathbf{j}} + 2t\,\hat{\mathbf{k}}$

**Answer**

$\frac{e^{2t}}{\left(e^{2t} + 1\right)^2}$

21. Find the unit tangent vector, the unit normal vector, and the binormal vector for $\vec{\mathbf{r}}(t) = 2\cos t\,\hat{\mathbf{i}} + 3t\,\hat{\mathbf{j}} + 2sint\,\hat{\mathbf{k}}$.

22. Find the tangential and normal acceleration components with the position vector $\vec{\mathbf{r}}(t) = \langle \cos t, \sin t, e^t \rangle$.

**Answer**

$$a_T = \frac{e^{2t}}{1+e^{2t}},$$

$$a_N = \frac{\sqrt{2e^{2t}+4e^{2t}\sin t\cos t+1}}{1+e^{2t}}$$

23. A Ferris wheel car is moving at a constant speed $v$ and has a constant radius $r$. Find the tangential and normal acceleration of the Ferris wheel car.

24. The position of a particle is given by $\vec{\mathbf{r}}(t) = \langle t^2, \ln t, \sin(\pi t)\rangle$, where $t$ is measured in seconds and $r$ is measured in meters. Find the velocity, acceleration, and speed functions. What are the position, velocity, speed, and acceleration of the particle at 1 sec?

**Answer**

$\vec{\mathbf{v}}(t) = \left\langle 2t, \frac{1}{t}, \pi\cos(\pi t)\right\rangle$ m/sec,
$\vec{\mathbf{a}}(t) = \left\langle 2, -\frac{1}{t^2}, -\pi^2\sin(\pi t)\right\rangle$ m/sec$^2$,
$\text{speed}(t) = \sqrt{4t^2+\frac{1}{t^2}+\pi^2\cos^2(\pi t)}$ m/sec;
At $t=1$, $\vec{\mathbf{r}}(1) = \langle 1,0,0\rangle$ m, $\vec{\mathbf{v}}(1) = \langle 2,-1,\pi\rangle$ m/sec, $\vec{\mathbf{a}}(1) = \langle 2,-1,0\rangle$ m/sec$^2$, and $\text{speed}(1) = \sqrt{5+\pi^2}$ m/sec

**The following problems consider launching a cannonball out of a cannon. The cannonball is shot out of the cannon with an angle $\theta$ and initial velocity $\vec{\mathbf{v}}_0$. The only force acting on the cannonball is gravity, so we begin with a constant acceleration $\vec{\mathbf{a}}(t) = -g\,\hat{\mathbf{j}}$.**

25. Find the velocity vector function $\vec{\mathbf{v}}(t)$.

26. Find the position vector $\vec{\mathbf{r}}(t)$ and the parametric representation for the position.

**Answer**

$\vec{\mathbf{r}}(t) = \vec{\mathbf{v}}_0 t - \frac{gt^2}{2}\hat{\mathbf{j}}$,
$\vec{\mathbf{r}}(t) = \langle v_0(\cos\theta)t,\ v_0(\sin\theta)t, -\frac{gt^2}{2}\rangle$ where $v_0 = \|\vec{\mathbf{v}}_0\|$.

27. At what angle do you need to fire the cannonball for the horizontal distance to be greatest? What is the total distance it would travel?

# CHAPTER OVERVIEW

## 14: Differentiation of Functions of Several Variables

When dealing with a function of more than one independent variable, several questions naturally arise. For example, how do we calculate limits of functions of more than one variable? The definition of derivative we used before involved a limit. Does the new definition of derivative involve limits as well? Do the rules of differentiation apply in this context? Can we find relative extrema of functions using derivatives? All these questions are answered in this chapter.

# 14.1: Prelude to Differentiation of Functions of Several Variables

In Introduction to Applications of Derivatives, we studied how to determine the maximum and minimum of a function of one variable over a closed interval. This function might represent the temperature over a given time interval, the position of a car as a function of time, or the altitude of a jet plane as it travels from New York to San Francisco. In each of these examples, the function has one independent variable.

Figure **14.1.1**: Americans use (and lose) millions of golf balls a year, which keeps golf ball manufacturers in business. In this chapter, we study a profit model and learn methods for calculating optimal production levels for a typical golf ball manufacturing company. (credit: modification of work by oatsy40, Flickr)

Suppose, however, that we have a quantity that depends on more than one variable. For example, temperature can depend on location and the time of day, or a company's profit model might depend on the number of units sold and the amount of money spent on advertising. In this chapter, we look at a company that produces golf balls. We develop a profit model and, under various restrictions, we find that the optimal level of production and advertising dollars spent determines the maximum possible profit. Depending on the nature of the restrictions, both the method of solution and the solution itself changes.

When dealing with a function of more than one independent variable, several questions naturally arise. For example, how do we calculate limits of functions of more than one variable? The definition of derivative we used before involved a limit. Does the new definition of derivative involve limits as well? Do the rules of differentiation apply in this context? Can we find relative extrema of functions using derivatives? All these questions are answered in this chapter.

# 14.2: Functions of Several Variables

**Learning Objectives**

- Recognize a function of two variables and identify its domain and range.
- Sketch a graph of a function of two variables.
- Sketch several traces or level curves of a function of two variables.
- Recognize a function of three or more variables and identify its level surfaces.

Our first step is to explain what a function of more than one variable is, starting with functions of two independent variables. This step includes identifying the domain and range of such functions and learning how to graph them. We also examine ways to relate the graphs of functions in three dimensions to graphs of more familiar planar functions.

## Functions of Two Variables

The definition of a function of two variables is very similar to the definition for a function of one variable. The main difference is that, instead of mapping values of one variable to values of another variable, we map ordered pairs of variables to another variable.

**Definition: Function of Two Variables**

A *function of two variables* $z = f(x, y)$ maps each ordered pair $(x, y)$ in a subset $D$ of the real plane $R^2$ to a unique real number $z$. The set $D$ is called the domain of the function. The range of $f$ is the set of all real numbers $z$ that has at least one ordered pair $(x, y) \in D$ such that $f(x, y) = z$ as shown in Figure 14.2.1.

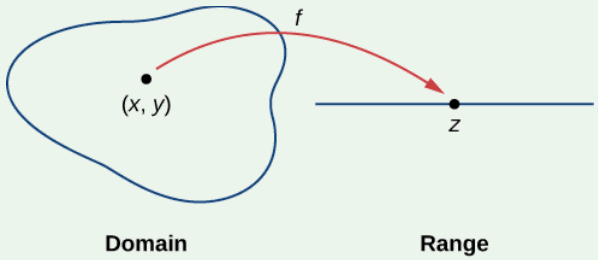

Figure 14.2.1: The domain of a function of two variables consists of ordered pairs $(x, y)$.

Determining the domain of a function of two variables involves taking into account any domain restrictions that may exist. Let's take a look.

**Example 14.2.1: Domains and Ranges for Functions of Two Variables**

Find the domain and range of each of the following functions:

a. $f(x, y) = 3x + 5y + 2$
b. $g(x, y) = \sqrt{9 - x^2 - y^2}$

**Solution**

a. This is an example of a linear function in two variables. There are no values or combinations of $x$ and $y$ that cause $f(x, y)$ to be undefined, so the domain of $f$ is $R^2$. To determine the range, first pick a value for $z$. We need to find a solution to the equation $f(x, y) = z$, or $3x - 5y + 2 = z$. One such solution can be obtained by first setting $y = 0$, which yields the equation $3x + 2 = z$. The solution to this equation is $x = \frac{z-2}{3}$, which gives the ordered pair $\left(\frac{z-2}{3}, 0\right)$ as a solution to the equation $f(x, y) = z$ for any value of $z$. Therefore, the range of the function is all real numbers, or $R$.

b. For the function $g(x, y)$ to have a real value, the quantity under the square root must be nonnegative:

$$9 - x^2 - y^2 \geq 0.$$

This inequality can be written in the form

$$x^2 + y^2 \leq 9.$$

Therefore, the domain of $g(x, y)$ is $\{(x, y) \in R^2 \mid x^2 + y^2 \leq 9\}$. The graph of this set of points can be described as a disk of radius 3 centered at the origin. The domain includes the boundary circle as shown in the following graph.

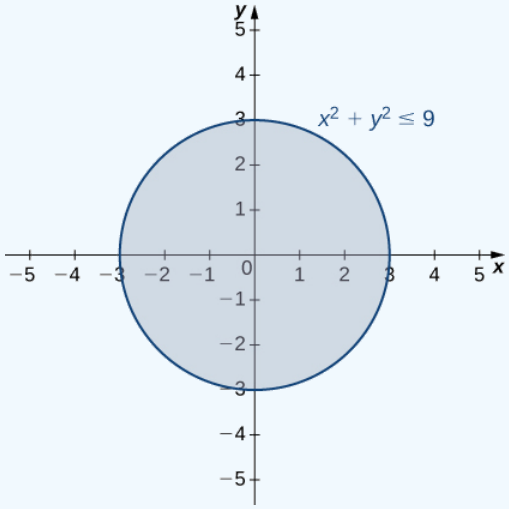

Figure **14.2.2**: The domain of the function $g(x, y) = \sqrt{9 - x^2 - y^2}$ is a closed disk of radius 3.

To determine the range of $g(x, y) = \sqrt{9 - x^2 - y^2}$ we start with a point $(x_0, y_0)$ on the boundary of the domain, which is defined by the relation $x^2 + y^2 = 9$. It follows that $x_0^2 + y_0^2 = 9$ and

$$\begin{aligned} g(x_0, y_0) &= \sqrt{9 - x_0^2 - y_0^2} \\ &= \sqrt{9 - (x_0^2 + y_0^2)} \\ &= \sqrt{9 - 9} \\ &= 0. \end{aligned}$$

If $x_0^2 + y_0^2 = 0$ (in other words, $x_0 = y_0 = 0$), then

$$\begin{aligned} g(x_0, y_0) &= \sqrt{9 - x_0^2 - y_0^2} \\ &= \sqrt{9 - (x_0^2 + y_0^2)} \\ &= \sqrt{9 - 0} = 3. \end{aligned}$$

This is the maximum value of the function. Given any value $c$ between $0$ and $3$, we can find an entire set of points inside the domain of $g$ such that $g(x, y) = c$:

$$\begin{aligned} \sqrt{9 - x^2 - y^2} &= c \\ 9 - x^2 - y^2 &= c^2 \\ x^2 + y^2 &= 9 - c^2. \end{aligned}$$

Since $9 - c^2 > 0$, this describes a circle of radius $\sqrt{9 - c^2}$ centered at the origin. Any point on this circle satisfies the equation $g(x, y) = c$. Therefore, the range of this function can be written in interval notation as $[0, 3]$.

## ? Exercise 14.2.1

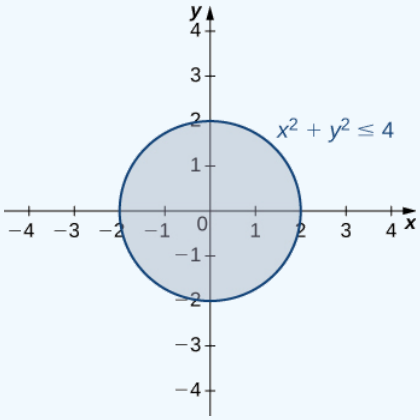
Find the domain and range of the function $f(x, y) = \sqrt{36 - 9x^2 - 9y^2}$.

**Hint**

Determine the set of ordered pairs that do not make the radicand negative.

**Solution**

The domain is $\{(x,y)|x^2+y^2 \leq 4\}$ the shaded circle defined by the inequality $x^2+y^2 \leq 4$, which has a circle of radius $2$ as its boundary. The range is $[0,6]$.



## Graphing Functions of Two Variables

Suppose we wish to graph the function $z=f(x,y)$. This function has two independent variables ($x$ and $y$) and one dependent variable ($z$). When graphing a function $y=f(x)$ of one variable, we use the Cartesian plane. We are able to graph any ordered pair $(x,y)$ in the plane, and every point in the plane has an ordered pair $(x,y)$ associated with it. With a function of two variables, each ordered pair $(x,y)$ in the domain of the function is mapped to a real number $z$. Therefore, the graph of the function $f$ consists of ordered triples $(x,y,z)$. The graph of a function $z=f(x,y)$ of two variables is called a surface.

To understand more completely the concept of plotting a set of ordered triples to obtain a surface in three-dimensional space, imagine the $(x,y)$ coordinate system laying flat. Then, every point in the domain of the function f has a unique $z$-value associated with it. If $z$ is positive, then the graphed point is located above the $xy$-plane, if $z$ is negative, then the graphed point is located below the $xy$-plane. The set of all the graphed points becomes the two-dimensional surface that is the graph of the function $f$.

### Example 14.2.2: Graphing Functions of Two Variables

Create a graph of each of the following functions:

a. $g(x,y)=\sqrt{9-x^2-y^2}$
b. $f(x,y)=x^2+y^2$

**Solution**

a. In Example 14.2.2, we determined that the domain of $g(x,y)=\sqrt{9-x^2-y^2}$ is $\{(x,y) \in R^2 \mid x^2+y^2 \leq 9\}$ and the range is $\{z \in R^2 \mid 0 \leq z \leq 3\}$. When $x^2+y^2=9$ we have $g(x,y)=0$. Therefore any point on the circle of radius $3$ centered at the origin in the $xy$-plane maps to $z=0$ in $R^3$. If $x^2+y^2=8$, then $g(x,y)=1$, so any point on the circle of radius $2\sqrt{2}$ centered at the origin in the $xy$-plane maps to $z=1$ in $R^3$. As $x^2+y^2$ gets closer to zero, the value of $z$ approaches $3$. When $x^2+y^2=0$, then $g(x,y)=3$. This is the origin in the $xy$-plane If $x^2+y^2$ is equal to any other value between $0$ and $9$, then $g(x,y)$ equals some other constant between $0$ and $3$. The surface described by this function is a hemisphere centered at the origin with radius $3$ as shown in the following graph.

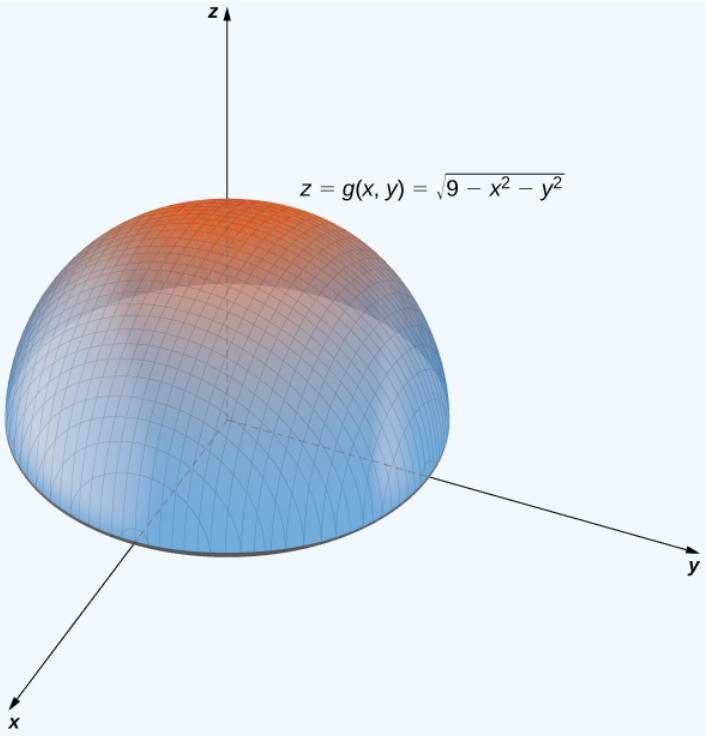


Figure **14.2.3**: Graph of the hemisphere represented by the given function of two variables.

b. This function also contains the expression $x^2 + y^2$. Setting this expression equal to various values starting at zero, we obtain circles of increasing radius. The minimum value of $f(x, y) = x^2 + y^2$ is zero (attained when $x = y = 0$.. When $x = 0$, the function becomes $z = y^2$, and when $y = 0$, then the function becomes $z = x^2$. These are cross-sections of the graph, and are parabolas. Recall from Introduction to Vectors in Space that the name of the graph of $f(x, y) = x^2 + y^2$ is a **paraboloid**. The graph of $f$ appears in the following graph.

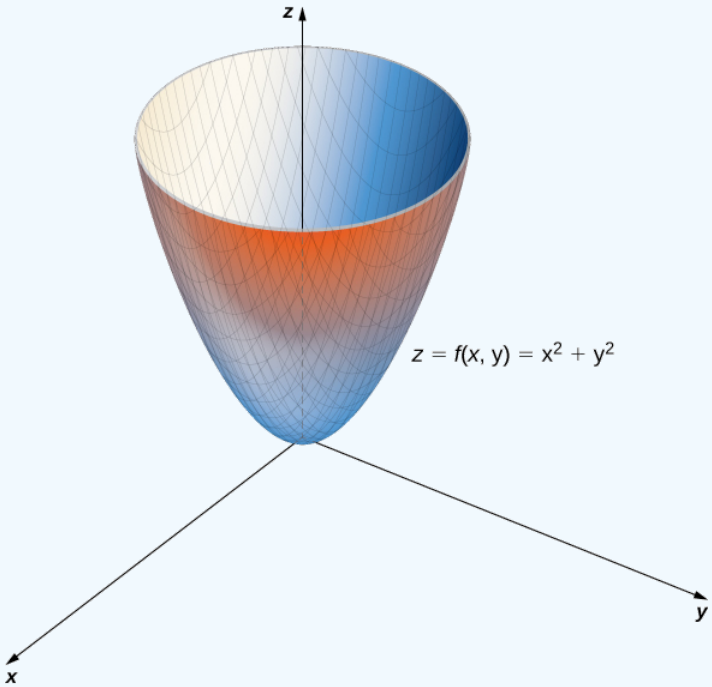

Figure **14.2.4**: A paraboloid is the graph of the given function of two variables.

### Example 14.2.3: Nuts and Bolts

A profit function for a hardware manufacturer is given by

$$f(x,y) = 16 - (x-3)^2 - (y-2)^2,$$

where $x$ is the number of nuts sold per month (measured in thousands) and $y$ represents the number of bolts sold per month (measured in thousands). Profit is measured in thousands of dollars. Sketch a graph of this function.

**Solution**

This function is a polynomial function in two variables. The domain of $f$ consists of $(x,y)$ coordinate pairs that yield a nonnegative profit:

$$16 - (x-3)^2 - (y-2)^2 \geq 0$$
$$(x-3)^2 + (y-2)^2 \leq 16.$$

This is a disk of radius $4$ centered at $(3,2)$. A further restriction is that both $x$ and $y$ must be nonnegative. When $x = 3$ and $y = 2, f(x,y) = 16$. Note that it is possible for either value to be a noninteger; for example, it is possible to sell $2.5$ thousand nuts in a month. The domain, therefore, contains thousands of points, so we can consider all points within the disk. For any $z < 16$, we can solve the equation $f(x,y) = 16$ :

$$16 - (x-3)^2 - (y-2)^2 = z$$
$$(x-3)^2 + (y-2)^2 = 16 - z.$$

Since $z < 16$, we know that $16 - z > 0$, so the previous equation describes a circle with radius $\sqrt{16-z}$ centered at the point $(3,2)$. Therefore. the range of $f(x,y)$ is $\{z \in \mathbb{R} | z \leq 16\}$. The graph of $f(x,y)$ is also a paraboloid, and this paraboloid points downward as shown.

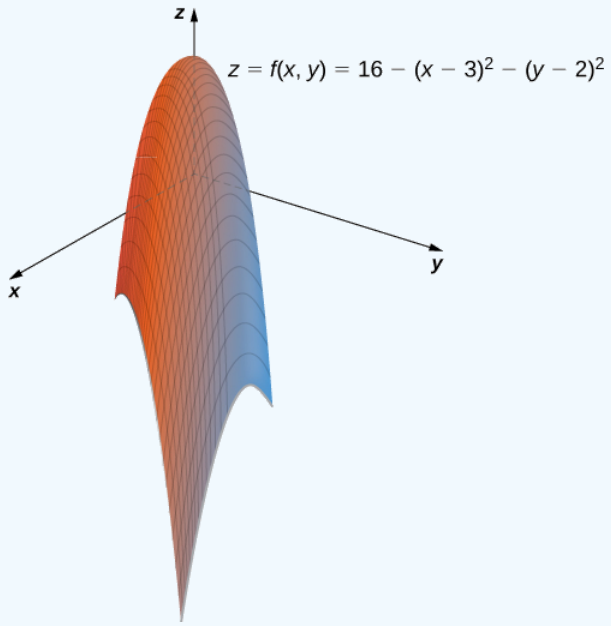

Figure 14.2.5: The graph of the given function of two variables is also a paraboloid.

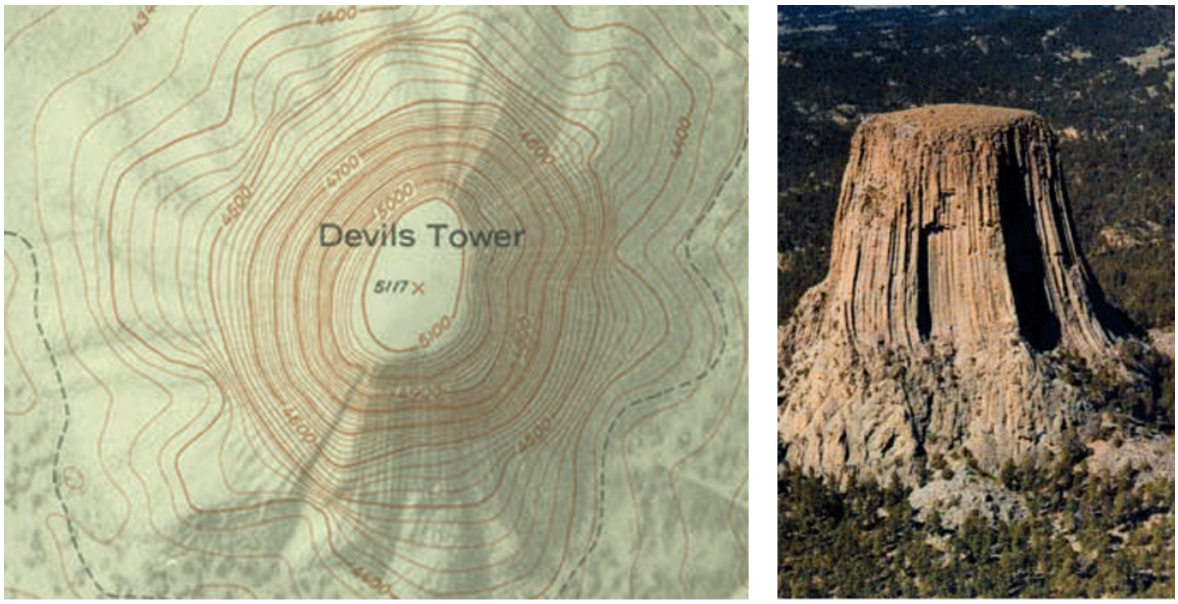
## Level Curves

If hikers walk along rugged trails, they might use a topographical map that shows how steeply the trails change. A *topographical map* contains curved lines called contour lines. Each contour line corresponds to the points on the map that have equal elevation (Figure 14.2.6). A level curve of a function of two variables $f(x,y)$ is completely analogous to a contour line on a topographical map.



(a) (b)

Figure 14.2.6: (a) A topographical map of Devil's Tower, Wyoming. Lines that are close together indicate very steep terrain. (b) A perspective photo of Devil's Tower shows just how steep its sides are. Notice the top of the tower has the same shape as the center of the topographical map.

**Definition: Level Curves**

Given a function $f(x,y)$ and a number $c$ in the range of $f$, a level curve of a function of two variables for the value $c$ is defined to be the set of points satisfying the equation $f(x,y)=c$.

Returning to the function $g(x,y)=\sqrt{9-x^2-y^2}$, we can determine the level curves of this function. The range of $g$ is the closed interval $[0,3]$. First, we choose any number in this closed interval—say, $c=2$. The level curve corresponding to $c=2$ is described by the equation

$$\sqrt{9-x^2-y^2}=2.$$

To simplify, square both sides of this equation:

$$9-x^2-y^2=4.$$

Now, multiply both sides of the equation by $-1$ and add $9$ to each side:

$$x^2+y^2=5.$$

This equation describes a circle centered at the origin with radius $\sqrt{5}$. Using values of $c$ between $0$ and $3$ yields other circles also centered at the origin. If $c=3$, then the circle has radius $0$, so it consists solely of the origin. Figure 14.2.7 is a graph of the level curves of this function corresponding to $c=0,1,2,$ and $3$. Note that in the previous derivation it may be possible that we introduced extra solutions by squaring both sides. This is not the case here because the range of the square root function is nonnegative.

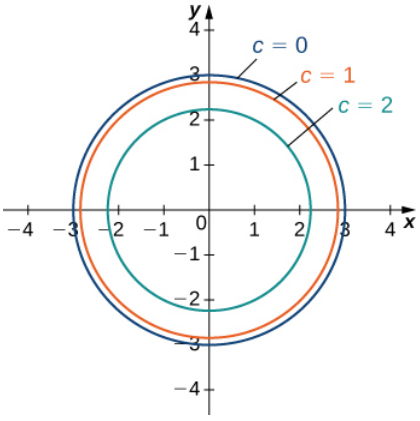


Figure 14.2.7: Level curves of the function $g(x,y)=\sqrt{9-x^2-y^2}$, using $c=0,1,2$, and $3(c=3$ corresponds to the origin).

A graph of the various level curves of a function is called a *contour map*.

### Example 14.2.4: Making a Contour Map

Given the function $f(x,y)=\sqrt{8+8x-4y-4x^2-y^2}$, find the level curve corresponding to $c=0$. Then create a contour map for this function. What are the domain and range of $f$?

**Solution**

To find the level curve for $c=0$, we set $f(x,y)=0$ and solve. This gives

$$0=\sqrt{8+8x-4y-4x^2-y^2}.$$

We then square both sides and multiply both sides of the equation by $-1$:

$$4x^2+y^2-8x+4y-8=0.$$

Now, we rearrange the terms, putting the $x$ terms together and the $y$ terms together, and add $8$ to each side:

$$4x^2-8x+y^2+4y=8.$$

Next, we group the pairs of terms containing the same variable in parentheses, and factor $4$ from the first pair:

$$4(x^2-2x)+(y^2+4y)=8.$$

Then we complete the square in each pair of parentheses and add the correct value to the right-hand side:

$$4(x^2-2x+1)+(y^2+4y+4)=8+4(1)+4.$$

Next, we factor the left-hand side and simplify the right-hand side:

$$4(x-1)^2+(y+2)^2=16.$$

Last, we divide both sides by $16$ :

$$\frac{(x-1)^2}{4}+\frac{(y+2)^2}{16}=1. \tag{14.2.1}$$

This equation describes an ellipse centered at $(1,-2)$. The graph of this ellipse appears in the following graph.

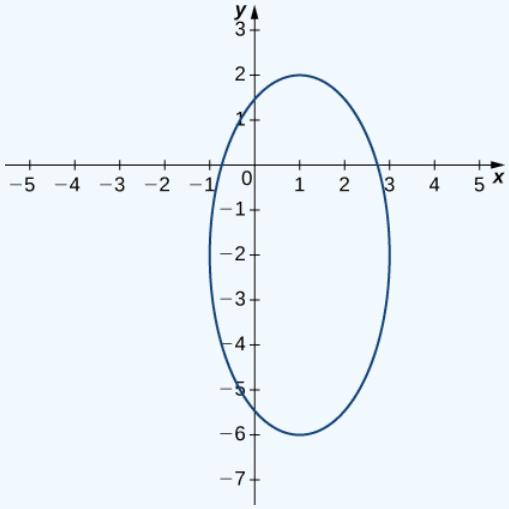

Figure 14.2.8: Level curve of the function $f(x,y)=\sqrt{8+8x-4y-4x^2-y^2}$ corresponding to $c=0$

We can repeat the same derivation for values of $c$ less than 4. Then, Equation 14.2.1 becomes

$$\frac{4(x-1)^2}{16-c^2}+\frac{(y+2)^2}{16-c^2}=1$$

for an arbitrary value of $c$. Figure 14.2.9 shows a contour map for $f(x,y)$ using the values $c=0,1,2,$ and 3. When $c=4$, the level curve is the point $(-1,2)$.

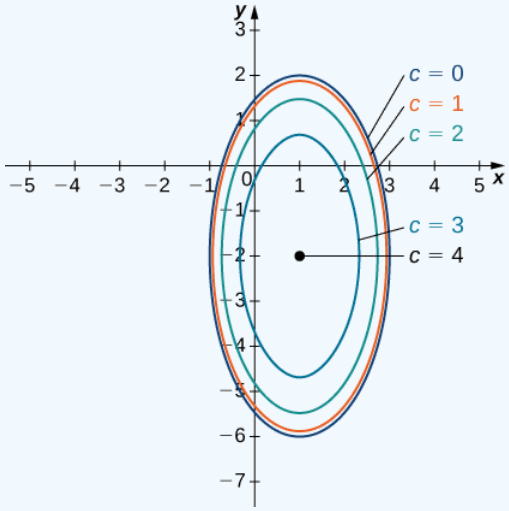

Figure 14.2.9: Contour map for the function $f(x,y)=\sqrt{8+8x-4y-4x^2-y^2}$ using the values $c=0,1,2,3,$ and 4.

**Finding the Domain & Range**

Since this is a square root function, the radicand must not be negative. So we have

$$8+8x-4y-4x^2-y^2\geq 0$$

Recognizing that the boundary of the domain is an ellipse, we repeat the steps we showed above to obtain

$$\frac{(x-1)^2}{4}+\frac{(y+2)^2}{16}\leq 1$$

So the domain of $f$ can be written: $\left\{(x,y)\,|\,\frac{(x-1)^2}{4}+\frac{(y+2)^2}{16}\leq 1\right\}$.

To find the range of $f$, we need to consider the possible outputs of this square root function. We know the output cannot be negative, so we need to next check if its output is ever 0. From the work we completed above to find the level curve for $c=0$, we know the value of $f$ is 0 for any point on that level curve (on the ellipse, $\frac{(x-1)^2}{4}+\frac{(y+2)^2}{16}=1$). So we know the lower bound of the range of this function is 0.

To determine the upper bound for the range of the function in this problem, it's easier if we first complete the square under the radical.

$$\begin{aligned} f(x,y) &= \sqrt{8+8x-4y-4x^2-y^2} \\ &= \sqrt{8-4(x^2-2x\quad)-(y^2+4y\quad)} \\ &= \sqrt{8-4(x^2-2x+1-1)-(y^2+4y+4-4)} \\ &= \sqrt{8-4(x^2-2x+1)+4-(y^2+4y+4)+4} \\ &= \sqrt{16-4(x-1)^2-(y+2)^2} \end{aligned}$$

Now that we have $f$ in this form, we can see how large the radicand can be. Since we are subtracting two perfect squares from $16$, we know that the value of the radicand cannot be greater than $16$. At the point $(1,-2)$, we can see the radicand will be 16 (since we will be subtracting $0$ from $16$ at this point. This gives us the maximum value of $f$, that is $f(1,-2)=\sqrt{16}=4$.

So the range of this function is $[0,4]$.

## Exercise 14.2.2

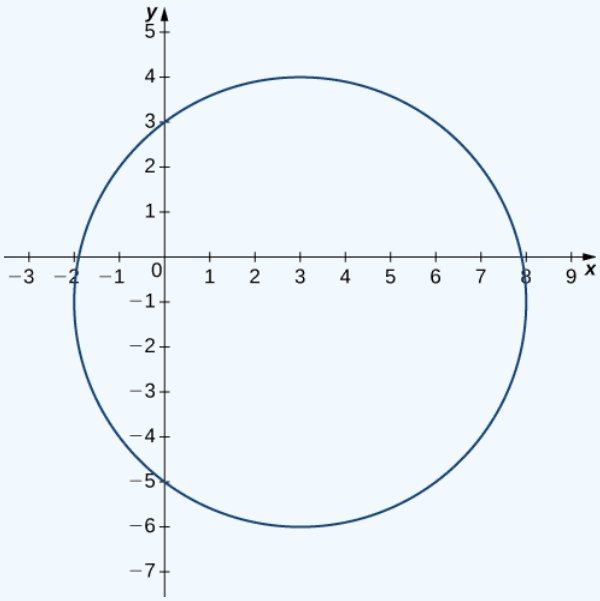
Find and graph the level curve of the function $g(x,y)=x^2+y^2-6x+2y$ corresponding to $c=15$.

**Hint**

First, set $g(x,y)=15$ and then complete the square.

**Solution**

The equation of the level curve can be written as $(x-3)^2+(y+1)^2=25$, which is a circle with radius $5$ centered at $(3,-1)$.



Another useful tool for understanding the **graph of a function of two variables** is called a vertical trace. Level curves are always graphed in the $xy$-plane, but as their name implies, vertical traces are graphed in the $xz$- or $yz$-planes.

### Definition: Vertical Traces

Consider a function $z=f(x,y)$ with domain $D\subseteq\mathbb{R}^2$. A *vertical trace* of the function can be either the set of points that solves the equation $f(a,y)=z$ for a given constant $x=a$ or $f(x,b)=z$ for a given constant $y=b$.

## Example 14.2.5: Finding Vertical Traces

Find vertical traces for the function $f(x,y) = \sin x \cos y$ corresponding to $x = -\frac{\pi}{4}, 0$, and $\frac{\pi}{4}$, and $y = -\frac{\pi}{4}, 0$, and $\frac{\pi}{4}$.

### Solution

First set $x = -\frac{\pi}{4}$ in the equation $z = \sin x \cos y$:

$$z = \sin\left(-\frac{\pi}{4}\right)\cos y = -\frac{\sqrt{2}\cos y}{2} \approx -0.7071 \cos y.$$

This describes a cosine graph in the plane $x = -\frac{\pi}{4}$. The other values of $z$ appear in the following table.

Vertical Traces Parallel to the $xz$-Plane for the Function $f(x,y) = \sin x \cos y$

| $c$ | Vertical Trace for $x = c$ |
|---|---|
| $-\frac{\pi}{4}$ | $z = -\frac{\sqrt{2}\cos y}{2}$ |
| 0 | $z = 0$ |
| $\frac{\pi}{4}$ | $z = \frac{\sqrt{2}\cos y}{2}$ |

In a similar fashion, we can substitute the $y$-values in the equation $f(x,y)$ to obtain the traces in the $yz$-plane, as listed in the following table.

Vertical Traces Parallel to the $yz$-Plane for the Function $f(x,y) = \sin x \cos y$

| $d$ | Vertical Trace for $y = d$ |
|---|---|
| $\frac{\pi}{4}$ | $z = \frac{\sqrt{2}\sin x}{2}$ |
| 0 | $z = \sin x$ |
| $-\frac{\pi}{4}$ | $z = \frac{\sqrt{2}\sin x}{2}$ |

The three traces in the $xz$-plane are cosine functions; the three traces in the $yz$-plane are sine functions. These curves appear in the intersections of the surface with the planes $x = -\frac{\pi}{4}, x = 0, x = \frac{\pi}{4}$ and $y = -\frac{\pi}{4}, y = 0, y = \frac{\pi}{4}$ as shown in the following figure.

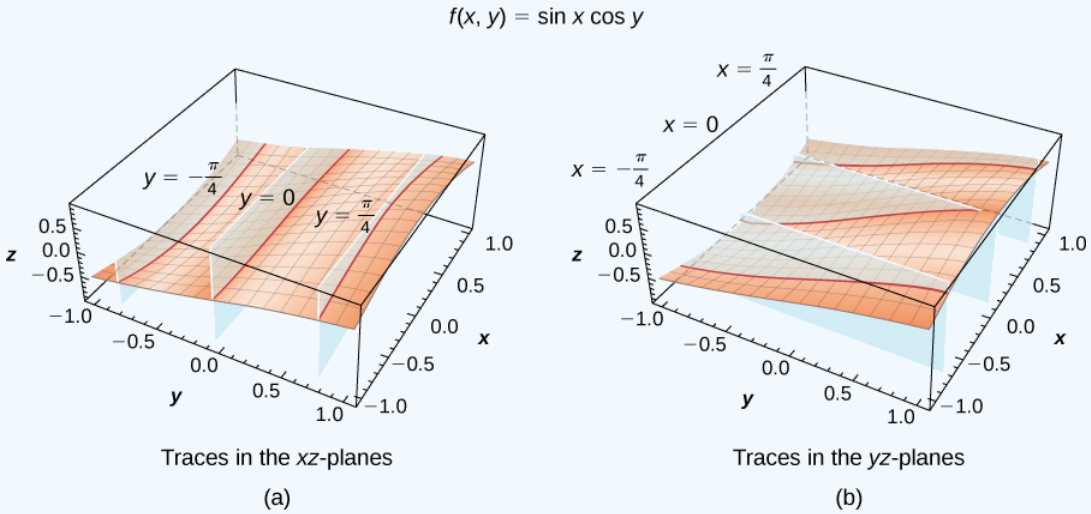


Figure 14.2.10: Vertical traces of the function $f(x,y)$ are cosine curves in the $xz-planes$ (a) and sine curves in the $yz-planes$ (b).

## Exercise 14.2.3

Determine the equation of the vertical trace of the function $g(x,y) = -x^2 - y^2 + 2x + 4y - 1$ corresponding to $y = 3$, and describe its graph.

**Hint**

Set $y = 3$ in the equation $z = -x^2 - y^2 + 2x + 4y - 1$ and complete the square.

**Solution**

$z = 3 - (x-1)^2$. This function describes a parabola opening downward in the plane $y = 3$.

Functions of two variables can produce some striking-looking surfaces. Figure 14.2.11 shows two examples.

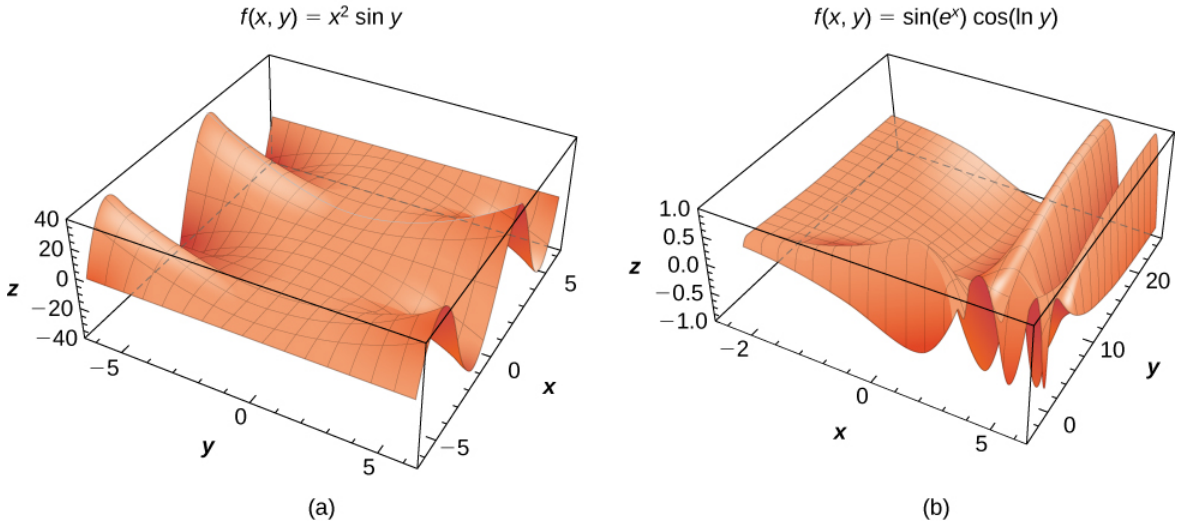

Figure 14.2.11: Examples of surfaces representing functions of two variables: (a) a combination of a power function and a sine function and (b) a combination of trigonometric, exponential, and logarithmic functions.

## Functions of More Than Two Variables

So far, we have examined only functions of two variables. However, it is useful to take a brief look at functions of more than two variables. Two such examples are

$$\underbrace{f(x,y,z) = x^2 - 2xy + y^2 + 3yz - z^2 + 4x - 2y + 3x - 6}_{\text{a polynomial in three variables}}$$

and

$$g(x,y,t) = (x^2 - 4xy + y^2)\sin t - (3x + 5y)\cos t.$$

In the first function, $(x,y,z)$ represents a point in space, and the function $f$ maps each point in space to a fourth quantity, such as temperature or wind speed. In the second function, $(x,y)$ can represent a point in the plane, and $t$ can represent time. The function might map a point in the plane to a third quantity (for example, pressure) at a given time $t$. The method for finding the domain of a function of more than two variables is analogous to the method for functions of one or two variables.

## Example 14.2.6: Domains for Functions of Three Variables

Find the domain of each of the following functions:

a. $f(x,y,z) = \dfrac{3x - 4y + 2z}{\sqrt{9 - x^2 - y^2 - z^2}}$

b. $g(x,y,t) = \dfrac{\sqrt{2t - 4}}{x^2 - y^2}$

**Solution**:

a. For the function $f(x,y,z) = \dfrac{3x-4y+2z}{\sqrt{9-x^2-y^2-z^2}}$ to be defined (and be a real value), two conditions must hold:

1. The denominator **cannot** be zero.
2. The radicand **cannot** be negative.

Combining these conditions leads to the inequality

$$9-x^2-y^2-z^2>0.$$

Moving the variables to the other side and reversing the inequality gives the domain as

$$domain(f) = \{(x,y,z) \in R^3 \mid x^2+y^2+z^2<9\},$$

which describes a ball of radius $3$ centered at the origin. (Note: The surface of the ball is not included in this domain.)

b. For the function $g(x,y,t) = \dfrac{\sqrt{2t-4}}{x^2-y^2}$ to be defined (and be a real value), two conditions must hold:

1. The radicand cannot be negative.
2. The denominator cannot be zero.

Since the radicand cannot be negative, this implies $2t-4 \geq 0$, and therefore that $t \geq 2$. Since the denominator cannot be zero, $x^2-y^2 \neq 0$, or $x^2 \neq y^2$, Which can be rewritten as $y = \pm x$, which are the equations of two lines passing through the origin. Therefore, the domain of $g$ is

$$domain(g) = \{(x,y,t) | y \neq \pm x, t \geq 2\}.$$

## ? Exercise 14.2.4

Find the domain of the function $h(x,y,t) = (3t-6)\sqrt{y-4x^2+4}$.

**Hint**

Check for values that make radicands negative or denominators equal to zero.

**Solution**

$$domain(h) = \{(x,y,t) \in \mathbb{R}^3 \mid y \geq 4x^2-4\}$$

Functions of two variables have level curves, which are shown as curves in the $xy-plane$. However, when the function has three variables, the curves become surfaces, so we can define level surfaces for functions of three variables.

## Definition: Level Surface of a Function of Three Variables

Given a function $f(x,y,z)$ and a number $c$ in the range of $f$, a *level surface of a function of three variables* is defined to be the set of points satisfying the equation $f(x,y,z) = c$.

## ✓ Example 14.2.7: Finding a Level Surface

Find the level surface for the function $f(x,y,z) = 4x^2+9y^2-z^2$ corresponding to $c = 1$.

**Solution**

The level surface is defined by the equation $4x^2+9y^2-z^2 = 1$. This equation describes a hyperboloid of one sheet as shown in Figure 14.2.12.

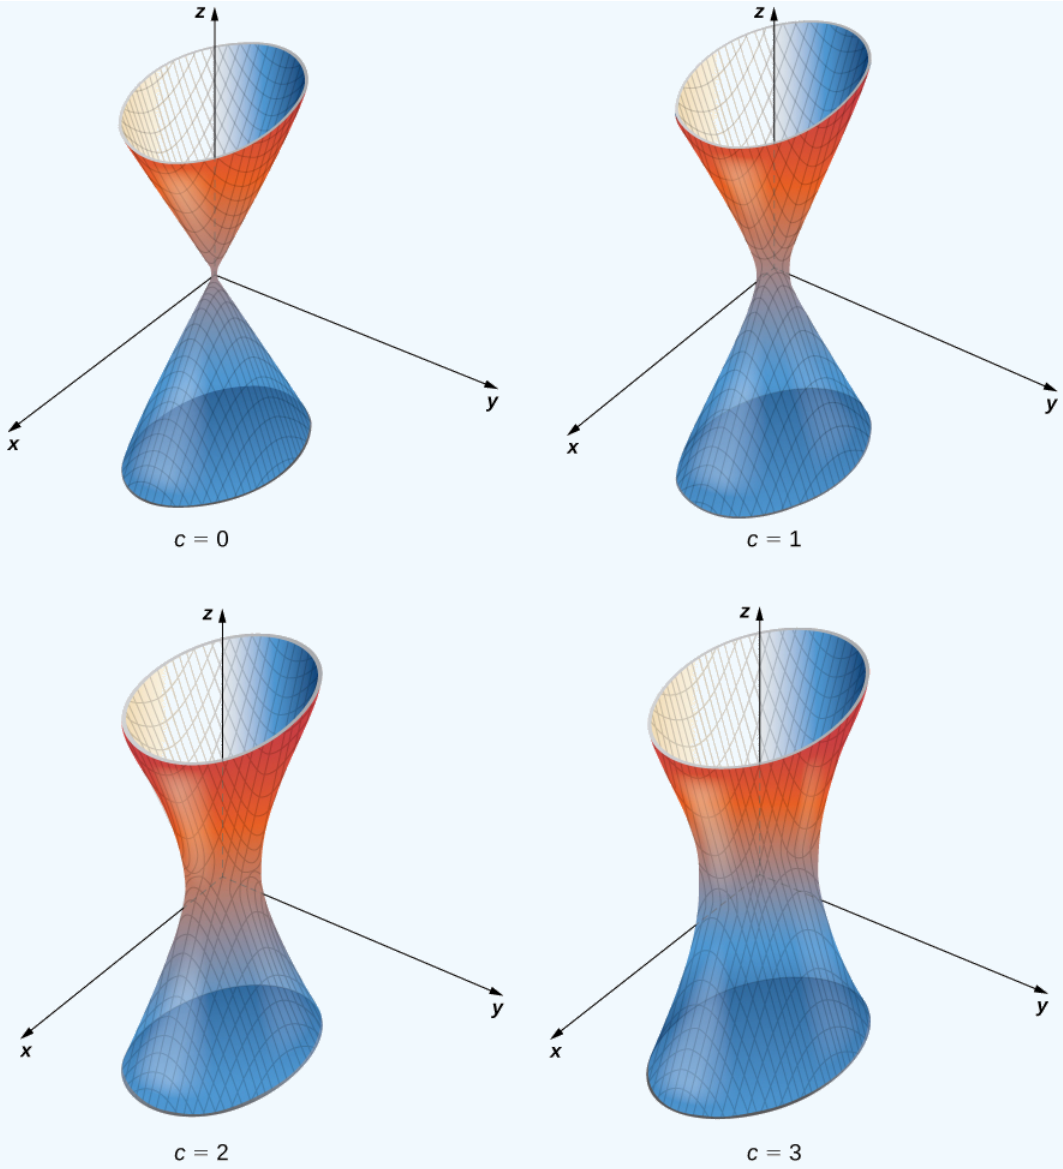

Figure 14.2.12: A hyperboloid of one sheet with some of its level surfaces.

## ? Exercise 14.2.5

Find the equation of the level surface of the function

$$g(x,y,z) = x^2 + y^2 + z^2 - 2x + 4y - 6z$$

corresponding to $c = 2$, and describe the surface, if possible.

**Hint**

Set $g(x,y,z) = c$ and complete the square.

**Solution**

$(x-1)^2 + (y+2)^2 + (z-3)^2 = 16$ describes a sphere of radius $4$ centered at the point $(1,-2,3)$.

## Summary

- The graph of a function of two variables is a surface in $\mathbb{R}^3$ and can be studied using level curves and vertical traces.
- A set of level curves is called a contour map.

## Key Equations

- **Vertical trace**

  $f(a, y) = z$ for $x = a$ or $f(x, b) = z$ for $y = b$

- **Level surface of a function of three variables**

  $f(x, y, z) = c$

## Glossary

**contour map**
a plot of the various level curves of a given function $f(x, y)$

**function of two variables**
a function $z = f(x, y)$ that maps each ordered pair $(x, y)$ in a subset $D$ of $R^2$ to a unique real number $z$

**graph of a function of two variables**
a set of ordered triples $(x, y, z)$ that satisfies the equation $z = f(x, y)$ plotted in three-dimensional Cartesian space

**level curve of a function of two variables**
the set of points satisfying the equation $f(x, y) = c$ for some real number $c$ in the range of $f$

**level surface of a function of three variables**
the set of points satisfying the equation $f(x, y, z) = c$ for some real number $c$ in the range of $f$

**surface**
the graph of a function of two variables, $z = f(x, y)$

**vertical trace**
the set of ordered triples $(c, y, z)$ that solves the equation $f(c, y) = z$ for a given constant $x = c$ or the set of ordered triples $(x, d, z)$ that solves the equation $f(x, d) = z$ for a given constant $y = d$

# 14.2E: EXERCISES FOR SECTION 14.1

For the following exercises, evaluate each function at the indicated values.

1) $W(x,y) = 4x^2 + y^2$. Find $W(2,-1), W(-3,6)$.

**Answer**

$W(2,-1) = 17, \quad W(-3,6) = 72$

2) $W(x,y) = 4x^2 + y^2$. Find $W(2+h, 3+h)$.

3) The volume of a right circular cylinder is calculated by a function of two variables, $V(x,y) = \pi x^2 y$, where $x$ is the radius of the right circular cylinder and $y$ represents the height of the cylinder. Evaluate $V(2,5)$ and explain what this means.

**Answer**

$V(2,5) = 20\pi \text{ units}^3$ This is the volume when the radius is $2$ and the height is $5$.

4) An oxygen tank is constructed of a right cylinder of height $y$ and radius $x$ with two hemispheres of radius $x$ mounted on the top and bottom of the cylinder. Express the volume of the cylinder as a function of two variables, $x$ and $y$, find $V(10,2)$, and explain what this means.

**For exercises 5 - 10, find the domain and range of the given function. State the domain in set-builder notation and the range in interval notation.**

5) $V(x,y) = 4x^2 + y^2$

**Answer**

Domain: $\{(x,y) \mid x \in \mathbb{R}, y \in \mathbb{R}\}$ That is, all points in the $xy$-plane

Range: $[0, \infty)$

6) $f(x,y) = \sqrt{x^2 + y^2 - 4}$

**Answer**

Domain: $\{(x,y) \mid x^2 + y^2 \geq 4\}$

Range: $[0, \infty)$

7) $f(x,y) = 4\ln(y^2 - x)$

**Answer**

Domain: $\{(x,y) \mid x < y^2\}$

Range: $(-\infty, \infty)$

8) $g(x,y) = \sqrt{16 - 4x^2 - y^2}$

**Answer**

Domain: $\{(x,y) \mid \frac{x^2}{4} + \frac{y^2}{16} \leq 1\}$

Range: $[0,4]$

9) $z = \arccos(y - x)$

**Answer**

Domain: $\{(x,y) \mid x - 1 \leq y \leq x + 1\}$ That is, all points between the graphs of $y = x - 1$ and $y = x + 1$.

Range: $[0, \pi]$

10) $f(x,y) = \frac{y+2}{x^2}$

**Answer**

Domain: $\{(x,y) \mid x \neq 0\}$

Range: $(-\infty, \infty)$

**Find the range of the functions.**

11) $g(x,y)=\sqrt{16-4x^2-y^2}$

**Answer**

$\{z \mid 0 \le z \le 4\}$ or in interval notation: $[0,4]$

12) $V(x,y)=4x^2+y^2$

13) $z=y^2-x^2$

**Answer**

The set $\mathbb{R}$

**In exercises 14 - 29, find the level curves of each function at the indicated values of $c$ to visualize the given function. Sketch a contour plot for those exercises where you are asked for more than 3 values of $c$.**

14) $z(x,y)=y^2-x^2, \quad c=1$

15) $z(x,y)=y^2-x^2, \quad c=4$

**Answer**

$y^2-x^2=4$, a hyperbola

16) $g(x,y)=x^2+y^2; \quad c=0,1,2,3,4,9$

17) $g(x,y)=4-x-y; \quad c=0,1,2,3,4$

**Answer**

Level curves are lines with $y=-x+(4-c)$.

For each value of $c$ these are:

$c=0: \ y=-x+4,$

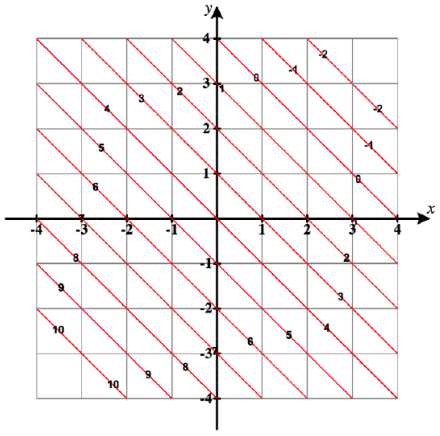
$c=1: \ y=-x+3,$

$c=2: \ y=-x+2,$

$c=3: \ y=-x+1,$

$c=4: \ y=-x.$

The contour plot consists of a series of parallel lines.



18) $f(x,y)=xy; c=1; \quad c=-1$

19) $h(x,y)=2x-y; \quad c=-2,0,2$

**Answer**

$2x-y=0, 2x-y=-2, 2x-y=2$; three lines

20) $f(x,y)=x^2-y; \quad c=1,2$

21) $g(x,y)=\dfrac{x}{x+y}; c=-1,0,1,2$

**Answer**

Level curves are lines with the form $y=x\left(\dfrac{1-c}{c}\right)$. At $c=0$, we solve it directly from the equation $\dfrac{x}{x+y}=0$ to get $x=0$.

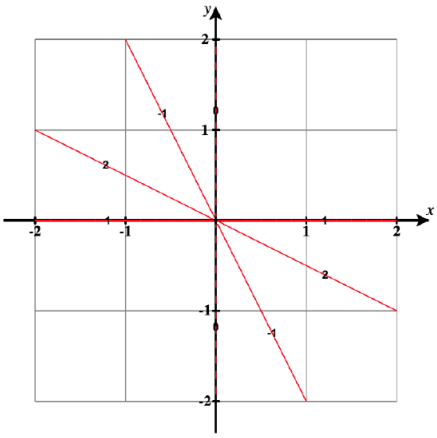
For each value of $c$ these are:

$c=-1: y=-2x$,

$c=0: x=0,$ with $y\neq 0$,

$c=1: y=0,$ with $x\neq 0$,

$c=2: y=-\frac{1}{2}x$.



22) $g(x,y)=x^3-y; \quad c=-1,0,2$

23) $g(x,y)=e^{xy}; \quad c=\frac{1}{2},3$

**Answer**

The level curves have the form, $y=\dfrac{\ln c}{x}$.

For each value of $c$ these are:

$c=\frac{1}{2}: y=\dfrac{\ln\frac{1}{2}}{x}$ that can be rewritten as, $y=-\dfrac{\ln 2}{x}$

$c=3: y=\dfrac{\ln 3}{x}$.

24) $f(x,y)=x^2; \quad c=4,9$

25) $f(x,y)=xy-x; \quad c=-2,0,2$

**Answer**

Level curves have the form: $y=\dfrac{c}{x}+1$.

Here $y=\dfrac{-2}{x}+1, \quad y=1, \quad y=\dfrac{2}{x}+1$ or $xy-x=-2$, $xy-x=0$, $xy-x=2$

26) $h(x,y)=\ln(x^2+y^2); \quad c=-1,0,1$

27) $g(x,y)=\ln\left(\dfrac{y}{x^2}\right); \quad c=-2,0,2$

**Answer**

The level curves have the form, $y=e^c x^2$.

For each value of $c$ these are:

$c=-2: y=e^{-2}x^2$,

$c=0: y=x^2$,

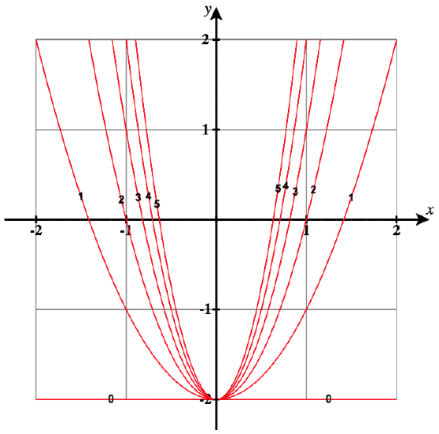
$c=2: y=e^2x^2$.

28) $z=f(x,y)=\sqrt{x^2+y^2}, \quad c=3$

29) $f(x,y)=\dfrac{y+2}{x^2}$, $c=$ any constant

**Answer**

The level curves are parabolas of the form $y=cx^2-2,$ **with** $x\neq 0$.



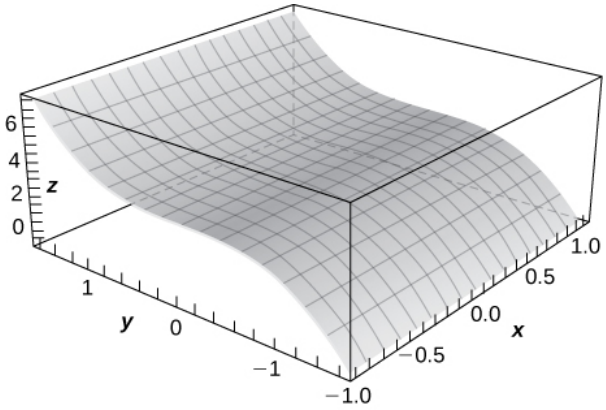
**In exercises 30-32, find the vertical traces of the functions at the indicated values of $x$ and $y$, and plot the traces.**

30) $z=4-x-y, \quad x=2$

31) $f(x,y)=3x+y^3, \quad x=1$

**Answer**

$z=3+y^3$, a curve in the $zy$-**plane** with rulings parallel to the $x$-axis



32) $z=\cos\sqrt{x^2+y^2}, \quad x=1$

**In exercises 33 - 38, find the domain and range of each function.**

33) $z=\sqrt{100-4x^2-25y^2}$

**Answer**

Domain: $\left\{(x,y)\,|\,\dfrac{x^2}{25}+\dfrac{y^2}{4}\leq 1\right\}$

Range: $[0,10]$

34) $z=\ln(x-y^2)$

35) $f(x,y,z)=\dfrac{1}{\sqrt{36-4x^2-9y^2-z^2}}$

**Answer**

Domain: $\left\{(x,y,z)\,|\,\dfrac{x^2}{9}+\dfrac{y^2}{4}+\dfrac{z^2}{36}<1\right\}$

Range: $\left[\frac{1}{6},\infty\right)$

36) $f(x,y,z) = \sqrt{49 - x^2 - y^2 - z^2}$

37) $f(x,y,z) = \sqrt[3]{16 - x^2 - y^2 - z^2}$

**Answer**

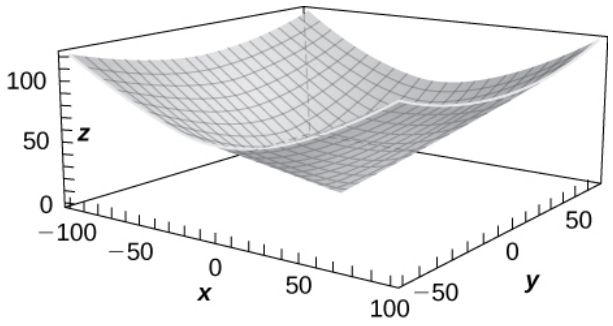
Domain: All points in $xyz$-space
Range: $\left(-\infty, \sqrt[3]{16}\right]$

38) $f(x,y) = \cos\sqrt{x^2 + y^2}$

**In exercises 39 - 40, plot a graph of the function.**

39) $z = f(x,y) = \sqrt{x^2 + y^2}$

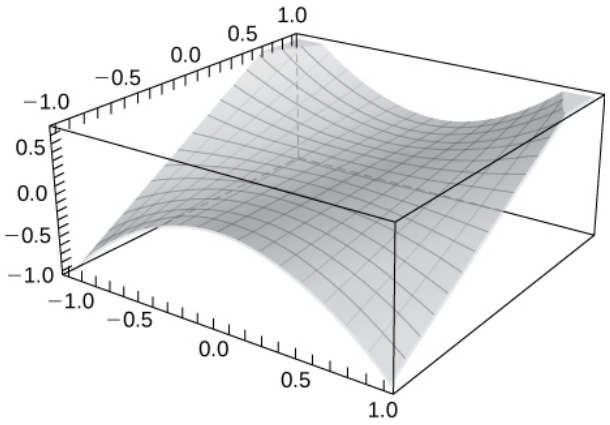
**Answer**



40) $z = x^2 + y^2$

41) Use technology to graph $z = x^2 y$.

**Answer**

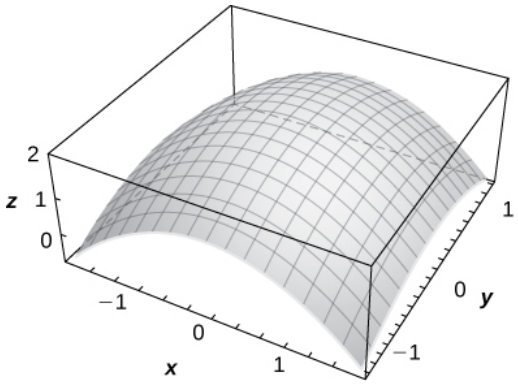


**In exercises 42 - 46, sketch the function by finding its level curves. Verify the graph using technology, such as CalcPlot3D.**

42) $f(x,y) = \sqrt{4 - x^2 - y^2}$

43) $f(x,y) = 2 - \sqrt{x^2 + y^2}$

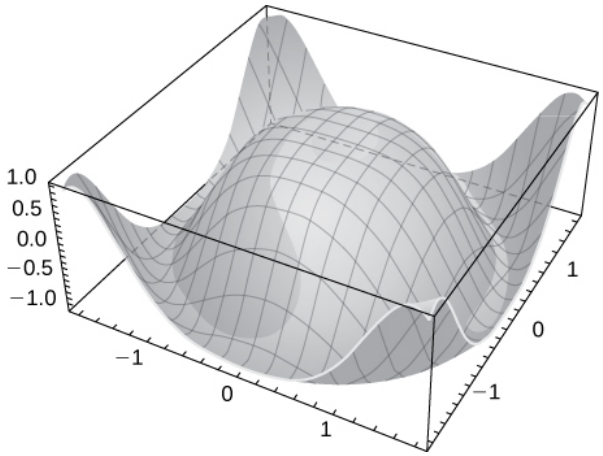
**Answer**



44) $z = 1 + e^{-x^2-y^2}$

45) $z = \cos\sqrt{x^2+y^2}$

**Answer**



46) $z = y^2 - x^2$

47) Describe the contour lines for several values of $c$ for $z = x^2 + y^2 - 2x - 2y$.

**Answer**

The contour lines are concentric circles centered at the point, $(1,1)$.
You can see this by completing the square after setting this function equal to $c$.
That is, we write $x^2 - 2x + 1 + y^2 - 2y + 1 = c + 2$ which can be rewritten as, $(x-1)^2 + (y-1)^2 = c + 2$.
This gives us circles centered at the point, $(1,1)$, each with a radius of $\sqrt{c+2}$.

**In exercises, 48 - 52, find the level surface for the given value of $c$ for each function of three variables and describe it.**

48) $w(x,y,z) = x - 2y + z, \quad c = 4$

49) $w(x,y,z) = x^2 + y^2 + z^2, \quad c = 9$

**Answer**

$x^2 + y^2 + z^2 = 9$, a sphere of radius $3$

50) $w(x,y,z) = x^2 + y^2 - z^2, \quad c = -4$

51) $w(x,y,z) = x^2 + y^2 - z^2, \quad c = 4$

**Answer**

$x^2 + y^2 - z^2 = 4$, a hyperboloid of one sheet

52) $w(x,y,z) = 9x^2 - 4y^2 + 36z^2, \quad c = 0$

**In exercises 53 - 55, find an equation of the level curve of $f$ that contains the point $P$.**

53) $f(x,y) = 1 - 4x^2 - y^2, \quad P(0,1)$

**Answer**

$4x^2 + y^2 = 1,$

54) $g(x,y) = y^2 \arctan x, \quad P(1,2)$

55) $g(x,y) = e^{xy}(x^2 + y^2), \quad P(1,0)$

**Answer**

$1 = e^{xy}(x^2 + y^2)$

56) The strength $E$ of an electric field at point $(x,y,z)$ resulting from an infinitely long charged wire lying along the $y$-axis is given by $E(x,y,z) = k/\sqrt{x^2 + y^2}$, where $k$ is a positive constant. For simplicity, let $k = 1$ and find the equations of the level surfaces for $E = 10$ and $E = 100$.

57) A thin plate made of iron is located in the $xy$-plane The temperature $T$ in degrees Celsius at a point $P(x,y)$ is inversely proportional to the square of its distance from the origin. Express $T$ as a function of $x$ and $y$.

**Answer**

$T(x,y) = \dfrac{k}{x^2 + y^2}$

58) Refer to the preceding problem. Using the temperature function found there, determine the proportionality constant if the temperature at point $P(1,2)$ is $50°C$. Use this constant to determine the temperature at point $Q(3,4)$.

59) Refer to the preceding problem. Find the level curves for $T = 40°C$ and $T = 100°C$, and describe what the level curves represent.

**Answer**

$x^2 + y^2 = \dfrac{k}{40}, \quad x^2 + y^2 = \dfrac{k}{100}$. The level curves represent circles of radii $\sqrt{10k}/20$ and $\sqrt{k}/10$

# 14.3: Limits and Continuity

**Learning Objectives**

- Calculate the limit of a function of two variables.
- Learn how a function of two variables can approach different values at a boundary point, depending on the path of approach.
- State the conditions for continuity of a function of two variables.
- Verify the continuity of a function of two variables at a point.
- Calculate the limit of a function of three or more variables and verify the continuity of the function at a point.

We have now examined functions of more than one variable and seen how to graph them. In this section, we see how to take the limit of a function of more than one variable, and what it means for a function of more than one variable to be continuous at a point in its domain. It turns out these concepts have aspects that just don't occur with functions of one variable.

## Limit of a Function of Two Variables

Recall from Section 2.5 that the definition of a limit of a function of one variable:

Let $f(x)$ be defined for all $x \neq a$ in an open interval containing $a$. Let $L$ be a real number. Then

$$\lim_{x \to a} f(x) = L$$

if for every $\varepsilon > 0$, there exists a $\delta > 0$, such that if $0 < |x - a| < \delta$ for all $x$ in the domain of $f$, then

$$|f(x) - L| < \varepsilon.$$

Before we can adapt this definition to define a limit of a function of two variables, we first need to see how to extend the idea of an open interval in one variable to an open interval in two variables.

**Definition: $\delta$ Disks**

Consider a point $(a, b) \in \mathbb{R}^2$. A **$\delta$ disk** centered at point $(a, b)$ is defined to be an open disk of radius $\delta$ centered at point $(a, b)$ — that is,

$$\{(x, y) \in \mathbb{R}^2 \mid (x - a)^2 + (y - b)^2 < \delta^2\}$$

as shown in Figure 14.3.1.

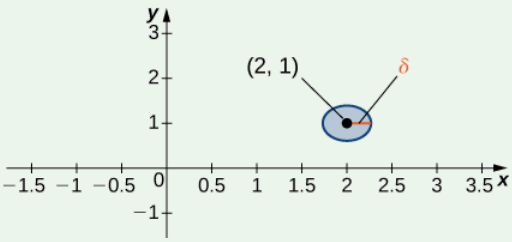

Figure 14.3.1: A $\delta$ disk centered around the point $(2, 1)$.

The idea of a $\delta$ disk appears in the definition of the limit of a function of two variables. If $\delta$ is small, then all the points $(x, y)$ in the $\delta$ disk are close to $(a, b)$. This is completely analogous to x being close to a in the definition of a limit of a function of one variable. In one dimension, we express this restriction as

$$a - \delta < x < a + \delta.$$

In more than one dimension, we use a $\delta$ disk.

### Definition: limit of a function of two variables

Let $f$ be a function of two variables, $x$ and $y$. The limit of $f(x,y)$ as $(x,y)$ approaches $(a,b)$ is $L$, written

$$\lim_{(x,y)\to(a,b)} f(x,y) = L$$

if for each $\varepsilon > 0$ there exists a small enough $\delta > 0$ such that for all points $(x,y)$ in a $\delta$ disk around $(a,b)$, except possibly for $(a,b)$ itself, the value of $f(x,y)$ is no more than $\varepsilon$ away from $L$ (Figure 14.3.2).

Using symbols, we write the following: For any $\varepsilon > 0$, there exists a number $\delta > 0$ such that

$$|f(x,y) - L| < \varepsilon$$

whenever

$$0 < \sqrt{(x-a)^2 + (y-b)^2} < \delta.$$

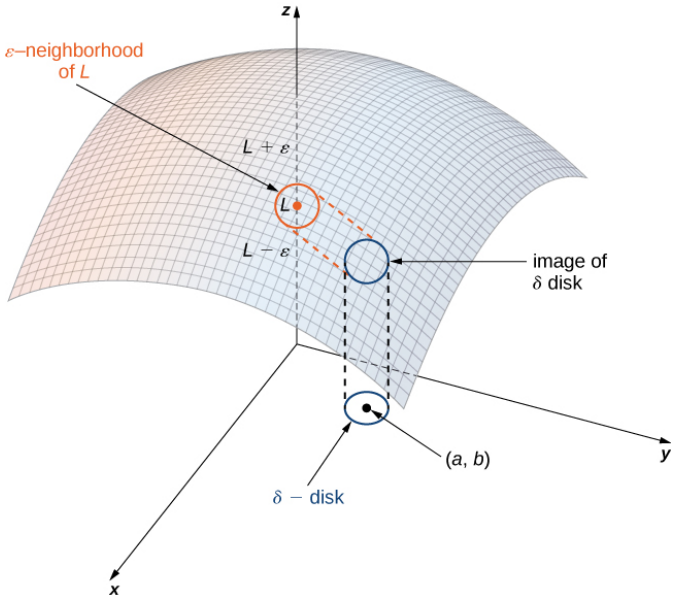

Figure 14.3.2: The limit of a function involving two variables requires that $f(x,y)$ be within $\varepsilon$ of $L$ whenever $(x,y)$ is within $\delta$ of $(a,b)$. The smaller the value of $\varepsilon$, the smaller the value of $\delta$.

Proving that a limit exists using the definition of a **limit of a function of two variables** can be challenging. Instead, we use the following theorem, which gives us shortcuts to finding limits. The formulas in this theorem are an extension of the formulas in the limit laws theorem in the section titled The Limit Laws in single-variable calculus.

### Theorem 14.3.1: Limit Laws for Functions of Two Variables

Let $f(x,y)$ and $g(x,y)$ be defined for all $(x,y) \neq (a,b)$ in a neighborhood around $(a,b)$, and assume the neighborhood is contained completely inside the domain of $f$. Assume that $L$ and $M$ are real numbers such that

$$\lim_{(x,y)\to(a,b)} f(x,y) = L$$

and

$$\lim_{(x,y)\to(a,b)} g(x,y) = M,$$

and let $c$ be a constant. Then each of the following statements holds:

**Constant Law:**

$$\lim_{(x,y)\to(a,b)} c = c$$

**Identity Laws:**

$$\lim_{(x,y)\to(a,b)} x = a$$

$$\lim_{(x,y)\to(a,b)} y = b$$

**Sum Law:**

$$\lim_{(x,y)\to(a,b)} (f(x,y) + g(x,y)) = L + M$$

**Difference Law:**

$$\lim_{(x,y)\to(a,b)} (f(x,y) - g(x,y)) = L - M$$

**Constant Multiple Law:**

$$\lim_{(x,y)\to(a,b)} (cf(x,y)) = cL$$

**Product Law:**

$$\lim_{(x,y)\to(a,b)} (f(x,y)g(x,y)) = LM$$

**Quotient Law:**

$$\lim_{(x,y)\to(a,b)} \frac{f(x,y)}{g(x,y)} = \frac{L}{M} \text{ for } M \neq 0$$

**Power Law:**

$$\lim_{(x,y)\to(a,b)} (f(x,y))^n = L^n$$

for any positive integer $n$.

**Root Law:**

$$\lim_{(x,y)\to(a,b)} \sqrt[n]{f(x,y)} = \sqrt[n]{L}$$

for all $L$ if $n$ is odd and positive, and for $L \geq 0$ if n is even and positive.

The proofs of these properties are similar to those for the limits of functions of one variable. We can apply these laws to finding limits of various functions.

### Example 14.3.1: Finding the Limit of a Function of Two Variables

Find each of the following limits:

a. $\lim\limits_{(x,y)\to(2,-1)} (x^2 - 2xy + 3y^2 - 4x + 3y - 6)$

b. $\lim\limits_{(x,y)\to(2,-1)} \dfrac{2x + 3y}{4x - 3y}$

**Solution**

a. First use the sum and difference laws to separate the terms:

$$\begin{aligned}\lim_{(x,y)\to(2,-1)} (x^2 - 2xy + 3y^2 - 4x + 3y - 6) \\ = \left(\lim_{(x,y)\to(2,-1)} x^2\right) - \left(\lim_{(x,y)\to(2,-1)} 2xy\right) + \left(\lim_{(x,y)\to(2,-1)} 3y^2\right) - \left(\lim_{(x,y)\to(2,-1)} 4x\right) \\ + \left(\lim_{(x,y)\to(2,-1)} 3y\right) - \left(\lim_{(x,y)\to(2,-1)} 6\right).\end{aligned}$$

Next, use the constant multiple law on the second, third, fourth, and fifth limits:

$$= (\lim_{(x,y)\to(2,-1)} x^2) - 2(\lim_{(x,y)\to(2,-1)} xy) + 3(\lim_{(x,y)\to(2,-1)} y^2) - 4(\lim_{(x,y)\to(2,-1)} x)$$
$$+3(\lim_{(x,y)\to(2,-1)} y) - \lim_{(x,y)\to(2,-1)} 6.$$

Now, use the power law on the first and third limits, and the product law on the second limit:

$$\left(\lim_{(x,y)\to(2,-1)} x\right)^2 - 2\left(\lim_{(x,y)\to(2,-1)} x\right)\left(\lim_{(x,y)\to(2,-1)} y\right) + 3\left(\lim_{(x,y)\to(2,-1)} y\right)^2$$
$$-4\left(\lim_{(x,y)\to(2,-1)} x\right) + 3\left(\lim_{(x,y)\to(2,-1)} y\right) - \lim_{(x,y)\to(2,-1)} 6.$$

Last, use the identity laws on the first six limits and the constant law on the last limit:

$$\lim_{(x,y)\to(2,-1)} (x^2 - 2xy + 3y^2 - 4x + 3y - 6) = (2)^2 - 2(2)(-1) + 3(-1)^2 - 4(2) + 3(-1) - 6$$
$$= -6.$$

b. Before applying the quotient law, we need to verify that the limit of the denominator is nonzero. Using the difference law, constant multiple law, and identity law,

$$\lim_{(x,y)\to(2,-1)} (4x - 3y) = \lim_{(x,y)\to(2,-1)} 4x - \lim_{(x,y)\to(2,-1)} 3y$$
$$= 4(\lim_{(x,y)\to(2,-1)} x) - 3(\lim_{(x,y)\to(2,-1)} y)$$
$$= 4(2) - 3(-1) = 11.$$

Since the limit of the denominator is nonzero, the quotient law applies. We now calculate the limit of the numerator using the difference law, constant multiple law, and identity law:

$$\lim_{(x,y)\to(2,-1)} (2x + 3y) = \lim_{(x,y)\to(2,-1)} 2x + \lim_{(x,y)\to(2,-1)} 3y$$
$$= 2(\lim_{(x,y)\to(2,-1)} x) + 3(\lim_{(x,y)\to(2,-1)} y)$$
$$= 2(2) + 3(-1) = 1.$$

Therefore, according to the quotient law we have

$$\lim_{(x,y)\to(2,-1)} \frac{2x + 3y}{4x - 3y} = \frac{\lim_{(x,y)\to(2,-1)} (2x + 3y)}{\lim_{(x,y)\to(2,-1)} (4x - 3y)}$$
$$= \frac{1}{11}.$$

**? Exercise 14.3.1:**

Evaluate the following limit:

$$\lim_{(x,y)\to(5,-2)} \sqrt[3]{\frac{x^2 - y}{y^2 + x - 1}}.$$

**Hint**

Use the limit laws.

**Answer**

$$\lim_{(x,y)\to(5,-2)} \sqrt[3]{\frac{x^2 - y}{y^2 + x - 1}} = \frac{3}{2}$$

Since we are taking the limit of a function of two variables, the point $(a, b)$ is in $\mathbb{R}^2$, and it is possible to approach this point from an infinite number of directions. Sometimes when calculating a limit, the answer varies depending on the path taken toward $(a, b)$. If

this is the case, then the limit fails to exist. In other words, the limit must be unique, regardless of path taken.

### Example 14.3.2: Limits That Fail to Exist

Show that neither of the following limits exist:

a. $\lim\limits_{(x,y)\to(0,0)} \dfrac{2xy}{3x^2+y^2}$

b. $\lim\limits_{(x,y)\to(0,0)} \dfrac{4xy^2}{x^2+3y^4}$

**Solution**

a. The domain of the function $f(x,y)=\dfrac{2xy}{3x^2+y^2}$ consists of all points in the $xy$-plane except for the point $(0,0)$ (Figure 14.3.3). To show that the limit does not exist as $(x,y)$ approaches $(0,0)$, we note that it is impossible to satisfy the definition of a limit of a function of two variables because of the fact that the function takes different values along different lines passing through point $(0,0)$. First, consider the line $y=0$ in the $xy$-plane. Substituting $y=0$ into $f(x,y)$ gives

$$f(x,0)=\frac{2x(0)}{3x^2+0^2}=0$$

for any value of $x$. Therefore the value of $f$ remains constant for any point on the $x$-axis, and as $y$ approaches zero, the function remains fixed at zero.

Next, consider the line $y=x$. Substituting $y=x$ into $f(x,y)$ gives

$$f(x,x)=\frac{2x(x)}{3x^2+x^2}=\frac{2x^2}{4x^2}=\tfrac{1}{2}.$$

This is true for any point on the line $y=x$. If we let $x$ approach zero while staying on this line, the value of the function remains fixed at $\frac{1}{2}$, regardless of how small $x$ is.

Choose a value for ε that is less than $1/2$—say, $1/4$. Then, no matter how small a $\delta$ disk we draw around $(0,0)$, the values of $f(x,y)$ for points inside that $\delta$ disk will include both $0$ and $\frac{1}{2}$. Therefore, the definition of limit at a point is never satisfied and the limit fails to exist.

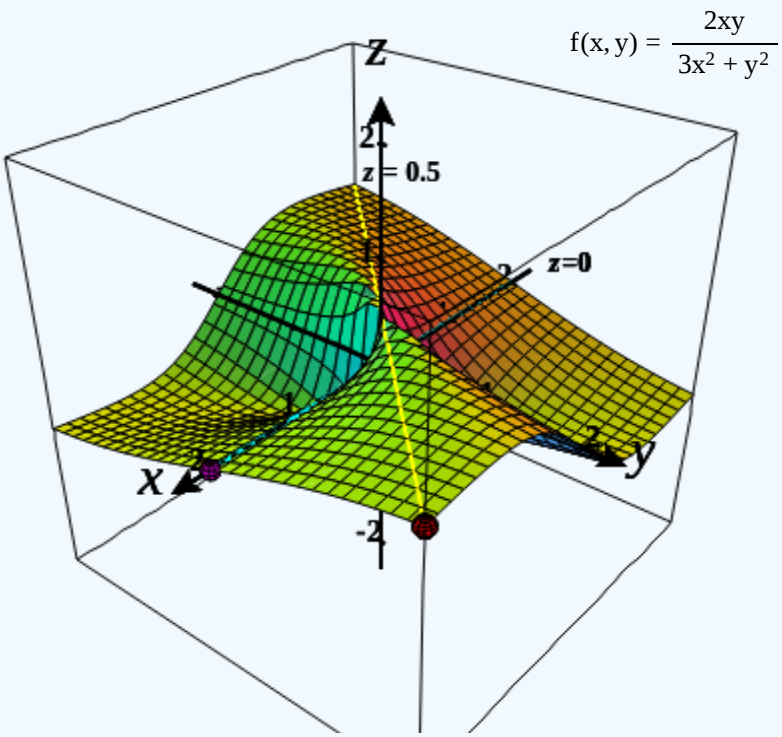

Figure 14.3.3: Graph of the function $f(x,y)=\frac{2xy}{3x^2+y^2}$. Along the line $y=0$, the function is equal to zero; along the line $y=x$, the function is equal to $\frac{1}{2}$.

b. In a similar fashion to a., we can approach the origin along any straight line passing through the origin. If we try the $x$-axis (i.e., $y=0$), then the function remains fixed at zero. The same is true for the $y$-axis. Suppose we approach the origin along a straight line of slope $k$. The equation of this line is $y=kx$. Then the limit becomes

$$\begin{aligned}\lim_{(x,y)\to(0,0)}\frac{4xy^2}{x^2+3y^4} &= \lim_{(x,y)\to(0,0)}\frac{4x(kx)^2}{x^2+3(kx)^4}\\ &= \lim_{(x,y)\to(0,0)}\frac{4k^2x^3}{x^2+3k^4x^4}\\ &= \lim_{(x,y)\to(0,0)}\frac{4k^2x}{1+3k^4x^2}\\ &= \frac{\lim\limits_{(x,y)\to(0,0)}(4k^2x)}{\lim\limits_{(x,y)\to(0,0)}(1+3k^4x^2)}\\ &= 0.\end{aligned}$$

regardless of the value of $k$. It would seem that the limit is equal to zero. What if we chose a curve passing through the origin instead? For example, we can consider the parabola given by the equation $x=y^2$. Substituting $y^2$ in place of $x$ in $f(x,y)$ gives

$$\begin{aligned}\lim_{(x,y)\to(0,0)}\frac{4xy^2}{x^2+3y^4} &= \lim_{(x,y)\to(0,0)}\frac{4(y^2)y^2}{(y^2)^2+3y^4}\\ &= \lim_{(x,y)\to(0,0)}\frac{4y^4}{y^4+3y^4}\\ &= \lim_{(x,y)\to(0,0)}1\\ &= 1.\end{aligned}$$

By the same logic in part a, it is impossible to find a $\delta$ disk around the origin that satisfies the definition of the limit for any value of $\varepsilon<1$. Therefore,

$$\lim_{(x,y)\to(0,0)} \frac{4xy^2}{x^2+3y^4}$$

does **not** exist.

**Exercise 14.3.2:**

Show that

$$\lim_{(x,y)\to(2,1)} \frac{(x-2)(y-1)}{(x-2)^2+(y-1)^2}$$

does not exist.

**Hint**

Pick a line with slope $k$ passing through point $(2,1)$.

**Answer**

If $y=k(x-2)+1$, then $\lim_{(x,y)\to(2,1)} \frac{(x-2)(y-1)}{(x-2)^2+(y-1)^2} = \frac{k}{1+k^2}$. Since the answer depends on $k$, the limit fails to exist.

## Interior Points and Boundary Points

To study continuity and differentiability of a function of two or more variables, we first need to learn some new terminology.

**Definition: interior and boundary points**

Let $S$ be a subset of $\mathbb{R}^2$ (Figure 14.3.4).

1. A point $P_0$ is called an *interior point* of $S$ if there is a $\delta$ disk centered around $P_0$ contained completely in $S$.
2. A point $P_0$ is called a *boundary point* of $S$ if every $\delta$ disk centered around $P_0$ contains points both inside and outside $S$.

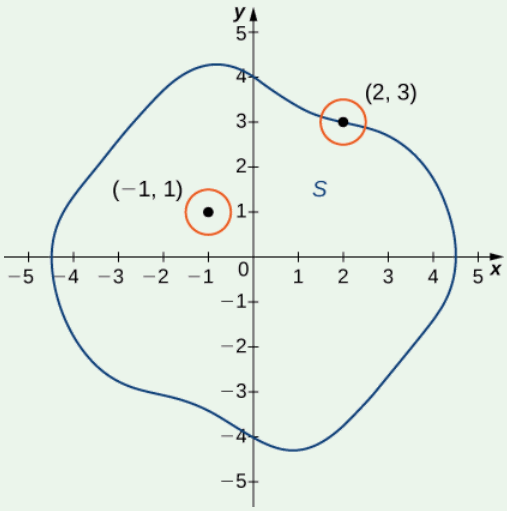

Figure 14.3.4: In the set $S$ shown, $(-1,1)$ is an interior point and $(2,3)$ is a boundary point.

**Definition: Open and closed sets**

Let $S$ be a subset of $\mathbb{R}^2$ (Figure 14.3.4).

1. $S$ is called an *open set* if every point of $S$ is an interior point.
2. $S$ is called a *closed set* if it contains all its boundary points.

An example of an open set is a $\delta$ disk. If we include the boundary of the disk, then it becomes a closed set. A set that contains some, but not all, of its boundary points is neither open nor closed. For example if we include half the boundary of a $\delta$ disk but not the other half, then the set is neither open nor closed.

### Definition: connected sets and Regions

Let $S$ be a subset of $\mathbb{R}^2$ (Figure 14.3.4).

1. An open set $S$ is a *connected set* if it cannot be represented as the union of two or more disjoint, nonempty open subsets.
2. A set $S$ is a *region* if it is open, connected, and nonempty.

The definition of a limit of a function of two variables requires the $\delta$ disk to be contained inside the domain of the function. However, if we wish to find the limit of a function at a boundary point of the domain, the **$\delta$ disk** is not contained inside the domain. By definition, some of the points of the **$\delta$ disk** are inside the domain and some are outside. Therefore, we need only consider points that are inside both the $\delta$ disk and the domain of the function. This leads to the definition of the limit of a function at a boundary point.

### Definition

Let $f$ be a function of two variables, $x$ and $y$, and suppose $(a,b)$ is on the boundary of the domain of $f$. Then, the limit of $f(x,y)$ as $(x,y)$ approaches $(a,b)$ is $L$, written

$$\lim_{(x,y)\to(a,b)} f(x,y) = L,$$

if for any $\varepsilon > 0$, there exists a number $\delta > 0$ such that for any point $(x,y)$ inside the domain of $f$ and within a suitably small distance positive $\delta$ of $(a,b)$, the value of $f(x,y)$ is no more than $\varepsilon$ away from $L$ (Figure 14.3.2). Using symbols, we can write: For any $\varepsilon > 0$, there exists a number $\delta > 0$ such that

$$|f(x,y) - L| < \varepsilon \text{ whenever } 0 < \sqrt{(x-a)^2 + (y-b)^2} < \delta.$$

### Example 14.3.3: Limit of a Function at a Boundary Point

Prove

$$\lim_{(x,y)\to(4,3)} \sqrt{25 - x^2 - y^2} = 0.$$

#### Solution

The domain of the function $f(x,y) = \sqrt{25 - x^2 - y^2}$ is $\{(x,y) \in \mathbb{R}^2 \mid x^2 + y^2 \leq 25\}$, which is a circle of radius $5$ centered at the origin, along with its interior as shown in Figure 14.3.5.

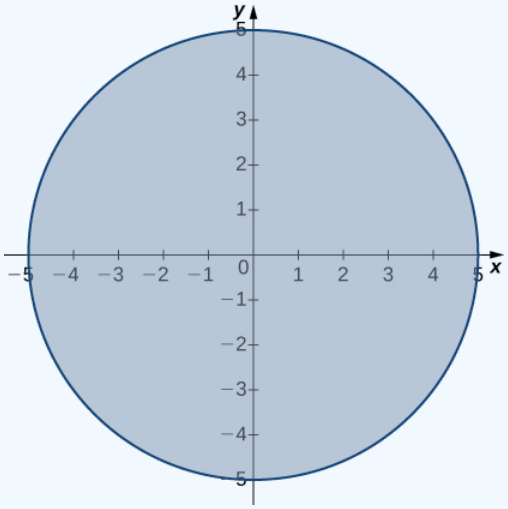

Figure **14.3.5**: Domain of the function $f(x,y)=\sqrt{25-x^2-y^2}$.

We can use the limit laws, which apply to limits at the boundary of domains as well as interior points:

$$\begin{aligned}\lim_{(x,y)\to(4,3)}\sqrt{25-x^2-y^2} &= \sqrt{\lim_{(x,y)\to(4,3)}(25-x^2-y^2)}\\ &= \sqrt{\lim_{(x,y)\to(4,3)}25-\lim_{(x,y)\to(4,3)}x^2-\lim_{(x,y)\to(4,3)}y^2}\\ &= \sqrt{25-4^2-3^2}\\ &= 0\end{aligned}$$

See the following graph.

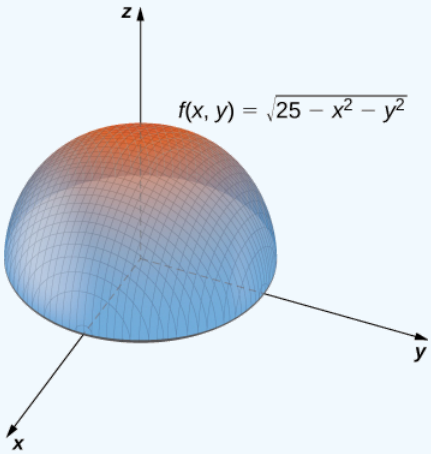

Figure **14.3.6**: Graph of the function $f(x,y)=\sqrt{25-x^2-y^2}$.

## ? Exercise 14.3.3

Evaluate the following limit:

$$\lim_{(x,y)\to(5,-2)}\sqrt{29-x^2-y^2}.$$

**Hint**

Determine the domain of $f(x,y)=\sqrt{29-x^2-y^2}$.

**Answer**

$$\lim_{(x,y)\to(5,-2)} \sqrt{29-x^2-y^2} = \sqrt{29-5^2-(-2)^2} = \sqrt{29-25-4} = \sqrt{0} = 0$$

## Continuity of Functions of Two Variables

In Continuity, we defined the continuity of a function of one variable and saw how it relied on the limit of a function of one variable. In particular, three conditions are necessary for $f(x)$ to be continuous at point $x = a$

1. $f(a)$ exists.
2. $\lim_{x\to a} f(x)$ exists.
3. $\lim_{x\to a} f(x) = f(a)$.

These three conditions are necessary for continuity of a function of two variables as well.

### Definition: continuous Functions

A function $f(x,y)$ is continuous at a point $(a,b)$ in its domain if the following conditions are satisfied:

1. $f(a,b)$ exists.
2. $\lim_{(x,y)\to(a,b)} f(x,y)$ exists.
3. $\lim_{(x,y)\to(a,b)} f(x,y) = f(a,b)$.

### Example 14.3.4: Demonstrating Continuity for a Function of Two Variables

Show that the function

$$f(x,y) = \frac{3x+2y}{x+y+1}$$

is continuous at point $(5,-3)$.

#### Solution

There are three conditions to be satisfied, per the definition of continuity. In this example, $a = 5$ and $b = -3$.

1. $f(a,b)$ exists. This is true because the domain of the function f consists of those ordered pairs for which the denominator is nonzero (i.e., $x+y+1 \neq 0$). Point $(5,-3)$ satisfies this condition. Furthermore,

$$f(a,b) = f(5,-3) = \frac{3(5)+2(-3)}{5+(-3)+1} = \frac{15-6}{2+1} = 3.$$

2. $\lim_{(x,y)\to(a,b)} f(x,y)$ exists. This is also true:

$$\begin{aligned}\lim_{(x,y)\to(a,b)} f(x,y) &= \lim_{(x,y)\to(5,-3)} \frac{3x+2y}{x+y+1} \\ &= \frac{\lim_{(x,y)\to(5,-3)}(3x+2y)}{\lim_{(x,y)\to(5,-3)}(x+y+1)} \\ &= \frac{15-6}{5-3+1} \\ &= 3.\end{aligned}$$

3. $\lim_{(x,y)\to(a,b)} f(x,y) = f(a,b)$. This is true because we have just shown that both sides of this equation equal three.

### Exercise 14.3.4

Show that the function

$$f(x,y) = \sqrt{26-2x^2-y^2}$$

is continuous at point $(2, -3)$.

**Hint**

Use the three-part definition of continuity.

**Answer**

1. The domain of $f$ contains the ordered pair $(2, -3)$ because $f(a, b) = f(2, -3) = \sqrt{16 - 2(2)^2 - (-3)^2} = 3$
2. $\lim\limits_{(x,y)\to(a,b)} f(x, y) = 3$
3. $\lim\limits_{(x,y)\to(a,b)} f(x, y) = f(a, b) = 3$

Continuity of a function of any number of variables can also be defined in terms of delta and epsilon. A function of two variables is continuous at a point $(x_0, y_0)$ in its domain if for every $\varepsilon > 0$ there exists a $\delta > 0$ such that, whenever $\sqrt{(x - x_0)^2 + (y - y_0)^2} < \delta$ it is true, $|f(x, y) - f(a, b)| < \varepsilon$. This definition can be combined with the formal definition (that is, the *epsilon–delta definition*) of continuity of a function of one variable to prove the following theorems:

**Theorem 14.3.2: The Sum of Continuous Functions is Continuous**

If $f(x, y)$ is continuous at $(x_0, y_0)$, and $g(x, y)$ is continuous at $(x_0, y_0)$, then $f(x, y) + g(x, y)$ is continuous at $(x_0, y_0)$.

**Theorem 14.3.3: The Product of Continuous Functions is Continuous**

If $g(x)$ is continuous at $x_0$ and $h(y)$ is continuous at $y_0$, then $f(x, y) = g(x)h(y)$ is continuous at $(x_0, y_0)$.

**Theorem 14.3.4: The Composition of Continuous Functions is Continuous**

Let $g$ be a function of two variables from a domain $D \subseteq \mathbb{R}^2$ to a range $R \subseteq R$. Suppose $g$ is continuous at some point $(x_0, y_0) \in D$ and define $z_0 = g(x_0, y_0)$. Let f be a function that maps $R$ to $R$ such that $z_0$ is in the domain of $f$. Last, assume $f$ is continuous at $z_0$. Then $f \circ g$ is continuous at $(x_0, y_0)$ as shown in Figure 14.3.7.

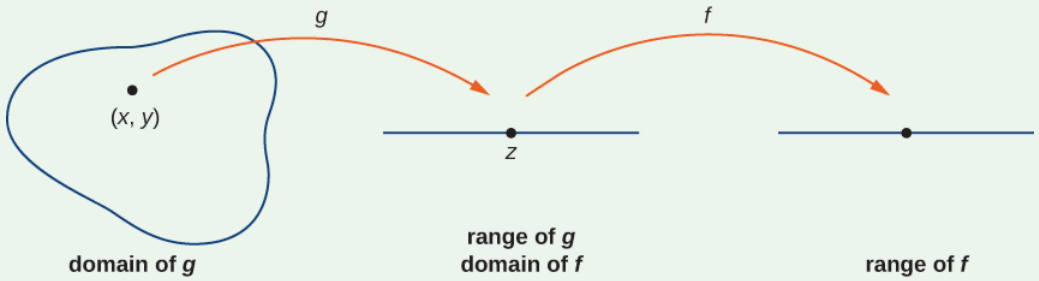

Figure 14.3.7: The composition of two continuous functions is continuous.

Let's now use the previous theorems to show continuity of functions in the following examples.

**Example 14.3.5: More Examples of Continuity of a Function of Two Variables**

Show that the functions $f(x, y) = 4x^3y^2$ and $g(x, y) = \cos(4x^3y^2)$ are continuous everywhere.

**Solution**

The polynomials $g(x) = 4x^3$ and $h(y) = y^2$ are continuous at every real number, and therefore by the product of continuous functions theorem, $f(x, y) = 4x^3y^2$ is continuous at every point $(x, y)$ in the $xy$-plane. Since $f(x, y) = 4x^3y^2$ is continuous at every point $(x, y)$ in the $xy$-plane and $g(x) = \cos x$ is continuous at every real number $x$, the continuity of the composition of functions tells us that $g(x, y) = \cos(4x^3y^2)$ is continuous at every point $(x, y)$ in the $xy$-plane.

**Exercise 14.3.5**

Show that the functions $f(x,y) = 2x^2y^3 + 3$ and $g(x,y) = (2x^2y^3 + 3)^4$ are continuous everywhere.

**Hint**

Use the continuity of the sum, product, and composition of two functions.

**Answer**

The polynomials $g(x) = 2x^2$ and $h(y) = y^3$ are continuous at every real number; therefore, by the product of continuous functions theorem, $f(x,y) = 2x^2y^3$ is continuous at every point $(x,y)$ in the $xy$-plane. Furthermore, any constant function is continuous everywhere, so $g(x,y) = 3$ is continuous at every point $(x,y)$ in the $xy$-plane. Therefore, $f(x,y) = 2x^2y^3 + 3$ is continuous at every point $(x,y)$ in the $xy$-plane. Last, $h(x) = x^4$ is continuous at every real number $x$, so by the continuity of composite functions theorem $g(x,y) = (2x^2y^3 + 3)^4$ is continuous at every point $(x,y)$ in the $xy$-plane.

## Functions of Three or More Variables

The limit of a function of three or more variables occurs readily in applications. For example, suppose we have a function $f(x,y,z)$ that gives the temperature at a physical location $(x,y,z)$ in three dimensions. Or perhaps a function $g(x,y,z,t)$ can indicate air pressure at a location $(x,y,z)$ at time $t$. How can we take a limit at a point in $\mathbb{R}^3$? What does it mean to be continuous at a point in four dimensions?

The answers to these questions rely on extending the concept of a $\delta$ disk into more than two dimensions. Then, the ideas of the limit of a function of three or more variables and the continuity of a function of three or more variables are very similar to the definitions given earlier for a function of two variables.

**Definition: $\delta$-balls**

Let $(x_0,y_0,z_0)$ be a point in $\mathbb{R}^3$. Then, a $\delta$-ball in three dimensions consists of all points in $\mathbb{R}^3$ lying at a distance of less than $\delta$ from $(x_0,y_0,z_0)$ —that is,

$$\{(x,y,z) \in \mathbb{R}^3 \mid \sqrt{(x-x_0)^2 + (y-y_0)^2 + (z-z_0)^2} < \delta\}.$$

To define a $\delta$-ball in higher dimensions, add additional terms under the radical to correspond to each additional dimension. For example, given a point $P = (w_0,x_0,y_0,z_0)$ in $\mathbb{R}^4$, a $\delta$ ball around $P$ can be described by

$$\{(w,x,y,z) \in \mathbb{R}^4 \mid \sqrt{(w-w_0)^2 + (x-x_0)^2 + (y-y_0)^2 + (z-z_0)^2} < \delta\}.$$

To show that a limit of a function of three variables exists at a point $(x_0,y_0,z_0)$, it suffices to show that for any point in a $\delta$ ball centered at $(x_0,y_0,z_0)$, the value of the function at that point is arbitrarily close to a fixed value (the limit value). All the limit laws for functions of two variables hold for functions of more than two variables as well.

**Example 14.3.6: Finding the Limit of a Function of Three Variables**

Find

$$\lim_{(x,y,z)\to(4,1,-3)} \frac{x^2y - 3z}{2x + 5y - z}.$$

**Solution**

Before we can apply the quotient law, we need to verify that the limit of the denominator is nonzero. Using the difference law, the identity law, and the constant law,

$$\begin{aligned}\lim_{(x,y,z)\to(4,1,-3)} (2x + 5y - z) &= 2\left(\lim_{(x,y,z)\to(4,1,-3)} x\right) + 5\left(\lim_{(x,y,z)\to(4,1,-3)} y\right) - \left(\lim_{(x,y,z)\to(4,1,-3)} z\right) \\ &= 2(4) + 5(1) - (-3) \\ &= 16.\end{aligned}$$

Since this is nonzero, we next find the limit of the numerator. Using the product law, power law, difference law, constant multiple law, and identity law,

$$\begin{aligned}\lim_{(x,y,z)\to(4,1,-3)}(x^2y-3z) &= (\lim_{(x,y,z)\to(4,1,-3)}x)^2(\lim_{(x,y,z)\to(4,1,-3)}y)-3\lim_{(x,y,z)\to(4,1,-3)}z \\ &= (4^2)(1)-3(-3) \\ &= 16+9 \\ &= 25\end{aligned}$$

Last, applying the quotient law:

$$\lim_{(x,y,z)\to(4,1,-3)}\frac{x^2y-3z}{2x+5y-z} = \frac{\lim_{(x,y,z)\to(4,1,-3)}(x^2y-3z)}{\lim_{(x,y,z)\to(4,1,-3)}(2x+5y-z)} = \frac{25}{16}$$

**? Exercise 14.3.6**

Find

$$\lim_{(x,y,z)\to(4,-1,3)}\sqrt{13-x^2-2y^2+z^2}$$

**Hint**

Use the limit laws and the continuity of the composition of functions.

**Answer**

$$\lim_{(x,y,z)\to(4,-1,3)}\sqrt{13-x^2-2y^2+z^2} = 2$$

## Key Concepts

- To study limits and continuity for functions of two variables, we use a $\delta$ disk centered around a given point.
- A function of several variables has a limit if for any point in a $\delta$ ball centered at a point $P$, the value of the function at that point is arbitrarily close to a fixed value (the limit value).
- The limit laws established for a function of one variable have natural extensions to functions of more than one variable.
- A function of two variables is continuous at a point if the limit exists at that point, the function exists at that point, and the limit and function are equal at that point.

## Glossary

**boundary point**

a point $P_0$ of $R$ is a boundary point if every $\delta$ disk centered around $P_0$ contains points both inside and outside $R$

**closed set**

a set $S$ that contains all its boundary points

**connected set**

an open set $S$ that cannot be represented as the union of two or more disjoint, nonempty open subsets

**$\delta$ disk**

an open disk of radius $\delta$ centered at point $(a,b)$

**$\delta$ ball**

all points in $\mathbb{R}^3$ lying at a distance of less than $\delta$ from $(x_0,y_0,z_0)$

**interior point**

a point $P_0$ of $\mathbb{R}$ is a boundary point if there is a $\delta$ disk centered around $P_0$ contained completely in $\mathbb{R}$

**open set**

a set $S$ that contains none of its boundary points

**region**

an open, connected, nonempty subset of $\mathbb{R}^2$

# 14.3E: EXERCISES FOR SECTION 14.2

1) Use the limit laws for functions of two variables to evaluate each limit below, given that $\lim_{(x,y)\to(a,b)} f(x,y) = 5$ and $\lim_{(x,y)\to(a,b)} g(x,y) = 2$.

a. $\lim_{(x,y)\to(a,b)} [f(x,y) + g(x,y)]$

b. $\lim_{(x,y)\to(a,b)} [f(x,y)g(x,y)]$

c. $\lim_{(x,y)\to(a,b)} \left[\dfrac{7f(x,y)}{g(x,y)}\right]$

d. $\lim_{(x,y)\to(a,b)} \left[\dfrac{2f(x,y) - 4g(x,y)}{f(x,y) - g(x,y)}\right]$

**Answer**

a. $\lim_{(x,y)\to(a,b)} [f(x,y) + g(x,y)] = \lim_{(x,y)\to(a,b)} f(x,y) + \lim_{(x,y)\to(a,b)} g(x,y) = 5 + 2 = 7$

b. $\lim_{(x,y)\to(a,b)} [f(x,y)g(x,y)] = \left(\lim_{(x,y)\to(a,b)} f(x,y)\right)\left(\lim_{(x,y)\to(a,b)} g(x,y)\right) = 5(2) = 10$

c. $\lim_{(x,y)\to(a,b)} \left[\dfrac{7f(x,y)}{g(x,y)}\right] = \dfrac{7\left(\lim_{(x,y)\to(a,b)} f(x,y)\right)}{\lim_{(x,y)\to(a,b)} g(x,y)} = \dfrac{7(5)}{2} = 17.5$

d. $\lim_{(x,y)\to(a,b)} \left[\dfrac{2f(x,y) - 4g(x,y)}{f(x,y) - g(x,y)}\right] = \dfrac{2\left(\lim_{(x,y)\to(a,b)} f(x,y)\right) - 4\left(\lim_{(x,y)\to(a,b)} g(x,y)\right)}{\lim_{(x,y)\to(a,b)} f(x,y) - \lim_{(x,y)\to(a,b)} g(x,y)} = \dfrac{2(5) - 4(2)}{5 - 2} = \dfrac{2}{3}$

**In exercises 2 - 4, find the limit of the function.**

2) $\lim_{(x,y)\to(1,2)} x$

3) $\lim_{(x,y)\to(1,2)} \dfrac{5x^2y}{x^2 + y^2}$

**Answer**

$\lim_{(x,y)\to(1,2)} \dfrac{5x^2y}{x^2 + y^2} = 2$

4) Show that the limit $\lim_{(x,y)\to(0,0)} \dfrac{5x^2y}{x^2 + y^2}$ exists and is the same along the paths: $y$-axis and $x$-axis, and along $y = x$.

**In exercises 5 - 19, evaluate the limits at the indicated values of $x$ and $y$. If the limit does not exist, state this and explain why the limit does not exist.**

5) $\lim_{(x,y)\to(0,0)} \dfrac{4x^2 + 10y^2 + 4}{4x^2 - 10y^2 + 6}$

**Answer**

$\lim_{(x,y)\to(0,0)} \dfrac{4x^2 + 10y^2 + 4}{4x^2 - 10y^2 + 6} = \dfrac{2}{3}$

6) $\lim_{(x,y)\to(11,13)} \sqrt{\dfrac{1}{xy}}$

7) $\lim_{(x,y)\to(0,1)} \dfrac{y^2 \sin x}{x}$

**Answer**

$\lim_{(x,y)\to(0,1)} \dfrac{y^2 \sin x}{x} = 1$

8) $\lim_{(x,y)\to(0,0)} \sin\left(\dfrac{x^8 + y^7}{x - y + 10}\right)$

9) $\lim_{(x,y)\to(\pi/4,1)} \dfrac{y \tan x}{y + 1}$

**Answer**

$\lim_{(x,y)\to(\pi/4,1)} \dfrac{y \tan x}{y + 1} = \dfrac{1}{2}$

10) $\lim_{(x,y)\to(0,\pi/4)} \dfrac{\sec x + 2}{3x - \tan y}$

11) $\lim_{(x,y)\to(2,5)} \left(\dfrac{1}{x} - \dfrac{5}{y}\right)$

**Answer**

$$\lim_{(x,y)\to(2,5)} \left(\frac{1}{x} - \frac{5}{y}\right) = -\frac{1}{2}$$

12) $\lim_{(x,y)\to(4,4)} x \ln y$

13) $\lim_{(x,y)\to(4,4)} e^{-x^2-y^2}$

**Answer**

$$\lim_{(x,y)\to(4,4)} e^{-x^2-y^2} = e^{-32}$$

14) $\lim_{(x,y)\to(0,0)} \sqrt{9 - x^2 - y^2}$

15) $\lim_{(x,y)\to(1,2)} (x^2y^3 - x^3y^2 + 3x + 2y)$

**Answer**

$$\lim_{(x,y)\to(1,2)} (x^2y^3 - x^3y^2 + 3x + 2y) = 11$$

16) $\lim_{(x,y)\to(\pi,\pi)} x \sin\left(\dfrac{x+y}{4}\right)$

17) $\lim_{(x,y)\to(0,0)} \dfrac{xy+1}{x^2+y^2+1}$

**Answer**

$$\lim_{(x,y)\to(0,0)} \frac{xy+1}{x^2+y^2+1} = 1$$

18) $\lim_{(x,y)\to(0,0)} \dfrac{x^2+y^2}{\sqrt{x^2+y^2+1}-1}$

19) $\lim_{(x,y)\to(0,0)} \ln(x^2+y^2)$

**Answer**

The limit does not exist because when $x$ and $y$ both approach zero, the function approaches $\ln 0$, which is undefined (approaches negative infinity).

**In exercises 20 - 21, complete the statement.**

20) A point $(x_0, y_0)$ in a plane region $R$ is an interior point of $R$ if _____.

21) A point $(x_0, y_0)$ in a plane region $R$ is called a boundary point of $R$ if _____.

**Answer**

Every open disk centered at $(x_0, y_0)$ contains points inside $R$ and outside $R$.

**In exercises 22 - 25, use algebraic techniques to evaluate the limit.**

22) $\lim_{(x,y)\to(2,1)} \dfrac{x-y-1}{\sqrt{x-y}-1}$

23) $\lim_{(x,y)\to(0,0)} \dfrac{x^4-4y^4}{x^2+2y^2}$

**Answer**

$$\lim_{(x,y)\to(0,0)} \frac{x^4-4y^4}{x^2+2y^2} = 0$$

24) $\lim_{(x,y)\to(0,0)} \dfrac{x^3-y^3}{x-y}$

25) $\lim\limits_{(x,y)\to(0,0)} \dfrac{x^2-xy}{\sqrt{x}-\sqrt{y}}$

**Answer**

$$\lim_{(x,y)\to(0,0)} \frac{x^2-xy}{\sqrt{x}-\sqrt{y}}=0$$

**In exercises 26 - 27, evaluate the limits of the functions of three variables.**

26) $\lim\limits_{(x,y,z)\to(1,2,3)} \dfrac{xz^2-y^2z}{xyz-1}$

27) $\lim\limits_{(x,y,z)\to(0,0,0)} \dfrac{x^2-y^2-z^2}{x^2+y^2-z^2}$

**Answer**

The limit does not exist.

**In exercises 28 - 31, evaluate the limit of the function by determining the value the function approaches along the indicated paths. If the limit does not exist, explain why not.**

28) $\lim\limits_{(x,y)\to(0,0)} \dfrac{xy+y^3}{x^2+y^2}$

a. Along the $x$-axis $(y=0)$

b. Along the $y$-axis $(x=0)$

c. Along the path $y=2x$

29) Evaluate $\lim\limits_{(x,y)\to(0,0)} \dfrac{xy+y^3}{x^2+y^2}$ using the results of previous problem.

**Answer**

The limit does not exist. The function approaches two different values along different paths.

30) $\lim\limits_{(x,y)\to(0,0)} \dfrac{x^2y}{x^4+y^2}$

a. Along the $x$-axis $(y=0)$

b. Along the $y$-axis $(x=0)$

c. Along the path $y=x^2$

31) Evaluate $\lim\limits_{(x,y)\to(0,0)} \dfrac{x^2y}{x^4+y^2}$ using the results of previous problem.

**Answer**

The limit does not exist because the function approaches two different values along the paths.

**In exercises 32 - 35, discuss the continuity of each function. Find the largest region in the $xy$-plane in which each function is continuous.**

32) $f(x,y)=\sin(xy)$

33) $f(x,y)=\ln(x+y)$

**Answer**

The function $f$ is continuous in the region $y>-x$.

34) $f(x,y)=e^{3xy}$

35) $f(x,y)=\dfrac{1}{xy}$

**Answer**

The function $f$ is continuous at all points in the $xy$-plane except at points on the $x$- and $y$-axes.

**In exercises 36 - 38, determine the region in which the function is continuous. Explain your answer.**

36) $f(x,y)=\dfrac{x^2y}{x^2+y^2}$

37) $f(x,y)=\begin{cases}\dfrac{x^2y}{x^2+y^2} & if (x,y)\neq(0,0)\\ 0 & if (x,y)=(0,0)\end{cases}$

**Hint:**

Show that the function approaches different values along two different paths.

**Answer**

The function is continuous at $(0,0)$ since the limit of the function at $(0,0)$ is $0$, the same value of $f(0,0)$.

38) $f(x,y)=\dfrac{\sin(x^2+y^2)}{x^2+y^2}$

39) Determine whether $g(x,y)=\dfrac{x^2-y^2}{x^2+y^2}$ is continuous at $(0,0)$.

**Answer**

The function is discontinuous at $(0,0)$. The limit at $(0,0)$ fails to exist and $g(0,0)$ does not exist.

40) Create a plot using graphing software to determine where the limit does not exist. Determine the region of the coordinate plane in which $f(x,y)=\dfrac{1}{x^2-y}$ is continuous.

41) Determine the region of the $xy$-plane in which the composite function $g(x,y)=\arctan(\frac{xy^2}{x+y})$ is continuous. Use technology to support your conclusion.

**Answer**

Since the function $\arctan x$ is continuous over $(-\infty,\infty)$, $g(x,y)=\arctan(\frac{xy^2}{x+y})$ is continuous where $z=\dfrac{xy^2}{x+y}$ is continuous. The inner function $z$ is continuous on all points of the $xy$-plane except where $y=-x$. Thus, $g(x,y)=\arctan(\frac{xy^2}{x+y})$ is continuous on all points of the coordinate plane except at points at which $y=-x$.

42) Determine the region of the $xy$-plane in which $f(x,y)=\ln(x^2+y^2-1)$ is continuous. Use technology to support your conclusion. (Hint: Choose the range of values for $x$ and $y$ carefully!)

43) At what points in space is $g(x,y,z)=x^2+y^2-2z^2$ continuous?

**Answer**

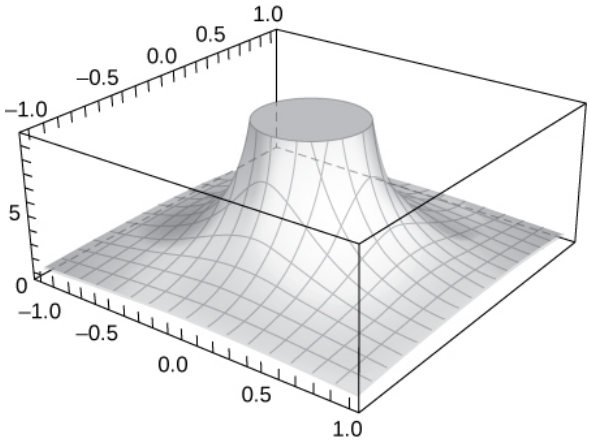
All points $P(x,y,z)$ in space

44) At what points in space is $g(x,y,z)=\dfrac{1}{x^2+z^2-1}$ continuous?

45) Show that $\lim\limits_{(x,y)\to(0,0)}\dfrac{1}{x^2+y^2}$ does not exist at $(0,0)$ by plotting the graph of the function.

**Answer**

The graph increases without bound as $x$ and $y$ both approach zero.



46) [T] Evaluate $\lim_{(x,y)\to(0,0)} \frac{-xy^2}{x^2+y^4}$ by plotting the function using a CAS. Determine analytically the limit along the path $x = y^2$.

47) [T]

a. Use a CAS to draw a contour map of $z = \sqrt{9-x^2-y^2}$.

b. What is the name of the geometric shape of the level curves?

c. Give the general equation of the level curves.

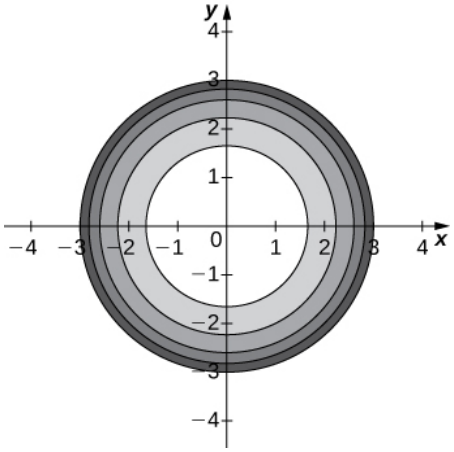
d. What is the maximum value of $z$?

e. What is the domain of the function?

f. What is the range of the function?

**Answer**

a.



b. The level curves are circles centered at $(0,0)$ with radius $9-c$.

c. $x^2+y^2 = 9-c$

d. $z = 3$

e. $\{(x,y) \in R^2 \mid x^2+y^2 \le 9\}$

f. $\{z | 0 \le z \le 3\}$

48) True or False: If we evaluate $\lim_{(x,y)\to(0,0)} f(x)$ along several paths and each time the limit is $1$, we can conclude that $\lim_{(x,y)\to(0,0)} f(x) = 1$.

49) Use polar coordinates to find $\lim_{(x,y)\to(0,0)} \frac{\sin\sqrt{x^2+y^2}}{\sqrt{x^2+y^2}}$. You can also find the limit using L'Hôpital's rule.

**Answer**

$$\lim_{(x,y)\to(0,0)} \frac{\sin\sqrt{x^2+y^2}}{\sqrt{x^2+y^2}} = 1$$

50) Use polar coordinates to find $\lim_{(x,y)\to(0,0)} \cos(x^2+y^2)$.

51) Discuss the continuity of $f(g(x,y))$ where $f(t) = 1/t$ and $g(x,y) = 2x - 5y$.

**Answer**

$f(g(x,y))$ is continuous at all points $(x,y)$ that are not on the line $2x - 5y = 0$.

52) Given $f(x,y) = x^2 - 4y$, find $\lim_{h\to 0} \frac{f(x+h,y) - f(x,y)}{h}$.

53) Given $f(x,y) = x^2 - 4y$, find $\lim_{h\to 0} \frac{f(1+h,y) - f(1,y)}{h}$.

**Answer**

$$\lim_{h\to 0} \frac{f(1+h,y) - f(1,y)}{h} = 2$$

# 14.4: Partial Derivatives

**Learning Objectives**

- Calculate the partial derivatives of a function of two variables.
- Calculate the partial derivatives of a function of more than two variables.
- Determine the higher-order derivatives of a function of two variables.
- Explain the meaning of a partial differential equation and give an example.

Now that we have examined limits and continuity of functions of two variables, we can proceed to study derivatives. Finding derivatives of functions of two variables is the key concept in this chapter, with as many applications in mathematics, science, and engineering as differentiation of single-variable functions. However, we have already seen that limits and continuity of multivariable functions have new issues and require new terminology and ideas to deal with them. This carries over into differentiation as well.

## Derivatives of a Function of Two Variables

When studying derivatives of functions of one variable, we found that one interpretation of the derivative is an instantaneous rate of change of $y$ as a function of $x$. Leibniz notation for the derivative is $dy/dx$, which implies that $y$ is the dependent variable and $x$ is the independent variable. For a function $z = f(x, y)$ of two variables, $x$ and $y$ are the independent variables and $z$ is the dependent variable. This raises two questions right away: How do we adapt Leibniz notation for functions of two variables? Also, what is an interpretation of the derivative? The answer lies in partial derivatives.

**Definition: Partial Derivatives**

Let $f(x, y)$ be a function of two variables. Then the *partial derivative* of $f$ with respect to $x$, written as $\partial f/\partial x$,, or $f_x$, is defined as

$$\frac{\partial f}{\partial x} = f_x(x, y) = \lim_{h \to 0} \frac{f(x + h, y) - f(x, y)}{h} \tag{14.4.1}$$

The partial derivative of $f$ with respect to $y$, written as $\partial f/\partial y$, or $f_y$, is defined as

$$\frac{\partial f}{\partial y} = f_y(x, y) = \lim_{k \to 0} \frac{f(x, y + k) - f(x, y)}{k}. \tag{14.4.2}$$

This definition shows two differences already. First, the notation changes, in the sense that we still use a version of Leibniz notation, but the $d$ in the original notation is replaced with the symbol $\partial$. (This rounded "$d$" is usually called "partial," so $\partial f/\partial x$ is spoken as the "partial of $f$ with respect to $x$.") This is the first hint that we are dealing with partial derivatives. Second, we now have two different derivatives we can take, since there are two different independent variables. Depending on which variable we choose, we can come up with different partial derivatives altogether, and often do.

**Example 14.4.1: Calculating Partial Derivatives from the Definition**

Use the definition of the partial derivative as a limit to calculate $\partial f/\partial x$ and $\partial f/\partial y$ for the function

$$f(x, y) = x^2 - 3xy + 2y^2 - 4x + 5y - 12.$$

**Solution**

First, calculate $f(x + h, y)$.

$$\begin{aligned} f(x + h, y) &= (x + h)^2 - 3(x + h)y + 2y^2 - 4(x + h) + 5y - 12 \\ &= x^2 + 2xh + h^2 - 3xy - 3hy + 2y^2 - 4x - 4h + 5y - 12. \end{aligned}$$

Next, substitute this into Equation 14.4.1 and simplify:

$$\begin{aligned}\frac{\partial f}{\partial x} &= \lim_{h\to 0}\frac{f(x+h,y)-f(x,y)}{h}\\ &= \lim_{h\to 0}\frac{(x^2+2xh+h^2-3xy-3hy+2y^2-4x-4h+5y-12)-(x^2-3xy+2y^2-4x+5y-12)}{h}\\ &= \lim_{h\to 0}\frac{x^2+2xh+h^2-3xy-3hy+2y^2-4x-4h+5y-12-x^2+3xy-2y^2+4x-5y+12}{h}\\ &= \lim_{h\to 0}\frac{2xh+h^2-3hy-4h}{h}\\ &= \lim_{h\to 0}\frac{h(2x+h-3y-4)}{h}\\ &= \lim_{h\to 0}(2x+h-3y-4)\\ &= 2x-3y-4.\end{aligned}$$

To calculate $\frac{\partial f}{\partial y}$, first calculate $f(x,y+h)$ :

$$\begin{aligned}f(x,y+h) &= x^2-3x(y+h)+2(y+h)^2-4x+5(y+h)-12\\ &= x^2-3xy-3xh+2y^2+4yh+2h^2-4x+5y+5h-12.\end{aligned}$$

Next, substitute this into Equation 14.4.2 and simplify:

$$\begin{aligned}\frac{\partial f}{\partial y} &= \lim_{h\to 0}\frac{f(x,y+h)-f(x,y)}{h}\\ &= \lim_{h\to 0}\frac{(x^2-3xy-3xh+2y^2+4yh+2h^2-4x+5y+5h-12)-(x^2-3xy+2y^2-4x+5y-12)}{h}\\ &= \lim_{h\to 0}\frac{x^2-3xy-3xh+2y^2+4yh+2h^2-4x+5y+5h-12-x^2+3xy-2y^2+4x-5y+12}{h}\\ &= \lim_{h\to 0}\frac{-3xh+4yh+2h^2+5h}{h}\\ &= \lim_{h\to 0}\frac{h(-3x+4y+2h+5)}{h}\\ &= \lim_{h\to 0}(-3x+4y+2h+5)\\ &= -3x+4y+5\end{aligned}$$

## ? Exercise 14.4.1

Use the definition of the partial derivative as a limit to calculate $\partial f/\partial x$ and $\partial f/\partial y$ for the function

$$f(x,y)=4x^2+2xy-y^2+3x-2y+5.$$

**Hint**

Use Equations 14.4.1 and 14.4.2 from the definition of partial derivatives.

**Answer**

$$\frac{\partial f}{\partial x}=8x+2y+3$$
$$\frac{\partial f}{\partial y}=2x-2y-2$$

The idea to keep in mind when calculating partial derivatives is to treat all independent variables, other than the variable with respect to which we are differentiating, as constants. Then proceed to differentiate as with a function of a single variable. To see why this is true, first fix $y$ and define $g(x)=f(x,y)$ as a function of $x$. Then

$$g'(x) = \lim_{h \to 0} \frac{g(x+h) - g(x)}{h}$$
$$= \lim_{h \to 0} \frac{f(x+h, y) - f(x, y)}{h}$$
$$= \frac{\partial f}{\partial x}.$$

The same is true for calculating the partial derivative of $f$ with respect to $y$. This time, fix $x$ and define $h(y) = f(x, y)$ as a function of $y$. Then

$$h'(x) = \lim_{k \to 0} \frac{h(x+k) - h(x)}{k}$$
$$= \lim_{k \to 0} \frac{f(x, y+k) - f(x, y)}{k}$$
$$= \frac{\partial f}{\partial y}.$$

All differentiation rules apply.

### Example 14.4.2: Calculating Partial Derivatives

Calculate $\partial f/\partial x$ and $\partial f/\partial y$ for the following functions by holding the opposite variable constant then differentiating:

a. $f(x, y) = x^2 - 3xy + 2y^2 - 4x + 5y - 12$
b. $g(x, y) = \sin(x^2 y - 2x + 4)$

**Solution**:

a. To calculate $\partial f/\partial x$, treat the variable $y$ as a constant. Then differentiate $f(x, y)$ with respect to $x$ using the sum, difference, and power rules:

$$\frac{\partial f}{\partial x} = \frac{\partial}{\partial x}\left[x^2 - 3xy + 2y^2 - 4x + 5y - 12\right]$$
$$= \frac{\partial}{\partial x}[x^2] - \frac{\partial}{\partial x}[3xy] + \frac{\partial}{\partial x}[2y^2] - \frac{\partial}{\partial x}[4x] + \frac{\partial}{\partial x}[5y] - \frac{\partial}{\partial x}[12]$$
$$= 2x - 3y + 0 - 4 + 0 - 0$$
$$= 2x - 3y - 4.$$

The derivatives of the third, fifth, and sixth terms are all zero because they do not contain the variable $x$, so they are treated as constant terms. The derivative of the second term is equal to the coefficient of $x$, which is $-3y$. Calculating $\partial f/\partial y$:

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y}\left[x^2 - 3xy + 2y^2 - 4x + 5y - 12\right]$$
$$= \frac{\partial}{\partial y}[x^2] - \frac{\partial}{\partial y}[3xy] + \frac{\partial}{\partial y}[2y^2] - \frac{\partial}{\partial y}[4x] + \frac{\partial}{\partial y}[5y] - \frac{\partial}{\partial y}[12]$$
$$= 0 - 3x + 4y - 0 + 5 - 0$$
$$= -3x + 4y + 5.$$

These are the same answers obtained in Example 14.4.1.

b. To calculate $\partial g/\partial x$, treat the variable $y$ as a constant. Then differentiate $g(x, y)$ with respect to $x$ using the chain rule and power rule:

$$\frac{\partial g}{\partial x} = \frac{\partial}{\partial x}\left[\sin(x^2 y - 2x + 4)\right]$$
$$= \cos(x^2 y - 2x + 4)\frac{\partial}{\partial x}[x^2 y - 2x + 4]$$
$$= (2xy - 2)\cos(x^2 y - 2x + 4).$$

To calculate $\partial g/\partial y$, treat the variable $x$ as a constant. Then differentiate $g(x,y)$ with respect to $y$ using the chain rule and power rule:

$$\begin{aligned}\frac{\partial g}{\partial y} &= \frac{\partial}{\partial y}\left[\sin(x^2y-2x+4)\right] \\ &= \cos(x^2y-2x+4)\frac{\partial}{\partial y}[x^2y-2x+4] \\ &= x^2\cos(x^2y-2x+4).\end{aligned}$$

**? Exercise 14.4.2**

Calculate $\partial f/\partial x$ and $\partial f/\partial y$ for the function

$$f(x,y)=\tan(x^3-3x^2y^2+2y^4)$$

by holding the opposite variable constant, then differentiating.

**Hint**

Use Equations 14.4.1 and 14.4.1 from the definition of partial derivatives.

**Answer**

$$\frac{\partial f}{\partial x}=(3x^2-6xy^2)\sec^2(x^3-3x^2y^2+2y^4)$$
$$\frac{\partial f}{\partial y}=(-6x^2y+8y^3)\sec^2(x^3-3x^2y^2+2y^4)$$

How can we interpret these partial derivatives? Recall that the graph of a function of two variables is a surface in $R^3$. If we remove the limit from the definition of the partial derivative with respect to $x$, the difference quotient remains:

$$\frac{f(x+h,y)-f(x,y)}{h}.$$

This resembles the difference quotient for the derivative of a function of one variable, except for the presence of the $y$ variable. Figure 14.4.1 illustrates a surface described by an arbitrary function $z=f(x,y)$.

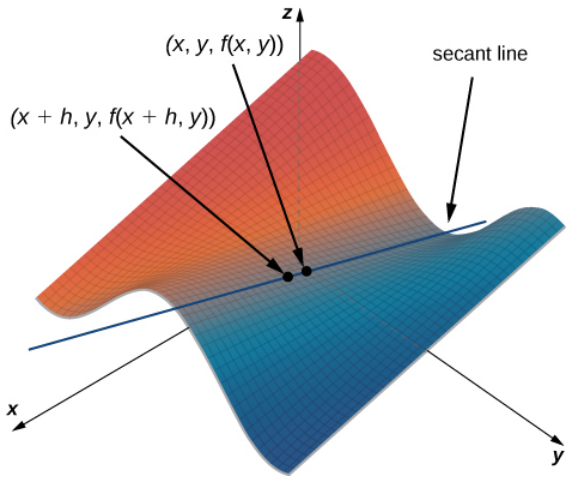

Figure 14.4.1: Secant line passing through the points $(x,y,f(x,y))$ and $(x+h,y,f(x+h,y))$.

In Figure 14.4.1, the value of $h$ is positive. If we graph $f(x,y)$ and $f(x+h,y)$ for an arbitrary point $(x,y)$, then the slope of the secant line passing through these two points is given by

$$\frac{f(x+h,y)-f(x,y)}{h}.$$

This line is parallel to the $x$-axis. Therefore, the slope of the secant line represents an average rate of change of the function $f$ as we travel parallel to the $x$-axis. As $h$ approaches zero, the slope of the secant line approaches the slope of the tangent line.

If we choose to change $y$ instead of $x$ by the same incremental value $h$, then the secant line is parallel to the $y$-axis and so is the tangent line. Therefore, $\partial f/\partial x$ represents the slope of the tangent line passing through the point $(x, y, f(x, y))$ parallel to the $x$-axis and $\partial f/\partial y$ represents the slope of the tangent line passing through the point $(x, y, f(x, y))$ parallel to the $y$-axis. If we wish to find the slope of a tangent line passing through the same point in any other direction, then we need what are called directional derivatives.

We now return to the idea of contour maps, which we introduced in Functions of Several Variables. We can use a **contour map** to estimate partial derivatives of a function $g(x, y)$.

### Example 14.4.3: Partial Derivatives from a Contour Map

Use a contour map to estimate $\partial g/\partial x$ at the point $(\sqrt{5}, 0)$ for the function

$$g(x, y) = \sqrt{9 - x^2 - y^2}.$$

#### Solution

Figure 14.4.2 represents a contour map for the function $g(x, y)$.

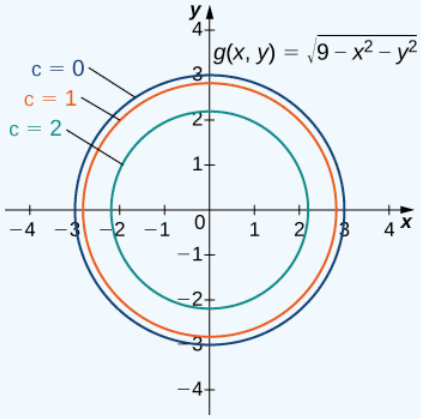

Figure 14.4.2: Contour map for the function $g(x, y) = \sqrt{9 - x^2 - y^2}$, using $c = 0, 1, 2$, and $3 (c = 3$ corresponds to the origin).

The inner circle on the contour map corresponds to $c = 2$ and the next circle out corresponds to $c = 1$. The first circle is given by the equation $2 = \sqrt{9 - x^2 - y^2}$; the second circle is given by the equation $1 = \sqrt{9 - x^2 - y^2}$. The first equation simplifies to $x^2 + y^2 = 5$ and the second equation simplifies to $x^2 + y^2 = 8$. The $x$-intercept of the first circle is $(\sqrt{5}, 0)$ and the $x$-intercept of the second circle is $(2\sqrt{2}, 0)$. We can estimate the value of $\partial g/\partial x$ evaluated at the point $(\sqrt{5}, 0)$ using the slope formula:

$$\begin{aligned} \frac{\partial g}{\partial x}\Big|_{(x,y)=(\sqrt{5},0)} &\approx \frac{g(\sqrt{5}, 0) - g(2\sqrt{2}, 0)}{\sqrt{5} - 2\sqrt{2}} \\ &= \frac{2 - 1}{\sqrt{5} - 2\sqrt{2}} \\ &= \frac{1}{\sqrt{5} - 2\sqrt{2}} \approx -1.688. \end{aligned}$$

To calculate the exact value of $\partial g/\partial x$ evaluated at the point $(\sqrt{5}, 0)$, we start by finding $\partial g/\partial x$ using the chain rule. First, we rewrite the function as

$$g(x, y) = \sqrt{9 - x^2 - y^2} = (9 - x^2 - y^2)^{1/2}$$

and then differentiate with respect to $x$ while holding $y$ constant:

$$\begin{aligned} \frac{\partial g}{\partial x} &= \frac{1}{2}(9 - x^2 - y^2)^{-1/2}(-2x) \\ &= -\frac{x}{\sqrt{9 - x^2 - y^2}}. \end{aligned}$$

Next, we evaluate this expression using $x = \sqrt{5}$ and $y = 0$:

$$\begin{aligned}\frac{\partial g}{\partial x}\Big|_{(x,y)=(\sqrt{5},0)} &= -\frac{\sqrt{5}}{\sqrt{9-(\sqrt{5})^2-(0)^2}} \\ &= -\frac{\sqrt{5}}{\sqrt{4}} \\ &= -\frac{\sqrt{5}}{2} \approx -1.118.\end{aligned}$$

The estimate for the partial derivative corresponds to the slope of the secant line passing through the points $(\sqrt{5}, 0, g(\sqrt{5}, 0))$ and $(2\sqrt{2}, 0, g(2\sqrt{2}, 0))$. It represents an approximation to the slope of the tangent line to the surface through the point $(\sqrt{5}, 0, g(\sqrt{5}, 0))$, which is parallel to the $x$-axis.

**? Exercise 14.4.3**

Use a contour map to estimate $\partial f/\partial y$ at point $(0, \sqrt{2})$ for the function

$$f(x, y) = x^2 - y^2.$$

Compare this with the exact answer.

**Hint**

Create a contour map for $f$ using values of $c$ from $-3$ to $3$. Which of these curves passes through point $(0, \sqrt{2})$?

**Answer**

Using the curves corresponding to $c = -2$ and $c = -3$, we obtain

$$\begin{aligned}\frac{\partial f}{\partial y}\Big|_{(x,y)=(0,\sqrt{2})} &\approx \frac{f(0,\sqrt{3}) - f(0,\sqrt{2})}{\sqrt{3}-\sqrt{2}} \\ &= \frac{-3-(-2)}{\sqrt{3}-\sqrt{2}} \cdot \frac{\sqrt{3}+\sqrt{2}}{\sqrt{3}+\sqrt{2}} \\ &= -\sqrt{3}-\sqrt{2} \approx -3.146.\end{aligned}$$

The exact answer is

$$\frac{\partial f}{\partial y}\Big|_{(x,y)=(0,\sqrt{2})} = (-2y|_{(x,y)=(0,\sqrt{2})} = -2\sqrt{2} \approx -2.828.$$

## Functions of More Than Two Variables

Suppose we have a function of three variables, such as $w = f(x, y, z)$. We can calculate partial derivatives of $w$ with respect to any of the independent variables, simply as extensions of the definitions for partial derivatives of functions of two variables.

**Definition: Partial Derivatives**

Let $f(x, y, z)$ be a function of three variables. Then, the partial derivative of $f$ with respect to $x$, written as $\partial f/\partial x$, or $f_x$, is defined to be

$$\frac{\partial f}{\partial x} = f_x(x, y, z) = \lim_{h \to 0} \frac{f(x+h, y, z) - f(x, y, z)}{h}. \tag{14.4.3}$$

The *partial derivative* of $f$ with *respect* to $y$, written as $\partial f/\partial y$, or $f_y$, is defined to be

$$\frac{\partial f}{\partial y} = f_y(x, y, z) = \lim_{k \to 0} \frac{f(x, y+k, z) - f(x, y, z)}{k.} \tag{14.4.4}$$

The *partial derivative* of $f$ with respect to $z$, written as $\partial f/\partial z$, or $f_z$, is defined to be

$$\frac{\partial f}{\partial z} = f_z(x,y,z) = \lim_{m \to 0} \frac{f(x,y,z+m) - f(x,y,z)}{m}. \tag{14.4.5}$$

We can calculate a partial derivative of a function of three variables using the same idea we used for a function of two variables. For example, if we have a function $f$ of $x, y$, and $z$, and we wish to calculate $\partial f/\partial x$, then we treat the other two independent variables as if they are constants, then differentiate with respect to $x$.

### Example 14.4.4: Calculating Partial Derivatives for a Function of Three Variables

Use the limit definition of partial derivatives to calculate $\partial f/\partial x$ for the function

$$f(x,y,z) = x^2 - 3xy + 2y^2 - 4xz + 5yz^2 - 12x + 4y - 3z.$$

Then, find $\partial f/\partial y$ and $\partial f/\partial z$ by setting the other two variables constant and differentiating accordingly.

**Solution**:

We first calculate $\partial f/\partial x$ using Equation 14.4.3, then we calculate the other two partial derivatives by holding the remaining variables constant. To use the equation to find $\partial f/\partial x$, we first need to calculate $f(x+h,y,z)$ :

$$\begin{aligned} f(x+h,y,z) &= (x+h)^2 - 3(x+h)y + 2y^2 - 4(x+h)z + 5yz^2 - 12(x+h) + 4y - 3z \\ &= x^2 + 2xh + h^2 - 3xy - 3xh + 2y^2 - 4xz - 4hz + 5yz^2 - 12x - 12h + 4y - 3z \end{aligned}$$

and recall that $f(x,y,z) = x^2 - 3xy + 2y^2 - 4zx + 5yz^2 - 12x + 4y - 3z$. Next, we substitute these two expressions into the equation:

$$\begin{aligned} \frac{\partial f}{\partial x} &= \lim_{h \to 0} \left[ \frac{\begin{array}{l} x^2 + 2xh + h^2 - 3xy - 3hy + 2y^2 - 4xz - 4hz + 5yz^2 - 12x - 12h + 4y - 3zh - x^2 - 3xy \\ + 2y^2 - 4xz + 5yz^2 - 12x + 4y - 3z \end{array}}{h} \right] \\ &= \lim_{h \to 0} \left[ \frac{2xh + h^2 - 3hy - 4hz - 12h}{h} \right] \\ &= \lim_{h \to 0} \left[ \frac{h(2x + h - 3y - 4z - 12)}{h} \right] \\ &= \lim_{h \to 0} (2x + h - 3y - 4z - 12) \\ &= 2x - 3y - 4z - 12. \end{aligned}$$

Then we find $\partial f/\partial y$ by holding $x$ and $z$ constant. Therefore, any term that does not include the variable $y$ is constant, and its derivative is zero. We can apply the sum, difference, and power rules for functions of one variable:

$$\begin{aligned} &\frac{\partial}{\partial y}\left[x^2 - 3xy + 2y^2 - 4xz + 5yz^2 - 12x + 4y - 3z\right] \\ &= \frac{\partial}{\partial y}[x^2] - \frac{\partial}{\partial y}[3xy] + \frac{\partial}{\partial y}[2y^2] - \frac{\partial}{\partial y}[4xz] + \frac{\partial}{\partial y}[5yz^2] - \frac{\partial}{\partial y}[12x] + \frac{\partial}{\partial y}[4y] - \frac{\partial}{\partial z}[3z] \\ &= 0 - 3x + 4y - 0 + 5z^2 - 0 + 4 - 0 \\ &= -3x + 4y + 5z^2 + 4. \end{aligned}$$

To calculate $\partial f/\partial z$, we hold $x$ and $y$ constant and apply the sum, difference, and power rules for functions of one variable:

$$\begin{aligned} &\frac{\partial}{\partial z}[x^2 - 3xy + 2y^2 - 4xz + 5yz^2 - 12x + 4y - 3z] \\ &= \frac{\partial}{\partial z}[x^2] - \frac{\partial}{\partial z}[3xy] + \frac{\partial}{\partial z}[2y^2] - \frac{\partial}{\partial z}[4xz] + \frac{\partial}{\partial z}[5yz^2] - \frac{\partial}{\partial z}[12x] + \frac{\partial}{\partial z}[4y] - \frac{\partial}{\partial z}[3z] \\ &= 0 - 0 + 0 - 4x + 10yz - 0 + 0 - 3 \\ &= -4x + 10yz - 3 \end{aligned}$$

## Exercise 14.4.4

Use the limit definition of partial derivatives to calculate $\partial f/\partial x$ for the function

$$f(x,y,z) = 2x^2 - 4x^2y + 2y^2 + 5xz^2 - 6x + 3z - 8.$$

Then find $\partial f/\partial y$ and $\partial f/\partial z$ by setting the other two variables constant and differentiating accordingly.

**Hint**

Use the strategy in the preceding example.

**Answer**

$\dfrac{\partial f}{\partial x} = 4x - 8xy + 5z^2 - 6, \dfrac{\partial f}{\partial y} = -4x^2 + 4y, \dfrac{\partial f}{\partial z} = 10xz + 3$

## Example 14.4.5: Calculating Partial Derivatives for a Function of Three Variables

Calculate the three partial derivatives of the following functions.

a. $f(x,y,z) = \dfrac{x^2y - 4xz + y^2}{x - 3yz}$

b. $g(x,y,z) = \sin(x^2y - z) + \cos(x^2 - yz)$

### Solution

In each case, treat all variables as constants except the one whose partial derivative you are calculating.

a.

$$\begin{aligned}\frac{\partial f}{\partial x} &= \frac{\partial}{\partial x}\left[\frac{x^2y - 4xz + y^2}{x - 3yz}\right] \\ &= \frac{\frac{\partial}{\partial x}(x^2y - 4xz + y^2)(x - 3yz) - (x^2y - 4xz + y^2)\frac{\partial}{\partial x}(x - 3yz)}{(x - 3yz)^2} \\ &= \frac{(2xy - 4z)(x - 3yz) - (x^2y - 4xz + y^2)(1)}{(x - 3yz)^2} \\ &= \frac{2x^2y - 6xy^2z - 4xz + 12yz^2 - x^2y + 4xz - y^2}{(x - 3yz)^2} \\ &= \frac{x^2y - 6xy^2z - 4xz + 12yz^2 + 4xz - y^2}{(x - 3yz)^2}\end{aligned}$$

$$\begin{aligned}\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left[\frac{x^2y - 4xz + y^2}{x - 3yz}\right] \\ &= \frac{\frac{\partial}{\partial y}(x^2y - 4xz + y^2)(x - 3yz) - (x^2y - 4xz + y^2)\frac{\partial}{\partial y}(x - 3yz)}{(x - 3yz)^2} \\ &= \frac{(x^2 + 2y)(x - 3yz) - (x^2y - 4xz + y^2)(-3z)}{(x - 3yz)^2} \\ &= \frac{x^3 - 3x^2yz + 2xy - 6y^2z + 3x^2yz - 12xz^2 + 3y^2z}{(x - 3yz)^2} \\ &= \frac{x^3 + 2xy - 3y^2z - 12xz^2}{(x - 3yz)^2}\end{aligned}$$

$$\frac{\partial f}{\partial z} = \frac{\partial}{\partial z}\left[\frac{x^2y - 4xz + y^2}{x - 3yz}\right]$$

$$= \frac{\frac{\partial}{\partial z}(x^2y - 4xz + y^2)(x - 3yz) - (x^2y - 4xz + y^2)\frac{\partial}{\partial z}(x - 3yz)}{(x - 3yz)^2}$$

$$= \frac{(-4x)(x - 3yz) - (x^2y - 4xz + y^2)(-3y)}{(x - 3yz)^2}$$

$$= \frac{-4x^2 + 12xyz + 3x^2y^2 - 12xyz + 3y^3}{(x - 3yz)^2}$$

$$= \frac{-4x^2 + 3x^2y^2 + 3y^3}{(x - 3yz)^2}$$

b.

$$\frac{\partial f}{\partial x} = \frac{\partial}{\partial x}\left[\sin(x^2y - z) + \cos(x^2 - yz)\right]$$

$$= (\cos(x^2y - z))\frac{\partial}{\partial x}(x^2y - z) - (\sin(x^2 - yz))\frac{\partial}{\partial x}(x^2 - yz)$$

$$= 2xy\cos(x^2y - z) - 2x\sin(x^2 - yz)$$

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y}[\sin(x^2y - z) + \cos(x^2 - yz)]$$

$$= (\cos(x^2y - z))\frac{\partial}{\partial y}(x^2y - z) - (\sin(x^2 - yz))\frac{\partial}{\partial y}(x^2 - yz)$$

$$= x^2\cos(x^2y - z) + z\sin(x^2 - yz)$$

$$\frac{\partial f}{\partial z} = \frac{\partial}{\partial z}[\sin(x^2y - z) + \cos(x^2 - yz)]$$

$$= (\cos(x^2y - z))\frac{\partial}{\partial z}(x^2y - z) - (\sin(x^2 - yz))\frac{\partial}{\partial z}(x^2 - yz)$$

$$= -\cos(x^2y - z) + y\sin(x^2 - yz)$$

**? Exercise 14.4.5**

Calculate $\partial f/\partial x, \partial f/\partial y$, and $\partial f/\partial z$ for the function

$$f(x, y, z) = \sec(x^2y) - \tan(x^3yz^2).$$

**Hint**

Use the strategy in the preceding example.

**Answer**

$$\frac{\partial f}{\partial x} = 2xy\sec(x^2y)\tan(x^2y) - 3x^2yz^2\sec^2(x^3yz^2)$$

$$\frac{\partial f}{\partial y} = x^2\sec(x^2y)\tan(x^2y) - x^3z^2\sec^2(x^3yz^2)$$

$$\frac{\partial f}{\partial z} = -2x^3yz\sec^2(x^3yz^2)$$

## Higher-Order Partial Derivatives

Consider the function

$$f(x, y) = 2x^3 - 4xy^2 + 5y^3 - 6xy + 5x - 4y + 12.$$

Its partial derivatives are

$$\frac{\partial f}{\partial x} = 6x^2 - 4y^2 - 6y + 5$$

and

$$\frac{\partial f}{\partial y} = -8xy + 15y^2 - 6x - 4.$$

Each of these partial derivatives is a function of two variables, so we can calculate partial derivatives of these functions. Just as with derivatives of single-variable functions, we can call these *second-order derivatives*, third-order derivatives, and so on. In general, they are referred to as **higher-order partial derivatives.** There are four second-order partial derivatives for any function (provided they all exist):

$$\frac{\partial^2 f}{\partial x^2} = \frac{\partial}{\partial x}\left[\frac{\partial f}{\partial x}\right]$$
$$\frac{\partial^2 f}{\partial y \partial x} = \frac{\partial}{\partial y}\left[\frac{\partial f}{\partial x}\right]$$
$$\frac{\partial^2 f}{\partial x \partial y} = \frac{\partial}{\partial x}\left[\frac{\partial f}{\partial y}\right]$$
$$\frac{\partial^2 f}{\partial y^2} = \frac{\partial}{\partial y}\left[\frac{\partial f}{\partial y}\right].$$

An alternative notation for each is $f_{xx}, f_{xy}, f_{yx}$, and $f_{yy}$, respectively. Higher-order partial derivatives calculated with respect to different variables, such as $f_{xy}$ and $f_{yx}$, are commonly called **mixed partial derivatives.**

### Example 14.4.6: Calculating Second Partial Derivatives

Calculate all four second partial derivatives for the function

$$f(x, y) = xe^{-3y} + \sin(2x - 5y). \tag{14.4.6}$$

**Solution**:

To calculate $\frac{\partial^2 f}{\partial x^2}$ and $\frac{\partial^2 f}{\partial y \partial x}$, we first calculate $\partial f/\partial x$:

$$\frac{\partial f}{\partial x} = e^{-3y} + 2\cos(2x - 5y). \tag{14.4.7}$$

To calculate $\frac{\partial^2 f}{\partial x^2}$, differentiate $\partial f/\partial x$ (Equation 14.4.7) with respect to $x$:

$$\begin{aligned}\frac{\partial^2 f}{\partial x^2} &= \frac{\partial}{\partial x}\left[\frac{\partial f}{\partial x}\right] \\ &= \frac{\partial}{\partial x}[e^{-3y} + 2\cos(2x - 5y)] \\ &= -4\sin(2x - 5y).\end{aligned}$$

To calculate $\frac{\partial^2 f}{\partial y \partial x}$, differentiate $\partial f/\partial x$ (Equation 14.4.7) with respect to $y$:

$$\begin{aligned}\frac{\partial^2 f}{\partial y\, \partial x} &= \frac{\partial}{\partial y}\left[\frac{\partial f}{\partial x}\right] \\ &= \frac{\partial}{\partial y}[e^{-3y} + 2\cos(2x - 5y)] \\ &= -3e^{-3y} + 10\sin(2x - 5y).\end{aligned}$$

To calculate $\frac{\partial^2 f}{\partial x \partial y}$ and $\frac{\partial^2 f}{\partial y^2}$, first calculate $\partial f/\partial y$:

$$\frac{\partial f}{\partial y} = -3xe^{-3y} - 5\cos(2x - 5y). \tag{14.4.8}$$

To calculate $\frac{\partial^2 f}{\partial x \partial y}$, differentiate $\partial f/\partial y$ (Equation 14.4.8) with respect to $x$:

$$\begin{aligned}\frac{\partial^2 f}{\partial x \partial y} &= \frac{\partial}{\partial x}\left[\frac{\partial f}{\partial y}\right] \\ &= \frac{\partial}{\partial x}[-3xe^{-3y} - 5\cos(2x - 5y)] \\ &= -3e^{-3y} + 10\sin(2x - 5y).\end{aligned}$$

To calculate $\frac{\partial^2 f}{\partial y^2}$, differentiate $\partial f/\partial y$ (Equation 14.4.8) with respect to $y$:

$$\begin{aligned}\frac{\partial^2 f}{\partial y^2} &= \frac{\partial}{\partial y}\left[\frac{\partial f}{\partial y}\right] \\ &= \frac{\partial}{\partial y}[-3xe^{-3y} - 5\cos(2x - 5y)] \\ &= 9xe^{-3y} - 25\sin(2x - 5y).\end{aligned}$$

**? Exercise 14.4.6**

Calculate all four second partial derivatives for the function

$$f(x, y) = \sin(3x - 2y) + \cos(x + 4y).$$

**Hint**

Follow the same steps as in the previous example.

**Answer**

$$\frac{\partial^2 f}{\partial x^2} = -9\sin(3x - 2y) - \cos(x + 4y)$$

$$\frac{\partial^2 f}{\partial y \partial x} = 6\sin(3x - 2y) - 4\cos(x + 4y)$$

$$\frac{\partial^2 f}{\partial x \partial y} = 6\sin(3x - 2y) - 4\cos(x + 4y)$$

$$\frac{\partial^2 f}{\partial y^2} = -4\sin(3x - 2y) - 16\cos(x + 4y)$$

At this point we should notice that, in both Example 14.4.6 and the checkpoint, it was true that $\frac{\partial^2 f}{\partial y \partial x} = \frac{\partial^2 f}{\partial x \partial y}$. Under certain conditions, this is always true. In fact, it is a direct consequence of the following theorem.

**Theorem 14.4.1: Equality of Mixed Partial Derivatives (Clairaut's Theorem)**

Suppose that $f(x, y)$ is defined on an open disk $D$ that contains the point $(a, b)$. If the functions $f_{xy}$ and $f_{yx}$ are continuous on $D$, then $f_{xy}(a, b) = f_{yx}(a, b)$.

Clairaut's theorem guarantees that as long as mixed second-order derivatives are continuous, the order in which we choose to differentiate the functions (i.e., which variable goes first, then second, and so on) does not matter. It can be extended to higher-order derivatives as well. The proof of Clairaut's theorem can be found in most advanced calculus books.

Two other second-order partial derivatives can be calculated for any function $f(x, y)$. The partial derivative $f_{xx}$ is equal to the partial derivative of $f_x$ with respect to $x$, and $f_{yy}$ is equal to the partial derivative of $f_y$ with respect to $y$.

## Partial Differential Equations

Previously, we studied differential equations in which the unknown function had one independent variable. A partial differential equation is an equation that involves an unknown function of more than one independent variable and one or more of its partial

derivatives. Examples of partial differential equations are

$$u_t = c^2(u_{xx} + u_{yy})$$
heat equation in two dimensions

$$u_{tt} = c^2(u_{xx} + u_{yy})$$
wave equation in two dimensions

$$u_{xx} + u_{yy} = 0$$
Laplace's equation in two dimensions

In the heat and wave equations, the unknown function $u$ has three independent variables: $t$, $x$, and $y$ with $c$ is an arbitrary constant. The independent variables $x$ and $y$ are considered to be spatial variables, and the variable $t$ represents time. In Laplace's equation, the unknown function $u$ has two independent variables $x$ and $y$.

### Example 14.4.7: A Solution to the Wave Equation

Verify that

$$u(x, y, t) = 5\sin(3\pi x)\sin(4\pi y)\cos(10\pi t)$$

is a solution to the wave equation

$$u_{tt} = 4(u_{xx} + u_{yy}). \tag{14.4.9}$$

**Solution**

First, we calculate $u_{tt}, u_{xx}$, and $u_{yy}$ :

$$\begin{aligned} u_{tt}(x, y, t) &= \frac{\partial}{\partial t}\left[\frac{\partial u}{\partial t}\right] \\ &= \frac{\partial}{\partial t}[5\sin(3\pi x)\sin(4\pi y)(-10\pi\sin(10\pi t))] \\ &= \frac{\partial}{\partial t}[-50\pi\sin(3\pi x)\sin(4\pi y)\sin(10\pi t)] \\ &= -500\pi^2\sin(3\pi x)\sin(4\pi y)\cos(10\pi t) \end{aligned}$$

$$\begin{aligned} u_{xx}(x, y, t) &= \frac{\partial}{\partial x}\left[\frac{\partial u}{\partial x}\right] \\ &= \frac{\partial}{\partial x}[15\pi\cos(3\pi x)\sin(4\pi y)\cos(10\pi t)] \\ &= -45\pi^2\sin(3\pi x)\sin(4\pi y)\cos(10\pi t) \end{aligned}$$

$$\begin{aligned} u_{yy}(x, y, t) &= \frac{\partial}{\partial y}\left[\frac{\partial u}{\partial y}\right] \\ &= \frac{\partial}{\partial y}[5\sin(3\pi x)(4\pi\cos(4\pi y))\cos(10\pi t)] \\ &= \frac{\partial}{\partial y}[20\pi\sin(3\pi x)\cos(4\pi y)\cos(10\pi t)] \\ &= -80\pi^2\sin(3\pi x)\sin(4\pi y)\cos(10\pi t). \end{aligned}$$

Next, we substitute each of these into the right-hand side of Equation 14.4.9 and simplify:

$$\begin{aligned} 4(u_{xx} + u_{yy}) &= 4(-45\pi^2\sin(3\pi x)\sin(4\pi y)\cos(10\pi t) + -80\pi^2\sin(3\pi x)\sin(4\pi y)\cos(10\pi t)) \\ &= 4(-125\pi^2\sin(3\pi x)\sin(4\pi y)\cos(10\pi t)) \\ &= -500\pi^2\sin(3\pi x)\sin(4\pi y)\cos(10\pi t) \\ &= u_{tt}. \end{aligned}$$

This verifies the solution.

**? Exercise 14.4.7**: A Solution to the Heat Equation

Verify that

$$u(x,y,t) = 2\sin\left(\frac{x}{3}\right)\sin\left(\frac{y}{4}\right)e^{-25t/16}$$

is a solution to the heat equation

$$u_t = 9(u_{xx} + u_{yy}).$$

**Hint**

Calculate the partial derivatives and substitute into the right-hand side.

**Answer**

TBA

Since the solution to the two-dimensional heat equation is a function of three variables, it is not easy to create a visual representation of the solution. We can graph the solution for fixed values of $t$, which amounts to snapshots of the heat distributions at fixed times. These snapshots show how the heat is distributed over a two-dimensional surface as time progresses. The graph of the preceding solution at time $t = 0$ appears in Figure 14.4.3. As time progresses, the extremes level out, approaching zero as $t$ approaches infinity.

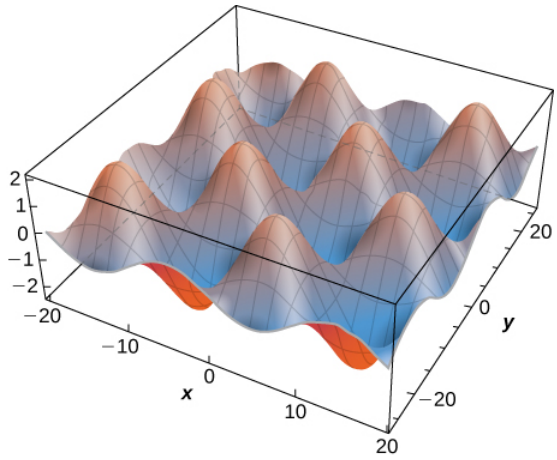

Figure 14.4.3

If we consider the heat equation in one dimension, then it is possible to graph the solution over time. The heat equation in one dimension becomes

$$u_t = c^2 u_{xx},$$

where $c^2$ represents the thermal diffusivity of the material in question. A solution of this differential equation can be written in the form

$$u_m(x,t) = e^{-\pi^2 m^2 c^2 t}\sin(m\pi x)$$

where $m$ is any positive integer. A graph of this solution using $m = 1$ appears in Figure 14.4.4, where the initial temperature distribution over a wire of length 1 is given by $u(x,0) = \sin \pi x$. Notice that as time progresses, the wire cools off. This is seen because, from left to right, the highest temperature (which occurs in the middle of the wire) decreases and changes color from red to blue.

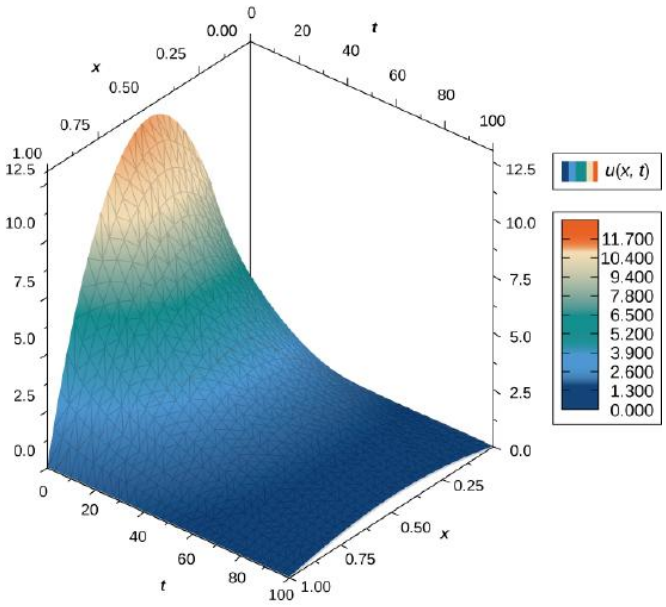

Figure **14.4.4**: Graph of a solution of the heat equation in one dimension over time.

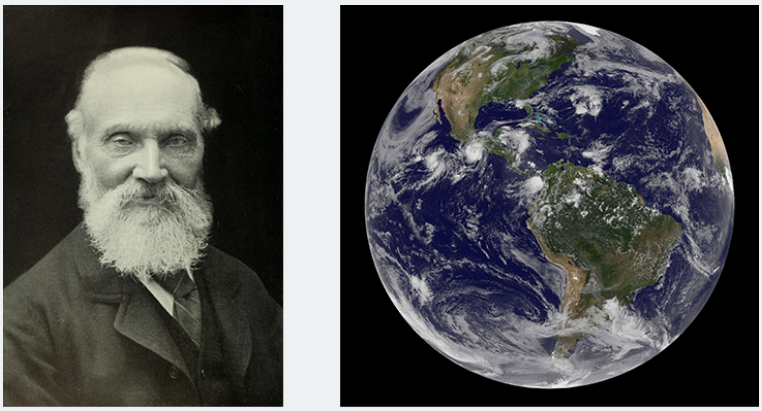
## Lord Kelvin and the Age of Earth

During the late 1800s, the scientists of the new field of geology were coming to the conclusion that Earth must be “millions and millions” of years old. At about the same time, Charles Darwin had published his treatise on evolution. Darwin’s view was that evolution needed many millions of years to take place, and he made a bold claim that the Weald chalk fields, where important fossils were found, were the result of **300** million years of erosion.



(a) (b)

Figure **14.4.5**: (a) William Thomson (Lord Kelvin), 1824-1907, was a British physicist and electrical engineer; (b) Kelvin used the heat diffusion equation to estimate the age of Earth (credit: modification of work by NASA).

At that time, eminent physicist William Thomson (Lord Kelvin) used an important partial differential equation, known as the heat diffusion equation, to estimate the age of Earth by determining how long it would take Earth to cool from molten rock to what we had at that time. His conclusion was a range of **20** to **400** million years, but most likely about **50** million years. For many decades, the proclamations of this irrefutable icon of science did not sit well with geologists or with Darwin.

- Read Kelvin’s paper on estimating the age of the Earth.

Kelvin made reasonable assumptions based on what was known in his time, but he also made several assumptions that turned out to be wrong. One incorrect assumption was that Earth is solid and that the cooling was therefore via conduction only, hence justifying the use of the diffusion equation. But the most serious error was a forgivable one—omission of the fact that Earth contains radioactive elements that continually supply heat beneath Earth’s mantle. The discovery of radioactivity came near the end of Kelvin’s life and he acknowledged that his calculation would have to be modified.

Kelvin used the simple one-dimensional model applied only to Earth's outer shell, and derived the age from graphs and the roughly known temperature gradient near Earth's surface. Let's take a look at a more appropriate version of the diffusion equation in radial coordinates, which has the form

$$\frac{\partial T}{\partial t} = K\left[\frac{\partial^2 T}{\partial^2 r} + \frac{2}{r}\frac{\partial T}{\partial r}\right] \tag{14.4.10}$$

.

Here, $T(r,t)$ is temperature as a function of $r$ (measured from the center of Earth) and time $t$.$K$ is the heat conductivity—for molten rock, in this case. The standard method of solving such a partial differential equation is by separation of variables, where we express the solution as the product of functions containing each variable separately. In this case, we would write the temperature as

$$T(r,t) = R(r)f(t).$$

1. Substitute this form into Equation 14.4.10 and, noting that $f(t)$ is constant with respect to distance $(r)$ and $R(r)$ is constant with respect to time $(t)$, show that

$$\frac{1}{f}\frac{\partial f}{\partial t} = \frac{K}{R}\left[\frac{\partial^2 R}{\partial r^2} + \frac{2}{r}\frac{\partial R}{\partial r}\right].$$

2. This equation represents the separation of variables we want. The left-hand side is only a function of $t$ and the right-hand side is only a function of $r$, and they must be equal for all values of $r$ and $t$. Therefore, they both must be equal to a constant. Let's call that constant $-\lambda^2$. (The convenience of this choice is seen on substitution.) So, we have

$$\frac{1}{f}\frac{\partial f}{\partial t} = -\lambda^2 \text{and} \frac{K}{R}\left[\frac{\partial^2 R}{\partial r^2} + \frac{2}{r}\frac{\partial R}{\partial r}\right] = -\lambda^2.$$

3. Now, we can verify through direct substitution for each equation that the solutions are $f(t) = Ae^{-\lambda^2 t}$ and $R(r) = B\left(\frac{\sin \alpha r}{r}\right) + C\left(\frac{\cos \alpha r}{r}\right)$, where $\alpha = \lambda/\sqrt{K}$. Note that $f(t) = Ae^{+\lambda n^2 t}$ is also a valid solution, so we could have chosen $+\lambda^2$for our constant. Can you see why it would not be valid for this case as time increases?
4. Let's now apply boundary conditions.
   a. The temperature must be finite at the center of Earth, $r = 0$. Which of the two constants, $B$ or $C$, must therefore be zero to keep $R$ finite at $r = 0$? (Recall that $\sin(\alpha r)/r \to \alpha =$ as $r \to 0$, but $\cos(\alpha r)/r$ behaves very differently.)
   b. Kelvin argued that when magma reaches Earth's surface, it cools very rapidly. A person can often touch the surface within weeks of the flow. Therefore, the surface reached a moderate temperature very early and remained nearly constant at a surface temperature $T_s$. For simplicity, let's set $T = 0$ at $r = R_E$ and find α such that this is the temperature there for all time $t$. (Kelvin took the value to be $300K \approx 80°F$. We can add this $300K$ constant to our solution later.) For this to be true, the sine argument must be zero at $r = R_E$. Note that α has an infinite series of values that satisfies this condition. Each value of $\alpha$ represents a valid solution (each with its own value for $A$). The total or general solution is the sum of all these solutions.
   c. At $t = 0$, we assume that all of Earth was at an initial hot temperature $T_0$ (Kelvin took this to be about $7000K$.) The application of this boundary condition involves the more advanced application of Fourier coefficients. As noted in part b. each value of $\alpha_n$ represents a valid solution, and the general solution is a sum of all these solutions. This results in a series solution:

$$T(r,t) = \left(\frac{T_0 R_E}{\pi}\right)\sum_n \frac{(-1)^{n-1}}{n} e^{-\lambda n^2 t}\frac{\sin(\alpha_n r)}{r}$$

   where $\alpha_n = n\pi/R_E$.

Note how the values of $\alpha_n$ come from the boundary condition applied in part b. The term $\frac{-1^{n-1}}{n}$ is the constant $A_n$ for each term in the series, determined from applying the Fourier method. Letting $\beta = \frac{\pi}{R_E}$, examine the first few terms of this solution shown here and note how $\lambda^2$ in the exponential causes the higher terms to decrease quickly as time progresses:

$$T(r,t) = \frac{T_0 R_E}{\pi r}\left(e^{-K\beta^2 t}(\sin\beta r) - \frac{1}{2}e^{-4K\beta^2 t}(\sin 2\beta r) + \frac{1}{3}e^{-9K\beta^2 t}(\sin 3\beta r) - \frac{1}{4}e^{-16K\beta^2 t}(\sin 4\beta r) + \frac{1}{5}e^{-25K\beta^2 t}(\sin 5\beta r)\ldots\right).$$

Near time $t = 0$, many terms of the solution are needed for accuracy. Inserting values for the conductivity $K$ and $\beta = \pi/R_E$ for time approaching merely thousands of years, only the first few terms make a significant contribution. Kelvin only needed to look at the solution near Earth's surface (Figure 14.4.6) and, after a long time, determine what time best yielded the estimated temperature gradient known during his era ($1°F$ increase per $50ft$). He simply chose a range of times with a gradient close to this value. In Figure 14.4.6, the solutions are plotted and scaled, with the $300 - K$ surface temperature added. Note that the center of Earth would be relatively cool. At the time, it was thought Earth must be solid.

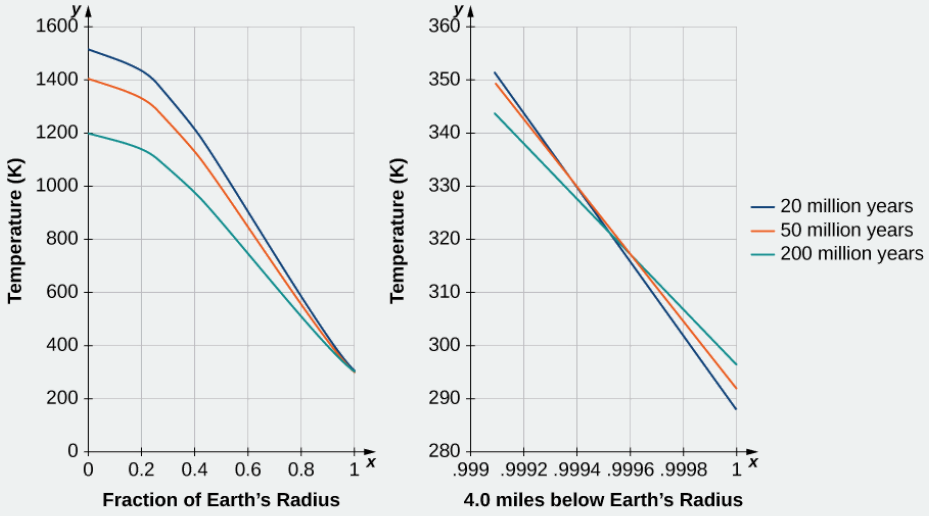


Figure 14.4.6: Temperature versus radial distance from the center of Earth. (a) Kelvin's results, plotted to scale. (b) A close-up of the results at a depth of 4.0 miles below Earth's surface.

**Epilog**

On May **20, 1904,** physicist **Ernest Rutherford** spoke at the Royal Institution to announce a revised calculation that included the contribution of radioactivity as a source of Earth's heat. In Rutherford's own words:

> "I came into the room, which was half-dark, and presently spotted Lord Kelvin in the audience, and realized that I was in for trouble at the last part of my speech dealing with the age of the Earth, where my views conflicted with his. To my relief, Kelvin fell fast asleep, but as I came to the important point, I saw the old bird sit up, open an eye and cock a baleful glance at me.
>
> Then a sudden inspiration came, and I said Lord Kelvin had limited the age of the Earth, provided no new source [of heat] was discovered. That prophetic utterance referred to what we are now considering tonight, radium! Behold! The old boy beamed upon me."

Rutherford calculated an age for Earth of about **500** million years. Today's accepted value of Earth's age is about **4.6** billion years.

## Key Concepts

- A partial derivative is a derivative involving a function of more than one independent variable.
- To calculate a partial derivative with respect to a given variable, treat all the other variables as constants and use the usual differentiation rules.
- Higher-order partial derivatives can be calculated in the same way as higher-order derivatives.

## Key Equations

**Partial derivative of $f$ with respect to $x$**

$$\frac{\partial f}{\partial x} = \lim_{h \to 0} \frac{f(x+h, y) - f(x, y)}{h}$$

**Partial derivative of $f$ with respect to $y$**

$$\frac{\partial f}{\partial y} = \lim_{k \to 0} \frac{f(x, y+k) - f(x, y)}{k}$$

## Glossary

**higher-order partial derivatives**
second-order or higher partial derivatives, regardless of whether they are mixed partial derivatives

**mixed partial derivatives**
second-order or higher partial derivatives, in which at least two of the differentiations are with respect to different variables

**partial derivative**
a derivative of a function of more than one independent variable in which all the variables but one are held constant

**partial differential equation**
an equation that involves an unknown function of more than one independent variable and one or more of its partial derivatives

# 14.4E: Exercises for Section 14.3

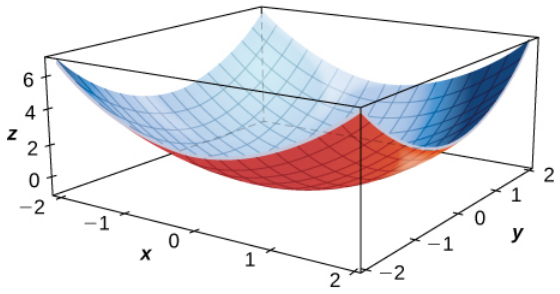
**In the following exercise, calculate the partial derivative using the limit definitions only.**

1) $\frac{\partial z}{\partial y}$ for $z = x^2 - 3xy + y^2$

**Answer**

$\frac{\partial z}{\partial y} = -3x + 2y$

**For exercises 2 - 5, calculate the sign of the partial derivative using the graph of the surface.**



2) $f_x(1,1)$

3) $f_x(-1,1)$

**Answer**

The sign is negative.

4) $f_y(1,1)$

5) $f_x(0,0)$

**Answer**

The partial derivative is zero at the origin.

**In exercises 6 - 16, calculate the requested partial derivatives.**

6) $\frac{\partial z}{\partial x}$ for $z = \sin(3x)\cos(3y)$

7) $\frac{\partial z}{\partial y}$ for $z = \sin(3x)\cos(3y)$

**Answer**

$\frac{\partial z}{\partial y} = -3\sin(3x)\sin(3y)$

8) $\frac{\partial z}{\partial x}$ and $\frac{\partial z}{\partial y}$ for $z = x^8 e^3 y$

9) $\frac{\partial z}{\partial x}$ and $\frac{\partial z}{\partial y}$ for $z = \ln(x^6 + y^4)$

**Answer**

$\frac{\partial z}{\partial x} = \frac{6x^5}{x^6+y^4}$; $\frac{\partial z}{\partial y} = \frac{4y^3}{x^6+y^4}$

10) Find $f_y(x,y)$ for $f(x,y) = e^{xy}\cos(x)\sin(y)$.

11) Let $z = e^{xy}$. Find $\frac{\partial z}{\partial x}$ and $\frac{\partial z}{\partial y}$.

**Answer**

$\frac{\partial z}{\partial x} = ye^{xy}; \quad \frac{\partial z}{\partial y} = xe^{xy}$

12) Let $z = \ln(\frac{x}{y})$. Find $\frac{\partial z}{\partial x}$ and $\frac{\partial z}{\partial y}$.

13) Let $z = \tan(2x - y)$. Find $\frac{\partial z}{\partial x}$ and $\frac{\partial z}{\partial y}$.

**Answer**

$\frac{\partial z}{\partial x} = 2\sec^2(2x - y), \quad \frac{\partial z}{\partial y} = -\sec^2(2x - y)$

14) Let $z = \sinh(2x + 3y)$. Find $\frac{\partial z}{\partial x}$ and $\frac{\partial z}{\partial y}$.

15) Let $f(x, y) = \arctan(\frac{y}{x})$. Evaluate $f_x(2, -2)$ and $f_y(2, -2)$.

**Answer**

$f_x(2, -2) = \frac{1}{4} = f_y(2, -2)$

16) Let $f(x, y) = \frac{xy}{x - y}$. Find $f_x(2, -2)$ and $f_y(2, -2)$.

17) Find $\frac{\partial z}{\partial x}$ at $(0, 1)$ for $z = e^{-x}cos(y)$.

**Answer**

$\frac{\partial z}{\partial x} = -\cos(1)$

18) Given $f(x, y, z) = x^3yz^2$, find $\frac{\partial^2 f}{\partial x \partial y}$ and $f_z(1, 1, 1)$.

19) Given $f(x, y, z) = 2\sin(x + y)$, find $f_x(0, \frac{\pi}{2}, -4)$, $f_y(0, \frac{\pi}{2}, -4)$, and $f_z(0, \frac{\pi}{2}, -4)$.

**Answer**

$f_x(x, y, z) = 0, \quad f_y(x, y, z) = 0, \quad f_z(x, y, z) = 0$

20) The area of a parallelogram with adjacent side lengths that are $a$ and $b$, and in which the angle between these two sides is $\theta$, is given by the function $A(a, b, \theta) = ba\sin(\theta)$.Find the rate of change of the area of the parallelogram with respect to the following:

a. Side $a$

b. Side $b$

c. Angle $\theta$

21) Express the volume of a right circular cylinder as a function of two variables:

a. its radius $r$ and its height $h$.

b. Show that the rate of change of the volume of the cylinder with respect to its radius is the product of its circumference multiplied by its height.

c. Show that the rate of change of the volume of the cylinder with respect to its height is equal to the area of the circular base.

**Answer**

$a. V(r, h) = \pi r^2 h$
$b. \frac{\partial V}{\partial r} = 2\pi rh$
$c. \frac{\partial V}{\partial h} = \pi r^2$

22) Calculate $\frac{\partial w}{\partial z}$ for $w = z\sin(xy^2 + 2z)$.

**In exercises 23 - 39, find the indicated higher-order partial derivatives.**

23) $f_{xy}(x,y)$ for $f(x,y)=\ln(x-y)$

**Answer**

$f_{xy}(x,y)=\frac{1}{(x-y)^2}$

24) $f_{yx}(x,y)$ for $f(x,y)=\ln(x-y)$

25) Let $z=x^2+3xy+2y^2$. Find $\dfrac{\partial^2 z}{\partial x^2}$ and $\dfrac{\partial^2 z}{\partial y^2}$.

**Answer**

$\dfrac{\partial^2 z}{\partial x^2}=2, \quad \dfrac{\partial^2 z}{\partial y^2}=4$

26) Given $z=e^x\tan y$, find $\dfrac{\partial^2 z}{\partial x\partial y}$ and $\dfrac{\partial^2 z}{\partial y\partial x}$.

27) Given $f(x,y,z)=xyz$, find $f_{xyy}(x,y,z)$, $f_{yxy}(x,y,z)$, and $f_{yyx}(x,y,z)$.

**Answer**

$f_{xyy}(x,y,z)=f_{yxy}(x,y,z)=f_{yyx}(x,y,z)=0$

28) Given $f(x,y,z)=e^{-2x}\sin(z^2y)$, show that $f_{xyy}(x,y,z)=f_{yxy}(x,y,z)$.

29) Show that $z=\frac{1}{2}(e^y-e^{-y})\sin x$ is a solution of the differential equation $\dfrac{\partial^2 z}{\partial x^2}+\dfrac{\partial^2 z}{\partial y^2}=0.$

**Answer**

$\dfrac{d^2z}{dx^2}=-\frac{1}{2}(e^y-e^{-y})\sin x$
$\dfrac{d^2z}{dy^2}=\frac{1}{2}(e^y-e^{-y})\sin x$
$\dfrac{d^2z}{dx^2}+\dfrac{d^2z}{dy^2}=0$

30) Find $f_{xx}(x,y)$ for $f(x,y)=\frac{4x^2}{y}+\frac{y^2}{2x}$.

31) Let $f(x,y,z)=x^2y^3z-3xy^2z^3+5x^2z-y^3z$. Find $f_{xyz}$.

**Answer**

$f_{xyz}(x,y,z)=6y^2x-18yz^2$

32) Let $F(x,y,z)=x^3yz^2-2x^2yz+3xz-2y^3z$. Find $F_{xyz}(x,y,z)$.

33) Given $f(x,y)=x^2+x-3xy+y^3-5$, find all points at which $f_x(x,y)=f_y(x,y)=0$ simultaneously.

**Answer**

$(\frac{1}{4},\frac{1}{2}), \quad (1,1)$

34) Given $f(x,y)=2x^2+2xy+y^2+2x-3$, find all points at which $\dfrac{\partial f}{\partial x}=0$ and $\dfrac{\partial f}{\partial y}=0$ simultaneously.

35) Given $f(x,y)=y^3-3yx^2-3y^2-3x^2+1$, find all points on $f$ at which $f_x(x,y)=f_y(x,y)=0$ simultaneously.

**Answer**

$(0,0), \quad (0,2), \quad (\sqrt{3},-1), \quad (-\sqrt{3},-1)$

36) Given $f(x,y)=15x^3-3xy+15y^3$, find all points at which $f_x(x,y)=f_y(x,y)=0$ simultaneously.

37) Show that $z=e^x\sin y$ satisfies the equation $\dfrac{\partial^2 z}{\partial x^2}+\dfrac{\partial^2 z}{\partial y^2}=0.$

**Answer**

$$\frac{\partial^2 z}{\partial x^2} + \frac{\partial^2 z}{\partial y^2} = e^x \sin y - e^x \sin y = 0$$

38) Show that $f(x,y) = \ln(x^2 + y^2)$ solves Laplace's equation $\dfrac{\partial^2 z}{\partial x^2} + \dfrac{\partial^2 z}{\partial y^2} = 0$.

39) Show that $z = e^{-t}\cos(\frac{x}{c})$ satisfies the heat equation $\dfrac{\partial z}{\partial t} = -e^{-t}\cos(\frac{x}{c})$.

**Answer**

$$c^2 \frac{\partial^2 z}{\partial x^2} = e^{-t}\cos(\tfrac{x}{c})$$

40) Find $\lim\limits_{\Delta x \to 0} \dfrac{f(x+\Delta x) - f(x,y)}{\Delta x}$ for $f(x,y) = -7x - 2xy + 7y$.

41) Find $\lim\limits_{\Delta y \to 0} \dfrac{f(x,y+\Delta y) - f(x,y)}{\Delta y}$ for $f(x,y) = -7x - 2xy + 7y$.

**Answer**

$$\frac{\partial f}{\partial y} = -2x + 7$$

42) Find $\lim\limits_{\Delta x \to 0} \dfrac{\Delta f}{\Delta x} = \lim\limits_{\Delta x \to 0} \dfrac{f(x+\Delta x, y) - f(x,y)}{\Delta x}$ for $f(x,y) = x^2y^2 + xy + y$.

43) Find $\lim\limits_{\Delta x \to 0} \dfrac{\Delta f}{\Delta x} = \lim\limits_{\Delta x \to 0} \dfrac{f(x+\Delta x, y) - f(x,y)}{\Delta x}$ for $f(x,y) = \sin(xy)$.

**Answer**

$$\frac{\partial f}{\partial x} = y\cos xy$$

44) The function $P(T,V) = \dfrac{nRT}{V}$ gives the pressure at a point in a gas as a function of temperature $T$ and volume $V$. The letters $n$ and $R$ are constants. Find $\dfrac{\partial P}{\partial V}$ and $\dfrac{\partial P}{\partial T}$, and explain what these quantities represent.

45) The equation for heat flow in the $xy$-plane is $\dfrac{\partial f}{\partial t} = \dfrac{\partial^2 f}{\partial x^2} + \dfrac{\partial^2 f}{\partial y^2}$. Show that $f(x,y,t) = e^{-2t}\sin x \sin y$ is a solution.

46) The basic wave equation is $f_{tt} = f_{xx}$. Verify that $f(x,t) = \sin(x+t)$ and $f(x,t) = \sin(x-t)$ are solutions.

47) The law of cosines can be thought of as a function of three variables. Let $x, y$, and $\theta$ be two sides of any triangle where the angle $\theta$ is the included angle between the two sides. Then, $F(x,y,\theta) = x^2 + y^2 - 2xy\cos\theta$ gives the square of the third side of the triangle. Find $\dfrac{\partial F}{\partial \theta}$ and $\dfrac{\partial F}{\partial x}$ when $x = 2$, $y = 3$, and $\theta = \frac{\pi}{6}$.

**Answer**

$$\frac{\partial F}{\partial \theta} = 6, \quad \frac{\partial F}{\partial x} = 4 - 3\sqrt{3}$$

48) Suppose the sides of a rectangle are changing with respect to time. The first side is changing at a rate of 2in./sec whereas the second side is changing at the rate of 4 in/sec. How fast is the diagonal of the rectangle changing when the first side measures 16 in. and the second side measures 20 in.? (Round answer to three decimal places.)

49) A **Cobb-Douglas production function** is $f(x,y) = 200x^{0.7}y^{0.3}$, where $x$ and $y$ represent the amount of labor and capital available. Let $x = 500$ and $y = 1000$. Find $\dfrac{\partial f}{\partial x}$ and $\dfrac{\partial f}{\partial y}$ at these values, which represent the marginal productivity of labor and capital, respectively.

**Answer**

$$\frac{\partial f}{\partial x} \text{ at } (500,1000) = 172.36, \quad \frac{\partial f}{\partial y} \text{ at } (500,1000) = 36.93$$

50) The apparent temperature index is a measure of how the temperature feels, and it is based on two variables: $h$, which is relative humidity, and $t$, which is the air temperature.

$A = 0.885t - 22.4h + 1.20th - 0.544$. Find $\frac{\partial A}{\partial t}$ and $\frac{\partial A}{\partial h}$ when $t = 20°F$ and $h = 0.90$.

# 14.5: Tangent Planes and Linear Approximations

**Learning Objectives**

- Determine the equation of a plane tangent to a given surface at a point.
- Use the tangent plane to approximate a function of two variables at a point.
- Explain when a function of two variables is differentiable.
- Use the total differential to approximate the change in a function of two variables.

In this section, we consider the problem of finding the tangent plane to a surface, which is analogous to finding the equation of a tangent line to a curve when the curve is defined by the graph of a function of one variable, $y = f(x)$. The slope of the tangent line at the point $x = a$ is given by $m = f'(a)$; what is the slope of a tangent plane? We learned about the equation of a plane in Equations of Lines and Planes in Space; in this section, we see how it can be applied to the problem at hand.

## Tangent Planes

Intuitively, it seems clear that, in a plane, only one line can be tangent to a curve at a point. However, in three-dimensional space, many lines can be tangent to a given point. If these lines lie in the same plane, they determine the tangent plane at that point. A more intuitive way to think of a tangent plane is to assume the surface is smooth at that point (no corners). Then, a tangent line to the surface at that point in any direction does not have any abrupt changes in slope because the direction changes smoothly. Therefore, in a small-enough neighborhood around the point, a tangent plane touches the surface at that point only.

**Definition: Tangent Lines**

Let $P_0 = (x_0, y_0, z_0)$ be a point on a surface $S$, and let $C$ be any curve passing through $P_0$ and lying entirely in $S$. If the tangent lines to all such curves $C$ at $P_0$ lie in the same plane, then this plane is called the *tangent plane* to $S$ at $P_0$ (Figure 14.5.1).

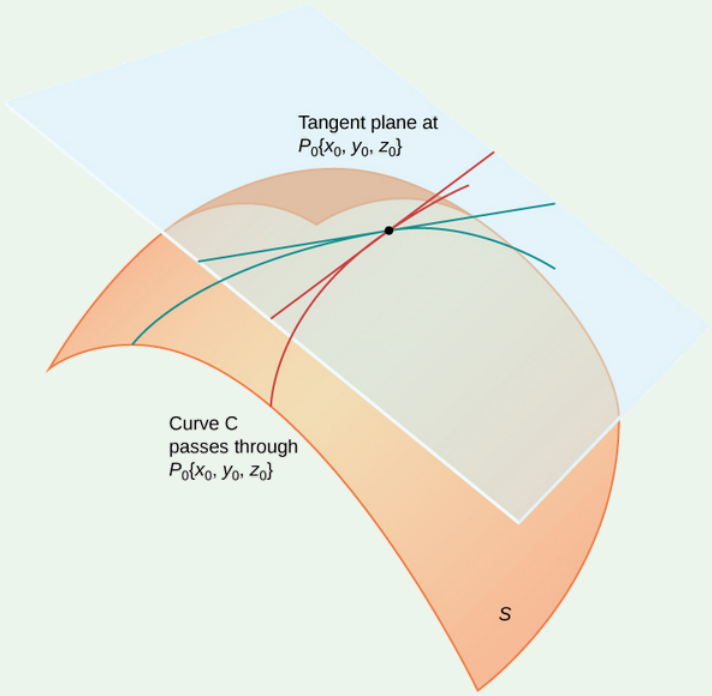

Figure 14.5.1: The tangent plane to a surface $S$ at a point $P_0$ contains all the tangent lines to curves in $S$ *that pass through* $P_0$.

For a tangent plane to a surface to exist at a point on that surface, it is sufficient for the function that defines the surface to be differentiable at that point. We define the term tangent plane here and then explore the idea intuitively.

**Definition: Tangent Planes**

Let $S$ be a surface defined by a differentiable function $z = f(x, y)$, and let $P_0 = (x_0, y_0)$ be a point in the domain of $f$. Then, the equation of the tangent plane to $S$ at $P_0$ is given by

$$z = f(x_0, y_0) + f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0). \tag{14.5.1}$$

To see why this formula is correct, let's first find two tangent lines to the surface $S$. The equation of the tangent line to the curve that is represented by the intersection of $S$ with the vertical trace given by $x = x_0$ is $z = f(x_0, y_0) + f_y(x_0, y_0)(y - y_0)$. Similarly, the equation of the tangent line to the curve that is represented by the intersection of $S$ with the vertical trace given by $y = y_0$ is $z = f(x_0, y_0) + f_x(x_0, y_0)(x - x_0)$. A parallel vector to the first tangent line is $\vec{\mathbf{a}} = \hat{\mathbf{j}} + f_y(x_0, y_0)\,\hat{\mathbf{k}}$; a parallel vector to the second tangent line is $\vec{\mathbf{b}} = \hat{\mathbf{i}} + f_x(x_0, y_0)\,\hat{\mathbf{k}}$. We can take the cross product of these two vectors:

$$\begin{aligned}
\vec{\mathbf{a}} \times \vec{\mathbf{b}} &= (\hat{\mathbf{j}} + f_y(x_0, y_0)\,\hat{\mathbf{k}}) \times (\hat{\mathbf{i}} + f_x(x_0, y_0)\,\hat{\mathbf{k}}) \\
&= \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 0 & 1 & f_y(x_0, y_0) \\ 1 & 0 & f_x(x_0, y_0) \end{vmatrix} \\
&= f_x(x_0, y_0)\,\hat{\mathbf{i}} + f_y(x_0, y_0)\,\hat{\mathbf{j}} - \hat{\mathbf{k}}.
\end{aligned}$$

This vector is perpendicular to both lines and is therefore perpendicular to the tangent plane. We can use this vector as a normal vector to the tangent plane, along with the point $P_0 = (x_0, y_0, f(x_0, y_0))$ in the equation for a plane:

$$\begin{aligned}
\vec{\mathbf{n}} \cdot ((x - x_0)\,\hat{\mathbf{i}} + (y - y_0)\,\hat{\mathbf{j}} + (z - f(x_0, y_0))\,\hat{\mathbf{k}}) &= 0 \\
(f_x(x_0, y_0)\,\hat{\mathbf{i}} + f_y(x_0, y_0)\,\hat{\mathbf{j}} - \hat{\mathbf{k}}) \cdot ((x - x_0)\,\hat{\mathbf{i}} + (y - y_0)\,\hat{\mathbf{j}} + (z - f(x_0, y_0))\,\hat{\mathbf{k}}) &= 0 \\
f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0) - (z - f(x_0, y_0)) &= 0.
\end{aligned}$$

Solving this equation for $z$ gives Equation 14.5.1.

**Example 14.5.1: Finding a Tangent Plane**

Find the equation of the tangent plane to the surface defined by the function $f(x, y) = 2x^2 - 3xy + 8y^2 + 2x - 4y + 4$ at point $(2, -1)$.

**Solution**

First, we must calculate $f_x(x, y)$ and $f_y(x, y)$, then use Equation with $x_0 = 2$ and $y_0 = -1$:

$$\begin{aligned}
f_x(x, y) &= 4x - 3y + 2 \\
f_y(x, y) &= -3x + 16y - 4 \\
f(2, -1) &= 2(2)^2 - 3(2)(-1) + 8(-1)^2 + 2(2) - 4(-1) + 4 = 34 \\
f_x(2, -1) &= 4(2) - 3(-1) + 2 = 13 \\
f_y(2, -1) &= -3(2) + 16(-1) - 4 = -26.
\end{aligned}$$

Then Equation 14.5.1 becomes

$$\begin{aligned}
z &= f(x_0, y_0) + f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0) \\
z &= 34 + 13(x - 2) - 26(y - (-1)) \\
z &= 34 + 13x - 26 - 26y - 26 \\
z &= 13x - 26y - 18.
\end{aligned}$$

(See the following figure).

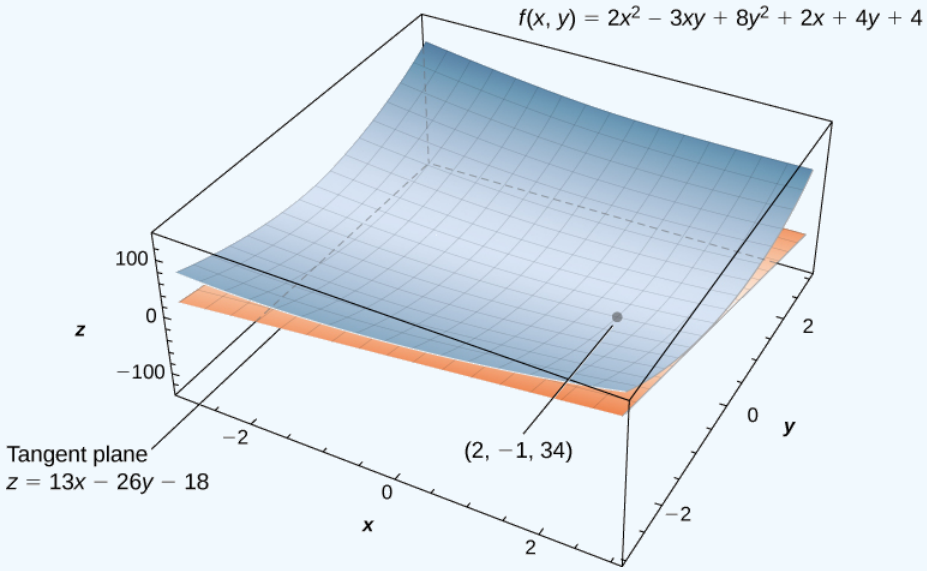

Figure **14.5.2**: Calculating the equation of a tangent plane to a given surface at a given point.

## ? Exercise 14.5.1

Find the equation of the tangent plane to the surface defined by the function $f(x,y) = x^3 - x^2y + y^2 - 2x + 3y - 2$ at point $(-1,3)$.

**Hint**

First, calculate $f_x(x,y)$ and $f_y(x,y)$, then use Equation 14.5.1.

**Answer**

$z = 7x + 8y - 3$

## ✓ Example 14.5.2: Finding Another Tangent Plane

Find the equation of the tangent plane to the surface defined by the function $f(x,y) = \sin(2x)\cos(3y)$ at the point $(\pi/3, \pi/4)$.

### Solution

First, calculate $f_x(x,y)$ and $f_y(x,y)$, then use Equation 14.5.1 with $x_0 = \pi/3$ and $y_0 = \pi/4$:

$$f_x(x,y) = 2\cos(2x)\cos(3y)$$
$$f_y(x,y) = -3\sin(2x)\sin(3y)$$
$$f\left(\frac{\pi}{3},\frac{\pi}{4}\right) = \sin\left(2\left(\frac{\pi}{3}\right)\right)\cos\left(3\left(\frac{\pi}{4}\right)\right) = \left(\frac{\sqrt{3}}{2}\right)\left(-\frac{\sqrt{2}}{2}\right) = -\frac{\sqrt{6}}{4}$$
$$f_x\left(\frac{\pi}{3},\frac{\pi}{4}\right) = 2\cos\left(2\left(\frac{\pi}{3}\right)\right)\cos\left(3\left(\frac{\pi}{4}\right)\right) = 2\left(-\frac{1}{2}\right)\left(-\frac{\sqrt{2}}{2}\right) = \frac{\sqrt{2}}{2}$$
$$f_y\left(\frac{\pi}{3},\frac{\pi}{4}\right) = -3\sin\left(2\left(\frac{\pi}{3}\right)\right)\sin\left(3\left(\frac{\pi}{4}\right)\right) = -3\left(\frac{\sqrt{3}}{2}\right)\left(\frac{\sqrt{2}}{2}\right) = -\frac{3\sqrt{6}}{4}.$$

Then Equation 14.5.1 becomes

$$z = f(x_0, y_0) + f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0)$$
$$= -\frac{\sqrt{6}}{4} + \frac{\sqrt{2}}{2}\left(x - \frac{\pi}{3}\right) - \frac{3\sqrt{6}}{4}\left(y - \frac{\pi}{4}\right)$$
$$= \frac{\sqrt{2}}{2}x - \frac{3\sqrt{6}}{4}y - \frac{\sqrt{6}}{4} - \frac{\pi\sqrt{2}}{6} + \frac{3\pi\sqrt{6}}{16}$$

A tangent plane to a surface does not always exist at every point on the surface. Consider the piecewise function

$$f(x,y) = \begin{cases} \dfrac{xy}{\sqrt{x^2+y^2}}, & (x,y) \neq (0,0) \\ 0, & (x,y) = (0,0) \end{cases}. \tag{14.5.2}$$

The graph of this function follows.

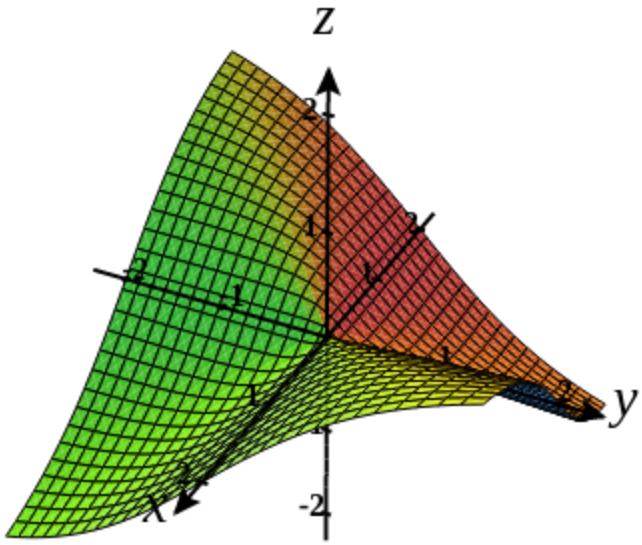

***Figure* 14.5.3:** *Graph of a function that does not have a tangent plane at the origin. Dynamic figure powered by CalcPlot3D.*

If either $x = 0$ or $y = 0$, then $f(x,y) = 0$, so the value of the function does not change on either the $x$- or $y$-axis. Therefore, $f_x(x,0) = f_y(0,y) = 0$, so as either $x$ or $y$ approach zero, these partial derivatives stay equal to zero. Substituting them into Equation gives $z = 0$ as the equation of the tangent line. However, if we approach the origin from a different direction, we get a different story. For example, suppose we approach the origin along the line $y = x$. If we put $y = x$ into the original function, it becomes

$$f(x,x) = \frac{x(x)}{\sqrt{x^2 + (x)^2}} = \frac{x^2}{\sqrt{2x^2}} = \frac{|x|}{\sqrt{2}}.$$

When $x > 0$, the slope of this curve is equal to $\sqrt{2}/2$; when $x < 0$, the slope of this curve is equal to $-(\sqrt{2}/2)$. This presents a problem. In the definition of tangent plane, we presumed that all tangent lines through point $P$ (in this case, the origin) lay in the

same plane. This is clearly not the case here. When we study differentiable functions, we will see that this function is not differentiable at the origin.

## Linear Approximations

Recall from Linear Approximations and Differentials that the formula for the linear approximation of a function $f(x)$ at the point $x = a$ is given by

$$y \approx f(a) + f'(a)(x - a).$$

The diagram for the linear approximation of a function of one variable appears in the following graph.

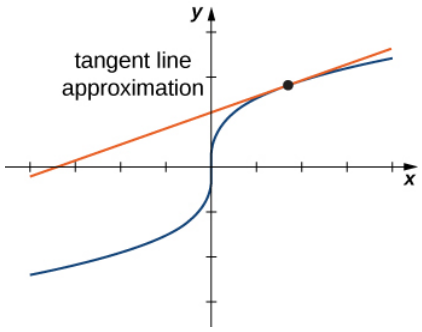

Figure 14.5.4: Linear approximation of a function in one variable.

The tangent line can be used as an approximation to the function $f(x)$ for values of $x$ reasonably close to $x = a$. When working with a function of two variables, the tangent line is replaced by a tangent plane, but the approximation idea is much the same.

**Definition: Linear Approximation**

Given a function $z = f(x, y)$ with continuous partial derivatives that exist at the point $(x_0, y_0)$, the linear approximation of $f$ at the point $(x_0, y_0)$ is given by the equation

$$L(x, y) = f(x_0, y_0) + f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0). \tag{14.5.3}$$

Notice that this equation also represents the tangent plane to the surface defined by $z = f(x, y)$ at the point $(x_0, y_0)$. The idea behind using a linear approximation is that, if there is a point $(x_0, y_0)$ at which the precise value of $f(x, y)$ is known, then for values of $(x, y)$ reasonably close to $(x_0, y_0)$, the linear approximation (i.e., tangent plane) yields a value that is also reasonably close to the exact value of $f(x, y)$ (Figure 14.5.5). Furthermore the plane that is used to find the linear approximation is also the tangent plane to the surface at the point $(x_0, y_0)$.

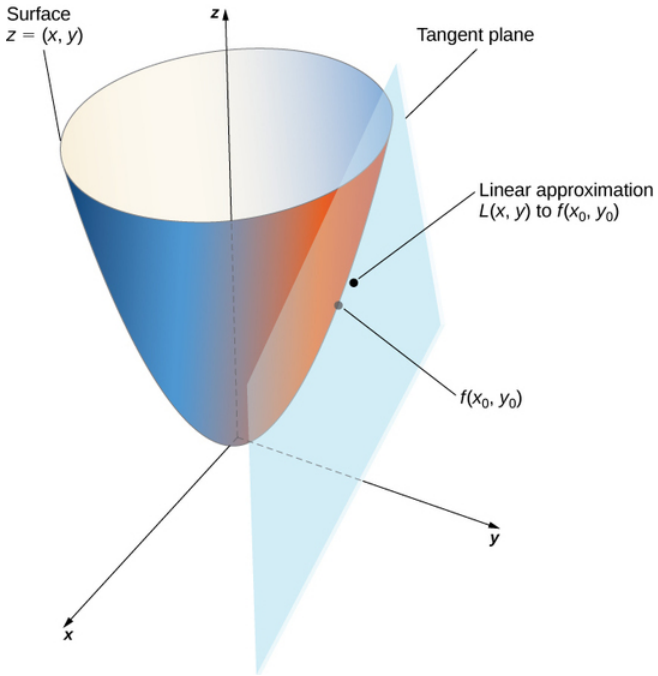

Figure 14.5.5: Using a tangent plane for linear approximation at a point.

## Example 14.5.3: Using a Tangent Plane Approximation

Given the function $f(x,y) = \sqrt{41-4x^2-y^2}$, approximate $f(2.1, 2.9)$ using point $(2,3)$ for $(x_0, y_0)$. What is the approximate value of $f(2.1, 2.9)$ to four decimal places?

### Solution

To apply Equation 14.5.3, we first must calculate $f(x_0,y_0)$, $f_x(x_0,y_0)$, and $f_y(x_0,y_0)$ using $x_0 = 2$ and $y_0 = 3$:

$$f(x_0,y_0) = f(2,3) = \sqrt{41-4(2)^2-(3)^2} = \sqrt{41-16-9} = \sqrt{16} = 4$$

$$f_x(x,y) = -\frac{4x}{\sqrt{41-4x^2-y^2}} \text{ so } f_x(x_0,y_0) = -\frac{4(2)}{\sqrt{41-4(2)^2-(3)^2}} = -2$$

$$f_y(x,y) = -\frac{y}{\sqrt{41-4x^2-y^2}} \text{ so } f_y(x_0,y_0) = -\frac{3}{\sqrt{41-4(2)^2-(3)^2}} = -\frac{3}{4}.$$

Now we substitute these values into Equation 14.5.3:

$$\begin{aligned} L(x,y) &= f(x_0,y_0) + f_x(x_0,y_0)(x-x_0) + f_y(x_0,y_0)(y-y_0) \\ &= 4 - 2(x-2) - \frac{3}{4}(y-3) \\ &= \frac{41}{4} - 2x - \frac{3}{4}y. \end{aligned}$$

Last, we substitute $x = 2.1$ and $y = 2.9$ into $L(x,y)$:

$$L(2.1, 2.9) = \frac{41}{4} - 2(2.1) - \frac{3}{4}(2.9) = 10.25 - 4.2 - 2.175 = 3.875.$$

The approximate value of $f(2.1, 2.9)$ to four decimal places is

$$f(2.1, 2.9) = \sqrt{41-4(2.1)^2-(2.9)^2} = \sqrt{14.95} \approx 3.8665,$$

which corresponds to a 0.2 error in approximation.

**? Exercise 14.5.2**

Given the function $f(x,y) = e^{5-2x+3y}$, approximate $f(4.1, 0.9)$ using point $(4,1)$ for $(x_0, y_0)$. Also state the approximate value of $f(4.1, 0.9)$ to four decimal places to compare the two values.

**Hint**

First calculate $f(x_0, y_0)$, $f_x(x_0, y_0)$, and $f_y(x_0, y_0)$ using $x_0 = 4$ and $y_0 = 1$, then use Equation 14.5.3.

**Answer**

$L(x,y) = 6 - 2x + 3y$, so $L(4.1, 0.9) = 6 - 2(4.1) + 3(0.9) = 0.5$
Note that $f(4.1, 0.9) = e^{5-2(4.1)+3(0.9)} = e^{-0.5} \approx 0.6065$.

## Differentiability

When working with a function $y = f(x)$ of one variable, the function is said to be differentiable at a point $x = a$ if $f'(a)$ exists. Furthermore, if a function of one variable is differentiable at a point, the graph is "smooth" at that point (i.e., no corners exist) and a tangent line is well-defined at that point.

The idea behind differentiability of a function of two variables is connected to the idea of smoothness at that point. In this case, a surface is considered to be smooth at point $P$ if a tangent plane to the surface exists at that point. If a function is differentiable at a point, then a tangent plane to the surface exists at that point. Recall the formula (Equation 14.5.1) for a tangent plane at a point $(x_0, y_0)$ is given by

$$z = f(x_0, y_0) + f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0)$$

For a tangent plane to exist at the point $(x_0, y_0)$, the partial derivatives must therefore exist at that point. However, this is not a sufficient condition for smoothness, as was illustrated in Figure 14.5.3. In that case, the partial derivatives existed at the origin, but the function also had a corner on the graph at the origin.

**Definition: Differentiable Functions**

A function $f(x,y)$ is *differentiable* at a point $P(x_0, y_0)$ if, for all points $(x,y)$ in a $\delta$ disk around $P$, we can write

$$f(x,y) = f(x_0, y_0) + f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0) + E(x,y), \tag{14.5.4}$$

where the error term $E$ satisfies

$$\lim_{(x,y)\to(x_0,y_0)} \frac{E(x,y)}{\sqrt{(x-x_0)^2 + (y-y_0)^2}} = 0. \tag{14.5.5}$$

The last term in Equation 14.5.4 is referred to as the **error term.** It represents how closely the tangent plane comes to the surface in a small neighborhood ($\delta$ disk) of point $P$. For the function $f$ to be differentiable at $P$, the function must be smooth—that is, the graph of $f$ must be close to the tangent plane for points near $P$.

**Example 14.5.4: Demonstrating Differentiability**

Show that the function $f(x,y) = 2x^2 - 4y$ is differentiable at point $(2, -3)$.

**Solution**

First, we calculate $f(x_0, y_0)$, $f_x(x_0, y_0)$, and $f_y(x_0, y_0)$ using $x_0 = 2$ and $y_0 = -3$, then we use Equation 14.5.4:

$$f(2,-3) = 2(2)^2 - 4(-3) = 8 + 12 = 20$$
$$f_x(2,-3) = 4(2) = 8$$
$$f_y(2,-3) = -4.$$

Therefore $m_1 = 8$ and $m_2 = -4$, and Equation 14.5.4 becomes

$$
\begin{aligned}
f(x,y) &= f(2,-3) + f_x(2,-3)(x-2) + f_y(2,-3)(y+3) + E(x,y) \\
2x^2 - 4y &= 20 + 8(x-2) - 4(y+3) + E(x,y) \\
2x^2 - 4y &= 20 + 8x - 16 - 4y - 12 + E(x,y) \\
2x^2 - 4y &= 8x - 4y - 8 + E(x,y) \\
E(x,y) &= 2x^2 - 8x + 8.
\end{aligned}
$$

Next, we calculate the limit in Equation 14.5.5:

$$
\begin{aligned}
\lim_{(x,y)\to(x_0,y_0)} \frac{E(x,y)}{\sqrt{(x-x_0)^2+(y-y_0)^2}} &= \lim_{(x,y)\to(2,-3)} \frac{2x^2-8x+8}{\sqrt{(x-2)^2+(y+3)^2}} \\
&= \lim_{(x,y)\to(2,-3)} \frac{2(x^2-4x+4)}{\sqrt{(x-2)^2+(y+3)^2}} \\
&= \lim_{(x,y)\to(2,-3)} \frac{2(x-2)^2}{\sqrt{(x-2)^2+(y+3)^2}} \\
&\le \lim_{(x,y)\to(2,-3)} \frac{2((x-2)^2+(y+3)^2)}{\sqrt{(x-2)^2+(y+3)^2}} \\
&= \lim_{(x,y)\to(2,-3)} 2\sqrt{(x-2)^2+(y+3)^2} \\
&= 0.
\end{aligned}
$$

Since $E(x,y) \ge 0$ for any value of $x$ or $y$, the original limit must be equal to zero. Therefore, $f(x,y) = 2x^2 - 4y$ is differentiable at point $(2,-3)$.

## ? Exercise 14.5.3

Show that the function $f(x,y) = 3x - 4y^2$ is differentiable at point $(-1,2)$.

**Hint**

First, calculate $f(x_0,y_0)$, $f_x(x_0,y_0)$, and $f_y(x_0,y_0)$ using $x_0 = -1$ and $y_0 = 2$, then use Equation 14.5.5 to find $E(x,y)$.

Since you will find that $E(x,y) \le 0$, show

$$
\lim_{(x,y)\to(x_0,y_0)} \frac{|E(x,y)|}{\sqrt{(x-x_0)^2+(y-y_0)^2}} = 0
$$

**Answer**

$$
f(-1,2) = -19, \quad f_x(-1,2) = 3, \quad f_y(-1,2) = -16, \quad E(x,y) = -4(y-2)^2.
$$

$$
\begin{aligned}
\lim_{(x,y)\to(x_0,y_0)} \frac{|E(x,y)|}{\sqrt{(x-x_0)^2+(y-y_0)^2}} &= \lim_{(x,y)\to(-1,2)} \frac{|-4(y-2)^2|}{\sqrt{(x+1)^2+(y-2)^2}} \\
&= \lim_{(x,y)\to(-1,2)} \frac{4(y-2)^2}{\sqrt{(x+1)^2+(y-2)^2}} \\
&\le \lim_{(x,y)\to(-1,2)} \frac{4((x+1)^2+(y-2)^2)}{\sqrt{(x+1)^2+(y-2)^2}} \\
&= \lim_{(x,y)\to(-1,2)} 4\sqrt{(x+1)^2+(y-2)^2} \\
&= 0.
\end{aligned}
$$

Since $\lim_{(x,y)\to(x_0,y_0)} \frac{|E(x,y)|}{\sqrt{(x-x_0)^2+(y-y_0)^2}} = 0$, we know it's also true that

$$
\lim_{(x,y)\to(x_0,y_0)} \frac{E(x,y)}{\sqrt{(x-x_0)^2+(y-y_0)^2}} = 0
$$

Therefore, $f(x,y) = 3x - 4y^2$ is differentiable at point $(-1, 2)$.

This function from (Equation 14.5.2)

$$f(x,y) = \begin{cases} \dfrac{xy}{\sqrt{x^2+y^2}}, & (x,y) \neq (0,0) \\ 0, & (x,y) = (0,0) \end{cases}$$

is not differentiable at the origin (Figure 14.5.3). We can see this by calculating the partial derivatives. This function appeared earlier in the section, where we showed that $f_x(0,0) = f_y(0,0) = 0$. Substituting this information into Equations 14.5.4 and 14.5.5 using $x_0 = 0$ and $y_0 = 0$, we get

$$f(x,y) = f(0,0) + f_x(0,0)(x-0) + f_y(0,0)(y-0) + E(x,y)$$
$$E(x,y) = \frac{xy}{\sqrt{x^2+y^2}}.$$

Calculating

$$\lim_{(x,y)\to(x_0,y_0)} \frac{E(x,y)}{\sqrt{(x-x_0)^2+(y-y_0)^2}}$$

gives

$$\lim_{(x,y)\to(x_0,y_0)} \frac{E(x,y)}{\sqrt{(x-x_0)^2+(y-y_0)^2}} = \lim_{(x,y)\to(0,0)} \frac{\dfrac{xy}{\sqrt{x^2+y^2}}}{\sqrt{x^2+y^2}}$$
$$= \lim_{(x,y)\to(0,0)} \frac{xy}{x^2+y^2}.$$

Depending on the path taken toward the origin, this limit takes different values. Therefore, the limit does not exist and the function $f$ is not differentiable at the origin as shown in the following figure.

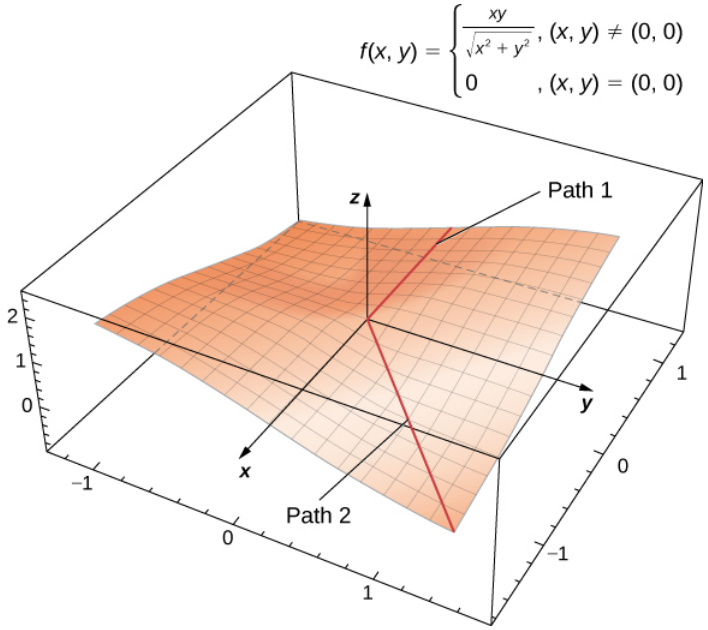

Figure 14.5.6: This function $f(x,y)$ (Equation 14.5.2) is not differentiable at the origin.

Differentiability and continuity for functions of two or more variables are connected, the same as for functions of one variable. In fact, with some adjustments of notation, the basic theorem is the same.

**Theorem 14.5.1: Differentiability Implies Continuity**

Let $z = f(x, y)$ be a function of two variables with $(x_0, y_0)$ in the domain of $f$. If $f(x, y)$ is differentiable at $(x_0, y_0)$, then $f(x, y)$ is continuous at $(x_0, y_0)$.

Theorem 14.5.1 shows that if a function is differentiable at a point, then it is continuous there. However, if a function is continuous at a point, then it is not necessarily differentiable at that point. For example, the function discussed above (Equation 14.5.2)

$$f(x, y) = \begin{cases} \dfrac{xy}{\sqrt{x^2 + y^2}}, & (x, y) \neq (0, 0) \\ 0, & (x, y) = (0, 0) \end{cases}$$

is *continuous* at the origin, but it is *not differentiable* at the origin. This observation is also similar to the situation in single-variable calculus.

We can further explore the connection between continuity and differentiability at a point. This next theorem says that if the function and its partial derivatives are continuous at a point, the function is differentiable.

**Theorem 14.5.2: Continuity of First Partials Implies Differentiability**

Let $z = f(x, y)$ be a function of two variables with $(x_0, y_0)$ in the domain of $f$. If $f(x, y)$, $f_x(x, y)$, and $f_y(x, y)$ all exist in a neighborhood of $(x_0, y_0)$ and are continuous at $(x_0, y_0)$, then $f(x, y)$ is differentiable there.

Recall that earlier we showed that the function in Equation 14.5.2 was not differentiable at the origin. Let's calculate the partial derivatives $f_x$ and $f_y$:

$$\frac{\partial f}{\partial x} = \frac{y^3}{(x^2 + y^2)^{3/2}}$$

and

$$\frac{\partial f}{\partial y} = \frac{x^3}{(x^2 + y^2)^{3/2}}.$$

The contrapositive of the preceding theorem states that if a function is not differentiable, then at least one of the hypotheses must be false. Let's explore the condition that $f_x(0, 0)$ must be continuous. For this to be true, it must be true that

$$\lim_{(x,y)\to(0,0)} f_x(x, y) = f_x(0, 0)$$

therefor

$$\lim_{(x,y)\to(0,0)} f_x(x, y) = \lim_{(x,y)\to(0,0)} \frac{y^3}{(x^2 + y^2)^{3/2}}.$$

Let $x = ky$. Then

$$\begin{aligned} \lim_{(x,y)\to(0,0)} \frac{y^3}{(x^2 + y^2)^{3/2}} &= \lim_{y\to 0} \frac{y^3}{((ky)^2 + y^2)^{3/2}} \\ &= \lim_{y\to 0} \frac{y^3}{(k^2y^2 + y^2)^{3/2}} \\ &= \lim_{y\to 0} \frac{y^3}{|y|^3(k^2 + 1)^{3/2}} \\ &= \frac{1}{(k^2 + 1)^{3/2}} \lim_{y\to 0} \frac{|y|}{y}. \end{aligned}$$

If $y > 0$, then this expression equals $1/(k^2 + 1)^{3/2}$; if $y < 0$, then it equals $-(1/(k^2 + 1)^{3/2})$. In either case, the value depends on $k$, so the limit fails to exist.

## Differentials

In Linear Approximations and Differentials we first studied the concept of differentials. The differential of $y$, written $dy$, is defined as $f'(x)dx$. The differential is used to approximate $\Delta y = f(x + \Delta x) - f(x)$, where $\Delta x = dx$. Extending this idea to the linear approximation of a function of two variables at the point $(x_0, y_0)$ yields the formula for the total differential for a function of two variables.

### Definition: Total Differential

Let $z = f(x, y)$ be a function of two variables with $(x_0, y_0)$ in the domain of $f$, and let $\Delta x$ and $\Delta y$ be chosen so that $(x_0 + \Delta x, y_0 + \Delta y)$ is also in the domain of $f$. If $f$ is differentiable at the point $(x_0, y_0)$, then the differentials $dx$ and $dy$ are defined as

$$dx = \Delta x$$

and

$$dy = \Delta y.$$

The differential $dz$, also called the ***total differential*** of $z = f(x, y)$ at $(x_0, y_0)$, is defined as

$$dz = f_x(x_0, y_0)dx + f_y(x_0, y_0)dy. \tag{14.5.6}$$

Notice that the symbol $\partial$ is not used to denote the total differential; rather, $d$ appears in front of $z$. Now, let's define $\Delta z = f(x + \Delta x, y + \Delta y) - f(x, y)$. We use $dz$ to approximate $\Delta z$, so

$$\Delta z \approx dz = f_x(x_0, y_0)dx + f_y(x_0, y_0)dy.$$

Therefore, the differential is used to approximate the change in the function $z = f(x_0, y_0)$ at the point $(x_0, y_0)$ for given values of $\Delta x$ and $\Delta y$. Since $\Delta z = f(x + \Delta x, y + \Delta y) - f(x, y)$, this can be used further to approximate $f(x + \Delta x, y + \Delta y)$ :

$$f(x + \Delta x, y + \Delta y) = f(x, y) + \Delta z \approx f(x, y) + f_x(x_0, y_0)\Delta x + f_y(x_0, y_0)\Delta y.$$

See the following figure.

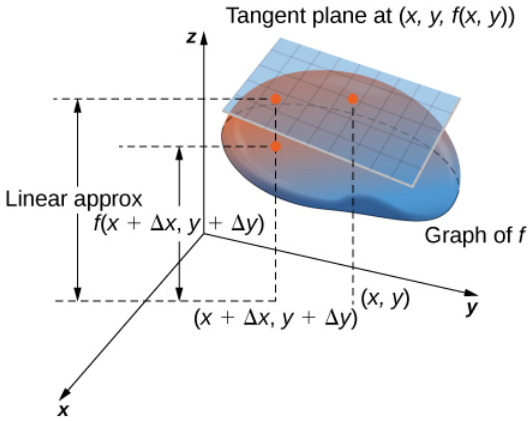

Figure 14.5.7: The linear approximation is calculated via the formula $f(x + \Delta x, y + \Delta y) \approx f(x, y) + f_x(x_0, y_0)\Delta x + f_y(x_0, y_0)\Delta y$.

One such application of this idea is to determine error propagation. For example, if we are manufacturing a gadget and are off by a certain amount in measuring a given quantity, the differential can be used to estimate the error in the total volume of the gadget.

### Example 14.5.5: Approximation by Differentials

Find the differential $dz$ of the function $f(x, y) = 3x^2 - 2xy + y^2$ and use it to approximate $\Delta z$ at point $(2, -3)$. Use $\Delta x = 0.1$ and $\Delta y = -0.05$. What is the exact value of $\Delta z$?

**Solution**

First, we must calculate $f(x_0, y_0)$, $f_x(x_0, y_0)$, and $f_y(x_0, y_0)$ using $x_0 = 2$ and $y_0 = -3$ :

$$f(x_0, y_0) = f(2, -3) = 3(2)^2 - 2(2)(-3) + (-3)^2 = 12 + 12 + 9 = 33$$
$$f_x(x, y) = 6x - 2y$$
$$f_y(x, y) = -2x + 2y$$
$$\begin{aligned} f_x(x_0, y_0) &= fx(2, -3) \\ &= 6(2) - 2(-3) = 12 + 6 = 18 \end{aligned}$$
$$\begin{aligned} f_y(x_0, y_0) &= f_y(2, -3) \\ &= -2(2) + 2(-3) \\ &= -4 - 6 = -10. \end{aligned}$$

Then, we substitute these quantities into Equation 14.5.6:

$$dz = f_x(x_0, y_0)dx + f_y(x_0, y_0)dy$$
$$dz = 18(0.1) - 10(-0.05) = 1.8 + 0.5 = 2.3.$$

This is the approximation to $\Delta z = f(x_0 + \Delta x, y_0 + \Delta y) - f(x_0, y_0)$. The exact value of $\Delta z$ is given by

$$\begin{aligned} \Delta z &= f(x_0 + \Delta x, y_0 + \Delta y) - f(x_0, y_0) \\ &= f(2 + 0.1, -3 - 0.05) - f(2, -3) \\ &= f(2.1, -3.05) - f(2, -3) \\ &= 2.3425. \end{aligned}$$

**? Exercise 14.5.4**

Find the differential $dz$ of the function $f(x, y) = 4y^2 + x^2y - 2xy$ and use it to approximate $\Delta z$ at point $(1, -1)$. Use $\Delta x = 0.03$ and $\Delta y = -0.02$. What is the exact value of $\Delta z$?

**Hint**

First, calculate $f_x(x_0, y_0)$ and $f_y(x_0, y_0)$ using $x_0 = 1$ and $y_0 = -1$, then use Equation 14.5.6.

**Answer**

$dz = 0.18$

$\Delta z = f(1.03, -1.02) - f(1, -1) = 0.180682$

## Differentiability of a Function of Three Variables

All of the preceding results for differentiability of functions of two variables can be generalized to functions of three variables. First, the definition:

**Definition: Differentiability at a Point**

A function $f(x, y, z)$ is differentiable at a point $P(x_0, y_0, z_0)$ if for all points $(x, y, z)$ in a $\delta$ disk around $P$ we can write

$$\begin{aligned} f(x, y) = f(x_0, y_0, z_0) + f_x(x_0, y_0, z_0)(x - x_0) + f_y(x_0, y_0, z_0)(y - y_0) \\ + f_z(x_0, y_0, z_0)(z - z_0) + E(x, y, z), \end{aligned}$$

where the error term $E$ satisfies

$$\lim_{(x,y,z)\to(x_0,y_0,z_0)} \frac{E(x, y, z)}{\sqrt{(x - x_0)^2 + (y - y_0)^2 + (z - z_0)^2}} = 0.$$

If a function of three variables is differentiable at a point $(x_0, y_0, z_0)$, then it is continuous there. Furthermore, continuity of first partial derivatives at that point guarantees differentiability.

## Key Concepts

- The analog of a tangent line to a curve is a tangent plane to a surface for functions of two variables.
- Tangent planes can be used to approximate values of functions near known values.
- A function is differentiable at a point if it is ”smooth” at that point (i.e., no corners or discontinuities exist at that point).
- The total differential can be used to approximate the change in a function $z = f(x_0, y_0)$ at the point $(x_0, y_0)$ for given values of $\Delta x$ and $\Delta y$.

## Key Equations

- **Tangent plane**

  $$z = f(x_0, y_0) + f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0)$$

- **Linear approximation**

  $$L(x, y) = f(x_0, y_0) + f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0)$$

- **Total differential**

  $$dz = f_x(x_0, y_0)dx + f_y(x_0, y_0)dy.$$

- **Differentiability (two variables)**

  $$f(x, y) = f(x_0, y_0) + f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0) + E(x, y),$$

  where the error term $E$ satisfies

  $$\lim_{(x,y)\to(x_0,y_0)} \frac{E(x, y)}{\sqrt{(x - x_0)^2 + (y - y_0)^2}} = 0.$$

- **Differentiability (three variables)**

  $$f(x, y) = f(x_0, y_0, z_0) + f_x(x_0, y_0, z_0)(x - x_0) + f_y(x_0, y_0, z_0)(y - y_0) + f_z(x_0, y_0, z_0)(z - z_0) + E(x, y, z),$$

  where the error term $E$ satisfies

  $$\lim_{(x,y,z)\to(x_0,y_0,z_0)} \frac{E(x, y, z)}{\sqrt{(x - x_0)^2 + (y - y_0)^2 + (z - z_0)^2}} = 0.$$

## Glossary

**differentiable**

a function $f(x, y)$ is differentiable at $(x_0, y_0)$ if $f(x, y)$ can be expressed in the form $f(x, y) = f(x_0, y_0) + f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0) + E(x, y)$,

where the error term $E(x, y)$ satisfies $\lim_{(x,y)\to(x_0,y_0)} \frac{E(x, y)}{\sqrt{(x - x_0)^2 + (y - y_0)^2}} = 0$

**linear approximation**

given a function $f(x, y)$ and a tangent plane to the function at a point $(x_0, y_0)$, we can approximate $f(x, y)$ for points near $(x_0, y_0)$ using the tangent plane formula

**tangent plane**

given a function $f(x, y)$ that is differentiable at a point $(x_0, y_0)$, the equation of the tangent plane to the surface $z = f(x, y)$ is given by $z = f(x_0, y_0) + f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0)$

**total differential**

the total differential of the function $f(x, y)$ at $(x_0, y_0)$ is given by the formula $dz = f_x(x_0, y_0)dx + fy(x_0, y_0)dy$

# 14.5E: Exercises for Section 14.4

**In exercises 1 - 2, find a unit normal vector to the surface at the indicated point.**

1) $f(x,y)=x^3, \quad (2,-1,8)$

**Answer**

$(\frac{\sqrt{145}}{145})(12\hat{\mathbf{i}}-\hat{\mathbf{k}})$

2) $\ln\left(\frac{x}{y-z}\right)=0$ when $x=y=1$

**In exercises 3 - 7, find a normal vector and a tangent vector at point $P$.**

3) $x^2+xy+y^2=3, \quad P(-1,-1)$

**Answer**

Normal vector: $\hat{\mathbf{i}}+\hat{\mathbf{j}}$, tangent vector: $\hat{\mathbf{i}}-\hat{\mathbf{j}}$

4) $(x^2+y^2)^2=9(x^2-y^2), \quad P(\sqrt{2},1)$

5) $xy^2-2x^2+y+5x=6, \quad P(4,2)$

**Answer**

Normal vector: $7\hat{\mathbf{i}}-17\hat{\mathbf{j}}$, tangent vector: $17\hat{\mathbf{i}}+7\hat{\mathbf{j}}$

6) $2x^3-x^2y^2=3x-y-7, \quad P(1,-2)$

7) $ze^{x^2-y^2}-3=0, \quad P(2,2,3)$

**Answer**

Normal vector: $-12\hat{\mathbf{i}}+12\hat{\mathbf{j}}-\hat{\mathbf{k}}$ or $12\hat{\mathbf{i}}-12\hat{\mathbf{j}}+\hat{\mathbf{k}}$,
Tangent vector: $0\hat{\mathbf{i}}+1\hat{\mathbf{j}}+12\hat{\mathbf{k}}$ or $1\hat{\mathbf{i}}+0\hat{\mathbf{j}}-12\hat{\mathbf{k}}$

**In exercises 8 - 19, find the equation for the tangent plane to the surface at the indicated point. (Hint: If the given function is not already solved for $z$, start by solving it for $z$ in terms of $x$ and $y$.)**

8) $-8x-3y-7z=-19, \quad P(1,-1,2)$

9) $z=-9x^2-3y^2, \quad P(2,1,-39)$

**Answer**

$-36x-6y-z=-39$

10) $x^2+10xyz+y^2+8z^2=0, \quad P(-1,-1,-1)$

11) $z=\ln(10x^2+2y^2+1), \quad P(0,0,0)$

**Answer**

$z=0$

12) $z=e^{7x^2+4y^2}, \quad P(0,0,1)$

13) $xy+yz+zx=11, \quad P(1,2,3)$

**Answer**

$5x+4y+3z-22=0$

14) $x^2+4y^2=z^2, \quad P(3,2,5)$

15) $x^3 + y^3 = 3xyz, \quad P(1, 2, \frac{3}{2})$

**Answer**

$4x - 5y + 4z = 0$

16) $z = axy, \quad P(1, \frac{1}{a}, 1)$

17) $z = \sin x + \sin y + \sin(x + y), \quad P(0, 0, 0)$

**Answer**

$2x + 2y - z = 0$

18) $h(x, y) = \ln \sqrt{x^2 + y^2}, \quad P(3, 4)$

19) $z = x^2 - 2xy + y^2, \quad P(1, 2, 1)$

**Answer**

$-2(x - 1) + 2(y - 2) - (z - 1) = 0$

**In exercises 20 - 25, find parametric equations for the normal line to the surface at the indicated point. (Recall that to find the equation of a line in space, you need a point on the line, $P_0(x_0, y_0, z_0)$, and a vector $\vec{\mathbf{v}} = \langle a, b, c \rangle$ that is parallel to the line. Then the equations of the line are: $x = x_0 + at, \quad y = y_0 + bt, \quad z = z_0 + ct.$)**

20) $-3x + 9y + 4z = -4, \quad P(1, -1, 2)$

21) $z = 5x^2 - 2y^2, \quad P(2, 1, 18)$

**Answer**

$x = 20t + 2, y = -4t + 1, z = -t + 18$

22) $x^2 - 8xyz + y^2 + 6z^2 = 0, \quad P(1, 1, 1)$

23) $z = \ln(3x^2 + 7y^2 + 1), \quad P(0, 0, 0)$

**Answer**

$x = 0, y = 0, z = t$

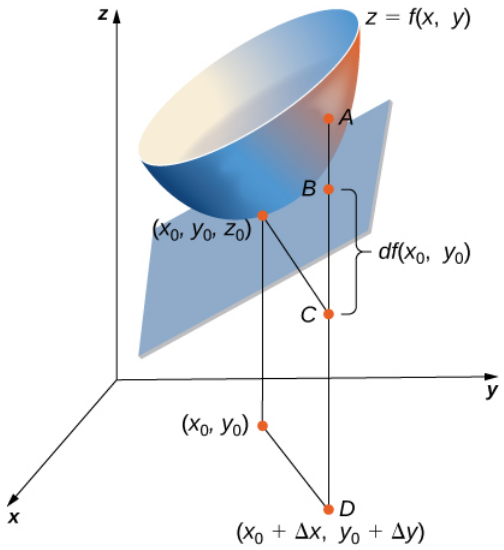
24) $z = e^{4x^2 + 6y^2}, \quad P(0, 0, 1)$

25) $z = x^2 - 2xy + y^2$ at point $P(1, 2, 1)$

**Answer**

$x - 1 = 2t; y - 2 = -2t; z - 1 = t$

**In exercises 26 - 28, use the figure shown here.**



26) The length of line segment $AC$ is equal to what mathematical expression?

27) The length of line segment $BC$ is equal to what mathematical expression?

**Answer**

The differential of the function $z(x,y) = dz = f_x dx + f_y dy$

28) Using the figure, explain what the length of line segment $AB$ represents.

29) Show that $f(x,y) = e^{xy}x$ is differentiable at point $(1,0)$.

**Answer**

Using the definition of differentiability, we have $e^{xy}x \approx x + y$.

30) Show that $f(x,y) = x^2 + 3y$ is differentiable at every point. In other words, show that $\Delta z = f(x + \Delta x, y + \Delta y) - f(x,y) = f_x \Delta x + f_y \Delta y + \varepsilon_1 \Delta x + \varepsilon_2 \Delta y$, where both $\varepsilon_1$ and $\varepsilon_2$ approach zero as $(\Delta x, \Delta y)$ approaches $(0,0)$.

**Answer**

$\Delta z = 2x\Delta x + 3\Delta y + (\Delta x)^2.(\Delta x)^2 \to 0$ for small $\Delta x$ and $z$ satisfies the definition of differentiability.

31) Find the total differential of each function:

a. $z = x^3 + y^3 - 5$
b. $z = e^{xy}$
c. $z = y\cos x + \sin y$
d. $P = t^2 + 3t + tu^3$
e. $w = e^y \cos(x) + z^2$

**Answers:**

a. $dz = 3x^2\,dx + 3y^2\,dy$
b. $dz = ye^{xy}\,dx + xe^{xy}\,dy$
c. $dz = -y\sin x\,dx + (\cos x + \cos y)\,dy$
d. $dP = (2t + 3 + u^3)\,dt + 3tu^2\,du$
e. $dw = -e^y \sin(x)\,dx + e^y \cos(x)\,dy + 2z\,dz$

32) a. Find the total differential $dz$ of the function $z = \dfrac{xy}{y + x}$ and then

b. State its value where $x$ changes from $10$ to $10.5$ and $y$ changes from $15$ to $13$.

**Answer**

a. $dz = \dfrac{y^2}{(x+y)^2}\,dx + \dfrac{x^2}{(x+y)^2}\,dy$
b. $dx = 0.5$ and $dy = -2$ so

$$\begin{aligned} dz &= f_x(10,15)\,dx + f_y(10,15)\,dy \\ &= \frac{15^2}{25^2}\,dx + \frac{10^2}{25^2}\,dy \\ &= \frac{225}{625}\,(0.5) + \frac{100}{625}(-2) \\ &= \frac{9}{25}\left(\frac{1}{2}\right) + \frac{4}{25}(-2) \\ &= \frac{18}{100} - \frac{32}{100} \\ &= .18 - .32 = -0.14 \end{aligned}$$

33) Let $z = f(x,y) = xe^y$. State its total differential. Then compute $\Delta z$ from $P(1,2)$ to $Q(1.05, 2.1)$ and then find the approximate change in $z$, $dz$, from point $P$ to point $Q$. Recall $\Delta z = f(x + \Delta x, y + \Delta y) - f(x,y)$, and $dz$ and $\Delta z$ should be approximately equal, if $dx$ and $dy$ are both reasonably small.

**Answer**

Total Differential: $dz = e^y\,dx + xe^y\,dy$
$\Delta z \approx 1.185422$ and $dz \approx 1.108$. Note that they are relatively close.

34) The volume of a right circular cylinder is given by $V(r,h) = \pi r^2 h$. Find the differential $dV$. Interpret the formula geometrically.

**Answer**

$dV = 2\pi rh\,dr + \pi r^2\,dh$

35) See the preceding problem. Use differentials to estimate the amount of aluminum in an enclosed aluminum can with diameter $8.0cm$ and height $12cm$ if the aluminum is $0.04$ cm thick.

**Answer**

$16\,\text{cm}^3$

36) Use the differential $dz$ to approximate the change in $z = \sqrt{4 - x^2 - y^2}$ as $(x,y)$ moves from point $(1,1)$ to point $(1.01, 0.97)$. Compare this approximation with the actual change in the function.

37) Let $z = f(x,y) = x^2 + 3xy - y^2$. Find the exact change in the function and the approximate change in the function as $x$ changes from $2.00$ to $2.05$ and $y$ changes from $3.00$ to $2.96$.

**Answer**

$\Delta z =$ exact change $= 0.6449$, approximate change is $dz = 0.65$. The two values are close.

38) The centripetal acceleration of a particle moving in a circle is given by $a(r,v) = \frac{v^2}{r}$, where $v$ is the velocity and $r$ is the radius of the circle. Approximate the maximum percent error in measuring the acceleration resulting from errors of $3\%$ in $v$ and $2\%$ in $r$. (Recall that the percentage error is the ratio of the amount of error over the original amount. So, in this case, the percentage error in a is given by $\frac{da}{a}$.)

39) The radius $r$ and height $h$ of a right circular cylinder are measured with possible errors of $4\%$ and $5\%$, respectively. Approximate the maximum possible percentage error in measuring the volume (Recall that the percentage error is the ratio of the amount of error over the original amount. So, in this case, the percentage error in $V$ is given by $\frac{dV}{V}$.)

**Answer**

$13\%$ or $0.13$

40) The base radius and height of a right circular cone are measured as $10$ in. and $25$ in., respectively, with a possible error in measurement of as much as $0.1$ in. each. Use differentials to estimate the maximum error in the calculated volume of the cone.

41) The **electrical resistance** $R$ produced by wiring resistors $R_1$ and $R_2$ in parallel can be calculated from the formula $\frac{1}{R} = \frac{1}{R_1} + \frac{1}{R_2}$. If $R_1$ and $R_2$ are measured to be $7\Omega$ and $6\Omega$, respectively, and if these measurements are accurate to within $0.05\Omega$, estimate the maximum possible error in computing $R$. (The symbol $\Omega$ represents an ohm, the unit of electrical resistance.)

**Answer**

$0.025$

42) The area of an ellipse with axes of length $2a$ and $2b$ is given by the formula $A = \pi ab$. Approximate the percent change in the area when $a$ increases by $2\%$ and $b$ increases by $1.5\%$.

43) The period $T$ of a **simple pendulum** with small oscillations is calculated from the formula $T = 2\pi\sqrt{\frac{L}{g}}$, where $L$ is the length of the pendulum and $g$ is the acceleration resulting from gravity. Suppose that $L$ and $g$ have errors of, at most, $0.5\%$ and $0.1\%$, respectively. Use differentials to approximate the maximum percentage error in the calculated value of $T$.

**Answer**

$0.3\%$

44) **Electrical power** $P$ is given by $P = \frac{V^2}{R}$, where $V$ is the voltage and $R$ is the resistance. Approximate the maximum percentage error in calculating power if $120V$ is applied to a $2000 - \Omega$ resistor and the possible percent errors in measuring $V$ and $R$ are $3\%$ and $4\%$, respectively.

**For exercises 45 - 49, find the linear approximation of each function at the indicated point.**

45) $f(x, y) = x\sqrt{y}, \quad P(1, 4)$

**Answer**

$L(x, y) = 2x + \frac{1}{4}y - 1$

46) $f(x, y) = e^x \cos y; \quad P(0, 0)$

47) $f(x, y) = \arctan(x + 2y), \quad P(1, 0)$

**Answer**

$L(x, y) = \frac{1}{2}x + y + \frac{1}{4}\pi - \frac{1}{2}$

48) $f(x, y) = \sqrt{20 - x^2 - 7y^2}, \quad P(2, 1)$

49) $f(x, y, z) = \sqrt{x^2 + y^2 + z^2}, \quad P(3, 2, 6)$

**Answer**

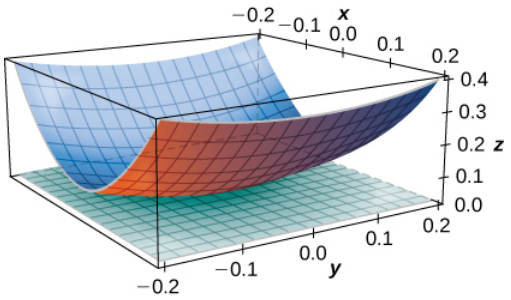
$L(x, y, z) = \frac{3}{7}x + \frac{2}{7}y + \frac{6}{7}z$

50) [T] Find the equation of the tangent plane to the surface $f(x, y) = x^2 + y^2$ at point $(1, 2, 5)$, and graph the surface and the tangent plane at the point.

51) [T] Find the equation for the tangent plane to the surface at the indicated point, and graph the surface and the tangent plane: $z = \ln(10x^2 + 2y^2 + 1), \quad P(0, 0, 0)$.

**Answer**

$z = 0$



52) [T] Find the equation of the tangent plane to the surface $z = f(x, y) = \sin(x + y^2)$ at point $\left(\frac{\pi}{4}, 0, \frac{\sqrt{2}}{2}\right)$, and graph the surface and the tangent plane.

# 14.6: The Chain Rule for Multivariable Functions

**Learning Objectives**

- State the chain rules for one or two independent variables.
- Use tree diagrams as an aid to understanding the chain rule for several independent and intermediate variables.
- Perform implicit differentiation of a function of two or more variables.

In single-variable calculus, we found that one of the most useful differentiation rules is the chain rule, which allows us to find the derivative of the composition of two functions. The same thing is true for multivariable calculus, but this time we have to deal with more than one form of the chain rule. In this section, we study extensions of the chain rule and learn how to take derivatives of compositions of functions of more than one variable.

## Chain Rules for One or Two Independent Variables

Recall that the chain rule for the derivative of a composite of two functions can be written in the form

$$\frac{d}{dx}\Big(f(g(x))\Big) = f'\big(g(x)\big)g'(x).$$

In this equation, both $f(x)$ and $g(x)$ are functions of one variable. Now suppose that $f$ is a function of two variables and $g$ is a function of one variable. Or perhaps they are both functions of two variables, or even more. How would we calculate the derivative in these cases? The following theorem gives us the answer for the case of one independent variable.

**Theorem 14.6.1: Chain Rule for One Independent Variable**

Suppose that $x = g(t)$ and $y = h(t)$ are differentiable functions of $t$ and $z = f(x, y)$ is a differentiable function of $x$ and $y$. Then $z = f(x(t), y(t))$ is a differentiable function of $t$ and

$$\frac{dz}{dt} = \frac{\partial z}{\partial x} \cdot \frac{dx}{dt} + \frac{\partial z}{\partial y} \cdot \frac{dy}{dt}, \tag{14.6.1}$$

where the ordinary derivatives are evaluated at $t$ and the partial derivatives are evaluated at $(x, y)$.

**Proof**

The proof of this theorem uses the definition of differentiability of a function of two variables. Suppose that $f$ is differentiable at the point $P(x_0, y_0)$, where $x_0 = g(t_0)$ and $y_0 = h(t_0)$ for a fixed value of $t_0$. We wish to prove that $z = f\big(x(t), y(t)\big)$ is differentiable at $t = t_0$ and that Equation 14.6.1 holds at that point as well.

Since $f$ is differentiable at $P$, we know that

$$z(t) = f(x, y) = f(x_0, y_0) + f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0) + E(x, y),$$

where

$$\lim_{(x,y)\to(x_0,y_0)} \frac{E(x, y)}{\sqrt{(x - x_0)^2 + (y - y_0)^2}} = 0.$$

We then subtract $z_0 = f(x_0, y_0)$ from both sides of this equation:

$$\begin{aligned} z(t) - z(t_0) &= f(x(t), y(t)) - f(x(t_0), y(t_0)) \\ &= f_x(x_0, y_0)(x(t) - x(t_0)) + f_y(x_0, y_0)(y(t) - y(t_0)) + E(x(t), y(t)). \end{aligned}$$

Next, we divide both sides by $t - t_0$:

$$\frac{z(t) - z(t_0)}{t - t_0} = f_x(x_0, y_0)\frac{x(t) - x(t_0)}{t - t_0} + f_y(x_0, y_0)\frac{y(t) - y(t_0)}{t - t_0} + \frac{E(x(t), y(t))}{t - t_0}.$$

Then we take the limit as $t$ approaches $t_0$:

$$\lim_{t\to t_0}\frac{z(t)-z(t_0)}{t-t_0}=f_x(x_0,y_0)\lim_{t\to t_0}\left(\frac{x(t)-x(t_0)}{t-t_0}\right)+f_y(x_0,y_0)\lim_{t\to t_0}\left(\frac{y(t)-y(t_0)}{t-t_0}\right)+\lim_{t\to t_0}\frac{E(x(t),y(t))}{t-t_0}.$$

The left-hand side of this equation is equal to $dz/dt$, which leads to

$$\frac{dz}{dt}=f_x(x_0,y_0)\frac{dx}{dt}+f_y(x_0,y_0)\frac{dy}{dt}+\lim_{t\to t_0}\frac{E(x(t),y(t))}{t-t_0}.$$

The last term can be rewritten as

$$\begin{aligned}\lim_{t\to t_0}\frac{E(x(t),y(t))}{t-t_0}&=\lim_{t\to t_0}\frac{E(x,y)}{\sqrt{(x-x_0)^2+(y-y_0)^2}}\frac{\sqrt{(x-x_0)^2+(y-y_0)^2}}{t-t_0})\\&=\lim_{t\to t_0}\left(\frac{E(x,y)}{\sqrt{(x-x_0)^2+(y-y_0)^2}}\right)\lim_{t\to t_0}\left(\frac{\sqrt{(x-x_0)^2+(y-y_0)^2}}{t-t_0}\right).\end{aligned}$$

As $t$ approaches $t_0$, $\big(x(t),y(t)\big)$ approaches $\big(x(t_0),y(t_0)\big)$, so we can rewrite the last product as

$$\lim_{(x,y)\to(x_0,y_0)}\frac{E(x,y)}{\sqrt{(x-x_0)^2+(y-y_0)^2}}\lim_{(x,y)\to(x_0,y_0)}\left(\frac{\sqrt{(x-x_0)^2+(y-y_0)^2}}{t-t_0}\right).$$

Since the first limit is equal to zero, we need only show that the second limit is finite:

$$\begin{aligned}\lim_{(x,y)\to(x_0,y_0)}\frac{\sqrt{(x-x_0)^2+(y-y_0)^2}}{t-t_0}&=\lim_{(x,y)\to(x_0,y_0)}\sqrt{\frac{(x-x_0)^2+(y-y_0)^2}{(t-t_0)^2}}\\&=\lim_{(x,y)\to(x_0,y_0)}\sqrt{\left(\frac{x-x_0}{t-t_0}\right)^2+\left(\frac{y-y_0}{t-t_0}\right)^2}\\&=\sqrt{\left[\lim_{(x,y)\to(x_0,y_0)}\left(\frac{x-x_0}{t-t_0}\right)\right]^2+\left[\lim_{(x,y)\to(x_0,y_0)}\left(\frac{y-y_0}{t-t_0}\right)\right]^2}.\end{aligned}$$

Since $x(t)$ and $y(t)$ are both differentiable functions of $t$, both limits inside the last radical exist. Therefore, this value is finite. This proves the chain rule at $t=t_0$; the rest of the theorem follows from the assumption that all functions are differentiable over their entire domains.

□

Closer examination of Equation 14.6.1 reveals an interesting pattern. The first term in the equation is $\frac{\partial f}{\partial x}\cdot\frac{dx}{dt}$ and the second term is $\frac{\partial f}{\partial y}\cdot\frac{dy}{dt}$. Recall that when multiplying fractions, cancelation can be used. If we treat these derivatives as fractions, then each product "simplifies" to something resembling $\partial f/dt$. The variables $x$ and $y$ that disappear in this simplification are often called **intermediate variables**: they are independent variables for the function $f$, but are dependent variables for the variable $t$. Two terms appear on the right-hand side of the formula, and $f$ is a function of two variables. This pattern works with functions of more than two variables as well, as we see later in this section.

### ✔ Example 14.6.1: Using the Chain Rule

Calculate $dz/dt$ for each of the following functions:

a. $z=f(x,y)=4x^2+3y^2,\quad x=x(t)=\sin t,\quad y=y(t)=\cos t$
b. $z=f(x,y)=\sqrt{x^2-y^2},\quad x=x(t)=e^{2t},\quad y=y(t)=e^{-t}$

#### Solution

a. To use the chain rule, we need four quantities—$\partial z/\partial x$, $\partial z/\partial y$, $dx/dt$, and $dy/dt$:

- $\frac{\partial z}{\partial x} = 8x$
- $\frac{dx}{dt} = \cos t$
- $\frac{\partial z}{\partial y} = 6y$
- $\frac{dy}{dt} = -\sin t$

Now, we substitute each of these into Equation 14.6.1:

$$\begin{aligned}\frac{dz}{dt} &= \frac{\partial z}{\partial x} \cdot \frac{dx}{dt} + \frac{\partial z}{\partial y} \cdot \frac{dy}{dt} \\ &= (8x)(\cos t) + (6y)(-\sin t) \\ &= 8x\cos t - 6y\sin t.\end{aligned}$$

This answer has three variables in it. To reduce it to one variable, use the fact that $x(t) = \sin t$ and $y(t) = \cos t$. We obtain

$$\begin{aligned}\frac{dz}{dt} &= 8x\cos t - 6y\sin t \\ &= 8(\sin t)\cos t - 6(\cos t)\sin t \\ &= 2\sin t\cos t.\end{aligned}$$

This derivative can also be calculated by first substituting $x(t)$ and $y(t)$ into $f(x, y)$, then differentiating with respect to $t$:

$$\begin{aligned}z = f(x, y) &= f\big(x(t), y(t)\big) \\ &= 4(x(t))^2 + 3(y(t))^2 \\ &= 4\sin^2 t + 3\cos^2 t.\end{aligned}$$

Then

$$\begin{aligned}\frac{dz}{dt} &= 2(4\sin t)(\cos t) + 2(3\cos t)(-\sin t) \\ &= 8\sin t\cos t - 6\sin t\cos t \\ &= 2\sin t\cos t,\end{aligned}$$

which is the same solution. However, it may not always be this easy to differentiate in this form.

b. To use the chain rule, we again need four quantities—$\partial z/\partial x, \partial z/dy, dx/dt$, and $dy/dt$ :

- $\frac{\partial z}{\partial x} = \frac{x}{\sqrt{x^2 - y^2}}$
- $\frac{dx}{dt} = 2e^{2t}$
- $\frac{\partial z}{\partial y} = \frac{-y}{\sqrt{x^2 - y^2}}$
- $\frac{dy}{dt} = -e^{-t}.$

We substitute each of these into Equation 14.6.1:

$$\begin{aligned}\frac{dz}{dt} &= \frac{\partial z}{\partial x} \cdot \frac{dx}{dt} + \frac{\partial z}{\partial y} \cdot \frac{dy}{dt} \\ &= \left(\frac{x}{\sqrt{x^2 - y^2}}\right)(2e^{2t}) + \left(\frac{-y}{\sqrt{x^2 - y^2}}\right)(-e^{-t}) \\ &= \frac{2xe^{2t} - ye^{-t}}{\sqrt{x^2 - y^2}}.\end{aligned}$$

To reduce this to one variable, we use the fact that $x(t) = e^{2t}$ and $y(t) = e^{-t}$. Therefore,

$$\begin{aligned}\frac{dz}{dt} &= \frac{2xe^2t + ye^{-t}}{\sqrt{x^2 - y^2}} \\ &= \frac{2(e^{2t})e^{2t} + (e^{-t})e^{-t}}{\sqrt{e^{4t} - e^{-2t}}} \\ &= \frac{2e^{4t} + e^{-2t}}{\sqrt{e^{4t} - e^{-2t}}}.\end{aligned}$$

To eliminate negative exponents, we multiply the top by $e^{2t}$ and the bottom by $\sqrt{e^{4t}}$:

$$\begin{aligned}\frac{dz}{dt} &= \frac{2e^{4t} + e^{-2t}}{\sqrt{e^{4t} - e^{-2t}}} \cdot \frac{e^{2t}}{\sqrt{e^{4t}}} \\ &= \frac{2e^{6t} + 1}{\sqrt{e^{8t} - e^{2t}}} \\ &= \frac{2e^{6t} + 1}{\sqrt{e^{2t}(e^{6t} - 1)}} \\ &= \frac{2e^{6t} + 1}{e^t\sqrt{e^{6t} - 1}}.\end{aligned}$$

Again, this derivative can also be calculated by first substituting $x(t)$ and $y(t)$ into $f(x, y)$, then differentiating with respect to $t$:

$$\begin{aligned}z &= f(x, y) \\ &= f(x(t), y(t)) \\ &= \sqrt{(x(t))^2 - (y(t))^2} \\ &= \sqrt{e^{4t} - e^{-2t}} \\ &= (e^{4t} - e^{-2t})^{1/2}.\end{aligned}$$

Then

$$\begin{aligned}\frac{dz}{dt} &= \frac{1}{2}(e^{4t} - e^{-2t})^{-1/2}\left(4e^{4t} + 2e^{-2t}\right) \\ &= \frac{2e^{4t} + e^{-2t}}{\sqrt{e^{4t} - e^{-2t}}}.\end{aligned}$$

This is the same solution.

## ? Exercise 14.6.1

Calculate $dz/dt$ given the following functions. Express the final answer in terms of $t$.

$$\begin{aligned}z = f(x, y) &= x^2 - 3xy + 2y^2, \\ x = x(t) &= 3\sin 2t, \\ y = y(t) &= 4\cos 2t\end{aligned}$$

**Hint**

Calculate $\partial z/\partial x, \partial z/dy, dx/dt$, and $dy/dt$, then use Equation 14.6.1.

**Answer**

$$\begin{aligned}\frac{dz}{dt} &= \frac{\partial f}{\partial x}\frac{dx}{dt} + \frac{\partial f}{\partial y}\frac{dy}{dt} \\ &= (2x - 3y)(6\cos 2t) + (-3x + 4y)(-8\sin 2t) \\ &= -92\sin 2t\cos 2t - 72(\cos^2 2t - \sin^2 2t) \\ &= -46\sin 4t - 72\cos 4t.\end{aligned}$$

It is often useful to create a visual representation of Equation 14.6.1 for the chain rule. This is called a **tree diagram** for the chain rule for functions of one variable and it provides a way to remember the formula (Figure 14.6.1). This diagram can be expanded for functions of more than one variable, as we shall see very shortly.

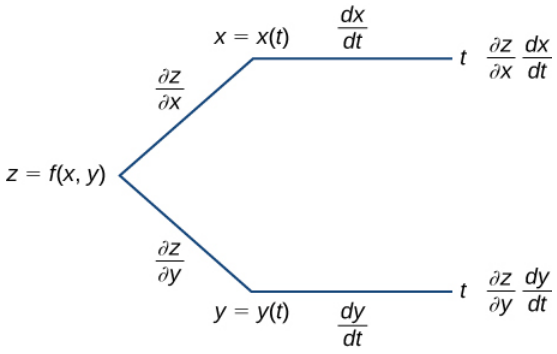

Figure 14.6.1: Tree diagram for the case $\frac{dz}{dt} = \frac{\partial z}{\partial x} \cdot \frac{dx}{dt} + \frac{\partial z}{\partial y} \cdot \frac{dy}{dt}$.

In this diagram, the leftmost corner corresponds to $z = f(x, y)$. Since $f$ has two **independent variables**, there are two lines coming from this corner. The upper branch corresponds to the variable $x$ and the lower branch corresponds to the variable $y$. Since each of these variables is then dependent on one variable $t$, one branch then comes from $x$ and one branch comes from $y$. Last, each of the branches on the far right has a label that represents the path traveled to reach that branch. The top branch is reached by following the $x$ branch, then the t branch; therefore, it is labeled $(\partial z/\partial x) \times (dx/dt)$. The bottom branch is similar: first the $y$ branch, then the $t$ branch. This branch is labeled $(\partial z/\partial y) \times (dy/dt)$. To get the formula for $dz/dt$, add all the terms that appear on the rightmost side of the diagram. This gives us Equation.

In Chain Rule for Two Independent Variables, $z = f(x, y)$ is a function of $x$ and $y$, and both $x = g(u, v)$ and $y = h(u, v)$ are functions of the independent variables $u$ and $v$.

**Theorem 14.6.2: Chain Rule for Two Independent Variables**

Suppose $x = g(u, v)$ and $y = h(u, v)$ are differentiable functions of $u$ and $v$, and $z = f(x, y)$ is a differentiable function of $x$ and $y$. Then, $z = f(g(u, v), h(u, v))$ is a differentiable function of $u$ and $v$, and

$$\frac{\partial z}{\partial u} = \frac{\partial z}{\partial x}\frac{\partial x}{\partial u} + \frac{\partial z}{\partial y}\frac{\partial y}{\partial u} \tag{14.6.2}$$

and

$$\frac{\partial z}{\partial v} = \frac{\partial z}{\partial x}\frac{\partial x}{\partial v} + \frac{\partial z}{\partial y}\frac{\partial y}{\partial v}. \tag{14.6.3}$$

We can draw a tree diagram for each of these formulas as well as follows.

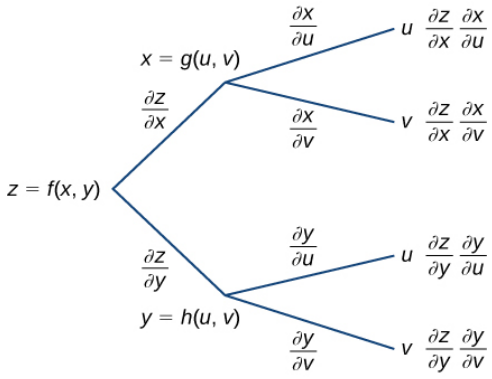

Figure 14.6.2: Tree diagram for $\frac{\partial z}{\partial u} = \frac{\partial z}{\partial x} \cdot \frac{\partial x}{\partial u} + \frac{\partial z}{\partial y} \cdot \frac{\partial y}{\partial u}$ and $\frac{\partial z}{\partial v} = \frac{\partial z}{\partial x} \cdot \frac{\partial x}{\partial v} + \frac{\partial z}{\partial y} \cdot \frac{\partial y}{\partial v}$.

To derive the formula for $\partial z/\partial u$, start from the left side of the diagram, then follow only the branches that end with $u$ and add the terms that appear at the end of those branches. For the formula for $\partial z/\partial v$, follow only the branches that end with $v$ and add the terms that appear at the end of those branches.

There is an important difference between these two chain rule theorems. In Chain Rule for One Independent Variable, the left-hand side of the formula for the derivative is not a partial derivative, but in Chain Rule for Two Independent Variables it is. The reason is that, in Chain Rule for One Independent Variable, $z$ is ultimately a function of $t$ alone, whereas in Chain Rule for Two Independent Variables, $z$ is a function of both $u$ and $v$.

### ✔ Example 14.6.2: Using the Chain Rule for Two Variables

Calculate $\partial z/\partial u$ and $\partial z/\partial v$ using the following functions:

$$z = f(x,y) = 3x^2 - 2xy + y^2,\ x = x(u,v) = 3u + 2v,\ y = y(u,v) = 4u - v.$$

**Solution**

To implement the chain rule for two variables, we need six partial derivatives—$\partial z/\partial x$, $\partial z/\partial y$, $\partial x/\partial u$, $\partial x/\partial v$, $\partial y/\partial u$, and $\partial y/\partial v$:

$$\frac{\partial z}{\partial x} = 6x - 2y \qquad \frac{\partial z}{\partial y} = -2x + 2y$$
$$\frac{\partial x}{\partial u} = 3 \qquad \frac{\partial x}{\partial v} = 2$$
$$\frac{\partial y}{\partial u} = 4 \qquad \frac{\partial y}{\partial v} = -1.$$

To find $\partial z/\partial u$, we use Equation 14.6.2:

$$\begin{aligned}\frac{\partial z}{\partial u} &= \frac{\partial z}{\partial x}\cdot\frac{\partial x}{\partial u} + \frac{\partial z}{\partial y}\cdot\frac{\partial y}{\partial u} \\ &= 3(6x - 2y) + 4(-2x + 2y) \\ &= 10x + 2y.\end{aligned}$$

Next, we substitute $x(u,v) = 3u + 2v$ and $y(u,v) = 4u - v$ :

$$\begin{aligned}\frac{\partial z}{\partial u} &= 10x + 2y \\ &= 10(3u + 2v) + 2(4u - v) \\ &= 38u + 18v.\end{aligned}$$

To find $\partial z/\partial v$, we use Equation 14.6.3:

$$\begin{aligned}\frac{\partial z}{\partial v} &= \frac{\partial z}{\partial x}\frac{\partial x}{\partial v} + \frac{\partial z}{\partial y}\frac{\partial y}{\partial v} \\ &= 2(6x - 2y) + (-1)(-2x + 2y) \\ &= 14x - 6y.\end{aligned}$$

Then we substitute $x(u,v) = 3u + 2v$ and $y(u,v) = 4u - v$ :

$$\begin{aligned}\frac{\partial z}{\partial v} &= 14x - 6y \\ &= 14(3u + 2v) - 6(4u - v) \\ &= 18u + 34v\end{aligned}$$

### ? Exercise 14.6.2

Calculate $\partial z/\partial u$ and $\partial z/\partial v$ given the following functions:

$$z = f(x,y) = \frac{2x-y}{x+3y}, \quad x(u,v) = e^{2u}\cos 3v, \quad y(u,v) = e^{2u}\sin 3v.$$

**Hint**

Calculate $\partial z/\partial x$, $\partial z/\partial y$, $\partial x/\partial u$, $\partial x/\partial v$, $\partial y/\partial u$, and $\partial y/\partial v$, then use Equation 14.6.2 and Equation 14.6.3.

**Answer**

$$\frac{\partial z}{\partial u} = 0, \quad \frac{\partial z}{\partial v} = \frac{-21}{(3\sin 3v + \cos 3v)^2}$$

## The Generalized Chain Rule

Now that we've see how to extend the original chain rule to functions of two variables, it is natural to ask: Can we extend the rule to more than two variables? The answer is yes, as the *generalized chain rule* states.

**Theorem 14.6.3: Generalized Chain Rule**

Let $w = f(x_1, x_2, \ldots, x_m)$ be a differentiable function of $m$ independent variables, and for each $i \in 1, \ldots, m$, let $x_i = x_i(t_1, t_2, \ldots, t_n)$ be a differentiable function of $n$ independent variables. Then

$$\frac{\partial w}{\partial t_j} = \frac{\partial w}{\partial x_1}\frac{\partial x_1}{\partial t_j} + \frac{\partial w}{\partial x_2}\frac{\partial x_2}{\partial t_j} + \cdots + \frac{\partial w}{\partial x_m}\frac{\partial x_m}{\partial t_j}$$

for any $j \in 1, 2, \ldots, n$.

In the next example we calculate the derivative of a function of three independent variables in which each of the three variables is dependent on two other variables.

**Example 14.6.3: Using the Generalized Chain Rule**

Calculate $\partial w/\partial u$ and $\partial w/\partial v$ using the following functions:

$$\begin{aligned} w &= f(x,y,z) = 3x^2 - 2xy + 4z^2 \\ x &= x(u,v) = e^u \sin v \\ y &= y(u,v) = e^u \cos v \\ z &= z(u,v) = e^u. \end{aligned}$$

**Solution**

The formulas for $\partial w/\partial u$ and $\partial w/\partial v$ are

$$\begin{aligned} \frac{\partial w}{\partial u} &= \frac{\partial w}{\partial x}\cdot\frac{\partial x}{\partial u} + \frac{\partial w}{\partial y}\cdot\frac{\partial y}{\partial u} + \frac{\partial w}{\partial z}\cdot\frac{\partial z}{\partial u} \\ \frac{\partial w}{\partial v} &= \frac{\partial w}{\partial x}\cdot\frac{\partial x}{\partial v} + \frac{\partial w}{\partial y}\cdot\frac{\partial y}{\partial v} + \frac{\partial w}{\partial z}\cdot\frac{\partial z}{\partial v}. \end{aligned}$$

Therefore, there are nine different partial derivatives that need to be calculated and substituted. We need to calculate each of them:

$$\begin{aligned} &\frac{\partial w}{\partial x} = 6x - 2y \quad \frac{\partial w}{\partial y} = -2x \quad \frac{\partial w}{\partial z} = 8z \\ &\frac{\partial x}{\partial u} = e^u \sin v \quad \frac{\partial y}{\partial u} = e^u \cos v \quad \frac{\partial z}{\partial u} = e^u \\ &\frac{\partial x}{\partial v} = e^u \cos v \quad \frac{\partial y}{\partial v} = -e^u \sin v \quad \frac{\partial z}{\partial v} = 0. \end{aligned}$$

Now, we substitute each of them into the first formula to calculate $\partial w/\partial u$:

$$\frac{\partial w}{\partial u} = \frac{\partial w}{\partial x} \cdot \frac{\partial x}{\partial u} + \frac{\partial w}{\partial y} \cdot \frac{\partial y}{\partial u} + \frac{\partial w}{\partial z} \cdot \frac{\partial z}{\partial u}$$
$$= (6x - 2y)e^u \sin v - 2xe^u \cos v + 8ze^u,$$

then substitute $x(u,v) = e^u \sin v$, $y(u,v) = e^u \cos v$, and $z(u,v) = e^u$ into this equation:

$$\begin{aligned}\frac{\partial w}{\partial u} &= (6x - 2y)e^u \sin v - 2xe^u \cos v + 8ze^u \\ &= (6e^u \sin v - 2eu \cos v)e^u \sin v - 2(e^u \sin v)e^u \cos v + 8e^{2u} \\ &= 6e^{2u} \sin^2 v - 4e^{2u} \sin v \cos v + 8e^{2u} \\ &= 2e^{2u}(3 \sin^2 v - 2 \sin v \cos v + 4).\end{aligned}$$

Next, we calculate $\partial w/\partial v$:

$$\frac{\partial w}{\partial v} = \frac{\partial w}{\partial x} \cdot \frac{\partial x}{\partial v} + \frac{\partial w}{\partial y} \cdot \frac{\partial y}{\partial v} + \frac{\partial w}{\partial z} \cdot \frac{\partial z}{\partial v}$$
$$= (6x - 2y)e^u \cos v - 2x(-e^u \sin v) + 8z(0),$$

then we substitute $x(u,v) = e^u \sin v$, $y(u,v) = e^u \cos v$, and $z(u,v) = e^u$ into this equation:

$$\begin{aligned}\frac{\partial w}{\partial v} &= (6x - 2y)e^u \cos v - 2x(-e^u \sin v) \\ &= (6e^u \sin v - 2e^u \cos v)e^u \cos v + 2(e^u \sin v)(e^u \sin v) \\ &= 2e^{2u} \sin^2 v + 6e^{2u} \sin v \cos v - 2e^{2u} \cos^2 v \\ &= 2e^{2u}(\sin^2 v + \sin v \cos v - \cos^2 v).\end{aligned}$$

## ? Exercise 14.6.3

Calculate $\partial w/\partial u$ and $\partial w/\partial v$ given the following functions:

$$w = f(x,y,z) = \frac{x + 2y - 4z}{2x - y + 3z}$$
$$x = x(u,v) = e^{2u} \cos 3v$$
$$y = y(u,v) = e^{2u} \sin 3v$$
$$z = z(u,v) = e^{2u}.$$

**Hint**

Calculate nine partial derivatives, then use the same formulas from Example **14.6.3**.

**Answer**

$$\frac{\partial w}{\partial u} = 0$$
$$\frac{\partial w}{\partial v} = \frac{15 - 33 \sin 3v + 6 \cos 3v}{(3 + 2 \cos 3v - \sin 3v)^2}$$

## ✓ Example 14.6.4: Drawing a Tree Diagram

Create a tree diagram for the case when

$$w = f(x,y,z), \quad x = x(t,u,v), \quad y = y(t,u,v), \quad z = z(t,u,v)$$

and write out the formulas for the three partial derivatives of $w$.

### Solution

Starting from the left, the function $f$ has three independent variables: $x$, $y$, and $z$. Therefore, three branches must be emanating from the first node. Each of these three branches also has three branches, for each of the variables $t$, $u$, and $v$.

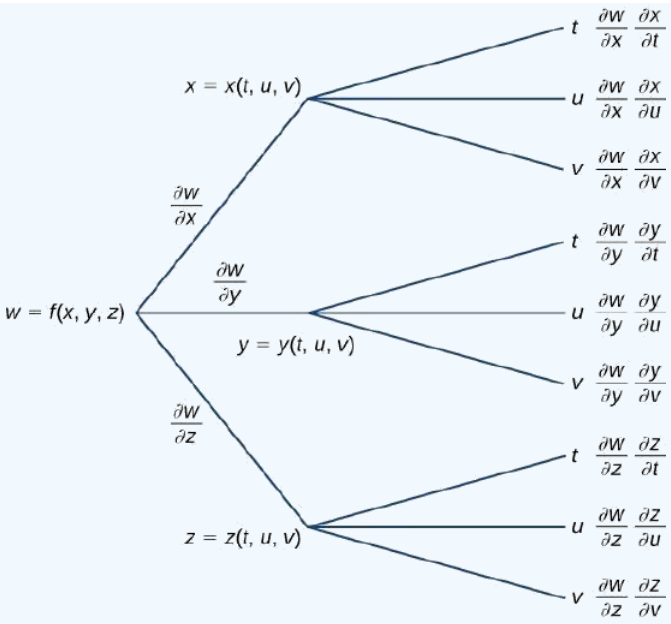

Figure **14.6.3**: Tree diagram for a function of three variables, each of which is a function of three independent variables.

The three formulas are

$$\frac{\partial w}{\partial t} = \frac{\partial w}{\partial x}\frac{\partial x}{\partial t} + \frac{\partial w}{\partial y}\frac{\partial y}{\partial t} + \frac{\partial w}{\partial z}\frac{\partial z}{\partial t}$$
$$\frac{\partial w}{\partial u} = \frac{\partial w}{\partial x}\frac{\partial x}{\partial u} + \frac{\partial w}{\partial y}\frac{\partial y}{\partial u} + \frac{\partial w}{\partial z}\frac{\partial z}{\partial u}$$
$$\frac{\partial w}{\partial v} = \frac{\partial w}{\partial x}\frac{\partial x}{\partial v} + \frac{\partial w}{\partial y}\frac{\partial y}{\partial v} + \frac{\partial w}{\partial z}\frac{\partial z}{\partial v}.$$

## ? Exercise 14.6.4

Create a tree diagram for the case when

$$w = f(x, y), \quad x = x(t, u, v), \quad y = y(t, u, v)$$

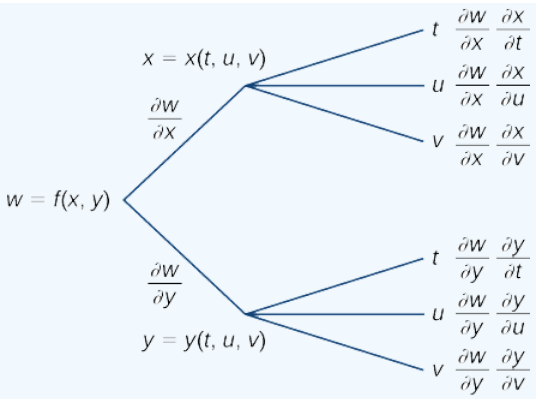
and write out the formulas for the three partial derivatives of $w$.

**Hint**

Determine the number of branches that emanate from each node in the tree.

**Answer**

$$\frac{\partial w}{\partial t} = \frac{\partial w}{\partial x}\frac{\partial x}{\partial t} + \frac{\partial w}{\partial y}\frac{\partial y}{\partial t}$$
$$\frac{\partial w}{\partial u} = \frac{\partial w}{\partial x}\frac{\partial x}{\partial u} + \frac{\partial w}{\partial y}\frac{\partial y}{\partial u}$$
$$\frac{\partial w}{\partial v} = \frac{\partial w}{\partial x}\frac{\partial x}{\partial v} + \frac{\partial w}{\partial y}\frac{\partial y}{\partial v}$$



## Implicit Differentiation

Recall from implicit differentiation provides a method for finding $dy/dx$ when $y$ is defined implicitly as a function of $x$. The method involves differentiating both sides of the equation defining the function with respect to $x$, then solving for $dy/dx$. Partial derivatives provide an alternative to this method.

Consider the ellipse defined by the equation $x^2 + 3y^2 + 4y - 4 = 0$ as follows.

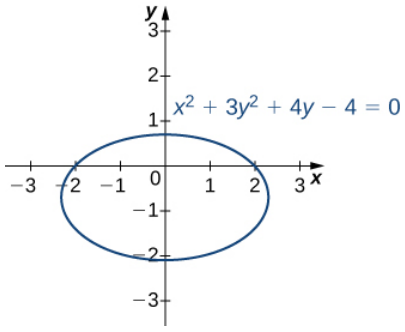


Figure 14.6.4: Graph of the ellipse defined by $x^2 + 3y^2 + 4y - 4 = 0$.

This equation implicitly defines $y$ as a function of $x$. As such, we can find the derivative $dy/dx$ using the method of implicit differentiation:

$$\begin{aligned} \frac{d}{dx}(x^2 + 3y^2 + 4y - 4) &= \frac{d}{dx}(0) \\ 2x + 6y\frac{dy}{dx} + 4\frac{dy}{dx} &= 0 \\ (6y + 4)\frac{dy}{dx} &= -2x \\ \frac{dy}{dx} &= -\frac{x}{3y + 2} \end{aligned}$$

We can also define a function $z = f(x, y)$ by using the left-hand side of the equation defining the ellipse. Then $f(x, y) = x^2 + 3y^2 + 4y - 4$. The ellipse $x^2 + 3y^2 + 4y - 4 = 0$ can then be described by the equation $f(x, y) = 0$. Using this function and the following theorem gives us an alternative approach to calculating $dy/dx$.

### Theorem 14.6.4: Implicit Differentiation of a Function of Two or More Variables

Suppose the function $z = f(x, y)$ defines $y$ implicitly as a function $y = g(x)$ of $x$ via the equation $f(x, y) = 0$. Then

$$\frac{dy}{dx} = -\frac{\partial f/\partial x}{\partial f/\partial y} \tag{14.6.4}$$

provided $f_y(x, y) \neq 0$.

If the equation $f(x, y, z) = 0$ defines $z$ implicitly as a differentiable function of $x$ and $y$, then

$$\frac{dz}{dx} = -\frac{\partial f/\partial x}{\partial f/\partial z} \quad \text{and} \quad \frac{dz}{dy} = -\frac{\partial f/\partial y}{\partial f/\partial z} \tag{14.6.5}$$

as long as $f_z(x, y, z) \neq 0$.

Equation 14.6.4 is a direct consequence of Equation 14.6.2. In particular, if we assume that $y$ is defined implicitly as a function of $x$ via the equation $f(x, y) = 0$, we can apply the chain rule to find $dy/dx$ :

$$\begin{aligned} \frac{d}{dx} f(x, y) &= \frac{d}{dx}(0) \\ \frac{\partial f}{\partial x} \cdot \frac{dx}{dx} + \frac{\partial f}{\partial y} \cdot \frac{dy}{dx} &= 0 \\ \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} \cdot \frac{dy}{dx} &= 0. \end{aligned}$$

Solving this equation for $dy/dx$ gives Equation 14.6.4. Equation 14.6.4 can be derived in a similar fashion.

Let's now return to the problem that we started before the previous theorem. Using Theorem 14.6.4 and the function $f(x, y) = x^2 + 3y^2 + 4y - 4$, we obtain

$$\begin{aligned} \frac{\partial f}{\partial x} &= 2x \\ \frac{\partial f}{\partial y} &= 6y + 4. \end{aligned}$$

Then Equation 14.6.4 gives

$$\frac{dy}{dx} = -\frac{\partial f/\partial x}{\partial f/\partial y} = -\frac{2x}{6y + 4} = -\frac{x}{3y + 2},$$

which is the same result obtained by the earlier use of implicit differentiation.

### Example 14.6.5: Implicit Differentiation by Partial Derivatives

a. Calculate $dy/dx$ if $y$ is defined implicitly as a function of $x$ via the equation $3x^2 - 2xy + y^2 + 4x - 6y - 11 = 0$. What is the equation of the tangent line to the graph of this curve at point $(2, 1)$?

b. Calculate $\partial z/\partial x$ and $\partial z/\partial y$, given $x^2 e^y - yze^x = 0$.

**Solution**

a. Set $f(x, y) = 3x^2 - 2xy + y^2 + 4x - 6y - 11 = 0$, then calculate $f_x$ and $f_y$ : $f_x(x, y) = 6x - 2y + 4$ and $f_y(x, y) = -2x + 2y - 6$.

The derivative is given by

$$\frac{dy}{dx} = -\frac{\partial f/\partial x}{\partial f/\partial y} = \frac{6x - 2y + 4}{-2x + 2y - 6} = \frac{3x - y + 2}{x - y + 3}.$$

The slope of the tangent line at point $(2, 1)$ is given by

$$\left.\frac{dy}{dx}\right|_{(x,y)=(2,1)} = \frac{3(2) - 1 + 2}{2 - 1 + 3} = \frac{7}{4}$$

To find the equation of the tangent line, we use the point-slope form (Figure 14.6.5):

$$\begin{aligned} y - y_0 &= m(x - x_0) \\ y - 1 &= \frac{7}{4}(x - 2) \\ y &= \frac{7}{4}x - \frac{7}{2} + 1 \\ y &= \frac{7}{4}x - \frac{5}{2}. \end{aligned}$$

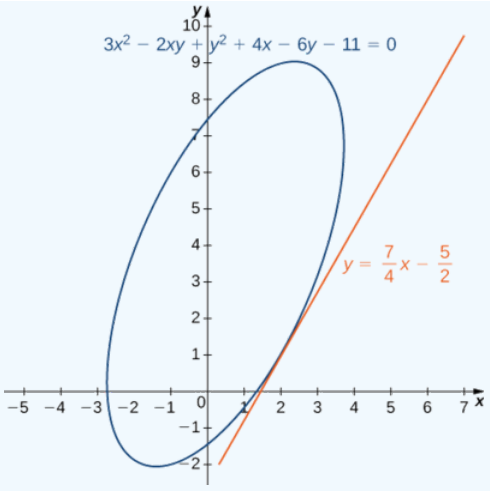

Figure **14.6.5**: Graph of the rotated ellipse defined by $3x^2 - 2xy + y^2 + 4x - 6y - 11 = 0$.

b. We have $f(x, y, z) = x^2e^y - yze^x$. Therefore,

$$\frac{\partial f}{\partial x} = 2xe^y - yze^x$$
$$\frac{\partial f}{\partial y} = x^2e^y - ze^x$$
$$\frac{\partial f}{\partial z} = -ye^x$$

Using Equation 14.6.5,

$$\frac{\partial z}{\partial x} = -\frac{\partial f/\partial x}{\partial f/\partial y} \qquad \text{and} \qquad \frac{\partial z}{\partial y} = -\frac{\partial f/\partial y}{\partial f/\partial z}$$
$$= -\frac{2xe^y - yze^x}{-ye^x} \qquad = -\frac{x^2e^y - ze^x}{-ye^x}$$
$$= \frac{2xe^y - yze^x}{ye^x} \qquad = \frac{x^2e^y - ze^x}{ye^x}$$

## ? Exercise 14.6.5

Find $dy/dx$ if $y$ is defined implicitly as a function of $x$ by the equation $x^2 + xy - y^2 + 7x - 3y - 26 = 0$. What is the equation of the tangent line to the graph of this curve at point $(3, -2)$?

**Hint**

Calculate $\partial f/dx$ and $\partial f/dy$, then use Equation 14.6.4.

**Solution**

$$\frac{dy}{dx} = \frac{2x + y + 7}{2y - x + 3}\Big|_{(3,-2)} = \frac{2(3) + (-2) + 7}{2(-2) - (3) + 3} = -\frac{11}{4}$$

Equation of the tangent line: $y = -\frac{11}{4}x + \frac{25}{4}$

## Key Concepts

- The chain rule for functions of more than one variable involves the partial derivatives with respect to all the independent variables.
- Tree diagrams are useful for deriving formulas for the chain rule for functions of more than one variable, where each independent variable also depends on other variables.

## Key Equations

- **Chain rule, one independent variable**

$$\frac{dz}{dt} = \frac{\partial z}{\partial x} \cdot \frac{dx}{dt} + \frac{\partial z}{\partial y} \cdot \frac{dy}{dt}$$

- **Chain rule, two independent variables**

$$\frac{dz}{du} = \frac{\partial z}{\partial x} \cdot \frac{\partial x}{\partial u} + \frac{\partial z}{\partial y} \cdot \frac{\partial y}{\partial u} \quad \frac{dz}{dv} = \frac{\partial z}{\partial x} \cdot \frac{\partial x}{\partial v} + \frac{\partial z}{\partial y} \cdot \frac{\partial y}{\partial v}$$

- **Generalized chain rule**

$$\frac{\partial w}{\partial t_j} = \frac{\partial w}{\partial x_1} \frac{\partial x_1}{\partial t_j} + \frac{\partial w}{\partial x_2} \frac{\partial x_1}{\partial t_j} + \cdots + \frac{\partial w}{\partial x_m} \frac{\partial x_m}{\partial t_j}$$

## Glossary

**generalized chain rule**

the chain rule extended to functions of more than one independent variable, in which each independent variable may depend on one or more other variables

**intermediate variable**

given a composition of functions (e.g., $f(x(t), y(t))$), the intermediate variables are the variables that are independent in the outer function but dependent on other variables as well; in the function $f(x(t), y(t))$, the variables $x$ and $y$ are examples of intermediate variables

**tree diagram**

illustrates and derives formulas for the generalized chain rule, in which each independent variable is accounted for

# 14.6E: Exercises for Section 14.5

**In exercises 1 - 6, use the information provided to solve the problem.**

1) Let $w(x,y,z) = xy\cos z$, where $x = t, y = t^2$, and $z = \arcsin t$. Find $\frac{dw}{dt}$.

**Answer**

$$\frac{dw}{dt} = y\cos z + x\cos z(2t) - \frac{xy\sin z}{\sqrt{1-t^2}}$$

2) Let $w(t,v) = e^{tv}$ where $t = r + s$ and $v = rs$. Find $\frac{\partial w}{\partial r}$ and $\frac{\partial w}{\partial s}$.

3) If $w = 5x^2 + 2y^2, \quad x = -3u + v$, and $y = u - 4v$, find $\frac{\partial w}{\partial u}$ and $\frac{\partial w}{\partial v}$.

**Answer**

$$\frac{\partial w}{\partial u} = -30x + 4y \quad = \quad -30(-3u+v) + 4(u-4v) \quad = \quad 90u - 30v + 4u - 16v \quad = \quad 94u - 46v,$$
$$\frac{\partial w}{\partial v} = 10x - 16y \quad = \quad 10(-3u+v) - 16(u-4v) \quad = \quad -30u + 10v - 16u + 64v \quad = \quad -46u + 74v$$

4) If $w = xy^2, x = 5\cos(2t)$, and $y = 5\sin(2t)$, find $\frac{\partial w}{\partial t}$.

5) If $f(x,y) = xy, x = r\cos\theta$, and $y = r\sin\theta$, find $\frac{\partial f}{\partial r}$ and express the answer in terms of $r$ and $\theta$.

**Answer**

$$\frac{\partial f}{\partial r} = r\sin(2\theta)$$

6) Suppose $f(x,y) = x + y, u = e^x\sin y, \quad x = t^2$ and $y = \pi t$, where $x = r\cos\theta$ and $y = r\sin\theta$. Find $\frac{\partial f}{\partial \theta}$.

**In exercises 7 - 12, find $\frac{dz}{dt}$ in two ways, first using the chain rule and then by direct substitution.**

7) $z = x^2 + y^2, \quad x = t, y = t^2$

**Answer**

$$\frac{dz}{dt} = 2t + 4t^3$$

8) $z = \sqrt{x^2 + y^2}, \quad y = t^2, x = t$

9) $z = xy, \quad x = 1 - \sqrt{t}, y = 1 + \sqrt{t}$

**Answer**

$$\frac{dz}{dt} = -1$$

10) $z = \frac{x}{y}, \quad x = e^t, y = 2e^t$

11) $z = \ln(x + y), \quad x = e^t, y = e^t$

**Answer**

$$\frac{dz}{dt} = 1$$

12) $z = x^4, \quad x = t, y = t$

13) Let $w(x,y,z) = x^2 + y^2 + z^2, \quad x = cost, y = sint$, and $z = e^t$. Express $w$ as a function of $t$ and find $\frac{dw}{dt}$ directly. Then, find $\frac{dw}{dt}$ using the chain rule.

**Answer**

$\frac{dw}{dt} = 2e^{2t}$ in both cases

14) Let $z = x^2y$, where $x = t^2$ and $y = t^3$. Find $\frac{dz}{dt}$.

15) Let $u = e^x \sin y$, where $x = -\ln 2t$ and $y = \pi t$. Find $\frac{du}{dt}$ when $x = \ln 2$ and $y = \frac{\pi}{4}$.

**Answer**

$\frac{du}{dt} = \sqrt{2}(\pi - 4)$

**In exercises 16 - 33, find $\frac{dy}{dx}$ using partial derivatives.**

16) $\sin(6x) + \tan(8y) + 5 = 0$

17) $x^3 + y^2x - 3 = 0$

**Answer**

$\frac{dy}{dx} = -\frac{3x^2 + y^2}{2xy}$

18) $\sin(x + y) + \cos(x - y) = 4$

19) $x^2 - 2xy + y^4 = 4$

**Answer**

$\frac{dy}{dx} = \frac{y - x}{-x + 2y^3}$

20) $xe^y + ye^x - 2x^2y = 0$

21) $x^{2/3} + y^{2/3} = a^{2/3}$

**Answer**

$\frac{dy}{dx} = -\sqrt[3]{\frac{y}{x}}$

22) $x\cos(xy) + y\cos x = 2$

23) $e^{xy} + ye^y = 1$

**Answer**

$\frac{dy}{dx} = -\frac{ye^{xy}}{xe^{xy} + e^y(1 + y)}$

24) $x^2y^3 + \cos y = 0$

25) Find $\frac{dz}{dt}$ using the chain rule where $z = 3x^2y^3$, $x = t^4$, and $y = t^2$.

**Answer**

$\frac{dz}{dt} = 42t^{13}$

26) Let $z = 3\cos x - \sin(xy), x = \frac{1}{t}$, and $y = 3t$. Find $\frac{dz}{dt}$.

27) Let $z = e^{1-xy}$, $x = t^{1/3}$, and $y = t^3$. Find $\frac{dz}{dt}$.

**Answer**

$\frac{dz}{dt} = -\frac{10}{3}t^{7/3} \times e^{1-t^{10/3}}$

28) Find $\frac{dz}{dt}$ by the chain rule where $z = \cosh^2(xy)$, $x = \frac{1}{2}t$, and $y = e^t$.

29) Let $z = \frac{x}{y}$, $x = 2\cos u$, and $y = 3\sin v$. Find $\frac{\partial z}{\partial u}$ and $\frac{\partial z}{\partial v}$.

**Answer**

$\frac{\partial z}{\partial u} = \frac{-2\sin u}{3\sin v}$ and $\frac{\partial z}{\partial v} = \frac{-2\cos u\cos v}{3\sin^2 v}$

30) Let $z = e^{x^2y}$, where $x = \sqrt{uv}$ and $y = \frac{1}{v}$. Find $\frac{\partial z}{\partial u}$ and $\frac{\partial z}{\partial v}$.

31) If $z = xye^{x/y}$, $x = r\cos\theta$, and $y = r\sin\theta$, find $\frac{\partial z}{\partial r}$ and $\frac{\partial z}{\partial \theta}$ when $r = 2$ and $\theta = \frac{\pi}{6}$.

**Answer**

$\frac{\partial z}{\partial r} = \sqrt{3}e^{\sqrt{3}}$, $\frac{\partial z}{\partial \theta} = (2 - 4\sqrt{3})e^{\sqrt{3}}$

32) Find $\frac{\partial w}{\partial s}$ if $w = 4x + y^2 + z^3$, $x = e^{rs^2}$, $y = \ln(\frac{r+s}{t})$, and $z = rst^2$.

33) If $w = \sin(xyz)$, $x = 1 - 3t$, $y = e^{1-t}$, and $z = 4t$, find $\frac{\partial w}{\partial t}$.

**Answer**

$\frac{\partial w}{\partial t} = -3yz\cos(xyz) - xze^{1-t}\cos(xyz) + 4xy\cos(xyz)$

**In exercises 34 - 36, use this information: A function $f(x,y)$ is said to be homogeneous of degree $n$ if $f(tx,ty) = t^n f(x,y)$. For all homogeneous functions of degree $n$, the following equation is true: $x\frac{\partial f}{\partial x} + y\frac{\partial f}{\partial y} = nf(x,y)$. Show that the given function is homogeneous and verify that $x\frac{\partial f}{\partial x} + y\frac{\partial f}{\partial y} = nf(x,y)$.**

34) $f(x,y) = 3x^2 + y^2$

35) $f(x,y) = \sqrt{x^2 + y^2}$

**Answer**

$f(tx,ty) = \sqrt{t^2x^2 + t^2y^2} = t^1 f(x,y)$, $\frac{\partial f}{\partial y} = x\frac{1}{2}(x^2+y^2)^{-1/2} \times 2x + y\frac{1}{2}(x^2+y^2)^{-1/2} \times 2y = 1f(x,y)$

36) $f(x,y) = x^2y - 2y^3$

37) The volume of a right circular cylinder is given by $V(x,y) = \pi x^2 y$, where $x$ is the radius of the cylinder and $y$ is the cylinder height. Suppose $x$ and $y$ are functions of $t$ given by $x = \frac{1}{2}t$ and $y = \frac{1}{3}t$ so that $x$ and $y$ are both increasing with time. How fast is the volume increasing when $x = 2$ and $y = 5$? Assume time is measured in seconds.

**Answer**

\ddfrac$dVdt = \frac{34\pi}{3}$ units$^3$/s

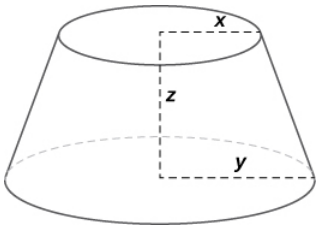
38) The pressure $P$ of a gas is related to the volume and temperature by the formula $PV = kT$, where temperature is expressed in kelvins. Express the pressure of the gas as a function of both $V$ and $T$. Find $\frac{dP}{dt}$ when $k = 1$, $\frac{dV}{dt} = 2$ cm$^3$/min, $\frac{dT}{dt} = 12$ K/min, $V = 20cm^3$, and $T = 20°F$.

39) The radius of a right circular cone is increasing at 3 cm/min whereas the height of the cone is decreasing at 2 cm/min. Find the rate of change of the volume of the cone when the radius is 13 cm and the height is 18 cm.

**Answer**

$\frac{dV}{dt} = \frac{1066\pi}{3}$ cm$^3$/min

40) The volume of a frustum of a cone is given by the formula $V = \frac{1}{3}\pi z(x^2 + y^2 + xy)$, where $x$ is the radius of the smaller circle, $y$ is the radius of the larger circle, and $z$ is the height of the frustum (see figure). Find the rate of change of the volume of this frustum when $x = 10$ in., $y = 12$ in., and $z = 18$ in.



41) A closed box is in the shape of a rectangular solid with dimensions $x, y$, and $z$. (Dimensions are in inches.) Suppose each dimension is changing at the rate of $0.5$ in./min. Find the rate of change of the total surface area of the box when $x = 2$ in., $y = 3$ in., and $z = 1$ in.

**Answer**

$\frac{dA}{dt} = 12 \text{ in.}^2/\text{min}$

42) The total resistance in a circuit that has three individual resistances represented by $x, y$, and $z$ is given by the formula $R(x, y, z) = \frac{xyz}{yz + xz + xy}$. Suppose at a given time the $x$ resistance is $100\ \Omega$, the $y$ resistance is $200\ \Omega$, and the $z$ resistance is $300\ \Omega$. Also, suppose the $x$ resistance is changing at a rate of $2\ \Omega/\text{min}$, the $y$ resistance is changing at the rate of $1\ \Omega/\text{min}$, and the $z$ resistance has no change. Find the rate of change of the total resistance in this circuit at this time.

43) The temperature $T$ at a point $(x, y)$ is $T(x, y)$ and is measured using the Celsius scale. A fly crawls so that its position after $t$ seconds is given by $x = \sqrt{1 + t}$ and $y = 2 + \frac{1}{3}t$, where $x$ and $y$ are measured in centimeters. The temperature function satisfies $T_x(2, 3) = 4$ and $T_y(2, 3) = 3$. How fast is the temperature increasing on the fly's path after $3$ sec?

**Answer**

$2$°C/sec

44) The $x$ and $y$ components of a fluid moving in two dimensions are given by the following functions: $u(x, y) = 2y$ and $v(x, y) = -2x$ with $x \geq 0$ and $y \geq 0$. The speed of the fluid at the point $(x, y)$ is $s(x, y) = \sqrt{u(x, y)^2 + v(x, y)^2}$. Find $\frac{\partial s}{\partial x}$ and $\frac{\partial s}{\partial y}$ using the chain rule.

45) Let $u = u(x, y, z)$, where $x = x(w, t)$, $y = y(w, t)$, $z = z(w, t)$, $w = w(r, s)$, and $t = t(r, s)$. Use a tree diagram and the chain rule to find an expression for $\frac{\partial u}{\partial r}$.

**Answer**

$\frac{\partial u}{\partial r} = \frac{\partial u}{\partial x}\left(\frac{\partial x}{\partial w}\frac{\partial w}{\partial r} + \frac{\partial x}{\partial t}\frac{\partial t}{\partial r}\right) + \frac{\partial u}{\partial y}\left(\frac{\partial y}{\partial w}\frac{\partial w}{\partial r} + \frac{\partial y}{\partial t}\frac{\partial t}{\partial r}\right) + \frac{\partial u}{\partial z}\left(\frac{\partial z}{\partial w}\frac{\partial w}{\partial r} + \frac{\partial z}{\partial t}\frac{\partial t}{\partial r}\right)$

---

# 14.7: Directional Derivatives and the Gradient

**Learning Objectives**

- Determine the directional derivative in a given direction for a function of two variables.
- Determine the gradient vector of a given real-valued function.
- Explain the significance of the gradient vector with regard to direction of change along a surface.
- Use the gradient to find the tangent to a level curve of a given function.
- Calculate directional derivatives and gradients in three dimensions.

A function $z = f(x, y)$ has two partial derivatives: $\partial z/\partial x$ and $\partial z/\partial y$. These derivatives correspond to each of the independent variables and can be interpreted as instantaneous rates of change (that is, as slopes of a tangent line). For example, $\partial z/\partial x$ represents the slope of a tangent line passing through a given point on the surface defined by $z = f(x, y)$, assuming the tangent line is parallel to the $x$-**axis**. Similarly, $\partial z/\partial y$ represents the slope of the tangent line parallel to the $y$-**axis.** Now we consider the possibility of a tangent line parallel to neither axis.

## Directional Derivatives

We start with the graph of a surface defined by the equation $z = f(x, y)$. Given a point $(a, b)$ in the domain of $f$, we choose a direction to travel from that point. We measure the direction using an angle $\theta$, which is measured counterclockwise in the $xy$-plane, starting at zero from the positive $x$-axis (Figure 14.7.1). The distance we travel is $h$ and the direction we travel is given by the unit vector $\vec{\mathbf{u}} = (\cos\theta)\,\hat{\mathbf{i}} + (\sin\theta)\,\hat{\mathbf{j}}$. Therefore, the $z$-coordinate of the second point on the graph is given by $z = f(a + h\cos\theta, b + h\sin\theta)$.

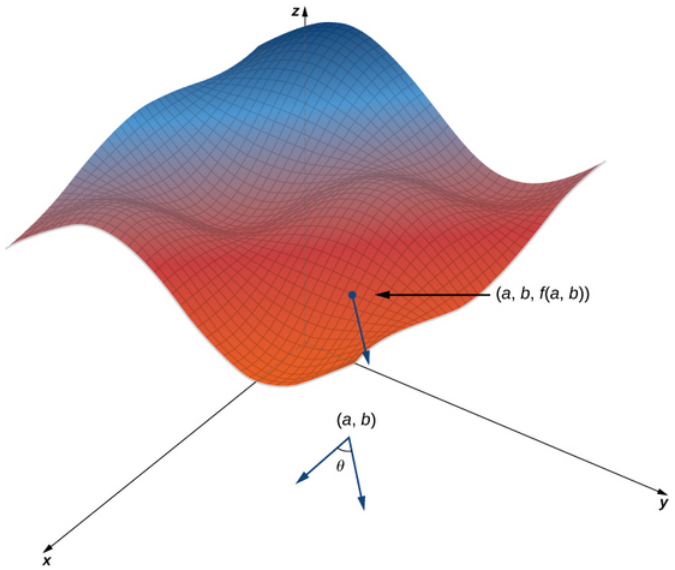

Figure 14.7.1: Finding the directional derivative at a point on the graph of $z = f(x, y)$. The slope of the blue arrow on the graph indicates the value of the directional derivative at that point.

We can calculate the slope of the secant line by dividing the difference in $z$-values by the length of the line segment connecting the two points in the domain. The length of the line segment is $h$. Therefore, the slope of the secant line is

$$m_{sec} = \frac{f(a + h\cos\theta, b + h\sin\theta) - f(a, b)}{h}$$

To find the slope of the tangent line in the same direction, we take the limit as $h$ approaches zero.

**Definition: Directional Derivatives**

Suppose $z = f(x, y)$ is a function of two variables with a domain of $D$. Let $(a, b) \in D$ and define $\vec{\mathbf{u}} = (\cos\theta)\,\hat{\mathbf{i}} + (\sin\theta)\,\hat{\mathbf{j}}$. Then the directional derivative of $f$ in the direction of $\vec{\mathbf{u}}$ is given by

$$D_{\vec{\mathbf{u}}} f(a,b) = \lim_{h \to 0} \frac{f(a + h\cos\theta, b + h\sin\theta) - f(a,b)}{h} \tag{14.7.1}$$

provided the limit exists.

Equation 14.7.1 provides a formal definition of the directional derivative that can be used in many cases to calculate a directional derivative.

Note that since the point $(a,b)$ is chosen randomly from the domain $D$ of the function $f$, we can use this definition to find the directional derivative as a function of $x$ and $y$.

That is,

$$D_{\vec{\mathbf{u}}} f(x,y) = \lim_{h \to 0} \frac{f(x + h\cos\theta, y + h\sin\theta) - f(x,y)}{h} \tag{14.7.2}$$

### Example 14.7.1: Finding a Directional Derivative from the Definition

Let $\theta = \arccos(3/5)$. Find the directional derivative $D_{\vec{\mathbf{u}}} f(x,y)$ of $f(x,y) = x^2 - xy + 3y^2$ in the direction of $\vec{\mathbf{u}} = (\cos\theta)\,\hat{\mathbf{i}} + (\sin\theta)\,\hat{\mathbf{j}}$.

Then determine $D_{\vec{\mathbf{u}}} f(-1,2)$.

#### Solution

First of all, since $\cos\theta = 3/5$ and $\theta$ is acute, this implies

$$\sin\theta = \sqrt{1 - \left(\frac{3}{5}\right)^2} = \sqrt{\frac{16}{25}} = \frac{4}{5}.$$

Using $f(x,y) = x^2 - xy + 3y^2$, we first calculate $f(x + h\cos\theta, y + h\sin\theta)$:

$$\begin{aligned} f(x + h\cos\theta, y + h\sin\theta) &= (x + h\cos\theta)^2 - (x + h\cos\theta)(y + h\sin\theta) + 3(y + h\sin\theta)^2 \\ &= x^2 + 2xh\cos\theta + h^2\cos^2\theta - xy - xh\sin\theta - yh\cos\theta - h^2\sin\theta\cos\theta \\ &\quad + 3y^2 + 6yh\sin\theta + 3h^2\sin^2\theta \\ &= x^2 + 2xh\left(\frac{3}{5}\right) + \frac{9h^2}{25} - xy - \frac{4xh}{5} - \frac{3yh}{5} - \frac{12h^2}{25} \\ &\quad + 3y^2 + 6yh\left(\frac{4}{5}\right) + 3h^2\left(\frac{16}{25}\right) \\ &= x^2 - xy + 3y^2 + \frac{2xh}{5} + \frac{9h^2}{5} + \frac{21yh}{5}. \end{aligned}$$

We substitute this expression into Equation 14.7.1 with $a = x$ and $b = y$:

$$\begin{aligned} D_{\vec{\mathbf{u}}} f(x,y) &= \lim_{h \to 0} \frac{f(x + h\cos\theta, y + h\sin\theta) - f(x,y)}{h} \\ &= \lim_{h \to 0} \frac{(x^2 - xy + 3y^2 + \frac{2xh}{5} + \frac{9h^2}{5} + \frac{21yh}{5}) - (x^2 - xy + 3y^2)}{h} \\ &= \lim_{h \to 0} \frac{\frac{2xh}{5} + \frac{9h^2}{5} + \frac{21yh}{5}}{h} \\ &= \lim_{h \to 0} \frac{2x}{5} + \frac{9h}{5} + \frac{21y}{5} \\ &= \frac{2x + 21y}{5}. \end{aligned}$$

To calculate $D_{\vec{\mathbf{u}}} f(-1,2)$, we substitute $x = -1$ and $y = 2$ into this answer (Figure 14.7.2):

$$D_{\vec{\mathbf{u}}} f(-1,2) = \frac{2(-1) + 21(2)}{5} = \frac{-2 + 42}{5} = 8.$$

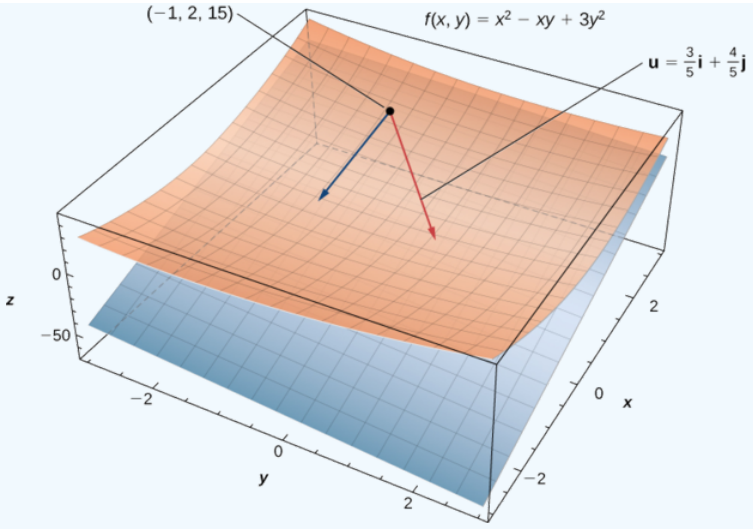

Figure 14.7.2: Finding the directional derivative in a given direction $\vec{\mathbf{u}}$ at a given point on a surface. The plane is tangent to the surface at the given point $(-1, 2, 15)$.

An easier approach to calculating directional derivatives that involves partial derivatives is outlined in the following theorem.

### Theorem 14.7.1: Directional Derivative of a Function of Two Variables

Let $z = f(x, y)$ be a function of two variables $x$ and $y$, and assume that $f_x$ and $f_y$ exist. Then the directional derivative of $f$ in the direction of $\vec{\mathbf{u}} = (\cos\theta)\,\hat{\mathbf{i}} + (\sin\theta)\,\hat{\mathbf{j}}$ is given by

$$D_{\vec{\mathbf{u}}} f(x, y) = f_x(x, y)\cos\theta + f_y(x, y)\sin\theta. \tag{14.7.3}$$

### Proof

Applying the definition of a directional derivative stated above in Equation 14.7.1, the directional derivative of $f$ in the direction of $\vec{\mathbf{u}} = (\cos\theta)\,\hat{\mathbf{i}} + (\sin\theta)\,\hat{\mathbf{j}}$ at a point $(x_0, y_0)$ in the domain of $f$ can be written

$$D_{\vec{\mathbf{u}}} f((x_0, y_0)) = \lim_{t\to 0} \frac{f(x_0 + t\cos\theta, y_0 + t\sin\theta) - f(x_0, y_0)}{t}.$$

Let $x = x_0 + t\cos\theta$ and $y = y_0 + t\sin\theta$, and define $g(t) = f(x, y)$. Since $f_x$ and $f_y$ both exist, we can use the chain rule for functions of two variables to calculate $g'(t)$:

$$g'(t) = \frac{\partial f}{\partial x}\frac{dx}{dt} + \frac{\partial f}{\partial y}\frac{dy}{dt} = f_x(x, y)\cos\theta + f_y(x, y)\sin\theta.$$

If $t = 0$, then $x = x_0$ and $y = y_0$, so

$$g'(0) = f_x(x_0, y_0)\cos\theta + f_y(x_0, y_0)\sin\theta$$

By the definition of $g'(t)$, it is also true that

$$g'(0) = \lim_{t\to 0}\frac{g(t) - g(0)}{t} = \lim_{t\to 0}\frac{f(x_0 + t\cos\theta, y_0 + t\sin\theta) - f(x_0, y_0)}{t}.$$

Therefore, $D_{\vec{\mathbf{u}}} f(x_0, y_0) = f_x(x_0, y_0)\cos\theta + f_y(x_0, y_0)\sin\theta$.

Since the point $(x_0, y_0)$ is an arbitrary point from the domain of $f$, this result holds for all points in the domain of $f$ for which the partials $f_x$ and $f_y$ exist.

Therefore,

$$D_{\vec{\mathbf{u}}} f(x, y) = f_x(x, y)\cos\theta + f_y(x, y)\sin\theta.$$

□

**Example 14.7.2: Finding a Directional Derivative: Alternative Method**

Let $\theta = \arccos(3/5)$. Find the directional derivative $D_{\vec{\mathbf{u}}} f(x,y)$ of $f(x,y) = x^2 - xy + 3y^2$ in the direction of $\vec{\mathbf{u}} = (\cos\theta)\,\hat{\mathbf{i}} + (\sin\theta)\,\hat{\mathbf{j}}$.

Then determine $D_{\vec{\mathbf{u}}} f(-1,2)$.

**Solution**

First, we must calculate the partial derivatives of $f$:

$$\begin{aligned} f_x(x,y) &= 2x - y \\ f_y(x,y) &= -x + 6y, \end{aligned}$$

Then we use Equation 14.7.3 with $\theta = \arccos(3/5)$:

$$\begin{aligned} D_{\vec{\mathbf{u}}} f(x,y) &= f_x(x,y)\cos\theta + f_y(x,y)\sin\theta \\ &= (2x-y)\frac{3}{5} + (-x+6y)\frac{4}{5} \\ &= \frac{6x}{5} - \frac{3y}{5} - \frac{4x}{5} + \frac{24y}{5} \\ &= \frac{2x+21y}{5}. \end{aligned}$$

To calculate $D_{\vec{\mathbf{u}}} f(-1,2)$, let $x = -1$ and $y = 2$:

$$D_{\vec{\mathbf{u}}} f(-1,2) = \frac{2(-1)+21(2)}{5} = \frac{-2+42}{5} = 8.$$

This is the same answer obtained in Example 14.7.1.

**Exercise 14.7.1:**

Find the directional derivative $D_{\vec{\mathbf{u}}} f(x,y)$ of $f(x,y) = 3x^2y - 4xy^3 + 3y^2 - 4x$ in the direction of $\vec{\mathbf{u}} = (\cos\frac{\pi}{3})\,\hat{\mathbf{i}} + (\sin\frac{\pi}{3})\,\hat{\mathbf{j}}$ using Equation 14.7.3.

What is $D_{\vec{\mathbf{u}}} f(3,4)$?

**Hint**

Calculate the partial derivatives and determine the value of $\theta$.

**Answer**

$$D_{\vec{\mathbf{u}}} f(x,y) = \frac{(6xy - 4y^3 - 4)(1)}{2} + \frac{(3x^2 - 12xy^2 + 6y)\sqrt{3}}{2}$$

$$D_{\vec{\mathbf{u}}} f(3,4) = \frac{72 - 256 - 4}{2} + \frac{(27 - 576 + 24)\sqrt{3}}{2} = -94 - \frac{525\sqrt{3}}{2}$$

If the vector that is given for the direction of the derivative is not a unit vector, then it is only necessary to divide by the norm of the vector. For example, if we wished to find the directional derivative of the function in Example 14.7.2 in the direction of the vector $\langle -5, 12\rangle$, we would first divide by its magnitude to get $\vec{\mathbf{u}}$. This gives us $\vec{\mathbf{u}} = \langle -\frac{5}{13}, \frac{12}{13}\rangle$.

Then

$$\begin{aligned} D_{\vec{\mathbf{u}}} f(x,y) &= f_x(x,y)\cos\theta + f_y(x,y)\sin\theta \\ &= -\frac{5}{13}(2x-y) + \frac{12}{13}(-x+6y) \\ &= -\frac{22}{13}x + \frac{17}{13}y \end{aligned}$$

## Gradient

The right-hand side of Equation 14.7.3 is equal to $f_x(x,y)\cos\theta + f_y(x,y)\sin\theta$, which can be written as the dot product of two vectors. Define the first vector as $\vec{\nabla} f(x,y) = f_x(x,y)\,\hat{\mathbf{i}} + f_y(x,y)\,\hat{\mathbf{j}}$ and the second vector as $\vec{\mathbf{u}} = (\cos\theta)\,\hat{\mathbf{i}} + (\sin\theta)\,\hat{\mathbf{j}}$. Then the right-hand side of the equation can be written as the dot product of these two vectors:

$$D_{\vec{\mathbf{u}}} f(x,y) = \vec{\nabla} f(x,y) \cdot \vec{\mathbf{u}}. \tag{14.7.4}$$

The first vector in Equation 14.7.4 has a special name: the gradient of the function $f$. The symbol $\nabla$ is called **nabla** and the vector $\vec{\nabla} f$ is read "**del** $f$."

**Definition: The Gradient**

Let $z = f(x,y)$ be a function of $x$ and $y$ such that $f_x$ and $f_y$ exist. The vector $\vec{\nabla} f(x,y)$ is called the **gradient** of $f$ and is defined as

$$\vec{\nabla} f(x,y) = f_x(x,y)\,\hat{\mathbf{i}} + f_y(x,y)\,\hat{\mathbf{j}}. \tag{14.7.5}$$

The vector $\vec{\nabla} f(x,y)$ is also written as "**grad** $f$."

**Example 14.7.3: Finding Gradients**

Find the gradient $\vec{\nabla} f(x,y)$ of each of the following functions:

a. $f(x,y) = x^2 - xy + 3y^2$
b. $f(x,y) = \sin 3x \cos 3y$

**Solution**

For both parts a. and b., we first calculate the partial derivatives $f_x$ and $f_y$, then use Equation 14.7.5.

a. $f_x(x,y) = 2x - y$ and $f_y(x,y) = -x + 6y$, so

$$\begin{aligned}\vec{\nabla} f(x,y) &= f_x(x,y)\,\hat{\mathbf{i}} + f_y(x,y)\,\hat{\mathbf{j}} \\ &= (2x - y)\,\hat{\mathbf{i}} + (-x + 6y)\,\hat{\mathbf{j}}.\end{aligned}$$

b. $f_x(x,y) = 3\cos 3x \cos 3y$ and $f_y(x,y) = -3\sin 3x \sin 3y$, so

$$\begin{aligned}\vec{\nabla} f(x,y) &= f_x(x,y)\,\hat{\mathbf{i}} + f_y(x,y)\,\hat{\mathbf{j}} \\ &= (3\cos 3x \cos 3y)\,\hat{\mathbf{i}} - (3\sin 3x \sin 3y)\,\hat{\mathbf{j}}.\end{aligned}$$

**Exercise 14.7.2**

Find the gradient $\vec{\nabla} f(x,y)$ of $f(x,y) = \dfrac{x^2 - 3y^2}{2x + y}$.

**Hint**

Calculate the partial derivatives, then use Equation 14.7.5.

**Answer**

$$\vec{\nabla} f(x,y) = \frac{2x^2 + 2xy + 6y^2}{(2x+y)^2}\,\hat{\mathbf{i}} - \frac{x^2 + 12xy + 3y^2}{(2x+y)^2}\,\hat{\mathbf{j}}$$

The gradient has some important properties. We have already seen one formula that uses the gradient: the formula for the directional derivative. Recall from The Dot Product that if the angle between two vectors $\vec{\mathbf{a}}$ and $\vec{\mathbf{b}}$ is $\varphi$, then $\vec{\mathbf{a}} \cdot \vec{\mathbf{b}} = \|\vec{\mathbf{a}}\|\|\vec{\mathbf{b}}\|\cos\varphi$. Therefore, if the angle between $\vec{\nabla} f(x_0,y_0)$ and $\vec{\mathbf{u}} = (\cos\theta)\,\hat{\mathbf{i}} + (\sin\theta)\,\hat{\mathbf{j}}$ is $\varphi$, we have

$$D_{\vec{\mathbf{u}}} f(x_0,y_0) = \vec{\nabla} f(x_0,y_0) \cdot \vec{\mathbf{u}} = \|\vec{\nabla} f(x_0,y_0)\|\|\vec{\mathbf{u}}\|\cos\varphi = \|\vec{\nabla} f(x_0,y_0)\|\cos\varphi.$$

The $\|\vec{\mathbf{u}}\|$ disappears because $\vec{\mathbf{u}}$ is a unit vector. Therefore, the directional derivative is equal to the magnitude of the gradient evaluated at $(x_0, y_0)$ multiplied by $\cos\varphi$. Recall that $\cos\varphi$ ranges from $-1$ to $1$.

If $\varphi = 0$, then $\cos\varphi = 1$ and $\vec{\nabla} f(x_0, y_0)$ and $\vec{\mathbf{u}}$ both point in the same direction.

If $\varphi = \pi$, then $\cos\varphi = -1$ and $\vec{\nabla} f(x_0, y_0)$ and $\vec{\mathbf{u}}$ point in opposite directions.

In the first case, the value of $D_{\vec{\mathbf{u}}} f(x_0, y_0)$ is maximized; in the second case, the value of $D_{\vec{\mathbf{u}}} f(x_0, y_0)$ is minimized.

We can also see that if $\vec{\nabla} f(x_0, y_0) = \vec{\mathbf{0}}$, then

$$D_{\vec{\mathbf{u}}} f(x_0, y_0) = \vec{\nabla} f(x_0, y_0) \cdot \vec{\mathbf{u}} = 0$$

for any vector $\vec{\mathbf{u}}$. These three cases are outlined in the following theorem.

### Theorem 14.7.2: Properties of the Gradient

Suppose the function $z = f(x, y)$ is differentiable at $(x_0, y_0)$ (Figure 14.7.3).

i. If $\vec{\nabla} f(x_0, y_0) = \vec{\mathbf{0}}$, then $D_{\vec{\mathbf{u}}} f(x_0, y_0) = 0$ for any unit vector $\vec{\mathbf{u}}$.
ii. If $\vec{\nabla} f(x_0, y_0) \neq \vec{\mathbf{0}}$, then $D_{\vec{\mathbf{u}}} f(x_0, y_0)$ is **maximized** when $\vec{\mathbf{u}}$ points in the same direction as $\vec{\nabla} f(x_0, y_0)$. The maximum value of $D_{\vec{\mathbf{u}}} f(x_0, y_0)$ is $\|\vec{\nabla} f(x_0, y_0)\|$.
iii. If $\vec{\nabla} f(x_0, y_0) \neq \vec{\mathbf{0}}$, then $D_{\vec{\mathbf{u}}} f(x_0, y_0)$ is **minimized** when $\vec{\mathbf{u}}$ points in the opposite direction from $\vec{\nabla} f(x_0, y_0)$. The minimum value of $D_{\vec{\mathbf{u}}} f(x_0, y_0)$ is $-\|\vec{\nabla} f(x_0, y_0)\|$.

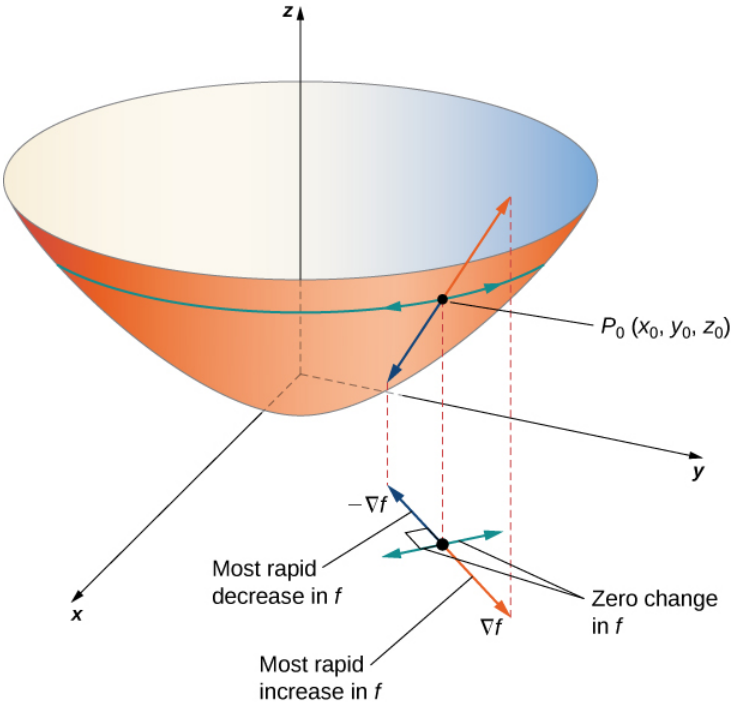

Figure 14.7.3: The gradient indicates the maximum and minimum values of the directional derivative at a point.

### Example 14.7.4: Finding a Maximum Directional Derivative

Find the direction for which the directional derivative of $f(x, y) = 3x^2 - 4xy + 2y^2$ at $(-2, 3)$ is a maximum. What is the maximum value?

**Solution**

The maximum value of the directional derivative occurs when $\vec{\nabla} f$ and the unit vector point in the same direction. Therefore, we start by calculating $\vec{\nabla} f(x, y)$:

$$f_x(x,y) = 6x - 4y \text{ and } f_y(x,y) = -4x + 4y$$

so

$$\vec{\nabla} f(x,y) = f_x(x,y)\,\hat{\mathbf{i}} + f_y(x,y)\,\hat{\mathbf{j}} = (6x - 4y)\,\hat{\mathbf{i}} + (-4x + 4y)\,\hat{\mathbf{j}}.$$

Next, we evaluate the gradient at $(-2,3)$:

$$\vec{\nabla} f(-2,3) = (6(-2) - 4(3))\,\hat{\mathbf{i}} + (-4(-2) + 4(3))\,\hat{\mathbf{j}} = -24\,\hat{\mathbf{i}} + 20\,\hat{\mathbf{j}}.$$

We need to find a unit vector that points in the same direction as $\vec{\nabla} f(-2,3)$, so the next step is to divide $\vec{\nabla} f(-2,3)$ by its magnitude, which is $\sqrt{(-24)^2 + (20)^2} = \sqrt{976} = 4\sqrt{61}$. Therefore,

$$\frac{\vec{\nabla} f(-2,3)}{\|\vec{\nabla} f(-2,3)\|} = \frac{-24}{4\sqrt{61}}i + \frac{20}{4\sqrt{61}}j = -\frac{6\sqrt{61}}{61}\,\hat{\mathbf{i}} + \frac{5\sqrt{61}}{61}\,\hat{\mathbf{j}}.$$

This is the unit vector that points in the same direction as $\vec{\nabla} f(-2,3)$. To find the angle corresponding to this unit vector, we solve the equations

$$\cos\theta = \frac{-6\sqrt{61}}{61} \text{ and } \sin\theta = \frac{5\sqrt{61}}{61}$$

for $\theta$. Since cosine is negative and sine is positive, the angle must be in the second quadrant. Therefore, $\theta = \pi - \arcsin((5\sqrt{61})/61) \approx 2.45$ rad.

The maximum value of the directional derivative at $(-2,3)$ is $\|\vec{\nabla} f(-2,3)\| = 4\sqrt{61}$ (Figure 14.7.4).

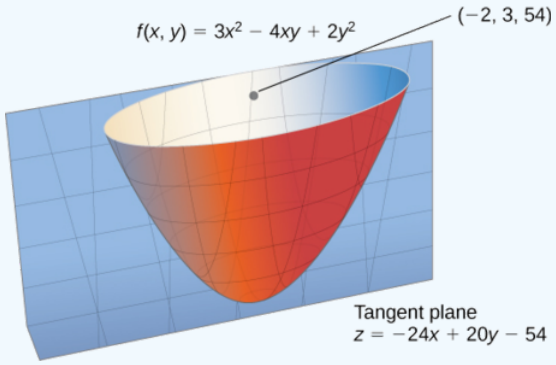

Figure 14.7.4: The maximum value of the directional derivative at $(-2,3)$ is in the direction of the gradient.

## ? Exercise 14.7.3

Find the direction for which the directional derivative of $g(x,y) = 4x - xy + 2y^2$ at $(-2,3)$ is a maximum. What is the maximum value?

**Hint**

Evaluate the gradient of $g$ at point $(-2,3)$.

**Answer**

The gradient of $g$ at $(-2,3)$ is $\vec{\nabla} g(-2,3) = \hat{\mathbf{i}} + 14\hat{\mathbf{j}}$. The unit vector that points in the same direction as $\vec{\nabla} g(-2,3)$ is

$$\frac{\vec{\nabla} g(-2,3)}{\|\vec{\nabla} g(-2,3)\|} = \frac{1}{\sqrt{197}}\,\hat{\mathbf{i}} + \frac{14}{\sqrt{197}}\,\hat{\mathbf{j}} = \frac{\sqrt{197}}{197}\,\hat{\mathbf{i}} + \frac{14\sqrt{197}}{197}\,\hat{\mathbf{j}},$$

which gives an angle of $\theta = \arcsin((14\sqrt{197})/197) \approx 1.499$ rad.

The maximum value of the directional derivative is $\|\vec{\nabla} g(-2,3)\| = \sqrt{197}$.

Figure 14.7.5 shows a portion of the graph of the function $f(x,y) = 3 + \sin x \sin y$. Given a point $(a,b)$ in the domain of $f$, the maximum value of the directional derivative at that point is given by $\|\vec{\nabla} f(a,b)\|$. This would equal the rate of greatest ascent if the surface represented a topographical map. If we went in the opposite direction, it would be the rate of greatest descent.

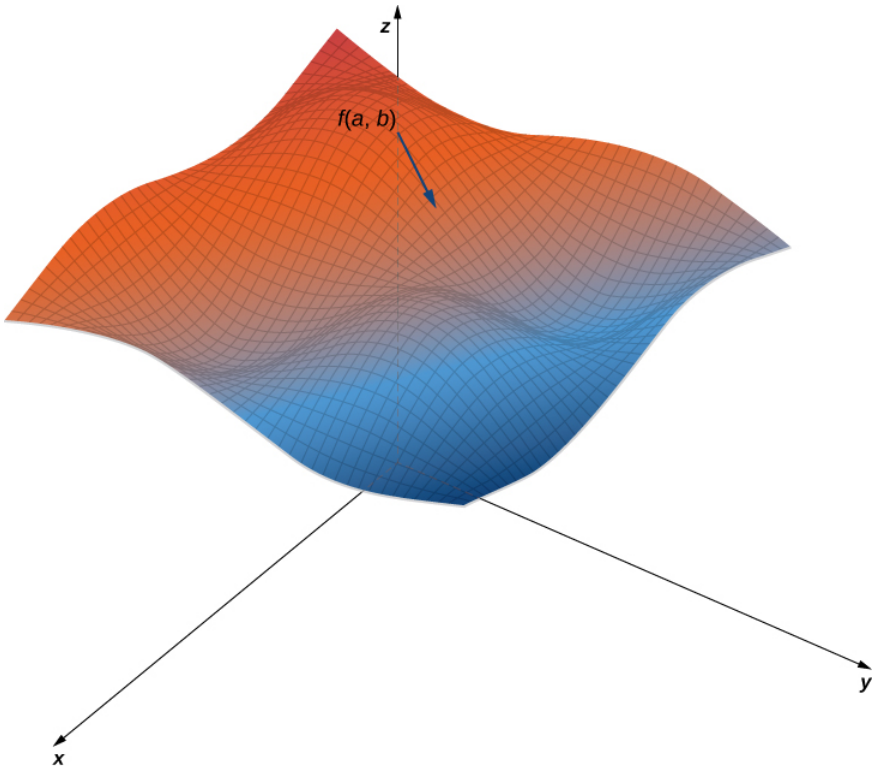

Figure 14.7.5: A typical surface in $\mathbb{R}^3$. Given a point on the surface, the directional derivative can be calculated using the gradient.

When using a topographical map, the steepest slope is always in the direction where the contour lines are closest together (Figure 14.7.6). This is analogous to the contour map of a function, assuming the level curves are obtained for equally spaced values throughout the range of that function.

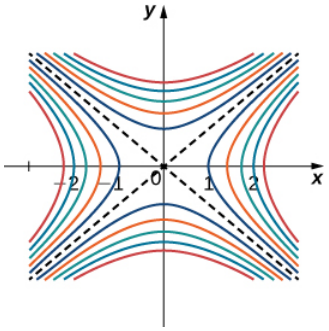

Figure 14.7.6: Contour map for the function $f(x,y) = x^2 - y^2$ using level values between $-5$ and $5$.

## Gradients and Level Curves

Recall that if a curve is defined parametrically by the function pair $(x(t), y(t))$, then the vector $x'(t)\,\hat{\mathbf{i}} + y'(t)\,\hat{\mathbf{j}}$ is tangent to the curve for every value of $t$ in the domain. Now let's assume $z = f(x,y)$ is a differentiable function of $x$ and $y$, and $(x_0, y_0)$ is in its domain. Let's suppose further that $x_0 = x(t_0)$ and $y_0 = y(t_0)$ for some value of $t$, and consider the level curve $f(x,y) = k$. Define $g(t) = f(x(t), y(t))$ and calculate $g'(t)$ on the level curve. By the chain Rule,

$$g'(t) = f_x(x(t), y(t))x'(t) + f_y(x(t), y(t))y'(t).$$

But $g'(t) = 0$ because $g(t) = k$ for all $t$. Therefore, on the one hand,

$$f_x(x(t), y(t))x'(t) + f_y(x(t), y(t))y'(t) = 0;$$

on the other hand,

$$f_x(x(t),y(t))x'(t)+f_y(x(t),y(t))y'(t)=\vec{\nabla}f(x,y)\cdot\langle x'(t),y'(t)\rangle.$$

Therefore,

$$\vec{\nabla}f(x,y)\cdot\langle x'(t),y'(t)\rangle=0.$$

Thus, the dot product of these vectors is equal to zero, which implies they are orthogonal. However, the second vector is tangent to the level curve, which implies the gradient must be normal to the level curve, which gives rise to the following theorem.

### Theorem 14.7.3: Gradient Is Normal to the Level Curve

Suppose the function $z=f(x,y)$ has continuous first-order partial derivatives in an open disk centered at a point $(x_0,y_0)$. If $\vec{\nabla}f(x_0,y_0)\neq 0$, then $\vec{\nabla}f(x_0,y_0)$ is normal to the level curve of $f$ at $(x_0,y_0)$.

We can use this theorem to find tangent and normal vectors to level curves of a function.

### Example 14.7.5: Finding Tangents to Level Curves

For the function $f(x,y)=2x^2-3xy+8y^2+2x-4y+4$, find a tangent vector to the level curve at point $(-2,1)$. Graph the level curve corresponding to $f(x,y)=18$ and draw in $\vec{\nabla}f(-2,1)$ and a tangent vector.

**Solution**

First, we must calculate $\vec{\nabla}f(x,y)$ :

$$f_x(x,y)=4x-3y+2 \text{ and } f_y=-3x+16y-4 \text{ so}$$
$$\vec{\nabla}f(x,y)=(4x-3y+2)\,\hat{\mathbf{i}}+(-3x+16y-4)\,\hat{\mathbf{j}}.$$

Next, we evaluate $\vec{\nabla}f(x,y)$ at $(-2,1)$ :

$$\vec{\nabla}f(-2,1)=(4(-2)-3(1)+2)\,\hat{\mathbf{i}}+(-3(-2)+16(1)-4)\,\hat{\mathbf{j}}=-9\,\hat{\mathbf{i}}+18\,\hat{\mathbf{j}}.$$

This vector is orthogonal to the curve at point $(-2,1)$. We can obtain a tangent vector by reversing the components and multiplying either one by $-1$. Thus, for example, $-18\,\hat{\mathbf{i}}-9\,\hat{\mathbf{j}}$ is a tangent vector (Figure 14.7.7).

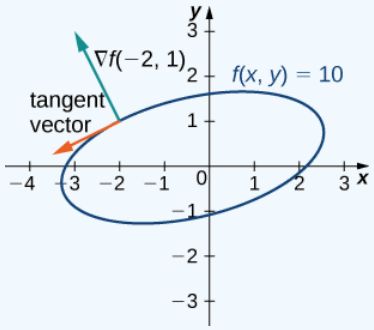

Figure 14.7.7: Tangent and normal vectors to $2x^2-3xy+8y^2+2x-4y+4=18$ at point $(-2,1)$.

### Exercise 14.7.4

For the function $f(x,y)=x^2-2xy+5y^2+3x-2y+3$, find the tangent to the level curve at point $(1,1)$. Draw the graph of the level curve corresponding to $f(x,y)=8$ and draw $\vec{\nabla}f(1,1)$ and a tangent vector.

**Hint**

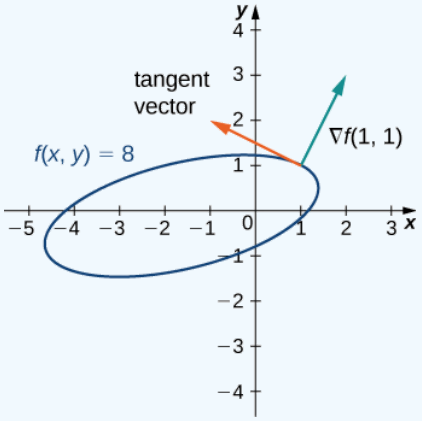
Calculate the gradient at point $(1,1)$.

**Answer**

$\vec{\nabla} f(x,y) = (2x - 2y + 3)\,\hat{\mathbf{i}} + (-2x + 10y - 2)\,\hat{\mathbf{j}}$

$\vec{\nabla} f(1,1) = 3\,\hat{\mathbf{i}} + 6\,\hat{\mathbf{j}}$

Tangent vector: $6\,\hat{\mathbf{i}} - 3\,\hat{\mathbf{j}}$ or $-6\,\hat{\mathbf{i}} + 3\,\hat{\mathbf{j}}$



## Three-Dimensional Gradients and Directional Derivatives

The definition of a gradient can be extended to functions of more than two variables.

**Definition: Gradients in 3D**

Let $w = f(x,y,z)$ be a function of three variables such that $f_x$, $f_y$, and $f_z$ exist. The vector $\vec{\nabla} f(x,y,z)$ is called the gradient of $f$ and is defined as

$$\vec{\nabla} f(x,y,z) = f_x(x,y,z)\,\hat{\mathbf{i}} + f_y(x,y,z)\,\hat{\mathbf{j}} + f_z(x,y,z)\,\hat{\mathbf{k}}. \tag{14.7.6}$$

$\vec{\nabla} f(x,y,z)$ can also be written as $\textbf{grad}\ f(x,y,z)$.

Calculating the gradient of a function in three variables is very similar to calculating the gradient of a function in two variables. First, we calculate the partial derivatives $f_x$, $f_y$, and $f_z$, and then we use Equation 14.7.6.

**Example 14.7.6: Finding Gradients in Three Dimensions**

Find the gradient $\vec{\nabla} f(x,y,z)$ of each of the following functions:

a. $f(x,y,z) = 5x^2 - 2xy + y^2 - 4yz + z^2 + 3xz$
b. $f(x,y,z) = e^{-2z}\sin 2x \cos 2y$

**Solution**

For both parts a. and b., we first calculate the partial derivatives $f_x, f_y$, and $f_z$, then use Equation 14.7.6.

a. $f_x(x,y,z) = 10x - 2y + 3z$, $f_y(x,y,z) = -2x + 2y - 4z$, and $f_z(x,y,z) = 3x - 4y + 2z$, so

$$\begin{aligned}\vec{\nabla} f(x,y,z) &= f_x(x,y,z)\,\hat{\mathbf{i}} + f_y(x,y,z)\,\hat{\mathbf{j}} + f_z(x,y,z)\,\hat{\mathbf{k}} \\ &= (10x - 2y + 3z)\,\hat{\mathbf{i}} + (-2x + 2y - 4z)\,\hat{\mathbf{j}} + (3x - 4y + 2z)\,\hat{\mathbf{k}}.\end{aligned}$$

b. $f_x(x,y,z) = 2e^{-2z}\cos 2x \cos 2y$, $f_y(x,y,z) = -2e^{-2z}\sin 2x \sin 2y$, and $f_z(x,y,z) = -2e^{-2z}\sin 2x \cos 2y$, so

$$\begin{aligned}\vec{\nabla} f(x,y,z) &= f_x(x,y,z)\,\hat{\mathbf{i}} + f_y(x,y,z)\,\hat{\mathbf{j}} + f_z(x,y,z)\,\hat{\mathbf{k}} \\ &= (2e^{-2z}\cos 2x \cos 2y)\,\hat{\mathbf{i}} + (-2e^{-2z}\sin 2x \sin 2y)\,\hat{\mathbf{j}} + (-2e^{-2z}\sin 2x \cos 2y)\,\hat{\mathbf{k}} \\ &= 2e^{-2z}(\cos 2x \cos 2y\,\hat{\mathbf{i}} - \sin 2x \sin 2y\,\hat{\mathbf{j}} - \sin 2x \cos 2y\,\hat{\mathbf{k}}).\end{aligned}$$

**Exercise 14.7.5:**

Find the gradient $\vec{\nabla} f(x,y,z)$ of $f(x,y,z) = \dfrac{x^2 - 3y^2 + z^2}{2x + y - 4z}$.

**Answer**

$$\vec{\nabla} f(x,y,z) = \frac{2x^2 + 2xy + 6y^2 - 8xz - 2z^2}{(2x + y - 4z)^2}\,\hat{\mathbf{i}} - \frac{x^2 + 12xy + 3y^2 - 24yz + z^2}{(2x + y - 4z)^2}\,\hat{\mathbf{j}} + \frac{4x^2 - 12y^2 - 4z^2 + 4xz + 2yz}{(2x + y - 4z)^2}\,\hat{\mathbf{k}}$$

The directional derivative can also be generalized to functions of three variables. To determine a direction in three dimensions, a vector with three components is needed. This vector is a unit vector, and the components of the unit vector are called *directional cosines*. Given a three-dimensional unit vector $\vec{\mathbf{u}}$ in standard form (i.e., the initial point is at the origin), this vector forms three different angles with the positive $x$-, $y$-, and $z$-axes. Let's call these angles $\alpha, \beta$, and $\gamma$. Then the directional cosines are given by $\cos\alpha, \cos\beta$, and $\cos\gamma$. These are the components of the unit vector $\vec{\mathbf{u}}$; since $\vec{\mathbf{u}}$ is a unit vector, it is true that $\cos^2\alpha + \cos^2\beta + \cos^2\gamma = 1$.

**Definition: Directional Derivative of a Function of Three variables**

Suppose $w = f(x,y,z)$ is a function of three variables with a domain of $D$. Let $(x_0, y_0, z_0) \in D$ and let $\vec{\mathbf{u}} = \cos\alpha\,\hat{\mathbf{i}} + \cos\beta\,\hat{\mathbf{j}} + \cos\gamma\,\hat{\mathbf{k}}$ be a unit vector. Then, the directional derivative of $f$ in the direction of $u$ is given by

$$D_{\vec{\mathbf{u}}} f(x_0, y_0, z_0) = \lim_{t \to 0} \frac{f(x_0 + t\cos\alpha, y_0 + t\cos\beta, z_0 + t\cos\gamma) - f(x_0, y_0, z_0)}{t}$$

provided the limit exists.

We can calculate the directional derivative of a function of three variables by using the gradient, leading to a formula that is analogous to Equation 14.7.3.

**Theorem 14.7.4: Directional Derivative of a Function of Three Variables**

Let $f(x,y,z)$ be a differentiable function of three variables and let $\vec{\mathbf{u}} = \cos\alpha\,\hat{\mathbf{i}} + \cos\beta\,\hat{\mathbf{j}} + \cos\gamma\,\hat{\mathbf{k}}$ be a unit vector. Then, the directional derivative of $f$ in the direction of $\vec{\mathbf{u}}$ is given by

$$\begin{aligned} D_{\vec{\mathbf{u}}} f(x,y,z) &= \vec{\nabla} f(x,y,z) \cdot \vec{\mathbf{u}} \\ &= f_x(x,y,z)\cos\alpha + f_y(x,y,z)\cos\beta + f_z(x,y,z)\cos\gamma. \end{aligned} \tag{14.7.7}$$

The three angles $\alpha, \beta$, and $\gamma$ determine the unit vector $\vec{\mathbf{u}}$. In practice, we can use an arbitrary (nonunit) vector, then divide by its magnitude to obtain a unit vector in the desired direction.

**Example 14.7.7: Finding a Directional Derivative in Three Dimensions**

Calculate $D_{\vec{\mathbf{v}}} f(1,-2,3)$ in the direction of $\vec{\mathbf{v}} = -\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 2\hat{\mathbf{k}}$ for the function

$$f(x,y,z) = 5x^2 - 2xy + y^2 - 4yz + z^2 + 3xz.$$

**Solution:**

First, we find the magnitude of $v$:

$$\|\vec{\mathbf{v}}\| = \sqrt{(-1)^2 + (2)^2 + (2)^2} = \sqrt{9} = 3.$$

Therefore, $\dfrac{\vec{\mathbf{v}}}{\|\vec{\mathbf{v}}\|} = \dfrac{-\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 2\hat{\mathbf{k}}}{3} = -\dfrac{1}{3}\hat{\mathbf{i}} + \dfrac{2}{3}\hat{\mathbf{j}} + \dfrac{2}{3}\hat{\mathbf{k}}$ is a unit vector in the direction of $\vec{\mathbf{v}}$, so $\cos\alpha = -\dfrac{1}{3}, \cos\beta = \dfrac{2}{3}$, and $\cos\gamma = \dfrac{2}{3}$. Next, we calculate the partial derivatives of $f$:

$$f_x(x,y,z) = 10x - 2y + 3z$$
$$f_y(x,y,z) = -2x + 2y - 4z$$
$$f_z(x,y,z) = -4y + 2z + 3x,$$

then substitute them into Equation 14.7.7:

$$\begin{aligned} D_{\vec{v}} f(x,y,z) &= f_x(x,y,z)\cos\alpha + f_y(x,y,z)\cos\beta + f_z(x,y,z)\cos\gamma \\ &= (10x - 2y + 3z)(-\tfrac{1}{3}) + (-2x + 2y - 4z)(\tfrac{2}{3}) + (-4y + 2z + 3x)(\tfrac{2}{3}) \\ &= -\frac{10x}{3} + \frac{2y}{3} - \frac{3z}{3} - \frac{4x}{3} + \frac{4y}{3} - \frac{8z}{3} - \frac{8y}{3} + \frac{4z}{3} + \frac{6x}{3} \\ &= -\frac{8x}{3} - \frac{2y}{3} - \frac{7z}{3}. \end{aligned}$$

Last, to find $D_{\vec{v}} f(1,-2,3)$, we substitute $x = 1$, $y = -2$, and $z = 3$ :

$$\begin{aligned} D_{\vec{v}} f(1,-2,3) &= -\frac{8(1)}{3} - \frac{2(-2)}{3} - \frac{7(3)}{3} \\ &= -\frac{8}{3} + \frac{4}{3} - \frac{21}{3} \\ &= -\frac{25}{3}. \end{aligned}$$

**? Exercise 14.7.6:**

Calculate $D_{\vec{v}} f(x,y,z)$ and $D_{\vec{v}} f(0,-2,5)$ in the direction of $\vec{\mathbf{v}} = -3\hat{\mathbf{i}} + 12\hat{\mathbf{j}} - 4\hat{\mathbf{k}}$ for the function

$$f(x,y,z) = 3x^2 + xy - 2y^2 + 4yz - z^2 + 2xz.$$

**Hint**

First, divide $\vec{\mathbf{v}}$ by its magnitude, calculate the partial derivatives of $f$, then use Equation 14.7.7.

**Answer**

$$D_{\vec{v}} f(x,y,z) = -\frac{3}{13}(6x + y + 2z) + \frac{12}{13}(x - 4y + 4z) - \frac{4}{13}(2x + 4y - 2z)$$

$$D_{\vec{v}} f(0,-2,5) = \frac{384}{13}$$

## Summary

- A directional derivative represents a rate of change of a function in any given direction.
- The gradient can be used in a formula to calculate the directional derivative.
- The gradient indicates the direction of greatest change of a function of more than one variable.

### Key Equations

- **directional derivative (two dimensions)**

$$D_{\vec{u}} f(a,b) = \lim_{h \to 0} \frac{f(a + h\cos\theta, b + h\sin\theta) - f(a,b)}{h}$$

or

$$D_{\vec{u}} f(x,y) = f_x(x,y)\cos\theta + f_y(x,y)\sin\theta$$

- **gradient (two dimensions)**

$$\vec{\nabla} f(x,y) = f_x(x,y)\hat{\mathbf{i}} + f_y(x,y)\hat{\mathbf{j}}$$

- **gradient (three dimensions)**

$$\vec{\nabla} f(x,y,z) = f_x(x,y,z)\hat{\mathbf{i}} + f_y(x,y,z)\hat{\mathbf{j}} + f_z(x,y,z)\hat{\mathbf{k}}$$

- **directional derivative (three dimensions)**

$$D_{\vec{\mathbf{u}}} f(x,y,z) = \vec{\nabla} f(x,y,z) \cdot \vec{\mathbf{u}} = f_x(x,y,z)\cos\alpha + f_y(x,y,z)\cos\beta + f_x(x,y,z)\cos\gamma$$

## Glossary

**directional derivative**

the derivative of a function in the direction of a given unit vector

**gradient**

the gradient of the function $f(x,y)$ is defined to be $\vec{\nabla} f(x,y) = (\partial f/\partial x)\,\hat{\mathbf{i}} + (\partial f/\partial y)\,\hat{\mathbf{j}}$, which can be generalized to a function of any number of independent variables

# 14.7E: Exercises for Section 14.6

**In exercise 1, find the directional derivative using the limit definition only.**

1) a. $f(x,y) = 5 - 2x^2 - \frac{1}{2}y^2$ at point $P(3,4)$ in the direction of $\vec{\mathbf{u}} = (\cos\frac{\pi}{4})\,\hat{\mathbf{i}} + (\sin\frac{\pi}{4})\,\hat{\mathbf{j}}$

**Answer**

a. $D_{\vec{\mathbf{u}}} f(3,4) = -8\sqrt{2}$

1) b. $f(x,y) = y^2\cos(2x)$ at point $P(\frac{\pi}{3},2)$ in the direction of $\vec{\mathbf{u}} = (\cos\frac{\pi}{4})\,\hat{\mathbf{i}} + (\sin\frac{\pi}{4})\,\hat{\mathbf{j}}$

**Answer**

b. $D_{\vec{\mathbf{u}}} f(\frac{\pi}{3},2) = -2\sqrt{6} - \sqrt{2}$

2) Find the directional derivative of $f(x,y) = y^2\sin(2x)$ at point $P(\frac{\pi}{4},2)$ in the direction of $\vec{\mathbf{u}} = 5\,\hat{\mathbf{i}} + 12\,\hat{\mathbf{j}}$.

**In exercises 3 - 13, find the directional derivative of the function in the direction of $\vec{\mathbf{v}}$ as a function of $x$ and $y$. Remember that you first need to find a unit vector in the direction of the direction vector. Then find the value of the directional derivative at point $P$.**

3) $f(x,y) = xy, \quad P(-2,0), \quad \vec{\mathbf{v}} = \frac{1}{2}\,\hat{\mathbf{i}} + \frac{\sqrt{3}}{2}\,\hat{\mathbf{j}}$

**Answer**

$D_{\vec{\mathbf{v}}} f(x,y) = \frac{1}{2}y + \frac{\sqrt{3}}{2}x$
$D_{\vec{\mathbf{v}}} f(-2,0) = -\sqrt{3}$

4) $h(x,y) = e^x\sin y, \quad P(1,\frac{\pi}{2}), \quad \vec{\mathbf{v}} = -\hat{\mathbf{i}}$

5) $f(x,y) = x^2y, \quad P(-5,5), \quad \vec{\mathbf{v}} = 3\,\hat{\mathbf{i}} - 4\,\hat{\mathbf{j}}$

**Answer**

$D_{\vec{\mathbf{v}}} f(x,y) = \frac{6}{5}xy - \frac{4}{5}x^2$
$D_{\vec{\mathbf{v}}} f(-5,5) = -50$

6) $f(x,y) = xy, \quad P(1,1), \quad \vec{\mathbf{u}} = \langle\frac{\sqrt{2}}{2},\frac{\sqrt{2}}{2}\rangle$

7) $f(x,y) = x^2 - y^2, \quad P(1,0), \quad \vec{\mathbf{u}} = \langle\frac{\sqrt{3}}{2},\frac{1}{2}\rangle$

**Answer**

$D_{\vec{\mathbf{u}}} f(x,y) = x\sqrt{3} - y$
$D_{\vec{\mathbf{u}}} f(1,0) = \sqrt{3}$

8) $f(x,y) = 3x + 4y + 7, \quad P(0,\frac{\pi}{2}), \quad \vec{\mathbf{u}} = \langle\frac{3}{5},\frac{4}{5}\rangle$

9) $f(x,y) = e^x\cos y, \quad P = (0,\frac{\pi}{2}), \quad \vec{\mathbf{u}} = \langle 0,5\rangle$

**Answer**

$D_{\vec{\mathbf{u}}} f(x,y) = -e^x\sin y$
$D_{\vec{\mathbf{u}}} f(0,\frac{\pi}{2}) = -1$

10) $f(x,y) = y^{10}, \quad \vec{\mathbf{u}} = \langle 0,-3\rangle, \quad P = (1,-1)$

11) $f(x,y) = \ln(x^2+y^2), \quad \vec{\mathbf{u}} = \langle 2,-5\rangle, \quad P(1,2)$

**Answer**

$D_{\vec{\mathbf{u}}} f(x,y) = \frac{\sqrt{29}}{29}\left(\frac{4x-10y}{x^2+y^2}\right)$
$D_{\vec{\mathbf{u}}} f(1,2) = -\frac{16\sqrt{29}}{145}$

12) $h(x,y,z) = xyz, \quad P(2,1,1), \quad \vec{\mathbf{v}} = 2\hat{\mathbf{i}} + \hat{\mathbf{j}} - \hat{\mathbf{k}}$

**Answer**

$D_{\vec{\mathbf{v}}} h(x,y,z) = \frac{\sqrt{6}}{6}(2yz + xz - xy)$
$D_{\vec{\mathbf{v}}} h(2,1,1) = \frac{2}{\sqrt{6}} = \frac{\sqrt{6}}{3}$

13) $f(x,y,z) = y^2 + xz, \quad P(1,2,2), \quad \vec{\mathbf{v}} = \langle 2,-1,2 \rangle$

**Answer**

$D_{\vec{\mathbf{v}}} f(x,y,z) = \frac{2}{3}(z - y + x)$
$D_{\vec{\mathbf{v}}} f(1,2,2) = \frac{2}{3}$

**In exercises 14 - 19, find the directional derivative of the function in the direction of the unit vector $\vec{\mathbf{u}} = \cos\theta\,\hat{\mathbf{i}} + \sin\theta\,\hat{\mathbf{j}}$.**

14) $f(x,y) = x^2 + 2y^2, \quad \theta = \frac{\pi}{6}$

15) $f(x,y) = \dfrac{y}{x+2y}, \quad \theta = -\frac{\pi}{4}$

**Answer**

$$D_{\vec{\mathbf{u}}} f(x,y) = \frac{-\sqrt{2}(x+y)}{2(x+2y)^2}$$

16) $f(x,y) = \cos(3x+y), \quad \theta = \frac{\pi}{4}$

17) $w(x,y) = ye^x, \quad \theta = \frac{\pi}{3}$

**Answer**

$$D_{\vec{\mathbf{u}}} f(x,y) = \frac{e^x(y+\sqrt{3})}{2}$$

18) $f(x,y) = x\arctan(y), \quad \theta = \frac{\pi}{2}$

19) $f(x,y) = \ln(x+2y), \quad \theta = \frac{\pi}{3}$

**Answer**

$$D_{\vec{\mathbf{u}}} f(x,y) = \frac{1+2\sqrt{3}}{2(x+2y)}$$

**In exercises 20 - 23, find the gradient $\vec{\nabla} f$.**

20) Find the gradient of $f(x,y) = 3x^2 + y^3 - 3x + y$. Then find it's value at the point $P(2,3)$.

21) Find the gradient of $f(x,y) = \dfrac{14 - x^2 - y^2}{3}$. Then, find the gradient at point $P(1,2)$.

**Answer**

$\vec{\nabla} f(x,y) = -\frac{2}{3}x\,\hat{\mathbf{i}} - \frac{2}{3}y\,\hat{\mathbf{j}}$
$\vec{\nabla} f(1,2) = -\frac{2}{3}\,\hat{\mathbf{i}} - \frac{4}{3}\,\hat{\mathbf{j}}$

22) Find the gradient of $f(x,y) = \ln(4x^3 - 3y)$. Then, find the gradient at point $P(1,1)$.

23) Find the gradient of $f(x,y,z) = xy + yz + xz$. Then find the gradient at point $P(1,2,3)$.

**Answer**

$\vec{\nabla} f(x,y,z) = \langle y+z, x+z, y+x \rangle$
$\vec{\nabla} f(1,2,3) = \langle 5,4,3 \rangle$

**In exercises 24 - 25, find the directional derivative of the function at point $P$ in the direction of $Q$.**

24) $f(x,y) = x^2 + 3y^2, \quad P(1,1), \quad Q(4,5)$

25) $f(x,y,z)=\dfrac{y}{x+z}, \quad P(2,1,-1), \quad Q(-1,2,0)$

**Answer**

$D_{\overrightarrow{PQ}}f(x,y)=\frac{3}{\sqrt{11}}$

26) Find the directional derivative of $f(x,y,z))$ at $P$ and in the direction of $\vec{\mathbf{u}}$: $f(x,y,z)=\ln(x^2+2y^2+3z^2), \quad P(2,1,4), \quad \vec{\mathbf{u}}=\frac{-3}{13}\,\hat{\mathbf{i}}-\frac{4}{13}\,\hat{\mathbf{j}}-\frac{12}{13}\,\hat{\mathbf{k}}$.

**In exercises 27 - 29, find the directional derivative of the function at $P$ in the direction of $\vec{\mathbf{u}}$.**

27) $f(x,y)=\ln(5x+4y), \quad P(3,9), \quad \vec{\mathbf{u}}=6\,\hat{\mathbf{i}}+8\,\hat{\mathbf{j}}$

**Answer**

$D_{\vec{\mathbf{u}}}f(3,9)=\frac{31}{255}$

28) $f(x,y)=-7x+2y, \quad P(2,-4), \quad \vec{\mathbf{u}}=4\,\hat{\mathbf{i}}-3\,\hat{\mathbf{j}}$

29) $f(x,y,z)=4x^5y^2z^3, \quad P(2,-1,1), \quad \vec{\mathbf{u}}=\frac{1}{3}\,\hat{\mathbf{i}}+\frac{2}{3}\,\hat{\mathbf{j}}-\frac{2}{3}\,\hat{\mathbf{k}}$

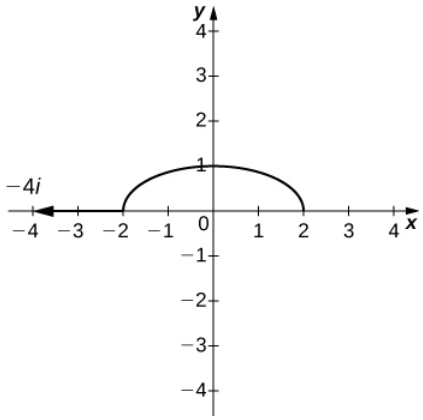
**Answer**

$D_{\vec{\mathbf{u}}}f(2,-1,1)=-320$

30) [T] Use technology to sketch the level curve of $f(x,y)=4x-2y+3$ that passes through $P(1,2)$ and draw the gradient vector at $P$.

31) [T] Use technology to sketch the level curve of $f(x,y)=x^2+4y^2$ that passes through $P(-2,0)$ and draw the gradient vector at $P$.

**Answer**



**In exercises 32 - 35, find the gradient vector at the indicated point.**

32) $f(x,y)=xy^2-yx^2, \quad P(-1,1)$

33) $f(x,y)=xe^y-\ln(x), \quad P(-3,0)$

**Answer**

$\vec{\nabla}f(-3,0)=\frac{4}{3}\,\hat{\mathbf{i}}-3\,\hat{\mathbf{j}}$

34) $f(x,y,z)=xy-\ln(z), \quad P(2,-2,2)$

35) $f(x,y,z)=x\sqrt{y^2+z^2}, \quad P(-2,-1,-1)$

**Answer**

$\vec{\nabla}f(-2,-1,-1)=\sqrt{2}\,\hat{\mathbf{i}}+\sqrt{2}\,\hat{\mathbf{j}}+\sqrt{2}\,\hat{\mathbf{k}}$

**In exercises 36 - 40, find the indicated directional derivative of the function.**

36) $f(x,y) = x^2 + xy + y^2$ at point $(-5,-4)$ in the direction the function increases most rapidly.

37) $f(x,y) = e^{xy}$ at point $(6,7)$ in the direction the function increases most rapidly.

**Answer**

$1.6(10^{19})$

38) $f(x,y) = \arctan\left(\frac{y}{x}\right)$ at point $(-9,9)$ in the direction the function increases most rapidly.

39) $f(x,y,z) = \ln(xy + yz + zx)$ at point $(-9,-18,-27)$ in the direction the function increases most rapidly.

**Answer**

$\frac{5\sqrt{2}}{99}$

40) $f(x,y,z) = \frac{x}{y} + \frac{y}{z} + \frac{z}{x}$ at point $(5,-5,5)$ in the direction the function increases most rapidly.

**In exercises 41 - 43, find the maximum rate of change of $f$ at the given point and the direction in which it occurs.**

41) $f(x,y) = xe^{-y}, \quad (-2,0)$

**Answer**

$\max\{D_{\vec{u}} f(-2,0)\} = \sqrt{5}, \quad \langle 1,2\rangle$

**Solution:**

$\vec{\nabla} f(x,y) = e^{-y}\hat{\mathbf{i}} - xe^{-y}\hat{\mathbf{j}}$. So $\max\{D_{\vec{u}} f(-2,0)\} = \|\vec{\nabla} f(-2,0)\| = \sqrt{5}$.
The direction in which it occurs will just be the direction of the gradient vector: $\vec{\nabla} f(-2,0) = \langle 1,2\rangle$.

42) $f(x,y) = \sqrt{x^2 + 2y}, \quad (4,10)$

43) $f(x,y) = \cos(3x + 2y), \quad \left(\frac{\pi}{6}, -\frac{\pi}{8}\right)$

**Answer**

$\max\{D_{\vec{u}} f\left(\frac{\pi}{6}, -\frac{\pi}{8}\right)\} = \sqrt{\frac{13}{2}} = \frac{\sqrt{26}}{2}, \quad \langle -3,-2\rangle$

**In exercises 44 - 47, find equations of**

**a. the tangent plane and**

**b. the normal line to the given surface at the given point.**

44) The level curve $f(x,y,z) = 12$ for $f(x,y,z) = 4x^2 - 2y^2 + z^2$ at point $(2,2,2)$.

45) $f(x,y,z) = xy + yz + xz = 3$ at point $(1,1,1)$

**Answer**

a. tangent plane equation: $x + y + z = 3$,
b. normal line equations: $x - 1 = y - 1 = z - 1$

46) $f(x,y,z) = xyz = 6$ at point $(1,2,3)$

47) $f(x,y,z) = xe^y \cos z - z = 1$ at point $(1,0,0)$

**Answer**

a. tangent plane equation: $x + y - z = 1$,
b. normal line equations: $x - 1 = y = -z$

**In exercises 48 - 51, solve the stated problem.**

48) The temperature $T$ in a metal sphere is inversely proportional to the distance from the center of the sphere (the origin: $(0,0,0)$). The temperature at point $(1,2,2)$ is $120°$C.

a. Find the rate of change of the temperature at point $(1,2,2)$ in the direction toward point $(2,1,3)$.

b. Show that, at any point in the sphere, the direction of greatest increase in temperature is given by a vector that points toward the origin.

49) The **electrical potential** (voltage) in a certain region of space is given by the function $V(x,y,z) = 5x^2 - 3xy + xyz$.

a. Find the rate of change of the voltage at point $(3,4,5)$ in the direction of the vector $\langle 1,1,-1\rangle$.

b. In which direction does the voltage change most rapidly at point $(3,4,5)$?

c. What is the maximum rate of change of the voltage at point $(3,4,5)$?

**Answer**

a. $\frac{32}{\sqrt{3}}$,
b. $\langle 38,6,12\rangle$,
c. $2\sqrt{406}$

50) If the electric potential at a point $(x,y)$ in the $xy$-plane is $V(x,y) = e^{-2x}\cos(2y)$, then the electric intensity vector at $(x,y)$ is $E = -\vec{\nabla}V(x,y)$.

a. Find the electric intensity vector at $(\frac{\pi}{4},0)$.

b. Show that, at each point in the plane, the electric potential decreases most rapidly in the direction of the vector $E$.

51) In two dimensions, the motion of an ideal fluid is governed by a velocity potential $\varphi$. The velocity components of the fluid $u$ in the $x$-direction and $v$ in the $y$-direction, are given by $\langle u,v\rangle = \vec{\nabla}\varphi$. Find the velocity components associated with the velocity potential $\varphi(x,y) = \sin\pi x \sin 2\pi y$.

**Answer**

$\langle u,v\rangle = \langle \pi\cos(\pi x)\sin(2\pi y), 2\pi\sin(\pi x)\cos(2\pi y)\rangle$

# 14.8: Maxima/Minima Problems

**Learning Objectives**

- Use partial derivatives to locate critical points for a function of two variables.
- Apply a second derivative test to identify a critical point as a local maximum, local minimum, or saddle point for a function of two variables.
- Examine critical points and boundary points to find absolute maximum and minimum values for a function of two variables.

One of the most useful applications for derivatives of a function of one variable is the determination of maximum and/or minimum values. This application is also important for functions of two or more variables, but as we have seen in earlier sections of this chapter, the introduction of more independent variables leads to more possible outcomes for the calculations. The main ideas of finding critical points and using derivative tests are still valid, but new wrinkles appear when assessing the results.

## Critical Points

For functions of a single variable, we defined critical points as the values of the variable at which the function's derivative equals zero or does not exist. For functions of two or more variables, the concept is essentially the same, except for the fact that we are now working with partial derivatives.

**Definition: Critical Points**

Let $z = f(x, y)$ be a function of two variables that is differentiable on an open set containing the point $(x_0, y_0)$. The point $(x_0, y_0)$ is called a *critical point* of a function of two variables $f$ if one of the two following conditions holds:

1. $f_x(x_0, y_0) = f_y(x_0, y_0) = 0$
2. Either $f_x(x_0, y_0)$ or $f_y(x_0, y_0)$ does not exist.

**Example 14.8.1: Finding Critical Points**

Find the critical points of each of the following functions:

a. $f(x, y) = \sqrt{4y^2 - 9x^2 + 24y + 36x + 36}$
b. $g(x, y) = x^2 + 2xy - 4y^2 + 4x - 6y + 4$

**Solution**

**a**. First, we calculate $f_x(x, y)$ and $f_y(x, y)$ :

$$f_x(x, y) = \frac{1}{2}(-18x + 36)(4y^2 - 9x^2 + 24y + 36x + 36)^{-1/2}$$
$$= \frac{-9x + 18}{\sqrt{4y^2 - 9x^2 + 24y + 36x + 36}}$$

$$f_y(x, y) = \frac{1}{2}(8y + 24)(4y^2 - 9x^2 + 24y + 36x + 36)^{-1/2}$$
$$= \frac{4y + 12}{\sqrt{4y^2 - 9x^2 + 24y + 36x + 36}}.$$

Next, we set each of these expressions equal to zero:

$$\frac{-9x + 18}{\sqrt{4y^2 - 9x^2 + 24y + 36x + 36}} = 0$$
$$\frac{4y + 12}{\sqrt{4y^2 - 9x^2 + 24y + 36x + 36}} = 0.$$

Then, multiply each equation by its common denominator:

$$-9x + 18 = 0$$
$$4y + 12 = 0.$$

Therefore, $x = 2$ and $y = -3$, so $(2, -3)$ is a critical point of $f$.

We must also check for the possibility that the denominator of each partial derivative can equal zero, thus causing the partial derivative not to exist. Since the denominator is the same in each partial derivative, we need only do this once:

$$4y^2 - 9x^2 + 24y + 36x + 36 = 0. \tag{14.8.1}$$

Equation 14.8.1 represents a hyperbola. We should also note that the domain of $f$ consists of points satisfying the inequality

$$4y^2 - 9x^2 + 24y + 36x + 36 \geq 0.$$

Therefore, any points on the hyperbola are not only critical points, they are also on the boundary of the domain. To put the hyperbola in standard form, we use the method of completing the square:

$$\begin{aligned} 4y^2 - 9x^2 + 24y + 36x + 36 &= 0 \\ 4y^2 - 9x^2 + 24y + 36x &= -36 \\ 4y^2 + 24y - 9x^2 + 36x &= -36 \\ 4(y^2 + 6y) - 9(x^2 - 4x) &= -36 \\ 4(y^2 + 6y + 9) - 9(x^2 - 4x + 4) &= -36 - 36 + 36 \\ 4(y + 3)^2 - 9(x - 2)^2 &= -36. \end{aligned}$$

Dividing both sides by $-36$ puts the equation in standard form:

$$\begin{aligned} \frac{4(y+3)^2}{-36} - \frac{9(x-2)^2}{-36} &= 1 \\ \frac{(x-2)^2}{4} - \frac{(y+3)^2}{9} &= 1. \end{aligned}$$

Notice that point $(2, -3)$ is the center of the hyperbola.

Thus, the critical points of the function $f$ are $(2, -3)$ and all points on the hyperbola, $\frac{(x-2)^2}{4} - \frac{(y+3)^2}{9} = 1$.

**b**. First, we calculate $g_x(x, y)$ and $g_y(x, y)$:

$$\begin{aligned} g_x(x, y) &= 2x + 2y + 4 \\ g_y(x, y) &= 2x - 8y - 6. \end{aligned}$$

Next, we set each of these expressions equal to zero, which gives a system of equations in $x$ and $y$:

$$\begin{aligned} 2x + 2y + 4 &= 0 \\ 2x - 8y - 6 &= 0. \end{aligned}$$

Subtracting the second equation from the first gives $10y + 10 = 0$, so $y = -1$. Substituting this into the first equation gives $2x + 2(-1) + 4 = 0$, so $x = -1$.

Therefore $(-1, -1)$ is a critical point of $g$. There are no points in $\mathbb{R}^2$ that make either partial derivative not exist.

Figure 14.8.1 shows the behavior of the surface at the critical point.

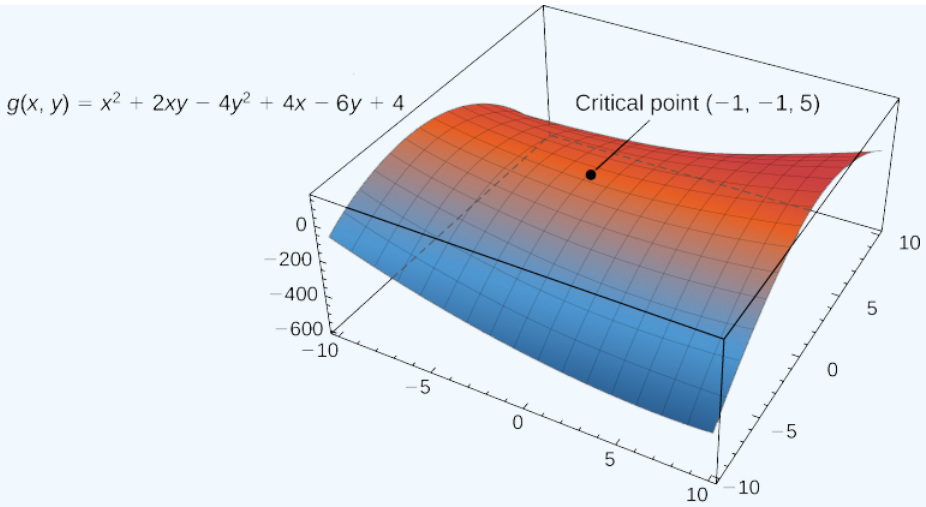

Figure **14.8.1**: The function $g(x, y)$ has a critical point at $(-1, -1, 5)$.

## Exercise 14.8.1

Find the critical point of the function $f(x, y) = x^3 + 2xy - 2x - 4y$.

**Hint**

Calculate $f_x(x, y)$ and $f_y(x, y)$, then set them equal to zero.

**Answer**

The only critical point of $f$ is $(2, -5)$.

The main purpose for determining critical points is to locate relative maxima and minima, as in single-variable calculus. When working with a function of one variable, the definition of a local extremum involves finding an interval around the critical point such that the function value is either greater than or less than all the other function values in that interval. When working with a function of two or more variables, we work with an open disk around the point.

## Definition: Global and Local Extrema

Let $z = f(x, y)$ be a function of two variables that is defined and continuous on an open set containing the point $(x_0, y_0)$. Then $f$ has a **local maximum** at $(x_0, y_0)$ if

$$f(x_0, y_0) \geq f(x, y)$$

for all points $(x, y)$ within some disk centered at $(x_0, y_0)$. The number $f(x_0, y_0)$ is called a local maximum value. If the preceding inequality holds for every point $(x, y)$ in the domain of $f$, then $f$ has a **global maximum** (also called an absolute maximum) at $(x_0, y_0)$.

The function $f$ has a local minimum at $(x_0, y_0)$ if

$$f(x_0, y_0) \leq f(x, y)$$

for all points $(x, y)$ within some disk centered at $(x_0, y_0)$. The number $f(x_0, y_0)$ is called a local minimum value. If the preceding inequality holds for every point $(x, y)$ in the domain of $f$, then $f$ has a **global minimum** (also called an absolute minimum) at $(x_0, y_0)$.

If $f(x_0, y_0)$ is either a local maximum or local minimum value, then it is called a **local extremum** (see the following figure).

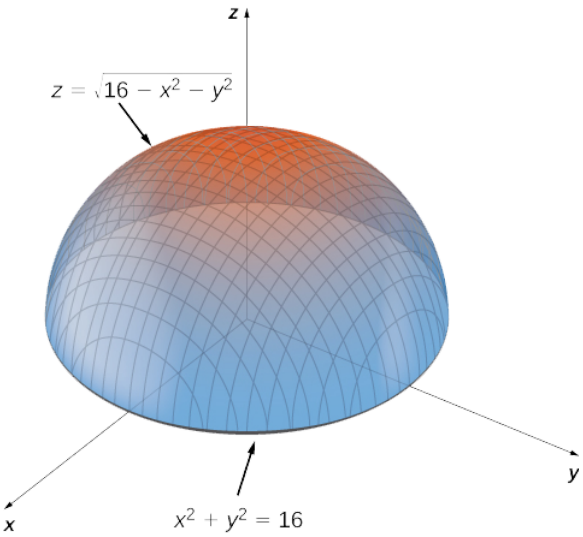

Figure 14.8.2: The graph of $z = \sqrt{16 - x^2 - y^2}$ has a maximum value when $(x, y) = (0, 0)$. It attains its minimum value at the boundary of its domain, which is the circle $x^2 + y^2 = 16$.

In Calculus 1, we showed that extrema of functions of one variable occur at critical points. The same is true for functions of more than one variable, as stated in the following theorem.

**Fermat's Theorem for Functions of Two Variables**

Let $z = f(x, y)$ be a function of two variables that is defined and continuous on an open set containing the point $(x_0, y_0)$. Suppose $f_x$ and $f_y$ each exist at $(x_0, y_0)$. If f has a local extremum at $(x_0, y_0)$, then $(x_0, y_0)$ is a critical point of $f$.

## Second Derivative Test

Consider the function $f(x) = x^3$. This function has a critical point at $x = 0$, since $f'(0) = 3(0)^2 = 0$. However, $f$ does not have an extreme value at $x = 0$. Therefore, the existence of a critical value at $x = x_0$ does not guarantee a local extremum at $x = x_0$. The same is true for a function of two or more variables. One way this can happen is at a **saddle point**. An example of a saddle point appears in the following figure.

$z = x^2 - y^2$

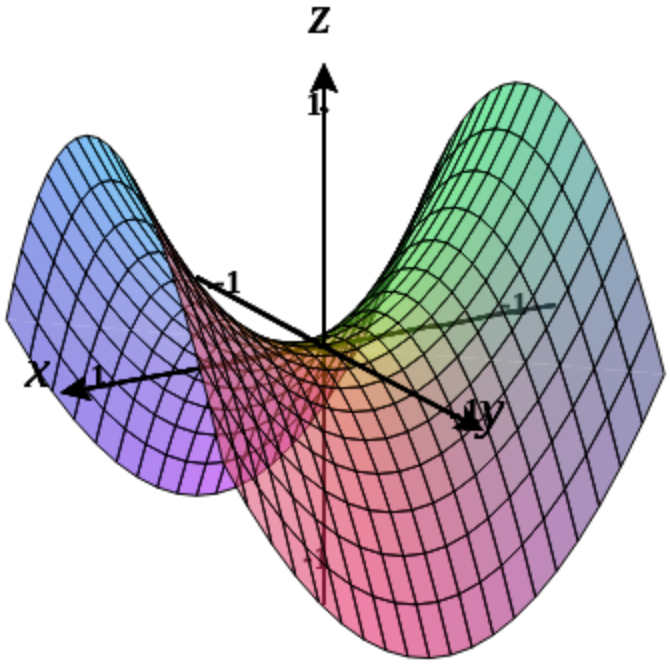

**Figure 14.8.3:** Graph of the function $z = x^2 - y^2$. This graph has a saddle point at the origin.

In this graph, the origin is a saddle point. This is because the first partial derivatives of $f(x, y) = x^2 - y^2$ are both equal to zero at this point, but it is neither a maximum nor a minimum for the function. Furthermore the vertical trace corresponding to $y = 0$ is $z = x^2$ (a parabola opening upward), but the vertical trace corresponding to $x = 0$ is $z = -y^2$ (a parabola opening downward). Therefore, it is both a global maximum for one trace and a global minimum for another.

**Definition: Saddle Point**

Given the function $z = f(x, y)$, the point $\big(x_0, y_0, f(x_0, y_0)\big)$ is a saddle point if both $f_x(x_0, y_0) = 0$ and $f_y(x_0, y_0) = 0$, but $f$ does not have a local extremum at $(x_0, y_0)$.

The second derivative test for a function of one variable provides a method for determining whether an extremum occurs at a critical point of a function. When extending this result to a function of two variables, an issue arises related to the fact that there are, in fact, four different second-order partial derivatives, although equality of mixed partials reduces this to three. The second derivative test for a function of two variables, stated in the following theorem, uses a **discriminant** $D$ that replaces $f''(x_0)$ in the second derivative test for a function of one variable.

**Second Derivative Test**

Let $z = f(x, y)$ be a function of two variables for which the first- and second-order partial derivatives are continuous on some disk containing the point $(x_0, y_0)$. Suppose $f_x(x_0, y_0) = 0$ and $f_y(x_0, y_0) = 0$. Define the quantity

$$D = f_{xx}(x_0, y_0) f_{yy}(x_0, y_0) - \big(f_{xy}(x_0, y_0)\big)^2.$$

Then:

i. If $D > 0$ and $f_{xx}(x_0, y_0) > 0$, then f has a local minimum at $(x_0, y_0)$.
ii. If $D > 0$ and $f_{xx}(x_0, y_0) < 0$, then f has a local maximum at $(x_0, y_0)$.
iii. If $D < 0$, then $f$ has a saddle point at $(x_0, y_0)$.

iv. If $D = 0$, then the test is inconclusive.

See Figure 14.8.4.

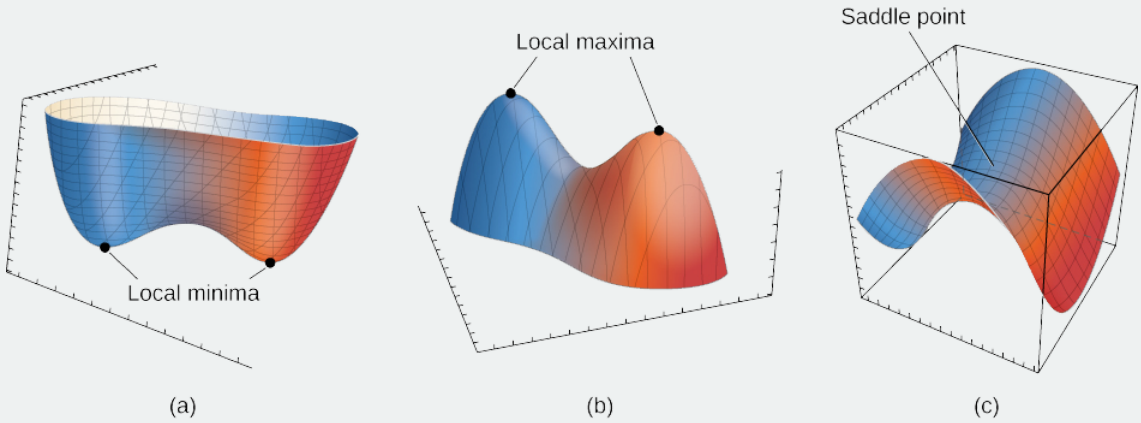

Figure 14.8.4: The second derivative test can often determine whether a function of two variables has local minima (a), local maxima (b), or a saddle point (c).

To apply the second derivative test, it is necessary that we first find the critical points of the function. There are several steps involved in the entire procedure, which are outlined in a problem-solving strategy.

### Problem-Solving Strategy: Using the Second Derivative Test for Functions of Two Variables

Let $z = f(x, y)$ be a function of two variables for which the first- and second-order partial derivatives are continuous on some disk containing the point $(x_0, y_0)$. To apply the second derivative test to find local extrema, use the following steps:

1. Determine the critical points $(x_0, y_0)$ of the function $f$ where $f_x(x_0, y_0) = f_y(x_0, y_0) = 0$. Discard any points where at least one of the partial derivatives does not exist.
2. Calculate the discriminant $D = f_{xx}(x_0, y_0) f_{yy}(x_0, y_0) - \left(f_{xy}(x_0, y_0)\right)^2$ for each critical point of $f$.
3. Apply the four cases of the test to determine whether each critical point is a local maximum, local minimum, or saddle point, or whether the theorem is inconclusive.

### Example 14.8.2: Using the Second Derivative Test

Find the critical points for each of the following functions, and use the second derivative test to find the local extrema:

a. $f(x, y) = 4x^2 + 9y^2 + 8x - 36y + 24$

b. $g(x, y) = \frac{1}{3}x^3 + y^2 + 2xy - 6x - 3y + 4$

#### Solution

a. **Step 1** of the problem-solving strategy involves finding the critical points of $f$. To do this, we first calculate $f_x(x, y)$ and $f_y(x, y)$, then set each of them equal to zero:

$$f_x(x, y) = 8x + 8$$
$$f_y(x, y) = 18y - 36.$$

Setting them equal to zero yields the system of equations

$$8x + 8 = 0$$
$$18y - 36 = 0.$$

The solution to this system is $x = -1$ and $y = 2$. Therefore $(-1, 2)$ is a critical point of $f$.

**Step 2** of the problem-solving strategy involves calculating $D$. To do this, we first calculate the second partial derivatives of $f$:

$$f_{xx}(x,y) = 8$$
$$f_{xy}(x,y) = 0$$
$$f_{yy}(x,y) = 18.$$

Therefore, $D = f_{xx}(-1,2)f_{yy}(-1,2) - \left(f_{xy}(-1,2)\right)^2 = (8)(18) - (0)^2 = 144.$

**Step 3** states to apply the four cases of the test to classify the function's behavior at this critical point.

Since $D > 0$ and $f_{xx}(-1,2) > 0$, this corresponds to case 1. Therefore, $f$ has a local minimum at $(-1,2)$ as shown in the following figure.

$z = 4x^2 + 9y^2 + 8x - 36y + 24$

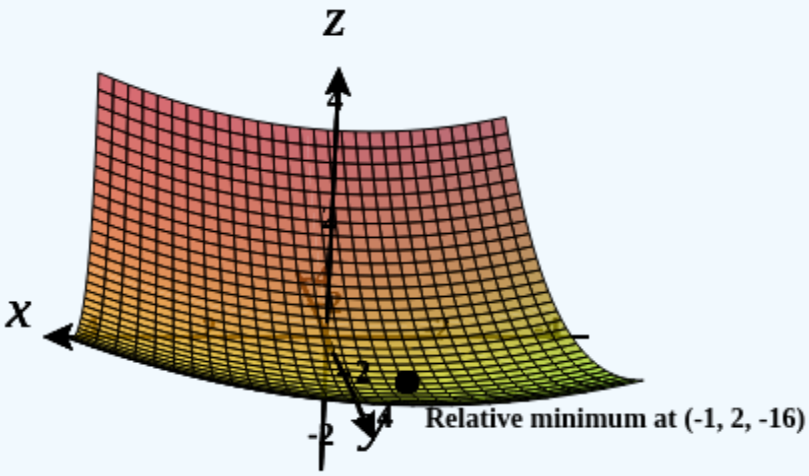

**Figure 14.8.5:** The function $f(x,y)$ has a local minimum at $(-1,2,-16)$. Note the scale on the $y$-axis in this plot is in thousands.

b. For **step 1**, we first calculate $g_x(x,y)$ and $g_y(x,y)$, then set each of them equal to zero:

$$g_x(x,y) = x^2 + 2y - 6$$
$$g_y(x,y) = 2y + 2x - 3.$$

Setting them equal to zero yields the system of equations

$$x^2 + 2y - 6 = 0$$
$$2y + 2x - 3 = 0.$$

To solve this system, first solve the second equation for $y$. This gives $y = \dfrac{3-2x}{2}$. Substituting this into the first equation gives

$$x^2 + 3 - 2x - 6 = 0$$
$$x^2 - 2x - 3 = 0$$
$$(x-3)(x+1) = 0.$$

Therefore, $x = -1$ or $x = 3$. Substituting these values into the equation $y = \dfrac{3-2x}{2}$ yields the critical points $\left(-1, \frac{5}{2}\right)$ and $\left(3, -\frac{3}{2}\right)$.

**Step 2** involves calculating the second partial derivatives of $g$:

$$g_{xx}(x,y) = 2x$$
$$g_{xy}(x,y) = 2$$
$$g_{yy}(x,y) = 2.$$

Then, we find a general formula for $D$:

$$\begin{aligned} D(x_0,y_0) &= g_{xx}(x_0,y_0)g_{yy}(x_0,y_0) - \left(g_{xy}(x_0,y_0)\right)^2 \\ &= (2x_0)(2) - 2^2 \\ &= 4x_0 - 4. \end{aligned}$$

Next, we substitute each critical point into this formula:

$$D\left(-1, \tfrac{5}{2}\right) = (2(-1))(2) - (2)^2 = -4 - 4 = -8$$
$$D\left(3, -\tfrac{3}{2}\right) = (2(3))(2) - (2)^2 = 12 - 4 = 8.$$

In step 3, we note that, applying Note to point $\left(-1, \frac{5}{2}\right)$ leads to case **3**, which means that $\left(-1, \frac{5}{2}\right)$ is a saddle point. Applying the theorem to point $\left(3, -\frac{3}{2}\right)$ leads to case **1**, which means that $\left(3, -\frac{3}{2}\right)$ corresponds to a local minimum as shown in the following figure.

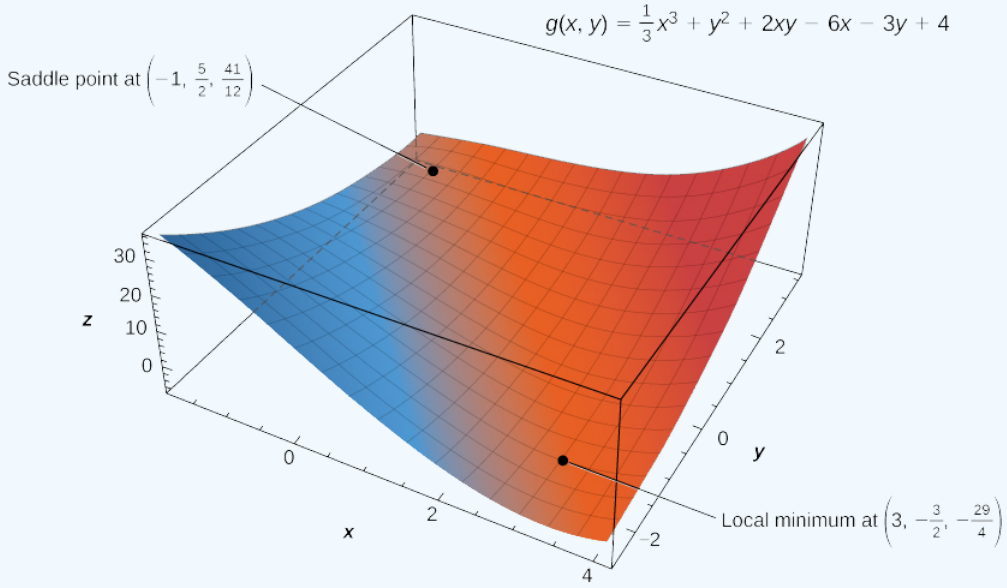

Figure 14.8.6: The function $g(x,y)$ has a local minimum and a saddle point.

## Exercise 14.8.2

Use the second derivative test to find the local extrema of the function

$$f(x,y) = x^3 + 2xy - 6x - 4y^2.$$

**Hint**

Follow the problem-solving strategy for applying the second derivative test.

**Answer**

$\left(\frac{4}{3}, \frac{1}{3}\right)$ is a saddle point, $\left(-\frac{3}{2}, -\frac{3}{8}\right)$ is a local maximum.

## Absolute Maxima and Minima

When finding global extrema of functions of one variable on a closed interval, we start by checking the critical values over that interval and then evaluate the function at the endpoints of the interval. When working with a function of two variables, the closed interval is replaced by a closed, bounded set. A set is bounded if all the points in that set can be contained within a ball (or disk) of finite radius. First, we need to find the critical points inside the set and calculate the corresponding critical values. Then, it is necessary to find the maximum and minimum value of the function on the boundary of the set. When we have all these values, the largest function value corresponds to the global maximum and the smallest function value corresponds to the absolute minimum. First, however, we need to be assured that such values exist. The following theorem does this.

### Extreme Value Theorem

A continuous function $f(x,y)$ on a closed and bounded set $D$ in the plane attains an absolute maximum value at some point of $D$ and an absolute minimum value at some point of $D$.

Now that we know any continuous function $f$ defined on a closed, bounded set attains its extreme values, we need to know how to find them.

### Finding Extreme Values of a Function of Two Variables

Assume $z = f(x,y)$ is a differentiable function of two variables defined on a closed, bounded set $D$. Then $f$ will attain the absolute maximum value and the absolute minimum value, which are, respectively, the largest and smallest values found among the following:

1. The values of $f$ at the critical points of $f$ in $D$.
2. The values of $f$ on the boundary of $D$.

The proof of this theorem is a direct consequence of the extreme value theorem and Fermat's theorem. In particular, if either extremum is not located on the boundary of $D$, then it is located at an interior point of $D$. But an interior point $(x_0, y_0)$ of $D$ that's an absolute extremum is also a local extremum; hence, $(x_0, y_0)$ is a critical point of $f$ by Fermat's theorem. Therefore the only possible values for the global extrema of $f$ on $D$ are the extreme values of $f$ on the interior or boundary of $D$.

### Problem-Solving Strategy: Finding Absolute Maximum and Minimum Values

Let $z = f(x,y)$ be a continuous function of two variables defined on a closed, bounded set $D$, and assume $f$ is differentiable on $D$. To find the absolute maximum and minimum values of $f$ on $D$, do the following:

1. Determine the critical points of $f$ in $D$.
2. Calculate $f$ at each of these critical points.
3. Determine the maximum and minimum values of $f$ on the boundary of its domain.
4. The maximum and minimum values of $f$ will occur at one of the values obtained in steps **2** and **3**.

Finding the maximum and minimum values of $f$ on the boundary of $D$ can be challenging. If the boundary is a rectangle or set of straight lines, then it is possible to parameterize the line segments and determine the maxima on each of these segments, as seen in Example **14.8.3**. The same approach can be used for other shapes such as circles and ellipses.

If the boundary of the set $D$ is a more complicated curve defined by a function $g(x,y) = c$ for some constant $c$, and the first-order partial derivatives of $g$ exist, then the method of Lagrange multipliers can prove useful for determining the extrema of $f$ on the boundary which is introduced in Lagrange Multipliers.

### Example 14.8.3: Finding Absolute Extrema

Use the problem-solving strategy for finding absolute extrema of a function to determine the absolute extrema of each of the following functions:

a. $f(x,y) = x^2 - 2xy + 4y^2 - 4x - 2y + 24$ on the domain defined by $0 \le x \le 4$ and $0 \le y \le 2$
b. $g(x,y) = x^2 + y^2 + 4x - 6y$ on the domain defined by $x^2 + y^2 \le 16$

### Solution

**a**. Using the problem-solving strategy, step 1 involves finding the critical points of $f$ on its domain. Therefore, we first calculate $f_x(x,y)$ and $f_y(x,y)$, then set them each equal to zero:

$$f_x(x,y) = 2x - 2y - 4$$
$$f_y(x,y) = -2x + 8y - 2.$$

Setting them equal to zero yields the system of equations

$$2x - 2y - 4 = 0$$
$$-2x + 8y - 2 = 0.$$

The solution to this system is $x = 3$ and $y = 1$. Therefore $(3,1)$ is a critical point of $f$. Calculating $f(3,1)$ gives $f(3,1) = 17$.

The next step involves finding the extrema of $f$ on the boundary of its domain. The boundary of its domain consists of four line segments as shown in the following graph:

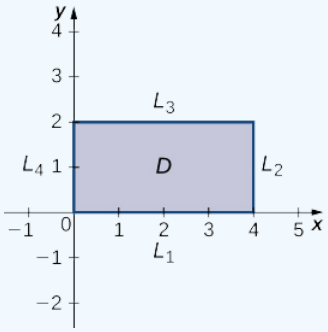

Figure 14.8.7: Graph of the domain of the function $f(x,y) = x^2 - 2xy + 4y^2 - 4x - 2y + 24$.

$L_1$ is the line segment connecting $(0,0)$ and $(4,0)$, and it can be parameterized by the equations $x(t) = t, y(t) = 0$ for $0 \le t \le 4$. Define $g(t) = f\big(x(t), y(t)\big)$. This gives $g(t) = t^2 - 4t + 24$. Differentiating $g$ leads to $g'(t) = 2t - 4$. Therefore, $g$ has a critical value at $t = 2$, which corresponds to the point $(2,0)$. Calculating $f(2,0)$ gives the $z$-value $20$.

$L_2$ is the line segment connecting $(4,0)$ and $(4,2)$, and it can be parameterized by the equations $x(t) = 4, y(t) = t$ for $0 \le t \le 2$. Again, define $g(t) = f\big(x(t), y(t)\big)$. This gives $g(t) = 4t^2 - 10t + 24$. Then, $g'(t) = 8t - 10$. g has a critical value at $t = \frac{5}{4}$, which corresponds to the point $\left(4, \frac{5}{4}\right)$. Calculating $f\left(4, \frac{5}{4}\right)$ gives the $z$-value $17.75$.

$L_3$ is the line segment connecting $(0,2)$ and $(4,2)$, and it can be parameterized by the equations $x(t) = t, y(t) = 2$ for $0 \le t \le 4$. Again, define $g(t) = f\big(x(t), y(t)\big)$. This gives $g(t) = t^2 - 8t + 36$. The critical value corresponds to the point $(4,2)$. So, calculating $f(4,2)$ gives the $z$-value $20$.

$L_4$ is the line segment connecting $(0,0)$ and $(0,2)$, and it can be parameterized by the equations $x(t) = 0, y(t) = t$ for $0 \le t \le 2$. This time, $g(t) = 4t^2 - 2t + 24$ and the critical value $t = \frac{1}{4}$ correspond to the point $\left(0, \frac{1}{4}\right)$. Calculating $f\left(0, \frac{1}{4}\right)$ gives the $z$-value $23.75$.

We also need to find the values of $f(x,y)$ at the corners of its domain. These corners are located at $(0,0), (4,0), (4,2)$ and $(0,2)$:

$$f(0,0) = (0)^2 - 2(0)(0) + 4(0)^2 - 4(0) - 2(0) + 24 = 24$$
$$f(4,0) = (4)^2 - 2(4)(0) + 4(0)^2 - 4(4) - 2(0) + 24 = 24$$
$$f(4,2) = (4)^2 - 2(4)(2) + 4(2)^2 - 4(4) - 2(2) + 24 = 20$$
$$f(0,2) = (0)^2 - 2(0)(2) + 4(2)^2 - 4(0) - 2(2) + 24 = 36.$$

The absolute maximum value is $36$, which occurs at $(0,2)$, and the global minimum value is $20$, which occurs at both $(4,2)$ and $(2,0)$ as shown in the following figure.

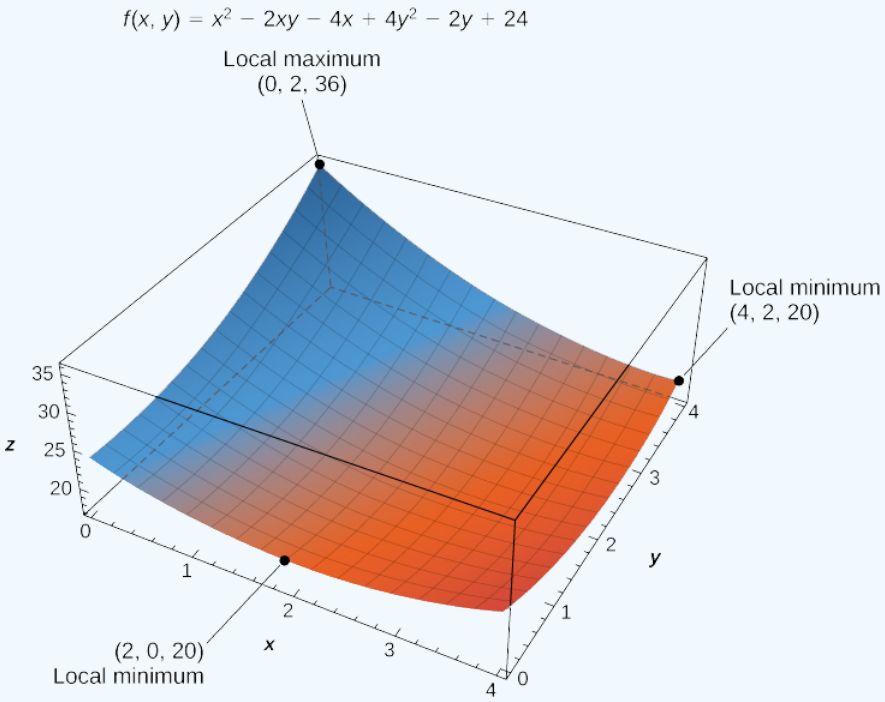

Figure 14.8.8: The function $f(x,y)$ has two global minima and one global maximum over its domain.

**b**. Using the problem-solving strategy, step 1 involves finding the critical points of $g$ on its domain. Therefore, we first calculate $g_x(x,y)$ and $g_y(x,y)$, then set them each equal to zero:

$$g_x(x,y) = 2x + 4$$
$$g_y(x,y) = 2y - 6.$$

Setting them equal to zero yields the system of equations

$$2x + 4 = 0$$
$$2y - 6 = 0.$$

The solution to this system is $x = -2$ and $y = 3$. Therefore, $(-2, 3)$ is a critical point of $g$. Calculating $g(-2,3)$, we get

$$g(-2,3) = (-2)^2 + 3^2 + 4(-2) - 6(3) = 4 + 9 - 8 - 18 = -13.$$

The next step involves finding the extrema of $g$ on the boundary of its domain. The boundary of its domain consists of a circle of radius 4 centered at the origin as shown in the following graph.

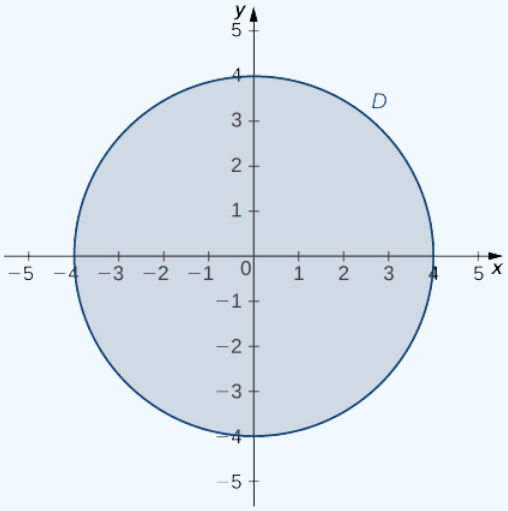

Figure 14.8.9: Graph of the restricted domain of the function $g(x,y)=x^2+y^2+4x-6y$.

The boundary of the domain of $g$ can be parameterized using the functions $x(t)=4\cos t$, $y(t)=4\sin t$ for $0\le t\le 2\pi$. Define $h(t)=g\big(x(t),y(t)\big)$:

$$\begin{aligned} h(t) &= g\big(x(t),y(t)\big) \\ &= (4\cos t)^2+(4\sin t)^2+4(4\cos t)-6(4\sin t) \\ &= 16\cos^2 t+16\sin^2 t+16\cos t-24\sin t \\ &= 16+16\cos t-24\sin t. \end{aligned}$$

Setting $h'(t)=0$ leads to

$$\begin{aligned} -16\sin t-24\cos t &= 0 \\ -16\sin t &= 24\cos t \\ \frac{-16\sin t}{-16\cos t} &= \frac{24\cos t}{-16\cos t} \\ \tan t &= -\frac{3}{2}. \end{aligned}$$

This equation has two solutions over the interval $0\le t\le 2\pi$. One is $t=\pi-\arctan\left(\frac{3}{2}\right)$ and the other is $t=2\pi-\arctan\left(\frac{3}{2}\right)$. For the first angle,

$$\sin t=\sin\left(\pi-\arctan\left(\tfrac{3}{2}\right)\right)=\sin\left(\arctan\left(\tfrac{3}{2}\right)\right)=\frac{3\sqrt{13}}{13}$$

$$\cos t=\cos\left(\pi-\arctan\left(\tfrac{3}{2}\right)\right)=-\cos\left(\arctan\left(\tfrac{3}{2}\right)\right)=-\frac{2\sqrt{13}}{13}.$$

Therefore, $x(t)=4\cos t=-\frac{8\sqrt{13}}{13}$ and $y(t)=4\sin t=\frac{12\sqrt{13}}{13}$, so $\left(-\frac{8\sqrt{13}}{13},\frac{12\sqrt{13}}{13}\right)$ is a critical point on the boundary and

$$\begin{aligned} g\left(-\tfrac{8\sqrt{13}}{13},\tfrac{12\sqrt{13}}{13}\right) &= \left(-\tfrac{8\sqrt{13}}{13}\right)^2+\left(\tfrac{12\sqrt{13}}{13}\right)^2+4\left(-\tfrac{8\sqrt{13}}{13}\right)-6\left(\tfrac{12\sqrt{13}}{13}\right) \\ &= \frac{144}{13}+\frac{64}{13}-\frac{32\sqrt{13}}{13}-\frac{72\sqrt{13}}{13} \\ &= \frac{208-104\sqrt{13}}{13}\approx -12.844. \end{aligned}$$

For the second angle,

$$\sin t=\sin\left(2\pi-\arctan\left(\tfrac{3}{2}\right)\right)=-\sin\left(\arctan\left(\tfrac{3}{2}\right)\right)=-\frac{3\sqrt{13}}{13}$$

$$\cos t=\cos\left(2\pi-\arctan\left(\tfrac{3}{2}\right)\right)=\cos\left(\arctan\left(\tfrac{3}{2}\right)\right)=\frac{2\sqrt{13}}{13}.$$

Therefore, $x(t) = 4\cos t = \frac{8\sqrt{13}}{13}$ and $y(t) = 4\sin t = -\frac{12\sqrt{13}}{13}$, so $\left(\frac{8\sqrt{13}}{13}, -\frac{12\sqrt{13}}{13}\right)$ is a critical point on the boundary and

$$\begin{aligned} g\left(\tfrac{8\sqrt{13}}{13}, -\tfrac{12\sqrt{13}}{13}\right) &= \left(\tfrac{8\sqrt{13}}{13}\right)^2 + \left(-\tfrac{12\sqrt{13}}{13}\right)^2 + 4\left(\tfrac{8\sqrt{13}}{13}\right) - 6\left(-\tfrac{12\sqrt{13}}{13}\right) \\ &= \frac{144}{13} + \frac{64}{13} + \frac{32\sqrt{13}}{13} + \frac{72\sqrt{13}}{13} \\ &= \frac{208 + 104\sqrt{13}}{13} \approx 44.844. \end{aligned}$$

The absolute minimum of $g$ is $-13$, which is attained at the point $(-2, 3)$, which is an interior point of $D$. The absolute maximum of $g$ is approximately equal to 44.844, which is attained at the boundary point $\left(\frac{8\sqrt{13}}{13}, -\frac{12\sqrt{13}}{13}\right)$. These are the absolute extrema of $g$ on $D$ as shown in the following figure.

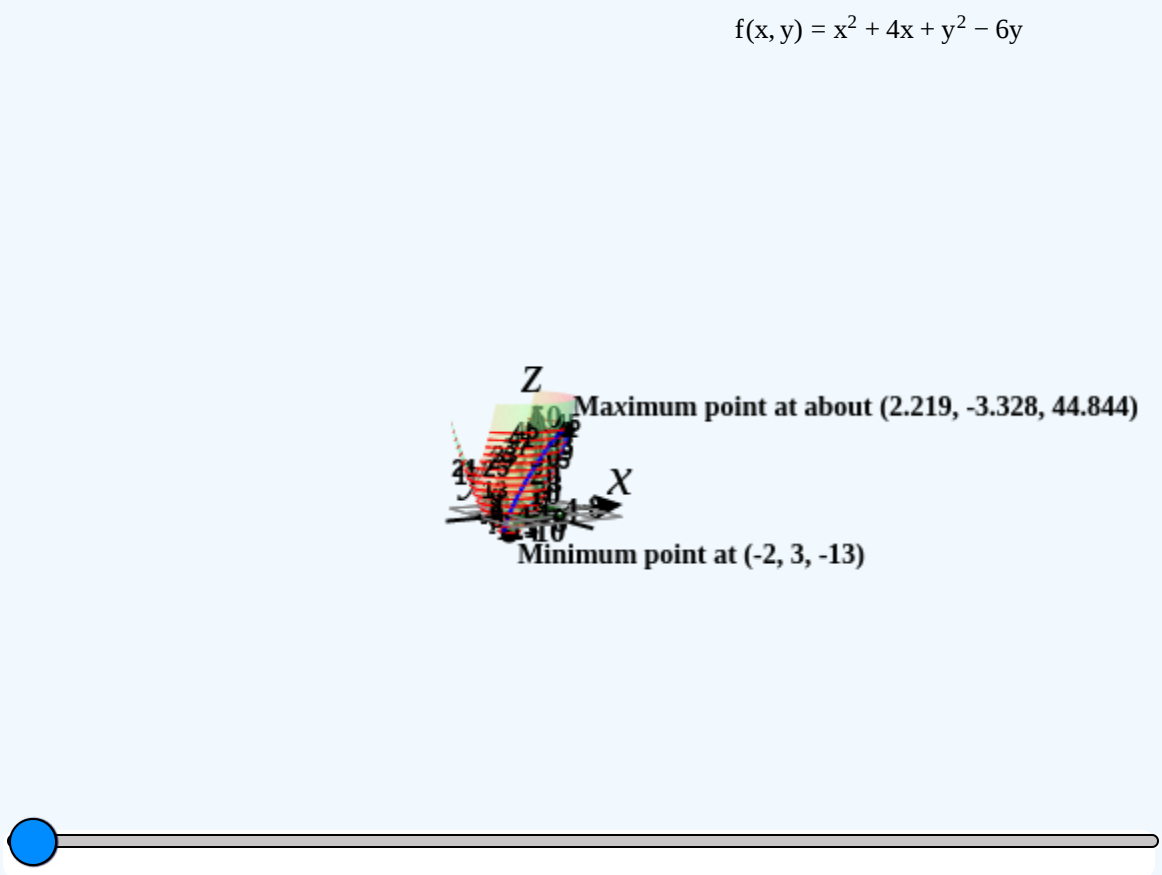

Figure 14.8.10: The function $f(x, y)$ has a local minimum and a local maximum.

## Exercise 14.8.3:

Use the problem-solving strategy for finding absolute extrema of a function to find the absolute extrema of the function

$$f(x, y) = 4x^2 - 2xy + 6y^2 - 8x + 2y + 3$$

on the domain defined by $0 \le x \le 2$ and $-1 \le y \le 3$.

**Hint**

Calculate $f_x(x, y)$ and $f_y(x, y)$, and set them equal to zero. Then, calculate $f$ for each critical point and find the extrema of $f$ on the boundary of $D$.

**Answer**

The absolute minimum occurs at $(1,0) : f(1,0) = -1$.

The absolute maximum occurs at $(0,3) : f(0,3) = 63$.

### Example 14.8.4: Profitable Golf Balls

Pro-$T$ company has developed a profit model that depends on the number $x$ of golf balls sold per month (measured in thousands), and the number of hours per month of advertising $y$, according to the function

$$z = f(x,y) = 48x + 96y - x^2 - 2xy - 9y^2,$$

where $z$ is measured in thousands of dollars. The maximum number of golf balls that can be produced and sold is $50,000$, and the maximum number of hours of advertising that can be purchased is $25$. Find the values of $x$ and $y$ that maximize profit, and find the maximum profit.

Figure 14.8.11: (credit: modification of work by oatsy40, Flickr)

**Solution**

Using the problem-solving strategy, step 1 involves finding the critical points of $f$ on its domain. Therefore, we first calculate $f_x(x,y)$ and $f_y(x,y)$, then set them each equal to zero:

$$f_x(x,y) = 48 - 2x - 2y$$
$$f_y(x,y) = 96 - 2x - 18y.$$

Setting them equal to zero yields the system of equations

$$48 - 2x - 2y = 0$$
$$96 - 2x - 18y = 0.$$

The solution to this system is $x = 21$ and $y = 3$. Therefore $(21,3)$ is a critical point of $f$. Calculating $f(21,3)$ gives $f(21,3) = 48(21) + 96(3) - 21^2 - 2(21)(3) - 9(3)^2 = 648$.

The domain of this function is $0 \le x \le 50$ and $0 \le y \le 25$ as shown in the following graph.

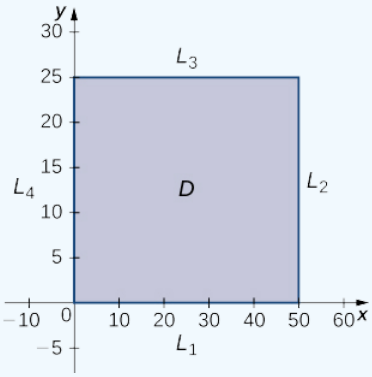

Figure 14.8.12: Graph of the domain of the function $f(x,y) = 48x + 96y - x^2 - 2xy - 9y^2$.

$L_1$ is the line segment connecting $(0,0)$ and $(50,0)$, and it can be parameterized by the equations $x(t)=t, y(t)=0$ for $0 \le t \le 50$. We then define $g(t)=f(x(t),y(t))$ :

$$\begin{aligned} g(t) &= f(x(t),y(t)) \\ &= f(t,0) \\ &= 48t+96(0)-y^2-2(t)(0)-9(0)^2 \\ &= 48t-t^2. \end{aligned}$$

Setting $g'(t)=0$ yields the critical point $t=24$, which corresponds to the point $(24,0)$ in the domain of $f$. Calculating $f(24,0)$ gives $576$.

$L_2$ is the line segment connecting $(50,0)$ and $(50,25)$, and it can be parameterized by the equations $x(t)=50, y(t)=t$ for $0 \le t \le 25$. Once again, we define $g(t)=f\big(x(t),y(t)\big)$ :

$$\begin{aligned} g(t) &= f\big(x(t),y(t)\big) \\ &= f(50,t) \\ &= 48(50)+96t-50^2-2(50)t-9t^2 \\ &= -9t^2-4t-100. \end{aligned}$$

This function has a critical point at $t=-\frac{2}{9}$, which corresponds to the point $(50,-29)$. This point is not in the domain of $f$.

$L_3$ is the line segment connecting $(0,25)$ and $(50,25)$, and it can be parameterized by the equations $x(t)=t, y(t)=25$ for $0 \le t \le 50$. We define $g(t)=f\big(x(t),y(t)\big)$:

$$\begin{aligned} g(t) &= f\big(x(t),y(t)\big) \\ &= f(t,25) \\ &= 48t+96(25)-t^2-2t(25)-9(25^2) \\ &= -t^2-2t-3225. \end{aligned}$$

This function has a critical point at $t=-1$, which corresponds to the point $(-1,25)$, which is not in the domain.

$L_4$ is the line segment connecting $(0,0)$ to $(0,25)$, and it can be parameterized by the equations $x(t)=0, y(t)=t$ for $0 \le t \le 25$. We define $g(t)=f\big(x(t),y(t)\big)$:

$$\begin{aligned} g(t) &= f\big(x(t),y(t)\big) \\ &= f(0,t) \\ &= 48(0)+96t-(0)^2-2(0)t-9t^2 \\ &= 96t-9t^2. \end{aligned}$$

This function has a critical point at $t=\frac{16}{3}$, which corresponds to the point $\left(0,\frac{16}{3}\right)$, which is on the boundary of the domain. Calculating $f\left(0,\frac{16}{3}\right)$ gives $256$.

We also need to find the values of $f(x,y)$ at the corners of its domain. These corners are located at $(0,0),(50,0),(50,25)$ and $(0,25)$:

$$\begin{aligned} f(0,0) &= 48(0)+96(0)-(0)^2-2(0)(0)-9(0)^2=0 \\ f(50,0) &= 48(50)+96(0)-(50)^2-2(50)(0)-9(0)^2=-100 \\ f(50,25) &= 48(50)+96(25)-(50)^2-2(50)(25)-9(25)^2=-5825 \\ f(0,25) &= 48(0)+96(25)-(0)^2-2(0)(25)-9(25)^2=-3225. \end{aligned}$$

The maximum value is $648$, which occurs at $(21,3)$. Therefore, a maximum profit of $\$648,000$ is realized when $21,000$ golf balls are sold and $3$ hours of advertising are purchased per month as shown in the following figure.

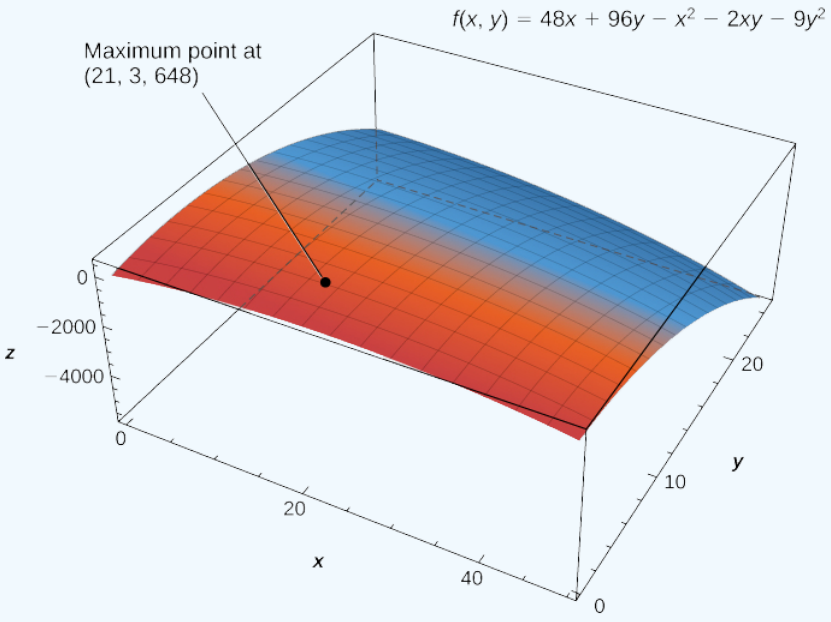

Figure **14.8.13**: The profit function $f(x, y)$ has a maximum at $(21, 3, 648)$.

## Key Concepts

- A critical point of the function $f(x, y)$ is any point $(x_0, y_0)$ where either $f_x(x_0, y_0) = f_y(x_0, y_0) = 0$, or at least one of $f_x(x_0, y_0)$ and $f_y(x_0, y_0)$ do not exist.
- A saddle point is a point $(x_0, y_0)$ where $f_x(x_0, y_0) = f_y(x_0, y_0) = 0$, but $f(x_0, y_0)$ is neither a maximum nor a minimum at that point.
- To find extrema of functions of two variables, first find the critical points, then calculate the discriminant and apply the second derivative test.

## Key Equations

- **Discriminant**

$$D = f_{xx}(x_0, y_0) f_{yy}(x_0, y_0) - (f_{xy}(x_0, y_0))^2$$

## Glossary

**critical point of a function of two variables**

the point $(x_0, y_0)$ is called a critical point of $f(x, y)$ if one of the two following conditions holds:

1. $f_x(x_0, y_0) = f_y(x_0, y_0) = 0$
2. At least one of $f_x(x_0, y_0)$ and $f_y(x_0, y_0)$ do not exist

**discriminant**

the discriminant of the function $f(x, y)$ is given by the formula $D = f_{xx}(x_0, y_0) f_{yy}(x_0, y_0) - (f_{xy}(x_0, y_0))^2$

**saddle point**

given the function $z = f(x, y)$, the point $(x_0, y_0, f(x_0, y_0))$ is a saddle point if both $f_x(x_0, y_0) = 0$ and $f_y(x_0, y_0) = 0$, but $f$ does not have a local extremum at $(x_0, y_0)$

# 14.8E: Exercises for Section 14.7

## Finding Critical Points

**In exercises 1 - 5, find all critical points.**

1) $f(x,y) = 1 + x^2 + y^2$

**Answer**

$(0,0)$

2) $f(x,y) = 1 - (x-2)^2 + (y+3)^2$

3) $f(x,y) = (3x-2)^2 + (y-4)^2$

**Answer**

$\left(\frac{2}{3}, 4\right)$

4) $f(x,y) = x^4 + y^4 - 16xy$

**Answer**

$(0,0), \quad (-2,-2), \quad (2,2)$

5) $f(x,y) = 15x^3 - 3xy + 15y^3$

**Answer**

$(0,0), \quad \left(\frac{1}{15}, \frac{1}{15}\right)$

## Finding Extrema & the Second Partials Test

**In exercises 6 - 9, find the critical points of the function and test for extrema or saddle points by using algebraic techniques (completing the square) or by examining the form of the equation. Where possible, verify your results using the Second Partials Test.**

6) $f(x,y) = -\sqrt{x^2 + y^2}$

**Answer**

Crit. pts.: $(0,0)$

Extrema: $f$ has a relative maximum of $0$ at $(0,0)$.

To justify this, consider the fact that the square root function cannot give a negative value, so this function cannot possibly return a positive value. Since it's value is $0$ at the critical point $(0,0)$, we know it must be the function's **absolute maximum** value.

7) $f(x,y) = -x^2 - 5y^2 + 8x - 10y - 13$

**Answer**

Crit. pts.: $(4,-1)$

Extrema: $f$ has a relative maximum of $8$ at $(4,-1)$.

To justify this, we complete the square on this function, being careful to factor out the coefficient of the squared terms before completing the square.

$$\begin{aligned} f(x,y) &= -x^2 - 5y^2 + 8x - 10y - 13 \\ &= -(x^2 - 8x \quad\;\; ) - 5(y^2 + 2y \quad\;\; ) - 13 \\ &= -(x^2 - 8x + 16) - 5(y^2 + 2y + 1) - 13 + 16 + 5 \\ &= -(x-4)^2 - 5(y+1)^2 + 8 \end{aligned}$$

Note that this quadratic polynomial function takes the form $z = -(x^2 + y^2)$, so we can see that it will have a **relative** (and, in fact, absolute) **maximum** at its vertex (the critical point $(4, -1)$). We can also argue that since we are subtracting squared terms from 8, we cannot possibly obtain a function value larger than 8, and since we do get a value of 8 at the critical point $(4, -1)$, we know it will be the absolute maximum value of this function.

8) $f(x, y) = x^2 + y^2 + 2x - 6y + 6$

9) $f(x, y) = \sqrt{x^2 + y^2} + 1$

**Answer**

Crit. Pts.: $(0, 0)$
Extrema: $f$ has a relative minimum of $1$ at $(0, 0)$.
To justify this, consider the fact that the square root function cannot give a negative value, so this function cannot possibly return a value less than $1$. Since it's value is $1$ at the critical point $(0, 0)$, we know $1$ must be the function's **absolute minimum** value.

**In exercises 10 - 34, identify any critical points and use the Second Partials Test to determine the behavior of the function at each critical point, whether there is a maximum, minimum, saddle point, or none of these. If the Second Partials Test fails, determine the function's behavior at the point using another method and justify your answer clearly.**

10) $f(x, y) = -x^3 + 4xy - 2y^2 + 1$

11) $f(x, y) = x^2 y^2$

**Answer**

Crit. pts.: All points on the lines $x = 0$ and $y = 0$ are critical points of this function.
Exrema: The Second Partials Test fails.
Since $x^2 y^2 > 0$ for all $x$ and $y$ different from zero, and $x^2 y^2 = 0$ when either $x$ or $y$ equals zero (or both), then the absolute minimum of $0$ occurs at all points on the $x$- or $y$-axes, that is, for all points on the lines $x = 0$ and $y = 0$.

12) $f(x, y) = x^2 - 6x + y^2 + 4y - 8$

13) $f(x, y) = 2xy + 3x + 4y$

**Answer**

Crit. pts.: $\left(-2, -\frac{3}{2}\right)$
Exrema: $f$ has a saddle point at $\left(-2, -\frac{3}{2}, -6\right)$.

14) $f(x, y) = 8xy(x + y) + 7$

15) $f(x, y) = x^2 + 4xy + y^2$

**Answer**

Crit. pts.: $(0, 0)$
Exrema: $f$ has a saddle point at $(0, 0, 0)$.

16) $f(x, y) = x^3 + y^3 - 300x - 75y - 3$

17) $f(x, y) = 9 - x^4 y^4$

**Answer**

Crit. pts.: All points on the lines $x = 0$ and $y = 0$ are critical points of this function.
Extrema: The Second Partials Test fails.
Since the term $-x^4 y^4 < 0$ for all $x$ and $y$ different from zero, and $-x^4 y^4 = 0$ when either $x$ or $y$ equals zero (or both), then

this function cannot attain a value greater than $9$ anywhere, but is $9$ at the critical points. Thus $f$ has an absolute maximum of $9$ at all points on the $x$- or $y$-axes, that is, for all points on the lines $x=0$ and $y=0$.

18) $f(x,y)=x^2+10xy+y^2$

**Answer**

Crit. pts.: $(0,0)$
Extrema: $f$ has a saddle point at $(0,0,0)$.

19) $f(x,y)=x^4+y^2+2xy+3$

**Answer**

Crit. pts.: $(0,0)$, $\left(-\frac{\sqrt{2}}{2},\frac{\sqrt{2}}{2}\right)$, $\left(\frac{\sqrt{2}}{2},-\frac{\sqrt{2}}{2}\right)$
Extrema: $f$ has a saddle point at $(0,0,3)$,
$f$ has a local minimum of $2.75$ at the point $\left(-\frac{\sqrt{2}}{2},\frac{\sqrt{2}}{2}\right)$.
$f$ has a local minimum of $2.75$ at the point $\left(\frac{\sqrt{2}}{2},-\frac{\sqrt{2}}{2}\right)$.

20) $f(x,y)=7x^2y+9xy^2$

21) $f(x,y)=3x^2-2xy+y^2-8y$

**Answer**

Crit. pts.: $(2,6)$
Extrema: $f$ has a relative minimum of $-24$ located at $(2,6)$.

22) $f(x,y)=3x^2+2xy+y^2$

23) $f(x,y)=y^2+xy+3y+2x+3$

**Answer**

Crit. pts.: $(1,-2)$
Extrema: $f$ has a saddle point at $(1,-2,1)$.

24) $f(x,y)=x^2+xy+y^2-3x$

25) $f(x,y)=x^2+2y^2-x^2y$

**Answer**

Crit. pts.: $(0,0)$, $(-2,1)$, $(2,1)$
Extrema: $f$ has a relative minimum of $0$ at $(0,0)$ and saddle points at $(2,1,2)$ and $(-2,1,2)$.

26) $f(x,y)=x^2+y-e^y$

27) $f(x,y)=e^{-(x^2+y^2+2x)}$

**Answer**

Crit. pts.: $(-1,0)$
Extrema: $f$ has a relative maximum of $e$ located at $(-1,0)$.
See this problem illustrated in CalcPlot3D.

28) $f(x,y)=x^2+xy+y^2-x-y+1$

29) $f(x,y)=x^2y(9-x+y)$

**Answer**

Crit. pts.: $\left(\frac{9}{2},-\frac{9}{4}\right)$, $(9,0)$, and all points on the line $x=0$
Extrema: $f$ has a saddle point at $(9,0,0)$ and a relative minimum of $-102.515625$ at $\left(\frac{9}{2},-\frac{9}{4}\right)$.
At the critical points on the line $x=0$, $f$ has neither relative extrema nor saddle points, but they do represent a sort of trough on the surface.

30) $f(x,y)=-x^2-5y^2+10x-30y-62$

31) $f(x,y)=120x+120y-xy-x^2-y^2$

**Answer**

Crit. pts.: $(40,40)$
Extrema: $f$ has a relative maximum of $4800$ located at $(40,40)$.

32) $f(x,y)=2x^2+2xy+y^2+2x-3$

33) $f(x,y)=x^2+x-3xy+y^3-5$

**Answer**

Crit. pts.: $\left(\frac{1}{4},\frac{1}{2}\right)$ and $(1,1)$
Extrema: $f$ has a saddle point at $\left(\frac{1}{4},\frac{1}{2},-\frac{79}{16}\right)$ and a relative minimum of $-5$ at $(1,1)$.

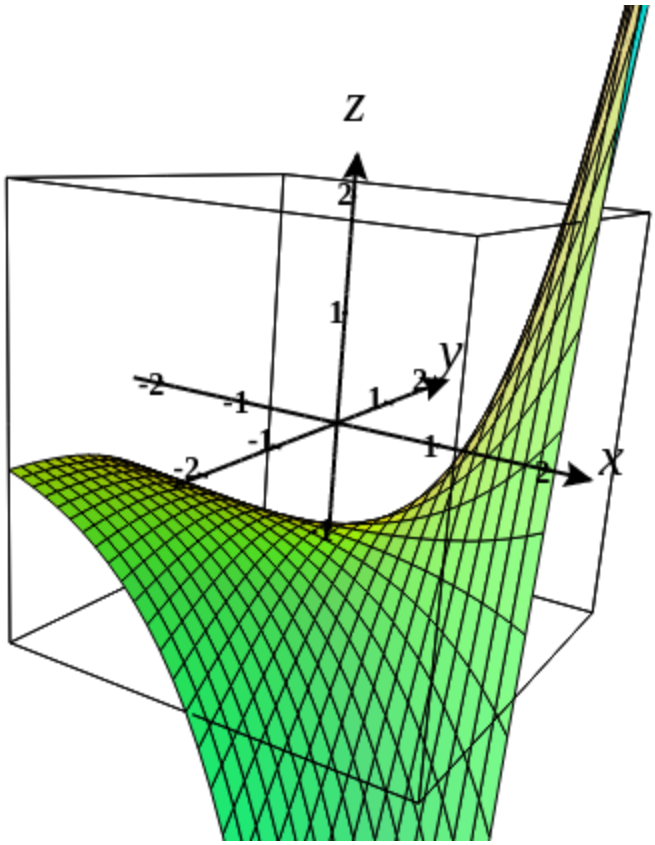
34) $f(x,y)=2xye^{-x^2-y^2}$

**In exercises 35 - 37, determine the extreme values and the saddle points. Use a CAS to graph the function.**

35) [T] $f(x,y)=ye^x-e^y$

**Answer**

A saddle point is located at $(0,0,-1)$.

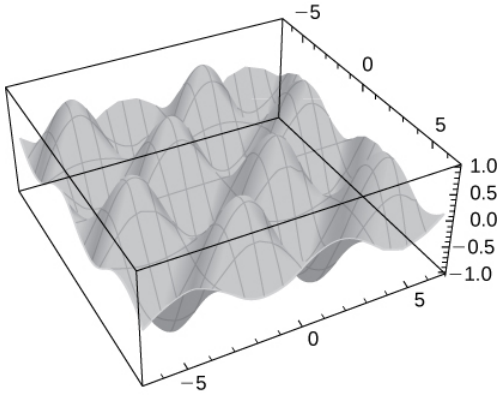


36) [T] $f(x,y) = x\sin(y)$

37) [T] $f(x,y) = \sin(x)\sin(y), \quad x \in (0,2\pi), \quad y \in (0,2\pi)$

**Answer**

There is a saddle point at $(\pi,\pi)$, local maxima at $\left(\frac{\pi}{2},\frac{\pi}{2}\right)$ and $\left(\frac{3\pi}{2},\frac{3\pi}{2}\right)$, and local minima at $\left(\frac{\pi}{2},\frac{3\pi}{2}\right)$ and $\left(\frac{3\pi}{2},\frac{\pi}{2}\right)$.



**In exercises 38 - 41, find the absolute extrema of the given function on the indicated closed and bounded set $R$.**

38) $f(x,y) = xy - x - 3y$ where $R$ is the triangular region with vertices $(0,0)$, $(0,4)$, and $(5,0)$.

39) Find the absolute maximum and minimum values of $f(x,y) = x^2 + y^2 - 2y + 1$ on the region $R = \{(x,y) \,|\, x^2 + y^2 \leq 4\}$.

**Answer**

$(0,1,0)$ is the absolute minimum and $(0,-2,9)$ is the absolute maximum.

40) $f(x,y)=x^3-3xy-y^3$ on $R=\{(x,y)\,|\,-2\le x\le 2,\ -2\le y\le 2\}$

41) $f(x,y)=\dfrac{-2y}{x^2+y^2+1}$ on $R=\{(x,y)\,|\,x^2+y^2\le 4\}$

**Answer**

There is an absolute minimum at $(0,1,-1)$ and an absolute maximum at $(0,-1,1)$.

42) Find three positive numbers the sum of which is $27$, such that the sum of their squares is as small as possible.

43) Find the points on the surface $x^2-yz=5$ that are closest to the origin.

**Answer**

$\left(\sqrt{5},0,0\right),\ \left(-\sqrt{5},0,0\right)$

44) Find the maximum volume of a rectangular box with three faces in the coordinate planes and a vertex in the first octant on the line $x+y+z=1$.

45) The sum of the length and the girth (perimeter of a cross-section) of a package carried by a delivery service cannot exceed $108$ in. Find the dimensions of the rectangular package of largest volume that can be sent.

**Answer**

$18$ by $36$ by $18$ in.

46) A cardboard box without a lid is to be made with a volume of $4$ ft$^3$. Find the dimensions of the box that requires the least amount of cardboard.

47) Find the point on the surface $f(x,y)=x^2+y^2+10$ nearest the plane $x+2y-z=0$. Identify the point on the plane.

**Answer**

$\left(\frac{47}{24},\frac{47}{12},\frac{235}{24}\right)$

48) Find the point in the plane $2x-y+2z=16$ that is closest to the origin.

49) A company manufactures two types of athletic shoes: jogging shoes and cross-trainers. The total revenue from $x$ units of jogging shoes and $y$ units of cross-trainers is given by $R(x,y)=-5x^2-8y^2-2xy+42x+102y$, where $x$ and $y$ are in thousands of units. Find the values of $x$ and $y$ to maximize the total revenue.

**Answer**

$x=3$ and $y=6$

50) A shipping company handles rectangular boxes provided the sum of the length, width, and height of the box does not exceed $96$ in. Find the dimensions of the box that meets this condition and has the largest volume.

51) Find the maximum volume of a cylindrical soda can such that the sum of its height and circumference is $120$ cm.

**Answer**

$V=\dfrac{64,000}{\pi}\approx 20,372\ \text{cm}^3$

# 14.9: Lagrange Multipliers

**Learning Objectives**

- Use the method of Lagrange multipliers to solve optimization problems with one constraint.
- Use the method of Lagrange multipliers to solve optimization problems with two constraints.

Solving optimization problems for functions of two or more variables can be similar to solving such problems in single-variable calculus. However, techniques for dealing with multiple variables allow us to solve more varied optimization problems for which we need to deal with additional conditions or constraints. In this section, we examine one of the more common and useful methods for solving optimization problems with constraints.

## Lagrange Multipliers

In the previous section, an applied situation was explored involving maximizing a profit function, subject to certain **constraints.** In that example, the constraints involved a maximum number of golf balls that could be produced and sold in $1$ month $(x)$, and a maximum number of advertising hours that could be purchased per month $(y)$. Suppose these were combined into a single budgetary constraint, such as $20x + 4y \leq 216$, that took into account both the cost of producing the golf balls and the number of advertising hours purchased per month. The goal is still to maximize profit, but now there is a different type of constraint on the values of $x$ and $y$. This constraint and the corresponding profit function

$$f(x, y) = 48x + 96y - x^2 - 2xy - 9y^2$$

is an example of an **optimization problem**, and the function $f(x, y)$ is called the **objective function**. A graph of various level curves of the function $f(x, y)$ follows.

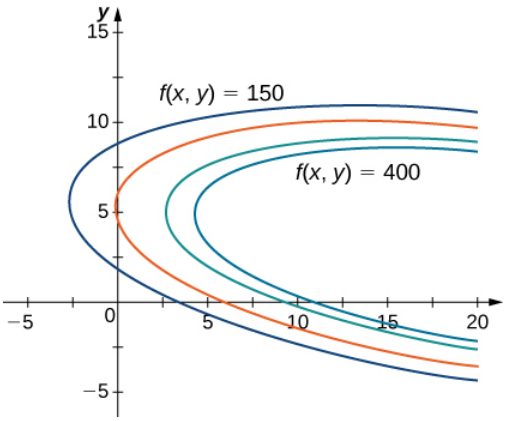

Figure 14.9.1: Graph showing level curves of the function $f(x, y) = 48x + 96y - x^2 - 2xy - 9y^2$ corresponding to $c = 150, 250, 350,$ and $400$.

In Figure 14.9.1, the value $c$ represents different profit levels (i.e., values of the function $f$). As the value of $c$ increases, the curve shifts to the right. Since our goal is to maximize profit, we want to choose a curve as far to the right as possible. If there were no restrictions on the number of golf balls the company could produce or the number of units of advertising available, then we could produce as many golf balls as we want, and advertise as much as we want, and there would be not be a maximum profit for the company. Unfortunately, we have a budgetary constraint that is modeled by the inequality $20x + 4y \leq 216$. To see how this constraint interacts with the profit function, Figure 14.9.2 shows the graph of the line $20x + 4y = 216$ superimposed on the previous graph.

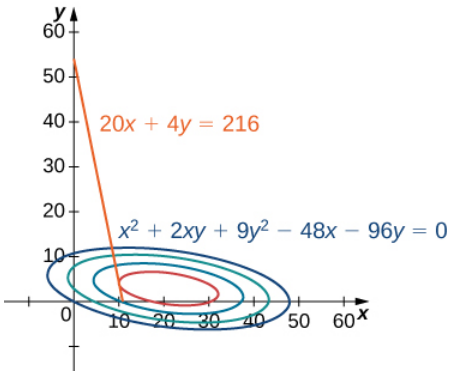

Figure 14.9.2: Graph of level curves of the function $f(x,y) = 48x + 96y - x^2 - 2xy - 9y^2$ corresponding to $c = 150, 250, 350,$ and $395$. The red graph is the constraint function.

As mentioned previously, the maximum profit occurs when the level curve is as far to the right as possible. However, the level of production corresponding to this maximum profit must also satisfy the budgetary constraint, so the point at which this profit occurs must also lie on (or to the left of) the red line in Figure 14.9.2. Inspection of this graph reveals that this point exists where the line is tangent to the level curve of $f$. Trial and error reveals that this profit level seems to be around $395$, when $x$ and $y$ are both just less than $5$. We return to the solution of this problem later in this section. From a theoretical standpoint, at the point where the profit curve is tangent to the constraint line, the gradient of both of the functions evaluated at that point must point in the same (or opposite) direction. Recall that the gradient of a function of more than one variable is a vector. If two vectors point in the same (or opposite) directions, then one must be a constant multiple of the other. This idea is the basis of the **method of Lagrange multipliers.**

### Theorem 14.9.1: Method of Lagrange Multipliers with One Constraint

Let $f$ and $g$ be functions of two variables with continuous partial derivatives at every point of some open set containing the smooth curve $g(x,y) = 0$. Suppose that $f$, when restricted to points on the curve $g(x,y) = 0$, has a local extremum at the point $(x_0, y_0)$ and that $\vec{\nabla} g(x_0, y_0) \neq 0$. Then there is a number $\lambda$ called a **Lagrange multiplier,** for which

$$\vec{\nabla} f(x_0, y_0) = \lambda \vec{\nabla} g(x_0, y_0).$$

### Proof

Assume that a constrained extremum occurs at the point $(x_0, y_0)$. Furthermore, we assume that the equation $g(x,y) = 0$ can be smoothly parameterized as

$$x = x(s) \text{ and } y = y(s)$$

where $s$ is an arc length parameter with reference point $(x_0, y_0)$ at $s = 0$. Therefore, the quantity $z = f(x(s), y(s))$ has a relative maximum or relative minimum at $s = 0$, and this implies that $\frac{dz}{ds} = 0$ at that point. From the chain rule,

$$\begin{aligned} \frac{dz}{ds} &= \frac{\partial f}{\partial x} \cdot \frac{\partial x}{\partial s} + \frac{\partial f}{\partial y} \cdot \frac{\partial y}{\partial s} \\ &= \left( \frac{\partial f}{\partial x} \hat{\mathbf{i}} + \frac{\partial f}{\partial y} \hat{\mathbf{j}} \right) \cdot \left( \frac{\partial x}{\partial s} \hat{\mathbf{i}} + \frac{\partial y}{\partial s} \hat{\mathbf{j}} \right) \\ &= 0, \end{aligned}$$

where the derivatives are all evaluated at $s = 0$. However, the first factor in the dot product is the gradient of $f$, and the second factor is the unit tangent vector $\vec{\mathbf{T}}(0)$ to the constraint curve. Since the point $(x_0, y_0)$ corresponds to $s = 0$, it follows from this equation that

$$\vec{\nabla} f(x_0, y_0) \cdot \vec{\mathbf{T}}(0) = 0,$$

which implies that the gradient is either the zero vector $\vec{\mathbf{0}}$ or it is normal to the constraint curve at a constrained relative extremum. However, the constraint curve $g(x,y) = 0$ is a level curve for the function $g(x,y)$ so that if $\vec{\nabla} g(x_0, y_0) \neq 0$ then

$\vec{\nabla} g(x_0, y_0)$ is normal to this curve at $(x_0, y_0)$ It follows, then, that there is some scalar $\lambda$ such that

$$\vec{\nabla} f(x_0, y_0) = \lambda \vec{\nabla} g(x_0, y_0)$$

□

To apply Theorem **14.9.1** to an optimization problem similar to that for the golf ball manufacturer, we need a problem-solving strategy.

### Problem-Solving Strategy: Steps for Using Lagrange Multipliers

1. Determine the objective function $f(x, y)$ and the constraint function $g(x, y)$. Does the optimization problem involve maximizing or minimizing the objective function?
2. Set up a system of equations using the following template:

$$\vec{\nabla} f(x_0, y_0) = \lambda \vec{\nabla} g(x_0, y_0) \quad (14.9.1)$$
$$g(x_0, y_0) = 0 \quad (14.9.2)$$

3. Solve for $x_0$ and $y_0$.
4. The largest of the values of $f$ at the solutions found in step **3** maximizes $f$; the smallest of those values minimizes $f$.

### Example 14.9.1: Using Lagrange Multipliers

Use the method of Lagrange multipliers to find the minimum value of $f(x, y) = x^2 + 4y^2 - 2x + 8y$ subject to the constraint $x + 2y = 7$.

**Solution**

Let's follow the problem-solving strategy:

1. The objective function is $f(x, y) = x^2 + 4y^2 - 2x + 8y$. To determine the constraint function, we must first subtract **7** from both sides of the constraint. This gives $x + 2y - 7 = 0$. The constraint function is equal to the left-hand side, so $g(x, y) = x + 2y - 7$. The problem asks us to solve for the minimum value of $f$, subject to the constraint (Figure **14.9.3**).

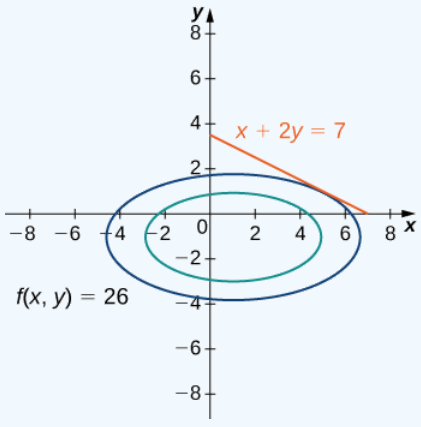

Figure **14.9.3**: Graph of level curves of the function $f(x, y) = x^2 + 4y^2 - 2x + 8y$ corresponding to $c = 10$ and **26**. The red graph is the constraint function.

2. We then must calculate the gradients of both $f$ and $g$:

$$\vec{\nabla} f(x, y) = (2x - 2)\,\hat{\mathbf{i}} + (8y + 8)\,\hat{\mathbf{j}}$$
$$\vec{\nabla} g(x, y) = \hat{\mathbf{i}} + 2\hat{\mathbf{j}}.$$

The equation $\vec{\nabla} f(x_0, y_0) = \lambda \vec{\nabla} g(x_0, y_0)$ becomes

$$(2x_0 - 2)\,\hat{\mathbf{i}} + (8y_0 + 8)\,\hat{\mathbf{j}} = \lambda\left(\hat{\mathbf{i}} + 2\hat{\mathbf{j}}\right),$$

which can be rewritten as

$$(2x_0 - 2)\,\hat{\mathbf{i}} + (8y_0 + 8)\,\hat{\mathbf{j}} = \lambda\hat{\mathbf{i}} + 2\lambda\hat{\mathbf{j}}.$$

Next, we set the coefficients of $\hat{\mathbf{i}}$ and $\hat{\mathbf{j}}$ equal to each other:

$$\begin{aligned} 2x_0 - 2 &= \lambda \\ 8y_0 + 8 &= 2\lambda. \end{aligned}$$

The equation $g(x_0, y_0) = 0$ becomes $x_0 + 2y_0 - 7 = 0$. Therefore, the system of equations that needs to be solved is

$$\begin{aligned} 2x_0 - 2 &= \lambda \\ 8y_0 + 8 &= 2\lambda \\ x_0 + 2y_0 - 7 &= 0. \end{aligned}$$

3. This is a linear system of three equations in three variables. We start by solving the second equation for $\lambda$ and substituting it into the first equation. This gives $\lambda = 4y_0 + 4$, so substituting this into the first equation gives

$$2x_0 - 2 = 4y_0 + 4.$$

Solving this equation for $x_0$ gives $x_0 = 2y_0 + 3$. We then substitute this into the third equation:

$$\begin{aligned} (2y_0 + 3) + 2y_0 - 7 &= 0 \\ 4y_0 - 4 &= 0 \\ y_0 &= 1. \end{aligned}$$

Since $x_0 = 2y_0 + 3$, this gives $x_0 = 5$.

4. Next, we evaluate $f(x, y) = x^2 + 4y^2 - 2x + 8y$ at the point $(5, 1)$,

$$f(5, 1) = 5^2 + 4(1)^2 - 2(5) + 8(1) = 27.$$

To ensure this corresponds to a minimum value on the constraint function, let's try some other points on the constraint from either side of the point $(5, 1)$, such as the intercepts of $g(x, y) = 0$, Which are $(7, 0)$ and $(0, 3.5)$.

We get $f(7, 0) = 35 > 27$ and $f(0, 3.5) = 77 > 27$.

So it appears that $f$ has a relative minimum of $27$ at $(5, 1)$, subject to the given constraint.

## ? Exercise 14.9.1

Use the method of Lagrange multipliers to find the maximum value of

$$f(x, y) = 9x^2 + 36xy - 4y^2 - 18x - 8y$$

subject to the constraint $3x + 4y = 32$.

**Hint**

Use the problem-solving strategy for the method of Lagrange multipliers.

**Answer**

Subject to the given constraint, $f$ has a maximum value of $976$ at the point $(8, 2)$.

Let's now return to the problem posed at the beginning of the section.

## ✓ Example 14.9.2: Golf Balls and Lagrange Multipliers

The golf ball manufacturer, Pro-T, has developed a profit model that depends on the number $x$ of golf balls sold per month (measured in thousands), and the number of hours per month of advertising $y$, according to the function

$$z = f(x, y) = 48x + 96y - x^2 - 2xy - 9y^2,$$

where $z$ is measured in thousands of dollars. The budgetary constraint function relating the cost of the production of thousands golf balls and advertising units is given by $20x + 4y = 216$. Find the values of $x$ and $y$ that maximize profit, and find the maximum profit.

**Solution:**

Again, we follow the problem-solving strategy:

1. The objective function is $f(x,y) = 48x + 96y - x^2 - 2xy - 9y^2$. To determine the constraint function, we first subtract $216$ from both sides of the constraint, then divide both sides by $4$, which gives $5x + y - 54 = 0$. The constraint function is equal to the left-hand side, so $g(x,y) = 5x + y - 54$. The problem asks us to solve for the maximum value of $f$, subject to this constraint.
2. So, we calculate the gradients of both $f$ and $g$:

$$\vec{\nabla} f(x,y) = (48 - 2x - 2y)\hat{\mathbf{i}} + (96 - 2x - 18y)\hat{\mathbf{j}}$$
$$\vec{\nabla} g(x,y) = 5\hat{\mathbf{i}} + \hat{\mathbf{j}}.$$

   The equation $\vec{\nabla} f(x_0,y_0) = \lambda \vec{\nabla} g(x_0,y_0)$ becomes

$$(48 - 2x_0 - 2y_0)\hat{\mathbf{i}} + (96 - 2x_0 - 18y_0)\hat{\mathbf{j}} = \lambda(5\hat{\mathbf{i}} + \hat{\mathbf{j}}),$$

   which can be rewritten as

$$(48 - 2x_0 - 2y_0)\hat{\mathbf{i}} + (96 - 2x_0 - 18y_0)\hat{\mathbf{j}} = \lambda 5\hat{\mathbf{i}} + \lambda\hat{\mathbf{j}}.$$

   We then set the coefficients of $\hat{\mathbf{i}}$ and $\hat{\mathbf{j}}$ equal to each other:

$$48 - 2x_0 - 2y_0 = 5\lambda$$
$$96 - 2x_0 - 18y_0 = \lambda.$$

   The equation $g(x_0,y_0) = 0$ becomes $5x_0 + y_0 - 54 = 0$. Therefore, the system of equations that needs to be solved is

$$\begin{aligned} 48 - 2x_0 - 2y_0 &= 5\lambda \\ 96 - 2x_0 - 18y_0 &= \lambda \\ 5x_0 + y_0 - 54 &= 0. \end{aligned}$$

3. We use the left-hand side of the second equation to replace $\lambda$ in the first equation:

$$\begin{aligned} 48 - 2x_0 - 2y_0 &= 5(96 - 2x_0 - 18y_0) \\ 48 - 2x_0 - 2y_0 &= 480 - 10x_0 - 90y_0 \\ 8x_0 &= 432 - 88y_0 \\ x_0 &= 54 - 11y_0. \end{aligned}$$

   Then we substitute this into the third equation:

$$\begin{aligned} 5(54 - 11y_0) + y_0 - 54 &= 0 \\ 270 - 55y_0 + y_0 - 54 &= 0 \\ 216 - 54y_0 &= 0 \\ y_0 &= 4. \end{aligned}$$

   Since $x_0 = 54 - 11y_0$, this gives $x_0 = 10$.
4. We then substitute $(10,4)$ into $f(x,y) = 48x + 96y - x^2 - 2xy - 9y^2$, which gives

$$\begin{aligned} f(10,4) &= 48(10) + 96(4) - (10)^2 - 2(10)(4) - 9(4)^2 \\ &= 480 + 384 - 100 - 80 - 144 \\ &= 540. \end{aligned}$$

Therefore the maximum profit that can be attained, subject to budgetary constraints, is $\$540,000$ with a production level of $10,000$ golf balls and $4$ hours of advertising bought per month. Let's check to make sure this truly is a maximum. The endpoints of the line that defines the constraint are $(10.8, 0)$ and $(0, 54)$ Let's evaluate $f$ at both of these points:

$$\begin{aligned} f(10.8, 0) &= 48(10.8) + 96(0) - 10.8^2 - 2(10.8)(0) - 9(0^2) \\ &= 401.76 \\ f(0, 54) &= 48(0) + 96(54) - 0^2 - 2(0)(54) - 9(54^2) \\ &= -21,060. \end{aligned}$$

The second value represents a loss, since no golf balls are produced. Neither of these values exceed $540$, so it seems that our extremum is a maximum value of $f$, subject to the given constraint.

### ? Exercise 14.9.2: Optimizing the Cobb-Douglas function

A company has determined that its production level is given by the Cobb-Douglas function $f(x, y) = 2.5x^{0.45}y^{0.55}$ where $x$ represents the total number of labor hours in $1$ year and $y$ represents the total capital input for the company. Suppose $1$ unit of labor costs $\$40$ and $1$ unit of capital costs $\$50$. Use the method of Lagrange multipliers to find the maximum value of $f(x, y) = 2.5x^{0.45}y^{0.55}$ subject to a budgetary constraint of $\$500,000$ per year.

**Hint**

Use the problem-solving strategy for the method of Lagrange multipliers.

**Answer**

Subject to the given constraint, a maximum production level of $13890$ occurs with $5625$ labor hours and $\$5500$ of total capital input.

In the case of an objective function with three variables and a single constraint function, it is possible to use the method of Lagrange multipliers to solve an optimization problem as well. An example of an objective function with three variables could be the **Cobb-Douglas function** in Exercise 14.9.2: $f(x, y, z) = x^{0.2}y^{0.4}z^{0.4}$, where $x$ represents the cost of labor, $y$ represents capital input, and $z$ represents the cost of advertising. The method is the same as for the method with a function of two variables; the equations to be solved are

$$\begin{aligned} \vec{\nabla} f(x, y, z) &= \lambda \vec{\nabla} g(x, y, z) \\ g(x, y, z) &= 0. \end{aligned}$$

### ✓ Example 14.9.3: Lagrange Multipliers with a Three-Variable objective function

Maximize the function $f(x, y, z) = x^2 + y^2 + z^2$ subject to the constraint $x + y + z = 1$.

**Solution**

1. The objective function is $f(x, y, z) = x^2 + y^2 + z^2$. To determine the constraint function, we subtract $1$ from each side of the constraint: $x + y + z - 1 = 0$ which gives the constraint function as $g(x, y, z) = x + y + z - 1$.

2. Next, we calculate $\vec{\nabla} f(x, y, z)$ and $\vec{\nabla} g(x, y, z)$ :

$$\begin{aligned} \vec{\nabla} f(x, y, z) &= \langle 2x, 2y, 2z \rangle \\ \vec{\nabla} g(x, y, z) &= \langle 1, 1, 1 \rangle. \end{aligned}$$

This leads to the equations

$$\begin{aligned} \langle 2x_0, 2y_0, 2z_0 \rangle &= \lambda \langle 1, 1, 1 \rangle \\ x_0 + y_0 + z_0 - 1 &= 0 \end{aligned}$$

which can be rewritten in the following form:

$$2x_0 = \lambda$$
$$2y_0 = \lambda$$
$$2z_0 = \lambda$$
$$x_0 + y_0 + z_0 - 1 = 0.$$

3. Since each of the first three equations has $\lambda$ on the right-hand side, we know that $2x_0 = 2y_0 = 2z_0$ and all three variables are equal to each other. Substituting $y_0 = x_0$ and $z_0 = x_0$ into the last equation yields $3x_0 - 1 = 0$, so $x_0 = \frac{1}{3}$ and $y_0 = \frac{1}{3}$ and $z_0 = \frac{1}{3}$ which corresponds to a critical point on the constraint curve.

4. Then, we evaluate $f$ at the point $\left(\frac{1}{3}, \frac{1}{3}, \frac{1}{3}\right)$:

$$f\left(\frac{1}{3}, \frac{1}{3}, \frac{1}{3}\right) = \left(\frac{1}{3}\right)^2 + \left(\frac{1}{3}\right)^2 + \left(\frac{1}{3}\right)^2 = \frac{3}{9} = \frac{1}{3}$$

Therefore, a possible extremum of the function is $\frac{1}{3}$. To verify it is a minimum, choose other points that satisfy the constraint from either side of the point we obtained above and calculate $f$ at those points. For example,

$$f(1, 0, 0) = 1^2 + 0^2 + 0^2 = 1$$
$$f(0, -2, 3) = 0^2 + (-2)^2 + 3^2 = 13.$$

Both of these values are greater than $\frac{1}{3}$, leading us to believe the extremum is a minimum, subject to the given constraint.

**? Exercise 14.9.3**

Use the method of Lagrange multipliers to find the minimum value of the function

$$f(x, y, z) = x + y + z$$

subject to the constraint $x^2 + y^2 + z^2 = 1$.

**Hint**

Use the problem-solving strategy for the method of Lagrange multipliers with an objective function of three variables.

**Answer**

Evaluating $f$ at both points we obtained, gives us,

$$f\left(\frac{\sqrt{3}}{3}, \frac{\sqrt{3}}{3}, \frac{\sqrt{3}}{3}\right) = \frac{\sqrt{3}}{3} + \frac{\sqrt{3}}{3} + \frac{\sqrt{3}}{3} = \sqrt{3}$$
$$f\left(-\frac{\sqrt{3}}{3}, -\frac{\sqrt{3}}{3}, -\frac{\sqrt{3}}{3}\right) = -\frac{\sqrt{3}}{3} - \frac{\sqrt{3}}{3} - \frac{\sqrt{3}}{3} = -\sqrt{3}$$

Since the constraint is continuous, we compare these values and conclude that $f$ has a relative minimum of $-\sqrt{3}$ at the point $\left(-\frac{\sqrt{3}}{3}, -\frac{\sqrt{3}}{3}, -\frac{\sqrt{3}}{3}\right)$, subject to the given constraint.

## Problems with Two Constraints

The method of Lagrange multipliers can be applied to problems with more than one constraint. In this case the objective function, $w$ is a function of three variables:

$$w = f(x, y, z)$$

and it is subject to two constraints:

$$g(x, y, z) = 0 \text{ and } h(x, y, z) = 0.$$

There are two Lagrange multipliers, $\lambda_1$ and $\lambda_2$, and the system of equations becomes

$$\vec{\nabla} f(x_0, y_0, z_0) = \lambda_1 \vec{\nabla} g(x_0, y_0, z_0) + \lambda_2 \vec{\nabla} h(x_0, y_0, z_0)$$
$$g(x_0, y_0, z_0) = 0$$
$$h(x_0, y_0, z_0) = 0$$

### Example 14.9.4: Lagrange Multipliers with Two Constraints

Find the maximum and minimum values of the function

$$f(x, y, z) = x^2 + y^2 + z^2$$

subject to the constraints $z^2 = x^2 + y^2$ and $x + y - z + 1 = 0$.

**Solution**

Let's follow the problem-solving strategy:

1. The objective function is $f(x, y, z) = x^2 + y^2 + z^2$. To determine the constraint functions, we first subtract $z^2$ from both sides of the first constraint, which gives $x^2 + y^2 - z^2 = 0$, so $g(x, y, z) = x^2 + y^2 - z^2$. The second constraint function is $h(x, y, z) = x + y - z + 1$.
2. We then calculate the gradients of $f$, $g$, and $h$:

$$\vec{\nabla} f(x, y, z) = 2x\hat{\mathbf{i}} + 2y\hat{\mathbf{j}} + 2z\hat{\mathbf{k}}$$
$$\vec{\nabla} g(x, y, z) = 2x\hat{\mathbf{i}} + 2y\hat{\mathbf{j}} - 2z\hat{\mathbf{k}}$$
$$\vec{\nabla} h(x, y, z) = \hat{\mathbf{i}} + \hat{\mathbf{j}} - \hat{\mathbf{k}}.$$

The equation $\vec{\nabla} f(x_0, y_0, z_0) = \lambda_1 \vec{\nabla} g(x_0, y_0, z_0) + \lambda_2 \vec{\nabla} h(x_0, y_0, z_0)$ becomes

$$2x_0\hat{\mathbf{i}} + 2y_0\hat{\mathbf{j}} + 2z_0\hat{\mathbf{k}} = \lambda_1(2x_0\hat{\mathbf{i}} + 2y_0\hat{\mathbf{j}} - 2z_0\hat{\mathbf{k}}) + \lambda_2(\hat{\mathbf{i}} + \hat{\mathbf{j}} - \hat{\mathbf{k}}),$$

which can be rewritten as

$$2x_0\hat{\mathbf{i}} + 2y_0\hat{\mathbf{j}} + 2z_0\hat{\mathbf{k}} = (2\lambda_1 x_0 + \lambda_2)\hat{\mathbf{i}} + (2\lambda_1 y_0 + \lambda_2)\hat{\mathbf{j}} - (2\lambda_1 z_0 + \lambda_2)\hat{\mathbf{k}}.$$

Next, we set the coefficients of $\hat{\mathbf{i}}$ and $\hat{\mathbf{j}}$ equal to each other:

$$2x_0 = 2\lambda_1 x_0 + \lambda_2$$
$$2y_0 = 2\lambda_1 y_0 + \lambda_2$$
$$2z_0 = -2\lambda_1 z_0 - \lambda_2.$$

The two equations that arise from the constraints are $z_0^2 = x_0^2 + y_0^2$ and $x_0 + y_0 - z_0 + 1 = 0$. Combining these equations with the previous three equations gives

$$2x_0 = 2\lambda_1 x_0 + \lambda_2$$
$$2y_0 = 2\lambda_1 y_0 + \lambda_2$$
$$2z_0 = -2\lambda_1 z_0 - \lambda_2$$
$$z_0^2 = x_0^2 + y_0^2$$
$$x_0 + y_0 - z_0 + 1 = 0.$$

3. The first three equations contain the variable $\lambda_2$. Solving the third equation for $\lambda_2$ and replacing into the first and second equations reduces the number of equations to four:

$$2x_0 = 2\lambda_1 x_0 - 2\lambda_1 z_0 - 2z_0$$
$$2y_0 = 2\lambda_1 y_0 - 2\lambda_1 z_0 - 2z_0$$
$$z_0^2 = x_0^2 + y_0^2$$
$$x_0 + y_0 - z_0 + 1 = 0.$$

Next, we solve the first and second equation for $\lambda_1$. The first equation gives $\lambda_1 = \dfrac{x_0 + z_0}{x_0 - z_0}$, the second equation gives $\lambda_1 = \dfrac{y_0 + z_0}{y_0 - z_0}$. We set the right-hand side of each equation equal to each other and cross-multiply:

$$\begin{aligned}
\frac{x_0 + z_0}{x_0 - z_0} &= \frac{y_0 + z_0}{y_0 - z_0} \\
(x_0 + z_0)(y_0 - z_0) &= (x_0 - z_0)(y_0 + z_0) \\
x_0 y_0 - x_0 z_0 + y_0 z_0 - z_0^2 &= x_0 y_0 + x_0 z_0 - y_0 z_0 - z_0^2 \\
2y_0 z_0 - 2x_0 z_0 &= 0 \\
2z_0(y_0 - x_0) &= 0.
\end{aligned}$$

Therefore, either $z_0 = 0$ or $y_0 = x_0$. If $z_0 = 0$, then the first constraint becomes $0 = x_0^2 + y_0^2$. The only real solution to this equation is $x_0 = 0$ and $y_0 = 0$, which gives the ordered triple $(0, 0, 0)$. This point does not satisfy the second constraint, so it is not a solution. Next, we consider $y_0 = x_0$, which reduces the number of equations to three:

$$\begin{aligned}
y_0 &= x_0 \\
z_0^2 &= x_0^2 + y_0^2 \\
x_0 + y_0 - z_0 + 1 &= 0.
\end{aligned}$$

We substitute the first equation into the second and third equations:

$$\begin{aligned}
z_0^2 &= x_0^2 + x_0^2 \\
&= x_0 + x_0 - z_0 + 1 \qquad = 0.
\end{aligned}$$

Then, we solve the second equation for $z_0$, which gives $z_0 = 2x_0 + 1$. We then substitute this into the first equation,

$$\begin{aligned}
z_0^2 &= 2x_0^2 \\
(2x_0 + 1)^2 &= 2x_0^2 \\
4x_0^2 + 4x_0 + 1 &= 2x_0^2 \\
2x_0^2 + 4x_0 + 1 &= 0,
\end{aligned}$$

and use the quadratic formula to solve for $x_0$:

$$x_0 = \frac{-4 \pm \sqrt{4^2 - 4(2)(1)}}{2(2)} = \frac{-4 \pm \sqrt{8}}{4} = \frac{-4 \pm 2\sqrt{2}}{4} = -1 \pm \frac{\sqrt{2}}{2}.$$

Recall $y_0 = x_0$, so this solves for $y_0$ as well. Then, $z_0 = 2x_0 + 1$, so

$$z_0 = 2x_0 + 1 = 2\left(-1 \pm \frac{\sqrt{2}}{2}\right) + 1 = -2 + 1 \pm \sqrt{2} = -1 \pm \sqrt{2}.$$

Therefore, there are two ordered triplet solutions:

$$\left(-1 + \frac{\sqrt{2}}{2}, -1 + \frac{\sqrt{2}}{2}, -1 + \sqrt{2}\right) \text{ and } \left(-1 - \frac{\sqrt{2}}{2}, -1 - \frac{\sqrt{2}}{2}, -1 - \sqrt{2}\right).$$

4. We substitute $\left(-1 + \dfrac{\sqrt{2}}{2}, -1 + \dfrac{\sqrt{2}}{2}, -1 + \sqrt{2}\right)$ into $f(x, y, z) = x^2 + y^2 + z^2$, which gives

$$\begin{aligned}
f\left(-1 + \frac{\sqrt{2}}{2}, -1 + \frac{\sqrt{2}}{2}, -1 + \sqrt{2}\right) &= \left(-1 + \frac{\sqrt{2}}{2}\right)^2 + \left(-1 + \frac{\sqrt{2}}{2}\right)^2 + (-1 + \sqrt{2})^2 \\
&= \left(1 - \sqrt{2} + \frac{1}{2}\right) + \left(1 - \sqrt{2} + \frac{1}{2}\right) + (1 - 2\sqrt{2} + 2) \\
&= 6 - 4\sqrt{2}.
\end{aligned}$$

Then, we substitute $\left(-1 - \dfrac{\sqrt{2}}{2}, -1 + \dfrac{\sqrt{2}}{2}, -1 + \sqrt{2}\right)$ into $f(x, y, z) = x^2 + y^2 + z^2$, which gives

$$f\left(-1-\frac{\sqrt{2}}{2},-1+\frac{\sqrt{2}}{2},-1+\sqrt{2}\right)=\left(-1-\frac{\sqrt{2}}{2}\right)^2+\left(-1-\frac{\sqrt{2}}{2}\right)^2+(-1-\sqrt{2})^2$$
$$=\left(1+\sqrt{2}+\frac{1}{2}\right)+\left(1+\sqrt{2}+\frac{1}{2}\right)+(1+2\sqrt{2}+2)$$
$$=6+4\sqrt{2}.$$

$6+4\sqrt{2}$ is the maximum value and $6-4\sqrt{2}$ is the minimum value of $f(x,y,z)$, subject to the given constraints.

**? Exercise 14.9.4**

Use the method of Lagrange multipliers to find the minimum value of the function

$$f(x,y,z)=x^2+y^2+z^2$$

subject to the constraints $2x+y+2z=9$ and $5x+5y+7z=29$.

**Hint**

Use the problem-solving strategy for the method of Lagrange multipliers with two constraints.

**Answer**

$f(2,1,2)=9$ is a minimum value of $f$, subject to the given constraints.

## Key Concepts

- An objective function combined with one or more constraints is an example of an optimization problem.
- To solve optimization problems, we apply the method of Lagrange multipliers using a four-step problem-solving strategy.

## Key Equations

- **Method of Lagrange multipliers, one constraint**

  $\vec{\nabla}f(x_0,y_0)=\lambda\vec{\nabla}g(x_0,y_0)$

  $g(x_0,y_0)=0$

- **Method of Lagrange multipliers, two constraints**

  $\vec{\nabla}f(x_0,y_0,z_0)=\lambda_1\vec{\nabla}g(x_0,y_0,z_0)+\lambda_2\vec{\nabla}h(x_0,y_0,z_0)$

  $g(x_0,y_0,z_0)=0$

  $h(x_0,y_0,z_0)=0$

## Glossary

**constraint**
an inequality or equation involving one or more variables that is used in an optimization problem; the constraint enforces a limit on the possible solutions for the problem

**Lagrange multiplier**
the constant (or constants) used in the method of Lagrange multipliers; in the case of one constant, it is represented by the variable $\lambda$

**method of Lagrange multipliers**
a method of solving an optimization problem subject to one or more constraints

**objective function**
the function that is to be maximized or minimized in an optimization problem

**optimization problem**

calculation of a maximum or minimum value of a function of several variables, often using Lagrange multipliers

# 14.9E: Exercises for Section 14.8

**In exercises 1-15, use the method of Lagrange multipliers to find the maximum and minimum values of the function subject to the given constraint.**

1) Objective function: $f(x,y) = 4xy$ Constraint: $\frac{x^2}{9} + \frac{y^2}{16} = 1$

**Answer**

Subject to the given constraint, the function $f$ has a relative minimum of $-24$ at both $\left(-\frac{3\sqrt{2}}{2}, 2\sqrt{2}\right)$ and $\left(\frac{3\sqrt{2}}{2}, -2\sqrt{2}\right)$ and a relative maximum of $24$ at both $\left(\frac{3\sqrt{2}}{2}, 2\sqrt{2}\right)$ and $\left(-\frac{3\sqrt{2}}{2}, -2\sqrt{2}\right)$

2) Objective function: $f(x,y) = x^2y$ Constraint: $x^2 + 2y^2 = 6$

3) Objective function: $f(x,y) = x^2 + y^2 + 2x - 2y + 1$ Constraint: $g(x,y) = x^2 + y^2 = 2$

**Answer**

Subject to the given constraint, $f$ has a relative minimum of $-1$ at $(-1,1)$ and a relative maximum of $7$ at $(1,-1)$.

4) Objective function: $f(x,y) = xy$ Constraint: $4x^2 + 8y^2 = 16$

5) Objective function: $f(x,y) = x^2 + y^2$ Constraint: $xy = 1$

**Answer**

$f$ has a relative minimum of $2$ at both $(-1,-1)$ and $(1,1)$, subject to the given constraint.

6) Objective function: $f(x,y) = x^2 - y^2$ Constraint: $x - 2y + 6 = 0$

7) Objective function: $f(x,y) = x^2 + y^2$ Constraint: $x + 2y - 5 = 0$

**Answer**

Subject to the given constraint, $f$ has a relative minimum of $f(1,2) = 5$ at the point $(1,2)$.

8) Objective function: $f(x,y) = x^2 + y^2$ Constraint: $(x-1)^2 + 4y^2 = 4$

9) Objective function: $f(x,y) = 4x^3 + y^2$ Constraint: $2x^2 + y^2 = 1$

**Answer**

Subject to the given constraint, the function $f$ has a relative minimum of $-\sqrt{2}$ at $\left(-\frac{\sqrt{2}}{2}, 0\right)$,
a relative minimum of $\frac{25}{27}$ at both points $\left(\frac{1}{3}, -\frac{\sqrt{7}}{3}\right)$ and $\left(\frac{1}{3}, \frac{\sqrt{7}}{3}\right)$,
a relative maximum of $\sqrt{2}$ at $\left(\frac{\sqrt{2}}{2}, 0\right)$, and a relative maximum of $1$ at both points $(0,1)$ and $(0,-1)$.

**Solution:**

Let $g(x,y) = 2x^2 + y^2$ be the constraint function. Then:

$\vec{\nabla} f(x,y) = 12x^2\,\hat{\mathbf{i}} + 2y\,\hat{\mathbf{j}}$ and $\vec{\nabla} g(x,y) = 4x\,\hat{\mathbf{i}} + 2y\,\hat{\mathbf{j}}$

Using the Lagrange Multiplier equation,

$$\vec{\nabla} f(x,y) = \lambda \vec{\nabla} g(x,y),$$

we have:

$$12x^2\,\hat{\mathbf{i}} + 2y\,\hat{\mathbf{j}} = 4x\lambda\,\hat{\mathbf{i}} + 2y\lambda\,\hat{\mathbf{j}}$$

giving us the system of equations:

$$12x^2 = 4x\lambda, \quad 2y = 2y\lambda, \quad \text{and the constraint} \quad 2x^2 + y^2 = 1$$

Rewriting the first two equations as zero-products (by moving to one-side and factoring), we get:

$$\begin{array}{ccc} 4x(3x-\lambda)=0 & \text{and} & 2y(1-\lambda)=0 \\ x=0 \quad \text{or} \quad \lambda = 3x & & y=0 \quad \text{or} \quad \lambda = 1 \end{array}$$

Now we consider the combinations of these solutions to the above two equations and plug each of these into the constraint equation to solve for the corresponding Lagrange points.

The combination $x = 0$ and $y = 0$ produces a contradiction when placed in the constraint equation, since this point is not on the ellipse.

Taking the combination $x = 0$ and $\lambda = 1$, we put $0$ in for $x$ in the constraint and solve for $y$, obtaining: $y = \pm 1$. This gives us two Lagrange points: $(0, 1)$ and $(0, -1)$.

Taking the combination $\lambda = 3x$ and $y = 0$, we put $0$ in for $y$ in the constraint and solve for $x$, obtaining: $x = \pm\frac{\sqrt{2}}{2}$. This gives us two Lagrange points: $\left(-\frac{\sqrt{2}}{2}, 0\right)$ and $\left(\frac{\sqrt{2}}{2}, 0\right)$.

Taking the combination $\lambda = 3x$ and $\lambda = 1$, we substitute $1$ into the first equation for $\lambda$, giving us $1 = 3x$ so $x = \frac{1}{3}$. Plugging this value in for $x$ in the constraint equation and solving for $y$, we obtain $y = \pm\frac{\sqrt{7}}{3}$ which gives us the two Lagrange points: $\left(\frac{1}{3}, -\frac{\sqrt{7}}{3}\right)$ and $\left(\frac{1}{3}, \frac{\sqrt{7}}{3}\right)$.

Evaluating the function $f$ at these Lagrange points, we find:

$$\begin{array}{ll} f(0,-1) = 1 & f(0,1) = 1 \\ f\left(-\frac{\sqrt{2}}{2}, 0\right) = \frac{-4(\sqrt{2})^3}{8} = -\sqrt{2} & f\left(\frac{\sqrt{2}}{2}, 0\right) = \frac{4(\sqrt{2})^3}{8} = \sqrt{2} \\ f\left(\frac{1}{3}, -\frac{\sqrt{7}}{3}\right) = \frac{25}{27} & f\left(\frac{1}{3}, \frac{\sqrt{7}}{3}\right) = \frac{25}{27} \end{array}$$

Comparing these values with where the corresponding Lagrange points lie on the constraint curve, we conclude the results stated in the answer above.

10) Objective function: $f(x, y) = 2x^2 + y^2$ Constraint: $g(x, y) = x^2 + y^2 = 1$

11) Objective function: $f(x, y, z) = x + 3y - z$ Constraint: $x^2 + y^2 + z^2 = 4$

**Answer**

Subject to the given constraint, $f$ has a relative minimum of $-2\sqrt{11}$ at the point $\left(-\frac{2\sqrt{11}}{11}, -\frac{6\sqrt{11}}{11}, \frac{2\sqrt{11}}{11}\right)$ and a relative maximum of $2\sqrt{11}$ at the point $\left(\frac{2\sqrt{11}}{11}, \frac{6\sqrt{11}}{11}, -\frac{2\sqrt{11}}{11}\right)$.

12) Objective function: $f(x, y, z) = x + y + z$ Constraint: $\frac{1}{x} + \frac{1}{y} + \frac{1}{z} = 1$

13) Objective function: $f(x, y, z) = xyz$ Constraint: $x^2 + 2y^2 + 3z^2 = 6$

**Answer**

Subject to the given constraint, $f$ has a relative minimum of $-\frac{2\sqrt{3}}{3}$ at $\left(\sqrt{2}, 1, -\frac{\sqrt{6}}{3}\right)$, $\left(\sqrt{2}, -1, \frac{\sqrt{6}}{3}\right)$, $\left(-\sqrt{2}, 1, \frac{\sqrt{6}}{3}\right)$, and $\left(-\sqrt{2}, -1, -\frac{\sqrt{6}}{3}\right)$ and a relative maximum of $\frac{2\sqrt{3}}{3}$ at $\left(\sqrt{2}, 1, \frac{\sqrt{6}}{3}\right)$, $\left(\sqrt{2}, -1, -\frac{\sqrt{6}}{3}\right)$, $\left(-\sqrt{2}, -1, \frac{\sqrt{6}}{3}\right)$, and $\left(-\sqrt{2}, 1, -\frac{\sqrt{6}}{3}\right)$.

14) Objective function: $f(x, y, z) = x^2 + y^2 + z^2$ Constraint: $x^4 + y^4 + z^4 = 1$

15) Objective function: $f(x, y, z) = x^2 + y^2 + z^2$ Constraint: $xyz = 4$

**Answer**

Subject to the given constraint, $f$ has a relative minimum of $6\sqrt[3]{2}$ at the points $\left(\sqrt[3]{4}, \sqrt[3]{4}, \sqrt[3]{4}\right)$, $\left(\sqrt[3]{4}, -\sqrt[3]{4}, -\sqrt[3]{4}\right)$, $\left(-\sqrt[3]{4}, \sqrt[3]{4}, -\sqrt[3]{4}\right)$, and $\left(-\sqrt[3]{4}, -\sqrt[3]{4}, \sqrt[3]{4}\right)$.
To see a 3D visualization of this problem, see: CalcPlot3D for Problem 15.

**In exercises 16-21, use the method of Lagrange multipliers to find the requested extremum of the given function subject to the given constraint.**

16) Maximize $f(x, y) = \sqrt{6 - x^2 - y^2}$ subject to the constraint, $x + y - 2 = 0$.

17) Maximize $f(x, y) = x^2 - y^2$ subject to the constraints, $g(x, y) = y - x^2 = 0, \quad x > 0, \quad y > 0$.

**Answer**

Subject to the given constraints, $f$ has a relative maximum of $f\left(\frac{\sqrt{2}}{2}, \frac{1}{2}\right) = \frac{1}{4}$ at the point $\left(\frac{\sqrt{2}}{2}, \frac{1}{2}\right)$. If $x > 0$ were not a constraint, there would have been two other Lagrange points with relative extrema of $f$ subject to the other two constraints. These would have been $(0, 0)$ and $\left(-\frac{\sqrt{2}}{2}, \frac{1}{2}\right)$.

To verify that $f$ really has a relative **maximum** at the point $\left(\frac{\sqrt{2}}{2}, \frac{1}{2}\right)$, we would need to check the value of $f$ on either side of this point on the constraint curve, $y - x^2 = 0$.

If $x = 0.5$ which is less than $\frac{\sqrt{2}}{2}$, $y$ would be $y = (0.5)^2 = 0.25$.
If $x = 1$ which is greater than $\frac{\sqrt{2}}{2}$, $y$ would be $y = (1)^2 = 1$.

Then we compare the value of $f$ at the Lagrange point, $\left(\frac{\sqrt{2}}{2}, \frac{1}{2}\right)$, with the values of $f$ at these other points on the constraint.
We have $f(0.5, 0.25) = (0.5)^2 - (0.25)^2 = 0.25 - 0.0625 = 0.1875 < \frac{1}{4}$ and $f(1, 1) = (1)^2 - (1)^2 = 0 < \frac{1}{4}$.

Therefore, we can conclude that $f$ indeed has a relative maximum of $\frac{1}{4}$ at the point $\left(\frac{\sqrt{2}}{2}, \frac{1}{2}\right)$.

18) Maximize $U(x, y) = 8x^{4/5}y^{1/5}$ subject to the constraint, $4x + 2y = 12$.

19) Minimize $f(x, y, z) = x^2 + y^2 + z^2$ subject to the constraint, $x + y + z = 1$.

**Answer**

Subject to the given constraint, $f$ has a relative minimum of $f\left(\frac{1}{3}, \frac{1}{3}, \frac{1}{3}\right) = \frac{1}{3}$ at the point $\left(\frac{1}{3}, \frac{1}{3}, \frac{1}{3}\right)$.

20) Minimize $f(x, y) = xy$ on the ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$.

21) Maximize $f(x, y, z) = 2x + 3y + 5z$ on the sphere $x^2 + y^2 + z^2 = 19$.

**Answer**

Subject to the given constraint, $f$ has a relative maximum of $19\sqrt{2}$ at the point $\left(\sqrt{2}, \frac{3\sqrt{2}}{2}, \frac{5\sqrt{2}}{2}\right)$.
Note that, subject to this constraint, $f$ also has a relative minimum of $-19\sqrt{2}$ at the point $\left(-\sqrt{2}, -\frac{3\sqrt{2}}{2}, -\frac{5\sqrt{2}}{2}\right)$.
To see a 3D visualization of this problem, see: CalcPlot3D for Problem 21.

**In exercises 22-23, use the method of Lagrange multipliers with two constraints.**

22) Optimize $f(x,y,z) = yz + xy$ subject to the constraints: $xy = 1, \quad y^2 + z^2 = 1$.

**Answer**

maximum: $\frac{3}{2}$, minimum: $\frac{1}{2}$

23) Minimize $f(x,y,z) = x^2 + y^2 + z^2$ when $x + y + z = 9$ and $x + 2y + 3z = 20$.

**Answer**

minimum: $f(2,3,4) = 29$

**Use the method of Lagrange multipliers to solve the following applied problems.**

24) A large container in the shape of a rectangular solid must have a volume of 480 $m^3$. The bottom of the container costs \$5/$m^2$ to construct whereas the top and sides cost \$3/$m^2$ to construct. Use Lagrange multipliers to find the dimensions of the container of this size that has the minimum cost.

25) A rectangular box without a top (a topless box) is to be made from 12 $ft^2$ of cardboard. Find the maximum volume of such a box.

**Answer**

The maximum volume is $4$ $ft^3$. The dimensions are $1 \times 2 \times 2$ ft.

26) Find the minimum distance from the parabola $y = x^2$ to point $(0,3)$.

27) Find the point on the line $y = 2x + 3$ that is closest to point $(4,2)$.

**Answer**

$(25, 195)$

29) Find the minimum distance from point $(0,1)$ to the parabola $x^2 = 4y$.

**Answer**

$1.0$ unit

30) Find the minimum and maximum distances between the ellipse $x^2 + xy + 2y^2 = 1$ and the origin.

31) Find the minimum distance from the plane $x + y + z = 1$ to point $(2,1,1)$.

**Answer**

$\sqrt{3}$ units

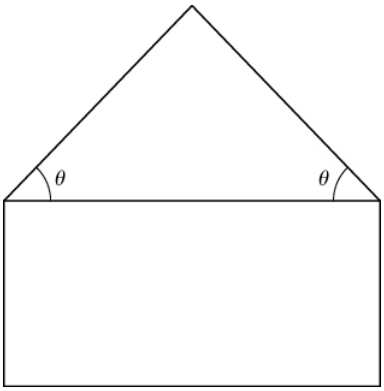
32) Find the point on the plane $4x + 3y + z = 2$ that is closest to the point $(1,-1,1)$.

33) Find the point on the surface $x^2 - 2xy + y^2 - x + y = 0$ closest to the point $(1,2,-3)$.

**Answer**

$(1, \frac{1}{2}, -3)$

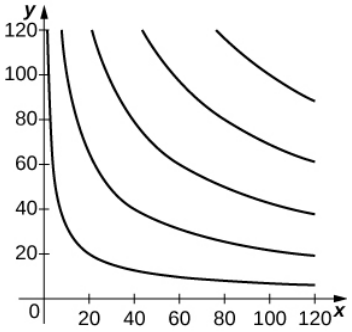
34) A pentagon is formed by placing an isosceles triangle on a rectangle, as shown in the diagram. If the perimeter of the pentagon is 10 in., find the lengths of the sides of the pentagon that will maximize the area of the pentagon.



35) **[T]** By investing $x$ units of labor and $y$ units of capital, a watch manufacturer can produce $P(x,y) = 50x^{0.4}y^{0.6}$ watches. Find the maximum number of watches that can be produced on a budget of $20,000 if labor costs $100/unit and capital costs $200/unit. Use a grapher like CalcPlot3D to sketch a contour plot of the function.

**Answer**

Roughly 3365 watches at the critical point $(80, 60)$.

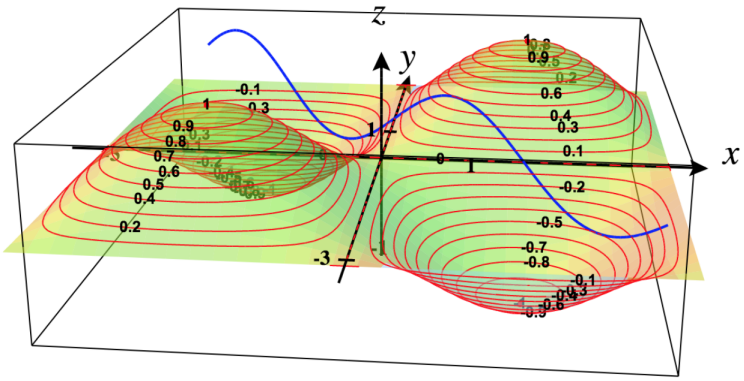


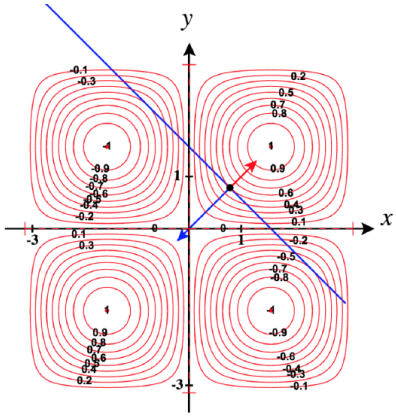
36) A rectangular solid is contained within a tetrahedron with vertices at $(1,0,0)$, $(0,1,0)$, $(0,0,1)$, and the origin. The base of the box has dimensions $x$ and $y$, and the height of the box is $z$. If the sum of $x$, $y$, and $z$ is 1, find the dimensions that maximizes the volume of the rectangular solid.

37) Find the maximum value of $f(x,y) = \sin x \sin y$, where $x$ and $y$ denote the acute angles of a right triangle. Draw the surface plot and contour plot of the function using a CAS.

**Answer**

Subject to this constraint, $f$ has a relative maximum of $\frac{1}{2}$ when $x = \frac{\pi}{4}$ and $y = \frac{\pi}{4}$.
Surface plot and contour plot for $f$:





38) Show that, of all the triangles inscribed in a circle of radius $R$ (see diagram), the equilateral triangle has the largest perimeter.

# 14.R: Chapter 14 Review Exercises

**For the following exercises, determine whether the statement is *true or false*. Justify your answer with a proof or a counterexample.**

1. The domain of $f(x,y) = x^3 \arcsin(y)$ is $\{(x,y) \mid x \in \mathbb{R} \text{ and } -\pi \leq y \leq \pi\}$.

2. If the function $f(x,y)$ is continuous everywhere, then $f_{xy}(x,y) = f_{yx}(x,y)$.

**Answer**

True, by Clairaut's theorem

3. The linear approximation to the function of $f(x,y) = 5x^2 + x\tan y$ at the point $(2,\pi)$ is given by $L(x,y) = 22 + 21(x-2) + (y-\pi)$.

4. $(34, 916)$ is a critical point of $g(x,y) = 4x^3 - 2x^2y + y^2 - 2$.

**Answer**

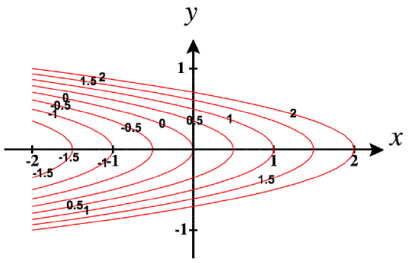
False

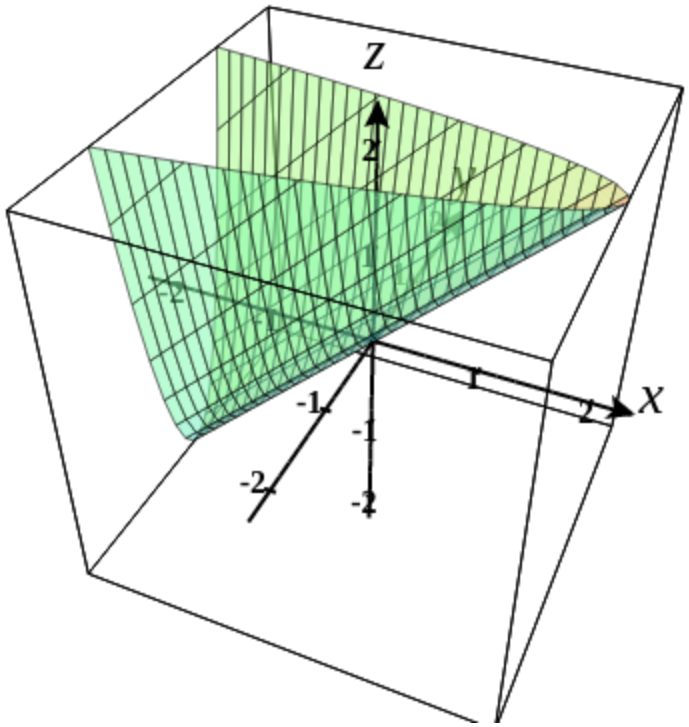
**For the following exercises, sketch the function in one graph and, in a second, sketch several level curves.**

5. $f(x,y) = e^{-(x^2+2y^2)}$

6. $f(x,y) = x + 4y^2$

**Answer**





**For the following exercises, evaluate the following limits, if they exist. If they do not exist, prove it.**

7. $\lim\limits_{(x,y)\to(1,1)} \dfrac{4xy}{x-2y^2}$

8. $\lim\limits_{(x,y)\to(0,0)} \dfrac{4xy}{x-2y^2}$

**Answer**

Does not exist.

**For the following exercises, find the largest interval of continuity for the function.**

9. $f(x,y)=x^3 \arcsin y$

10. $g(x,y)=\ln(4-x^2-y^2)$

**Answer**

Continuous at all points on the $xy$-plane, except where $x^2+y^2>4$.

**For the following exercises, find all first partial derivatives.**

11. $f(x,y)=x^2-y^2$

12. $u(x,y)=x^4-3xy+1$, with $x=2t$ and $y=t^3$

**Answer**

$$\frac{\partial u}{\partial x}=4x^3-3y,$$

$$\frac{\partial u}{\partial y}=-3x,$$

$$\frac{dx}{dt} = 2 \text{ and } \frac{dy}{dt} = 3t^2$$

$$\begin{aligned}\frac{du}{dt} &= \frac{\partial u}{\partial x} \cdot \frac{dx}{dt} + \frac{\partial u}{\partial y} \cdot \frac{dy}{dt} \\ &= 8x^3 - 6y - 9xt^2 \\ &= 8\left(2t\right)^3 - 6(t^3) - 9(2t)t^2 \\ &= 64t^3 - 6t^3 - 18t^3 \\ &= 40t^3\end{aligned}$$

**For the following exercises, find all second partial derivatives.**

13. $g(t,x) = 3t^2 - \sin(x+t)$

14. $h(x,y,z) = \dfrac{x^3e^{2y}}{z}$

**Answer**

$$\begin{aligned}h_{xx}(x,y,z) &= \frac{6xe^{2y}}{z}, \\ h_{xy}(x,y,z) &= \frac{6x^2e^{2y}}{z}, \\ h_{xz}(x,y,z) &= -\frac{3x^2e^{2y}}{z^2}, \\ h_{yx}(x,y,z) &= \frac{6x^2e^{2y}}{z}, \\ h_{yy}(x,y,z) &= \frac{4x^3e^{2y}}{z}, \\ h_{yz}(x,y,z) &= -\frac{2x^3e^{2y}}{z^2}, \\ h_{zx}(x,y,z) &= -\frac{3x^2e^{2y}}{z^2}, \\ h_{zy}(x,y,z) &= -\frac{2x^3e^{2y}}{z^2}, \\ h_{zz}(x,y,z) &= \frac{2x^3e^{2y}}{z^3}\end{aligned}$$

**For the following exercises, find the equation of the tangent plane to the specified surface at the given point.**

15. $z = x^3 - 2y^2 + y - 1$ at point $(1,1,-1)$

16. $z = e^x + \dfrac{2}{y}$ at point $(0,1,3)$

**Answer**

$z = x - 2y + 5$

17. Approximate $f(x,y) = e^{x^2} + \sqrt{y}$ at $(0.1, 9.1)$. Write down your linear approximation function $L(x,y)$. How accurate is the approximation to the exact answer, rounded to four digits?

18. Find the differential $dz$ of $h(x,y) = 4x^2 + 2xy - 3y$ and approximate $\Delta z$ at the point $(1,-2)$. Let $\Delta x = 0.1$ and $\Delta y = 0.01$.

**Answer**

$dz = 4\,dx - dy,\ dz(0.1, 0.01) = 0.39,\ \Delta z = 0.432$

19. Find the directional derivative of $f(x,y) = x^2 + 6xy - y^2$ in the direction $\vec{\mathbf{v}} = \hat{\mathbf{i}} + 4\hat{\mathbf{j}}$.

20. Find the maximal directional derivative magnitude and direction for the function $f(x,y) = x^3 + 2xy - \cos(\pi y)$ at point $(3,0)$.

**Answer**

$3\sqrt{85}\langle 27, 6\rangle$

**For the following exercises, find the gradient.**

21. $c(x,t) = e(t-x)^2 + 3\cos t$

22. $f(x,y) = \dfrac{\sqrt{x}+y^2}{xy}$

**Answer**

$$\vec{\nabla} f(x,y) = -\frac{\sqrt{x}+2y^2}{2x^2y}\,\hat{\mathbf{i}} + \left(\frac{1}{x} + \frac{1}{\sqrt{x}y^2}\right)\hat{\mathbf{j}}$$

**For the following exercise, find and classify the critical points.**

23. $z = x^3 - xy + y^2 - 1$

**For the following exercises, use Lagrange multipliers to find the maximum and minimum values for the functions with the given constraints.**

24. $f(x,y) = x^2y$, subject to the constraint: $x^2 + y^2 = 4$

**Answer**

maximum: $\dfrac{16}{3\sqrt{3}}$, minimum: $-\dfrac{16}{3\sqrt{3}}$,

25. $f(x,y) = x^2 - y^2$, subject to the constraint: $x + 6y = 4$

26. A machinist is constructing a right circular cone out of a block of aluminum. The machine gives an error of $5\%$ in height and $2\%$ in radius. Find the maximum error in the volume of the cone if the machinist creates a cone of height $6$ cm and radius $2$ cm.

**Answer**

$2.3228$ cm$^3$

27. A trash compactor is in the shape of a cuboid. Assume the trash compactor is filled with incompressible liquid. The length and width are decreasing at rates of $2$ ft/sec and $3$ ft/sec, respectively. Find the rate at which the liquid level is rising when the length is $14$ ft, the width is $10$ ft, and the height is $4$ ft.

# CHAPTER OVERVIEW

## 15: Multiple Integration

In this chapter we extend the concept of a definite integral of a single variable to double and triple integrals of functions of two and three variables, respectively. We examine applications involving integration to compute volumes, masses, and centroids of more general regions. We will also see how the use of other coordinate systems (such as polar, cylindrical, and spherical coordinates) makes it simpler to compute multiple integrals over some types of regions and functions. In the preceding chapter, we discussed differential calculus with multiple independent variables. Now we examine integral calculus in multiple dimensions. Just as a partial derivative allows us to differentiate a function with respect to one variable while holding the other variables constant, we will see that an iterated integral allows us to integrate a function with respect to one variable while holding the other variables constant.

# 15.1: Prelude to Multiple Integration

In this chapter we extend the concept of a definite integral of a single variable to double and triple integrals of functions of two and three variables, respectively. We examine applications involving integration to compute volumes, masses, and centroids of more general regions. We will also see how the use of other coordinate systems (such as polar, cylindrical, and spherical coordinates) makes it simpler to compute multiple integrals over some types of regions and functions. As an example, we will use polar coordinates to find the volume of structures such as l'Hemisfèric (Figure **15.1.1**).

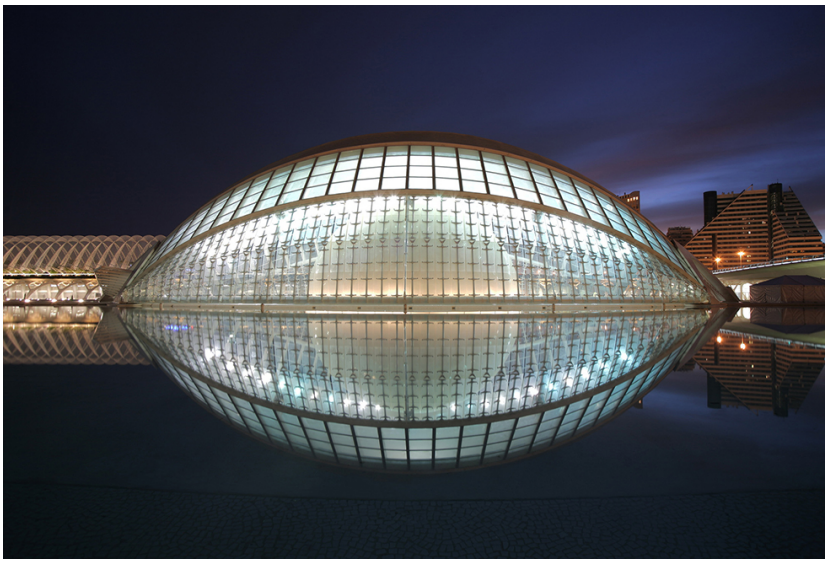

Figure **15.1.1**: The City of Arts and Sciences in Valencia, Spain, has a unique structure along an axis of just two kilometers that was formerly the bed of the River Turia. The l'Hemisfèric has an IMAX cinema with three systems of modern digital projections onto a concave screen of 900 square meters. An oval roof over 100 meters long has been made to look like a huge human eye that comes alive and opens up to the world as the "Eye of Wisdom." (credit: modification of work by Javier Yaya Tur, Wikimedia Commons)

In the preceding chapter, we discussed differential calculus with multiple independent variables. Now we examine integral calculus in multiple dimensions. Just as a partial derivative allows us to differentiate a function with respect to one variable while holding the other variables constant, we will see that an iterated integral allows us to integrate a function with respect to one variable while holding the other variables constant.

# 15.2: Double Integrals over Rectangular Regions

**Learning Objectives**

- Recognize when a function of two variables is integrable over a rectangular region.
- Recognize and use some of the properties of double integrals.
- Evaluate a double integral over a rectangular region by writing it as an iterated integral.
- Use a double integral to calculate the area of a region, volume under a surface, or average value of a function over a plane region.

In this section we investigate double integrals and show how we can use them to find the volume of a solid over a rectangular region in the xy-plane. Many of the properties of double integrals are similar to those we have already discussed for single integrals.

## Volumes and Double Integrals

We begin by considering the space above a rectangular region $R$. Consider a continuous function $f(x,y) \geq 0$ of two variables defined on the closed rectangle $R$:

$$R = [a,b] \times [c,d] = \{(x,y) \in \mathbb{R}^2 | \, a \leq x \leq b, \, c \leq y \leq d\}$$

Here $[a,b] \times [c,d]$ denotes the Cartesian product of the two closed intervals $[a,b]$ and $[c,d]$. It consists of rectangular pairs $(x,y)$ such that $a \leq x \leq b$ and $c \leq y \leq d$. The graph of $f$ represents a surface above the $xy$-plane with equation $z = f(x,y)$ where $z$ is the height of the surface at the point $(x,y)$. Let $S$ be the solid that lies above $R$ and under the graph of $f$ (Figure 15.2.1). The base of the solid is the rectangle $R$ in the $xy$-plane. We want to find the volume $V$ of the solid $S$.

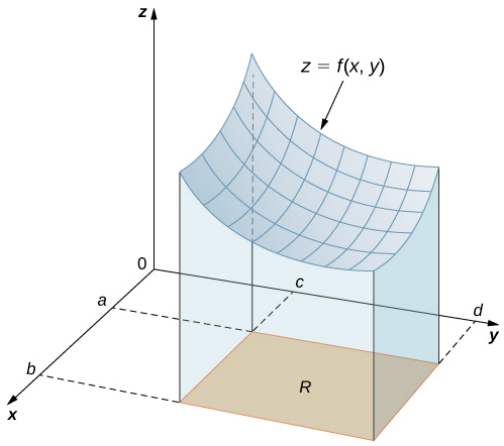

Figure 15.2.1: The graph of $f(x,y)$ *over the rectangle R in the* $xy$*-plane is a curved surface.*

We divide the region $R$ into small rectangles $R_{ij}$, each with area $\Delta A$ and with sides $\Delta x$ and $\Delta y$ (Figure 15.2.2). We do this by dividing the interval $[a,b]$ into $m$ subintervals and dividing the interval $[c,d]$ into $n$ subintervals. Hence $\Delta x = \frac{b-a}{m}$, $\Delta y = \frac{d-c}{n}$, and $\Delta A = \Delta x \Delta y$.

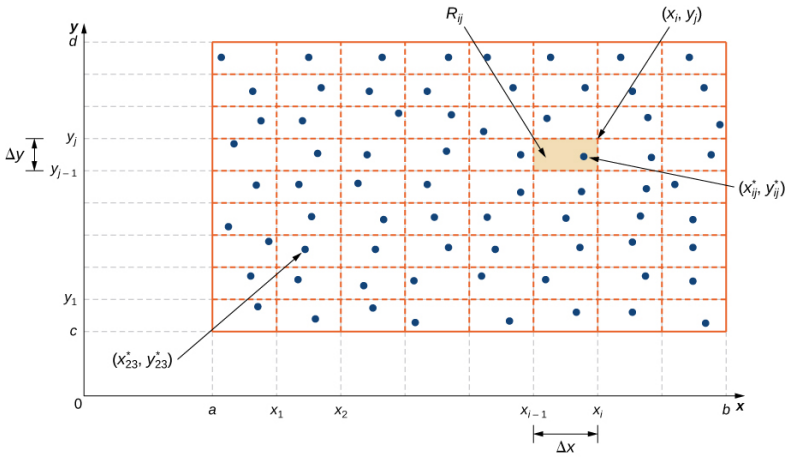

Figure **15.2.2**: Rectangle $R$ is divided into small rectangles $R_{ij}$ each with area $\Delta A$.

The volume of a thin rectangular box above $R_{ij}$ is $f(x_{ij}^*, y_{ij}^*)\,\Delta A$, where $(x_{ij}^*, y_{ij}^*)$ is an arbitrary sample point in each $R_{ij}$ as shown in the following figure, $f(x_{ij}^*, y_{ij}^*)$ is the height of the corresponding thin rectangular box, and $\Delta A$ is the area of each rectangle $R_{ij}$.

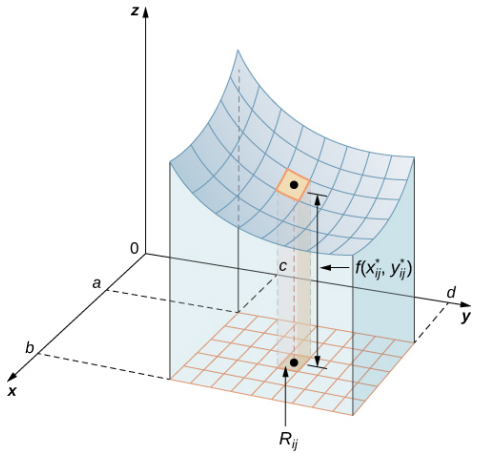

Figure **15.2.3**: A thin rectangular box above $R_{ij}$ with height $f(x_{ij}^*, y_{ij}^*)$.

Using the same idea for all the subrectangles, we obtain an approximate volume of the solid S as

$$V \approx \sum_{i=1}^{m}\sum_{j=1}^{n} f(x_{ij}^*, y_{ij}^*)\Delta A.$$

This sum is known as a **double Riemann sum** and can be used to approximate the value of the volume of the solid. Here the double sum means that for each subrectangle we evaluate the function at the chosen point, multiply by the area of each rectangle, and then add all the results.

As we have seen in the single-variable case, we obtain a better approximation to the actual volume if $m$ and $n$ become larger.

$$V = \lim_{m,n\to\infty} \sum_{i=1}^{m}\sum_{j=1}^{n} f(x_{ij}^*, y_{ij}^*)\Delta A$$

or

$$V = \lim_{\Delta x,\, \Delta y\to 0} \sum_{i=1}^{m}\sum_{j=1}^{n} f(x_{ij}^*, y_{ij}^*)\Delta A.$$

Note that the sum approaches a limit in either case and the limit is the volume of the solid with the base $R$. Now we are ready to define the double integral.

### Definition: Double Integral over a Rectangular Region R

The double integral of the function $f(x, y)$ over the rectangular region $R$ in the $xy$-plane is defined as

$$\iint_R f(x, y)dA = \lim_{m,n\to\infty} \sum_{i=1}^{m} \sum_{j=1}^{n} f(x_{ij}^*, y_{ij}^*)\Delta A.$$

If $f(x,y) \geq 0$, then the volume $V$ of the solid $S$, which lies above $R$ in the $xy$-plane and under the graph of $f$, is the double integral of the function $f(x,y)$ over the rectangle $R$. If the function is ever negative, then the double integral can be considered a "signed" volume in a manner similar to the way we defined net signed area in The Definite Integral.

### Example 15.2.1: Setting up a Double Integral and Approximating It by Double Sums

Consider the function $z = f(x, y) = 3x^2 - y$ over the rectangular region $R = [0,2] \times [0,2]$ (Figure 15.2.4).

a. Set up a double integral for finding the value of the signed volume of the solid $S$ that lies above $R$ and "under" the graph of $f$.

b. Divide $R$ into four squares with $m = n = 2$, and choose the sample point as the upper right corner point of each square (1,1), (2,1),(1,2), and (2,2) (Figure 15.2.4) to approximate the signed volume of the solid $S$ that lies above $R$ and "under" the graph of $f$.

c. Divide $R$ into four squares with $m = n = 2$, and choose the sample point as the midpoint of each square: (1/2, 1/2), (3/2, 1/2), (1/2,3/2), and (3/2, 3/2) to approximate the signed volume.

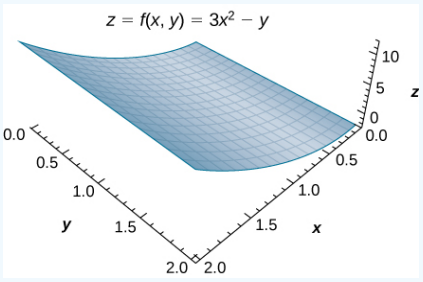

Figure 15.2.4: The function $z = f(x,y)$ graphed over the rectangular region $R = [0,2] \times [0,2]$.

**Solution**

a. As we can see, the function $z = f(x,y) = 3x^2 - y$ is above the plane. To find the signed volume of $S$, we need to divide the region $R$ into small rectangles $R_{ij}$, each with area $\Delta A$ and with sides $\Delta x$ and $\Delta y$, and choose $(x_{ij}^*, y_{ij}^*)$ as sample points in each $R_{ij}$. Hence, a double integral is set up as

$$V = \iint_R (3x^2 - y)dA = \lim_{m,n\to\infty} \sum_{i=1}^{m} \sum_{j=1}^{n} [3(x_{ij}^*)^2 - y_{ij}^*]\Delta A.$$

b. Approximating the signed volume using a Riemann sum with $m = n = 2$ we have $\Delta A = \Delta x \Delta y = 1 \times 1 = 1$. Also, the sample points are (1, 1), (2, 1), (1, 2), and (2, 2) as shown in the following figure.

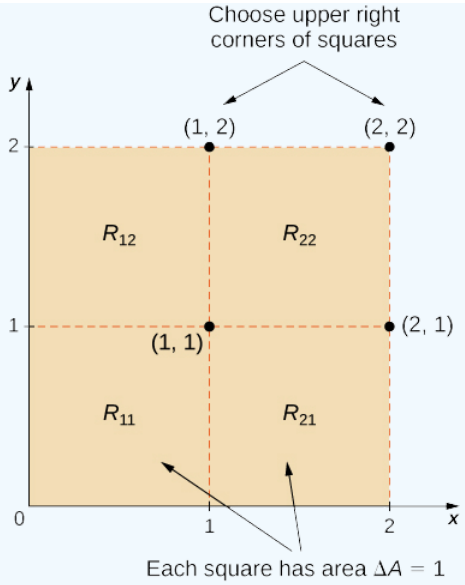

Figure 15.2.5: Subrectangles for the rectangular region $R = [0,2] \times [0,2]$.

Hence,

$$\begin{aligned} V &\approx \sum_{i=1}^{2}\sum_{j=1}^{2} f(x_{ij}^*, y_{ij}^*)\Delta A \\ &= \sum_{i=1}^{2}(f(x_{i1}^*, y_{i1}^*) + f(x_{i2}^*, y_{i2}^*))\Delta A \\ &= f(x_{11}^*, y_{11}^*)\Delta A + f(x_{21}^*, y_{21}^*)\Delta A + f(x_{12}^*, y_{12}^*)\Delta A + f(x_{22}^*, y_{22}^*)\Delta A \\ &= f(1,1)(1) + f(2,1)(1) + f(1,2)(1) + f(2,2)(1) \\ &= (3-1)(1) + (12-1)(1) + (3-2)(1) + (12-2)(1) \\ &= 2 + 11 + 1 + 10 = 24. \end{aligned}$$

c. Approximating the signed volume using a Riemann sum with $m = n = 2$ we have $\Delta A = \Delta x \Delta y = 1 \times 1 = 1$. In this case the sample points are (1/2, 1/2), (3/2, 1/2), (1/2, 3/2), and (3/2, 3/2).
Hence,

$$\begin{aligned} V &\approx \sum_{i=1}^{2}\sum_{j=1}^{2} f(x_{ij}^*, y_{ij}^*)\Delta A \\ &= f(x_{11}^*, y_{11}^*)\Delta A + f(x_{21}^*, y_{21}^*)\Delta A + f(x_{12}^*, y_{12}^*)\Delta A + f(x_{22}^*, y_{22}^*)\Delta A \\ &= f(1/2,1/2)(1) + f(3/2,1/2)(1) + f(1/2,3/2)(1) + f(3/2,3/2)(1) \\ &= \left(\frac{3}{4} - \frac{1}{4}\right)(1) + \left(\frac{27}{4} - \frac{1}{2}\right)(1) + \left(\frac{3}{4} - \frac{3}{2}\right)(1) + \left(\frac{27}{4} - \frac{3}{2}\right)(1) \\ &= \frac{2}{4} + \frac{25}{4} + \left(-\frac{3}{4}\right) + \frac{21}{4} = \frac{45}{4} = 11. \end{aligned}$$

### Analysis

Notice that the approximate answers differ due to the choices of the sample points. In either case, we are introducing some error because we are using only a few sample points. Thus, we need to investigate how we can achieve an accurate answer.

## ? Exercise 15.2.1

Use the same function $z = f(x,y) = 3x^2 - y$ over the rectangular region $R = [0,2] \times [0,2]$.

Divide $R$ into the same four squares with $m = n = 2$, and choose the sample points as the upper left corner point of each square (0,1), (1,1), (0,2), and (1,2) (Figure 15.2.5) to approximate the signed volume of the solid $S$ that lies above $R$ and "under" the graph of $f$.

**Hint**

Follow the steps of the previous example.

**Answer**

$$V \approx \sum_{i=1}^{2}\sum_{j=1}^{2} f(x_{ij}^*, y_{ij}^*)\,\Delta A = 0$$

Note that we developed the concept of double integral using a rectangular region $R$. This concept can be extended to any general region. However, when a region is not rectangular, the subrectangles may not all fit perfectly into $R$, particularly if the base area is curved. We examine this situation in more detail in the next section, where we study regions that are not always rectangular and subrectangles may not fit perfectly in the region $R$. Also, the heights may not be exact if the surface $z = f(x, y)$ is curved. However, the errors on the sides and the height where the pieces may not fit perfectly within the solid $S$ approach 0 as $m$ and $n$ approach infinity. Also, the double integral of the function $z = f(x, y)$ exists provided that the function $f$ is not too discontinuous. If the function is bounded and continuous over $R$ except on a finite number of smooth curves, then the double integral exists and we say that $f$ is integrable over $R$.

Since $\Delta A = \Delta x \Delta y = \Delta y \Delta x$, we can express $dA$ as $dx\,dy$ or $dy\,dx$. This means that, when we are using rectangular coordinates, the double integral over a region $R$ denoted by

$$\iint_R f(x, y)\,dA$$

can be written as

$$\iint_R f(x, y)\,dx\,dy$$

or

$$\iint_R f(x, y)\,dy\,dx.$$

Now let's list some of the properties that can be helpful to compute double integrals.

## Properties of Double Integrals

The properties of double integrals are very helpful when computing them or otherwise working with them. We list here six properties of double integrals. Properties 1 and 2 are referred to as the linearity of the integral, property 3 is the additivity of the integral, property 4 is the monotonicity of the integral, and property 5 is used to find the bounds of the integral. Property 6 is used if $f(x, y)$ is a product of two functions $g(x)$ and $h(y)$.

**Theorem: Properties of Double Integrals**

Assume that the functions $f(x, y)$ and $g(x, y)$ are integrable over the rectangular region $R$; $S$ and $T$ are subregions of $R$; and assume that $m$ and $M$ are real numbers.

i. The sum $f(x, y) + g(x, y)$ is integrable and

$$\iint_R [f(x, y) + g(x, y)]\,dA = \iint_R f(x, y)\,dA + \iint_R g(x, y)\,dA.$$

ii. If $c$ is a constant, then $cf(x, y)$ is integrable and

$$\iint_R cf(x, y)\,dA = c\iint_R f(x, y)\,dA.$$

iii. If $R = S \cup T$ and $S \cap T = \emptyset$ except an overlap on the boundaries, then

$$\iint_R f(x, y)\,dA = \iint_S f(x, y)\,dA + \iint_T f(x, y)\,dA.$$

iv. If $f(x,y) \geq g(x,y)$ for $(x,y)$ in $R$, then

$$\iint_R f(x,y)\,dA \geq \iint_R g(x,y)\,dA.$$

v. If $m \leq f(x,y) \leq M$ and $A(R) = \text{the area of } R$, then

$$m \cdot A(R) \leq \iint_R f(x,y)\,dA \leq M \cdot A(R).$$

vi. In the case where $f(x,y)$ can be factored as a product of a function $g(x)$ of $x$ only and a function $h(y)$ of $y$ only, then over the region $R = \{(x,y) \mid a \leq x \leq b,\ c \leq y \leq d\}$, the double integral can be written as

$$\iint_R f(x,y)\,dA = \left(\int_a^b g(x)\,dx\right)\left(\int_c^d h(y)\,dy\right).$$

These properties are used in the evaluation of double integrals, as we will see later. We will become skilled in using these properties once we become familiar with the computational tools of double integrals. So let's get to that now.

## Iterated Integrals

So far, we have seen how to set up a double integral and how to obtain an approximate value for it. We can also imagine that evaluating double integrals by using the definition can be a very lengthy process if we choose larger values for $m$ and $n$.Therefore, we need a practical and convenient technique for computing double integrals. In other words, we need to learn how to compute double integrals without employing the definition that uses limits and double sums.

The basic idea is that the evaluation becomes easier if we can break a double integral into single integrals by integrating first with respect to one variable and then with respect to the other. The key tool we need is called an iterated integral.

### Definitions: Iterated Integrals

Assume $a$, $b$, $c$, and $d$ are real numbers. We define an *iterated integral* for a function $f(x,y)$ over the rectangular region $R = [a,b] \times [c,d]$ as

$$\int_a^b \int_c^d f(x,y)\,dy\,dx = \int_a^b \left[\int_c^d f(x,y)\,dy\right] dx$$

or

$$\int_c^d \int_a^b f(x,y)\,dx\,dy = \int_c^d \left[\int_a^b f(x,y)\,dx\right] dy.$$

The notation $\int_a^b \left[\int_c^d f(x,y)\,dy\right] dx$ means that we integrate $f(x,y)$ with respect to $y$ while holding $x$ constant. Similarly, the notation $\int_c^d \left[\int_a^b f(x,y)\,dx\right] dy$ means that we integrate $f(x,y)$ with respect to $x$ while holding $y$ constant. The fact that double integrals can be split into iterated integrals is expressed in Fubini's theorem. Think of this theorem as an essential tool for evaluating double integrals.

### Theorem: Fubini's Theorem

Suppose that $f(x,y)$ is a function of two variables that is continuous over a rectangular region $R = \{(x,y) \in \mathbb{R}^2 \mid a \leq x \leq b,\ c \leq y \leq d\}$. Then we see from Figure **15.2.6** that the double integral of $f$ over the region equals an iterated integral,

$$\iint_R f(x,y)\,dA = \iint_R f(x,y)\,dx\,dy = \int_a^b \int_c^d f(x,y)\,dy\,dx = \int_c^d \int_a^b f(x,y)\,dx\,dy.$$

More generally, Fubini's theorem is true if $f$ is bounded on $R$ and $f$ is discontinuous only on a finite number of continuous curves. In other words, $f$ has to be integrable over $R$.

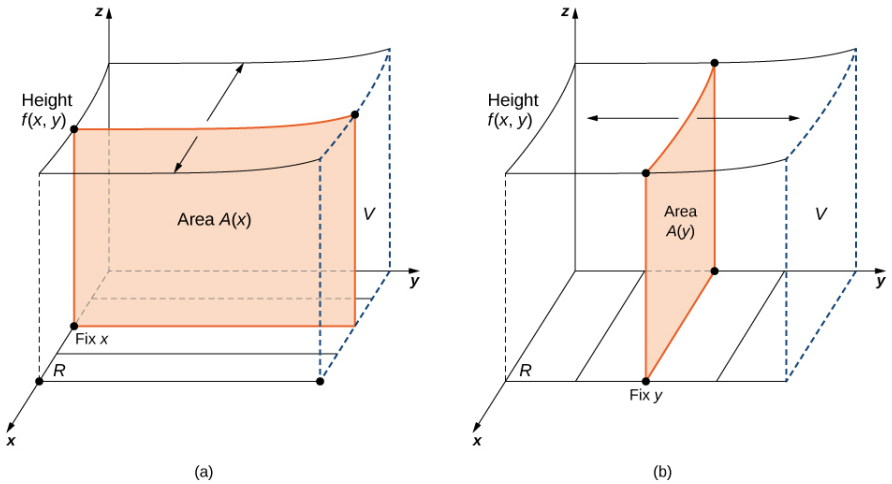

Figure 15.2.6: (a) Integrating first with respect to $y$ and then with respect to $x$ to find the area $A(x)$ and then the volume $V$; (b) integrating first with respect to $x$ and then with respect to $y$ to find the area $A(y)$ and then the volume $V$.

### Example 15.2.2: Using Fubini's Theorem

Use Fubini's theorem to compute the double integral $\iint_R f(x,y)\,dA$ where $f(x,y) = x$ and $R = [0,2] \times [0,1]$.

**Solution**

Fubini's theorem offers an easier way to evaluate the double integral by the use of an iterated integral. Note how the boundary values of the region $R$ become the upper and lower limits of integration.

$$\begin{aligned}\iint_R f(x,y)\,dA &= \iint_R f(x,y)\,dx\,dy \\ &= \int_{y=0}^{y=1}\int_{x=0}^{x=2} x\,dx\,dy \\ &= \int_{y=0}^{y=1}\left[\frac{x^2}{2}\Big|_{x=0}^{x=2}\right] dy \\ &= \int_{y=0}^{y=1} 2\,dy = 2y\Big|_{y=0}^{y=1} = 2\end{aligned}$$

The double integration in this example is simple enough to use Fubini's theorem directly, allowing us to convert a double integral into an iterated integral. Consequently, we are now ready to convert all double integrals to iterated integrals and demonstrate how the properties listed earlier can help us evaluate double integrals when the function $f(x,y)$ is more complex. Note that the order of integration can be changed (see Example 7).

### Example 15.2.3: Illustrating Properties i and ii

Evaluate the double integral

$$\iint_R (xy - 3xy^2)\,dA, \text{ where } R = \{(x,y) \mid 0 \le x \le 2,\ 1 \le y \le 2\}.$$

**Solution**

This function has two pieces: one piece is $xy$ and the other is $3xy^2$. Also, the second piece has a constant 3. Notice how we use properties i and ii to help evaluate the double integral.

$$\iint_R (xy - 3xy^2)\,dA = \iint_R xy\,dA + \iint_R (-3xy^2)\,dA$$ Property i: Integral of a sum is the sum of the integrals.

$$= \int_{y=1}^{y=2} \int_{x=0}^{x=2} xy\,dx\,dy - \int_{y=1}^{y=2} \int_{x=0}^{x=2} 3xy^2\,dx\,dy$$ Convert double integrals to iterated integrals.

$$= \int_{y=1}^{y=2} \left(\frac{x^2}{2}y\right)\Big|_{x=0}^{x=2} dy - 3\int_{y=1}^{y=2} \left(\frac{x^2}{2}y^2\right)\Big|_{x=0}^{x=2} dy$$ Integrate with respect to $x$, holding $y$ constant.

$$= \int_{y=1}^{y=2} 2y\,dy - \int_{y=1}^{y=2} 6y^2 dy$$ Property ii: Placing the constant before the integral.

$$= 2\int_1^2 y\,dy - 6\int_1^2 y^2\,dy$$ Integrate with respect to y.

$$= 2\frac{y^2}{2}\Big|_1^2 - 6\frac{y^3}{3}\Big|_1^2$$

$$= y^2\Big|_1^2 - 2y^3\Big|_1^2$$

$$= (4-1) - 2(8-1) = 3 - 2(7)$$

$$= 3 - 14 = -11.$$

## Example 15.2.4: Illustrating Property v.

Over the region $R = \{(x,y) \mid 1 \le x \le 3,\ 1 \le y \le 2\}$, we have $2 \le x^2 + y^2 \le 13$. Find a lower and an upper bound for the integral $\iint_R (x^2 + y^2)\,dA$.

### Solution

For a lower bound, integrate the constant function 2 over the region $R$. For an upper bound, integrate the constant function 13 over the region $R$.

$$\int_1^2 \int_1^3 2\,dx\,dy = \int_1^2 [2x\Big|_1^3]\,dy = \int_1^2 2(2)dy = 4y\Big|_1^2 = 4(2-1) = 4$$

$$\int_1^2 \int_1^3 13dx\,dy = \int_1^2 [13x\Big|_1^3]\,dy = \int_1^2 13(2)\,dy = 26y\Big|_1^2 = 26(2-1) = 26.$$

Hence, we obtain $4 \le \iint_R (x^2 + y^2)\,dA \le 26$.

## Example 15.2.5: Illustrating Property vi

Evaluate the integral $\iint_R e^y \cos x\,dA$ over the region $R = \{(x,y) \mid 0 \le x \le \frac{\pi}{2},\ 0 \le y \le 1\}$.

### Solution

This is a great example for property vi because the function $f(x,y)$ is clearly the product of two single-variable functions $e^y$ and $\cos x$. Thus we can split the integral into two parts and then integrate each one as a single-variable integration problem.

$$\iint_R e^y \cos x \, dA = \int_0^1 \int_0^{\pi/2} e^y \cos x \, dx \, dy$$
$$= \left( \int_0^1 e^y dy \right) \left( \int_0^{\pi/2} \cos x \, dx \right)$$
$$= (e^y \Big|_0^1)(\sin x \Big|_0^{\pi/2})$$
$$= e - 1.$$

**? Exercise 15.2.2**

a. Use the properties of the double integral and Fubini's theorem to evaluate the integral

$$\int_0^1 \int_{-1}^3 (3 - x + 4y) \, dy \, dx.$$

b. Show that $0 \le \iint_R \sin \pi x \, \cos \pi y \, dA \le \frac{1}{32}$ where $R = \left(0, \frac{1}{4}\right) \left(\frac{1}{4}, \frac{1}{2}\right)$.

**Hint**

Use properties i. and ii. and evaluate the iterated integral, and then use property v.

**Answer**

a. **26**

b. Answers may vary.

As we mentioned before, when we are using rectangular coordinates, the double integral over a region $R$ denoted by $\iint_R f(x,y) \, dA$ can be written as $\iint_R f(x,y) \, dx \, dy$ or $\iint_R f(x,y) \, dy \, dx$. The next example shows that the results are the same regardless of which order of integration we choose.

**✓ Example 15.2.6: Evaluating an Iterated Integral in Two Ways**

Let's return to the function $f(x,y) = 3x^2 - y$ from Example 1, this time over the rectangular region $R = [0,2] \times [0,3]$. Use Fubini's theorem to evaluate $\iint_R f(x,y) \, dA$ in two different ways:

a. First integrate with respect to $y$ and then with respect to $x$;
b. First integrate with respect to $x$ and then with respect to $y$.

**Solution**

Figure 15.2.6 shows how the calculation works in two different ways.

a. First integrate with respect to $y$ and then integrate with respect to $x$:

$$\iint_R f(x,y) \, dA = \int_{x=0}^{x=2} \int_{y=0}^{y=3} (3x^2 - y) \, dy \, dx$$
$$= \int_{x=0}^{x=2} \left( \int_{y=0}^{y=3} (3x^2 - y) \, dy \right) dx = \int_{x=0}^{x=2} \left[ 3x^2 y - \frac{y^2}{2} \Big|_{y=0}^{y=3} \right] dx$$
$$= \int_{x=0}^{x=2} \left( 9x^2 - \frac{9}{2} \right) dx = 3x^3 - \frac{9}{2} x \Big|_{x=0}^{x=2} = 15.$$

b. First integrate with respect to $x$ and then integrate with respect to $y$:

$$\begin{aligned}\iint_R f(x,y)\,dA &= \int_{y=0}^{y=3}\int_{x=0}^{x=2}(3x^2-y)\,dx\,dy \\ &= \int_{y=0}^{y=3}\left(\int_{x=0}^{x=2}(3x^2-y)\,dx\right)dy \\ &= \int_{y=0}^{y=3}\left[x^3-xy\Big|_{x=0}^{x=2}\right]dy \\ &= \int_{y=0}^{y=3}(8-2y)\,dy = 8y-y^2\Big|_{y=0}^{y=3} = 15.\end{aligned}$$

### Analysis

With either order of integration, the double integral gives us an answer of $15$. We might wish to interpret this answer as a volume in cubic units of the solid $S$ below the function $f(x,y)=3x^2-y$ over the region $R=[0,2]\times[0,3]$. However, remember that the interpretation of a double integral as a (non-signed) volume works only when the integrand $f$ is a nonnegative function over the base region $R$.

## ? Exercise 15.2.3

Evaluate

$$\int_{y=-3}^{y=2}\int_{x=3}^{x=5}(2-3x^2+y^2)\,dx\,dy.$$

**Hint**

Use Fubini's theorem.

**Answer**

$-\frac{1340}{3}$

In the next example we see that it can actually be beneficial to switch the order of integration to make the computation easier. We will come back to this idea several times in this chapter.

## ✓ Example 15.2.7: Switching the Order of Integration

Consider the double integral $\iint_R x\sin(xy)\,dA$ over the region $R=\{(x,y)\,|\,0\le x\le\pi,\ 1\le y\le 2\}$ (Figure 15.2.7).

a. Express the double integral in two different ways.
b. Analyze whether evaluating the double integral in one way is easier than the other and why.
c. Evaluate the integral.

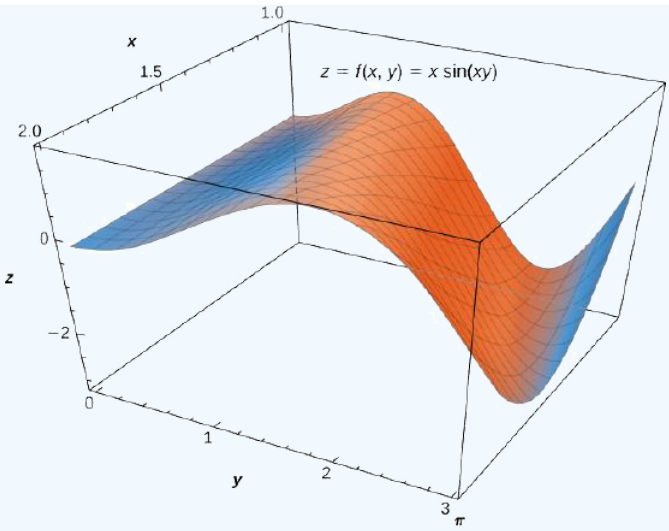

Figure 15.2.7: The function $z = f(x, y) = x \sin(xy)$ over the rectangular region $R = [0, \pi] \times [1, 2]$.

a. We can express $\iint_R x \sin(xy)\, dA$ in the following two ways: first by integrating with respect to $y$ and then with respect to $x$; second by integrating with respect to $x$ and then with respect to $y$.

$$\iint_R x \sin(xy)\, dA = \int_{x=0}^{x=\pi} \int_{y=1}^{y=2} x \sin(xy)\, dy\, dx$$

Integrate first with respect to $y$.

$$= \int_{y=1}^{y=2} \int_{x=0}^{x=\pi} x \sin(xy)\, dx\, dy$$

Integrate first with respect to $x$.

b. If we want to integrate with respect to $y$ first and then integrate with respect to $x$, we see that we can use the substitution $u = xy$, which gives $du = x\, dy$. Hence the inner integral is simply $\int \sin u\, du$ and we can change the limits to be functions of $x$,

$$\iint_R x \sin(xy)\, dA = \int_{x=0}^{x=\pi} \int_{y=1}^{y=2} x \sin(xy)\, dy\, dx = \int_{x=0}^{x=\pi} \left[ \int_{u=x}^{u=2x} \sin(u)\, du \right] dx.$$

However, integrating with respect to $x$ first and then integrating with respect to $y$ requires integration by parts for the inner integral, with $u = x$ and $dv = \sin(xy)dx$

Then $du = dx$ and $v = -\frac{\cos(xy)}{y}$, so

$$\iint_R x \sin(xy)\, dA = \int_{y=1}^{y=2} \int_{x=0}^{x=\pi} x \sin(xy)\, dx\, dy$$
$$= \int_{y=1}^{y=2} \left[ -\frac{x \cos(xy)}{y} \Big|_{x=0}^{x=\pi} + \frac{1}{y} \int_{x=0}^{x=\pi} \cos(xy)\, dx \right] dy.$$

Since the evaluation is getting complicated, we will only do the computation that is easier to do, which is clearly the first method.

c. Evaluate the double integral using the easier way.

$$\iint_R x\sin(xy)\,dA = \int_{x=0}^{x=\pi}\int_{y=1}^{y=2} x\sin(xy)\,dy\,dx$$
$$= \int_{x=0}^{x=\pi}\left[\int_{u=x}^{u=2x}\sin(u)\,du\right]dx = \int_{x=0}^{x=\pi}\left[-\cos u\Big|_{u=x}^{u=2x}\right]dx$$
$$= \int_{x=0}^{x=\pi}(-\cos 2x+\cos x)\,dx$$
$$= \left(-\frac{1}{2}\sin 2x+\sin x\right)\Big|_{x=0}^{x=\pi} = 0.$$

**? Exercise 15.2.4**

Evaluate the integral $\iint_R xe^{xy}\,dA$ where $R=[0,1]\times[0,\ln 5]$.

**Hint**

Integrate with respect to $y$ first.

**Answer**

$\frac{4-\ln 5}{\ln 5}$

## Applications of Double Integrals

Double integrals are very useful for finding the area of a region bounded by curves of functions. We describe this situation in more detail in the next section. However, if the region is a rectangular shape, we can find its area by integrating the constant function $f(x,y)=1$ over the region $R$.

**Definition: Area of a Region R**

The area of the region $R$ is given by

$$A(R)=\iint_R 1\,dA.$$

This definition makes sense because using $f(x,y)=1$ and evaluating the integral make it a product of length and width. Let's check this formula with an example and see how this works.

**✓ Example 15.2.8: Finding Area Using a Double Integral**

Find the area of the region $R=\{(x,y)\,|\,0\le x\le 3,\ 0\le y\le 2\}$ by using a double integral, that is, by integrating $1$ over the region $R$.

**Solution**

The region is rectangular with length $3$ and width $2$, so we know that the area is $6$. We get the same answer when we use a double integral:

$$A(R)=\int_0^2\int_0^3 1\,dx\,dy=\int_0^2\left[x\Big|_0^3\right]dy=\int_0^2 3dy=3\int_0^2 dy=3y\Big|_0^2=3(2)=6\text{ units}^2.$$

We have already seen how double integrals can be used to find the volume of a solid bounded above by a function $f(x,y)\ge 0$ over a region $R$ provided $f(x,y)\ge 0$ for all $(x,y)$ in $R$. Here is another example to illustrate this concept.

## Example 15.2.9: Volume of an Elliptic Paraboloid

Find the volume $V$ of the solid $S$ that is bounded by the elliptic paraboloid $2x^2 + y^2 + z = 27$, the planes $x = 3$ and $y = 3$, and the three coordinate planes.

### Solution

First notice the graph of the surface $z = 27 - 2x^2 - y^2$ in Figure 15.2.8(a) and above the square region $R_1 = [-3, 3] \times [-3, 3]$. However, we need the volume of the solid bounded by the elliptic paraboloid $2x^2 + y^2 + z = 27$, the planes $x = 3$ and $y = 3$, and the three coordinate planes.

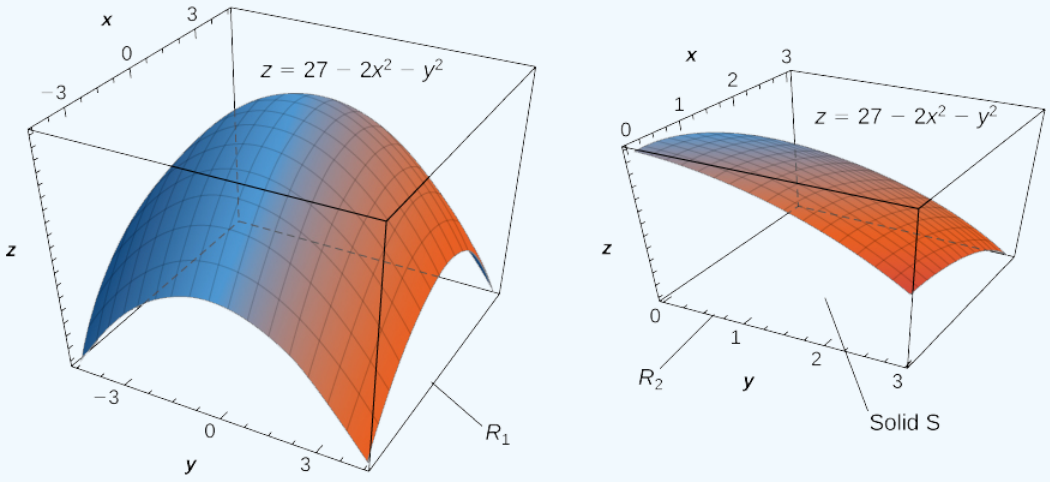

Figure 15.2.8: (a) The surface $z = 27 - 2x^2 - y^2$ above the square region $R1 = [-3, 3] \times [-3, 3]$. (b) The solid $S$ lies under the surface $z = 27 - 2x^2 - y^2$ above the square region $R1 = [0, 3] \times [0, 3]$.

Now let's look at the graph of the surface in Figure 15.2.8(b). We determine the volume $V$ by evaluating the double integral over $R_2$:

$$
\begin{aligned}
V &= \iint_R z\,dA = \iint_R (27 - 2x^2 - y^2)\,dA \\
&= \int_{y=0}^{y=3} \int_{x=0}^{x=3} (27 - 2x^2 - y^2)\,dx\,dy && \text{Convert to literal integral.} \\
&= \int_{y=0}^{y=3} \left[27x - \frac{2}{3}x^3 - y^2 x\right]\Big|_{x=0}^{x=3} dy && \text{Integrate with respect to } x. \\
&= \int_{y=0}^{y=3} (63 - 3y^2)dy = 63y - y^3\Big|_{y=0}^{y=3} = 162.
\end{aligned}
$$

## Exercise 15.2.5

Find the volume of the solid bounded above by the graph of $f(x, y) = xy\sin(x^2 y)$ and below by the $xy$-plane on the rectangular region $R = [0, 1] \times [0, \pi]$.

### Hint

Graph the function, set up the integral, and use an iterated integral.

### Answer

$\frac{\pi}{2}$

Recall that we defined the average value of a function of one variable on an interval $[a, b]$ as

$$f_{ave} = \frac{1}{b-a}\int_a^b f(x)\,dx.$$

Similarly, we can define the average value of a function of two variables over a region $R$. The main difference is that we divide by an area instead of the width of an interval.

**Definition: Average Value of a Function**

The **average value of a function** of two variables over a region $R$ is

$$F_{ave} = \frac{1}{\text{Area of } R}\iint_R f(x,y)\,dx\,dy.$$

In the next example we find the average value of a function over a rectangular region. This is a good example of obtaining useful information for an integration by making individual measurements over a grid, instead of trying to find an algebraic expression for a function.

**Example 15.2.10: Calculating Average Storm Rainfall**

The weather map in Figure 15.2.9 shows an unusually moist storm system associated with the remnants of Hurricane Karl, which dumped 4–8 inches (100–200 mm) of rain in some parts of the Midwest on September 22–23, 2010. The area of rainfall measured 300 miles east to west and 250 miles north to south. Estimate the average rainfall over the entire area in those two days.

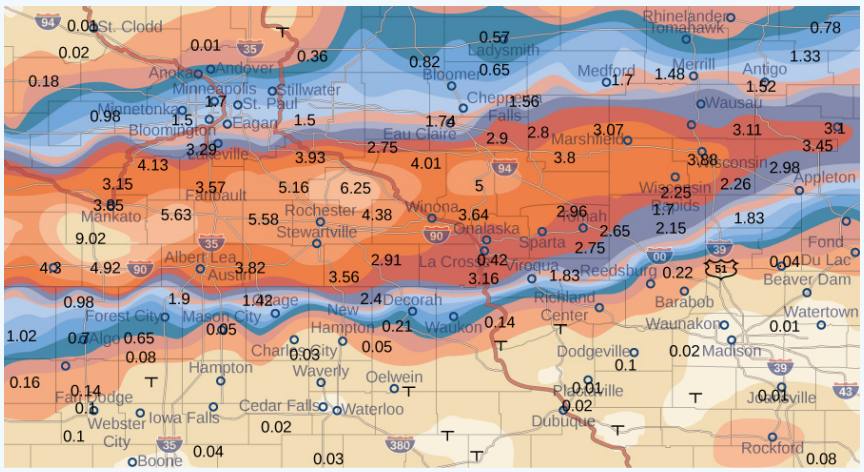

Figure 15.2.9: Effects of Hurricane Karl, which dumped 4–8 inches (100–200 mm) of rain in some parts of southwest Wisconsin, southern Minnesota, and southeast South Dakota over a span of 300 miles east to west and 250 miles north to south.

### Solution

Place the origin at the southwest corner of the map so that all the values can be considered as being in the first quadrant and hence all are positive. Now divide the entire map into six rectangles ($m = 2$ and $n = 3$), as shown in Figure 15.2.9. Assume $f(x,y)$ denotes the storm rainfall in inches at a point approximately $x$ miles to the east of the origin and $y$ miles to the north of the origin. Let $R$ represent the entire area of $250 \times 300 = 75000$ square miles. Then the area of each subrectangle is

$$\Delta A = \frac{1}{6}(75000) = 12500.$$

Assume $(x_{ij}*, y_{ij}*)$ are approximately the midpoints of each subrectangle $R_{ij}$. Note the color-coded region at each of these points, and estimate the rainfall. The rainfall at each of these points can be estimated as:

- At $(x_{11}, y_{11})$, the rainfall is 0.08.
- At $(x_{12}, y_{12})$, the rainfall is 0.08.
- At $(x_{13}, y_{13})$, the rainfall is 0.01.

- At $(x_{21}, y_{21})$, the rainfall is 1.70.
- At $(x_{22}, y_{22})$, the rainfall is 1.74.
- At $(x_{23}, y_{23})$, the rainfall is 3.00.

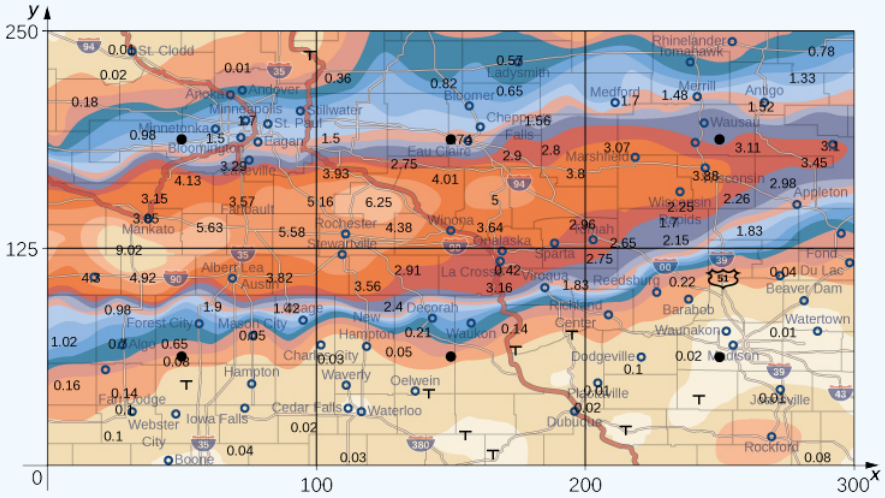

Figure **15.2.10**: Storm rainfall with rectangular axes and showing the midpoints of each subrectangle.

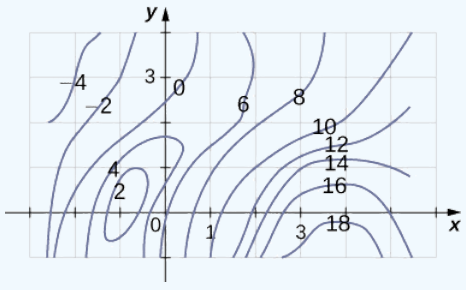
According to our definition, the average storm rainfall in the entire area during those two days was

$$
\begin{aligned}
f_{ave} &= \frac{1}{\text{Area } R} \\
\iint_R f(x,y)\,dx\,dy &= \frac{1}{75000}\iint_R f(x,y)\,dx\,dy \\
&\approx \frac{1}{75000}\sum_{i=1}^{3}\sum_{j=1}^{2} f(x_{ij}^*, y_{ij}^*)\Delta A \\
&= \frac{1}{75000}\Big[f(x_{11}^*, y_{11}^*)\Delta A + f(x_{12}^*, y_{12}^*)\Delta A + f(x_{13}^*, y_{13}^*)\Delta A \\
&\qquad + f(x_{21}^*, y_{21}^*)\Delta A + f(x_{22}^*, y_{22}^*)\Delta A + f(x_{23}^*, y_{23}^*)\Delta A\Big] \\
&\approx \frac{1}{75000}\Big[0.08 + 0.08 + 0.01 + 1.70 + 1.74 + 3.00\Big]\Delta A \\
&= \frac{1}{75000}\Big[0.08 + 0.08 + 0.01 + 1.70 + 1.74 + 3.00\Big]12500 \\
&= \frac{1}{6}\Big[0.08 + 0.08 + 0.01 + 1.70 + 1.74 + 3.00\Big] \\
&\approx 1.10 \text{ in.}
\end{aligned}
$$

During September 22–23, 2010 this area had an average storm rainfall of approximately 1.10 inches.

## ? Exercise 15.2.6

A contour map is shown for a function $f(x,y)$ on the rectangle $R = [-3,6] \times [-1,4]$.



a. Use the midpoint rule with $m = 3$ and $n = 2$ to estimate the value of $\iint_R f(x,y)\,dA$.

b. Estimate the average value of the function $f(x,y)$.

**Hint**

Divide the region into six rectangles, and use the contour lines to estimate the values for $f(x,y)$.

**Answer**

Answers to both parts a. and b. may vary.

## Key Concepts

- We can use a double Riemann sum to approximate the volume of a solid bounded above by a function of two variables over a rectangular region. By taking the limit, this becomes a double integral representing the volume of the solid.
- Properties of double integral are useful to simplify computation and find bounds on their values.
- We can use Fubini's theorem to write and evaluate a double integral as an iterated integral.
- Double integrals are used to calculate the area of a region, the volume under a surface, and the average value of a function of two variables over a rectangular region.

## Key Equations

- $$\iint_R f(x,y)\,dA = \lim_{m,n\to\infty} \sum_{i=1}^{m}\sum_{j=1}^{n} f(x_i j*, y_i j*)\,\Delta A$$
- $$\int_a^b \int_c^d f(x,y)\,dx\,dy = \int_a^b \left[\int_c^d f(x,y)\,dy\right] dx$$

  or

  $$\int_c^d \int_a^b f(x,y)\,dx\,dy = \int_c^d \left[\int_a^b f(x,y)\,dx\right] dy$$
- $$f_{ave} = \frac{1}{\text{Area of } R} \iint_R f(x,y)\,dx\,dy$$

## Glossary

**double integral**

of the function $f(x,y)$ over the region $R$ in the $xy$-plane is defined as the limit of a double Riemann sum,

$$\iint_R f(x,y)\,dA = \lim_{m,n\to\infty} \sum_{i=1}^{m}\sum_{j=1}^{n} f(x_{ij}^*, y_{ij}^*)\,\Delta A.$$

**double Riemann sum**

of the function $f(x,y)$ over a rectangular region $R$ is

$$\sum_{i=1}^{m}\sum_{j=1}^{n} f(x_{ij}^*, y_{ij}^*)\,\Delta A,$$

where $R$ is divided into smaller subrectangles $R_{ij}$ and $(x_{ij}^*, y_{ij}^*)$ is an arbitrary point in $R_{ij}$

**Fubini's theorem**

if $f(x,y)$ is a function of two variables that is continuous over a rectangular region $R = \{(x,y) \in \mathbb{R}^2 \,|\, a \le x \le b,\, c \le y \le d\}$, then the double integral of $f$ over the region equals an iterated integral,

$$\iint_R f(x,y)\,dA = \int_a^b \int_c^d f(x,y)\,dx\,dy = \int_c^d \int_a^b f(x,y)\,dx\,dy$$

**iterated integral**

for a function $f(x, y)$ over the region $R$ is

a. $\int_a^b \int_c^d f(x, y)\, dx\, dy = \int_a^b \left[ \int_c^d f(x, y)\, dy \right] dx,$

b. $\int_c^d \int_a^b f(x, y)\, dx\, dy = \int_c^d \left[ \int_a^b f(x, y)\, dx \right] dy,$

where $a, b, c$, and $d$ are any real numbers and $R = [a, b] \times [c, d]$

# 15.2E: Exercises for Section 15.1

**In exercises 1 and 2, use the midpoint rule with $m = 4$ and $n = 2$ to estimate the volume of the solid bounded by the surface $z = f(x, y)$, the vertical planes $x = 1$, $x = 2$, $y = 1$, and $y = 2$, and the horizontal plane $z = 0$.**

1) $f(x, y) = 4x + 2y + 8xy$

**Answer**

**27**

2) $f(x, y) = 16x^2 + \frac{y}{2}$

**In exercises 3 and 4, estimate the volume of the solid under the surface $z = f(x, y)$ and above the rectangular region $R$ by using a Riemann sum with $m = n = 2$ and the sample points to be the lower left corners of the sub-rectangles of the partition.**

3) $f(x, y) = \sin x - \cos y$, $R = [0, \pi] \times [0, \pi]$

**Answer**

**0**

4) $f(x, y) = \cos x + \cos y$, $R = [0, \pi] \times [0, \frac{\pi}{2}]$

5) Use the midpoint rule with $m = n = 2$ to estimate $\iint_R f(x, y)\, dA$, where the values of the function $f$ on $R = [8, 10] \times [9, 11]$ are given in the following table.

| | $y$ | | | | |
|---|---|---|---|---|---|
| $x$ | 9 | 9.5 | 10 | 10.5 | 11 |
| 8 | 9.8 | 5 | 6.7 | 5 | 5.6 |
| 8.5 | 9.4 | 4.5 | 8 | 5.4 | 3.4 |
| 9 | 8.7 | 4.6 | 6 | 5.5 | 3.4 |
| 9.5 | 6.7 | 6 | 4.5 | 5.4 | 6.7 |
| 10 | 6.8 | 6.4 | 5.5 | 5.7 | 6.8 |

**Answer**

**21.3**

6) The values of the function $f$ on the rectangle $R = [0, 2] \times [7, 9]$ are given in the following table. Estimate the double integral $\iint_R f(x, y)\, dA$ by using a Riemann sum with $m = n = 2$. Select the sample points to be the upper right corners of the sub-squares of $R$.

| | $y_0 = 7$ | $y_1 = 8$ | $y_2 = 9$ |
|---|---|---|---|
| $x_0 = 0$ | 10.22 | 10.21 | 9.85 |
| $x_1 = 1$ | 6.73 | 9.75 | 9.63 |
| $x_2 = 2$ | 5.62 | 7.83 | 8.21 |

7) The depth of a children's 4-ft by 4-ft swimming pool, measured at 1-ft intervals, is given in the following table.

a. Estimate the volume of water in the swimming pool by using a Riemann sum with $m = n = 2$. Select the sample points using the midpoint rule on $R = [0, 4] \times [0, 4]$.
b. Find the average depth of the swimming pool.

| | $y$ | | | | |
|---|---|---|---|---|---|
| $x$ | 0 | 1 | 2 | 3 | 4 |
| 0 | 1 | 1.5 | 2 | 2.5 | 3 |
| 1 | 1 | 1.5 | 2 | 2.5 | 3 |
| 2 | 1 | 1.5 | 1.5 | 2.5 | 3 |
| 3 | 1 | 1 | 1.5 | 2 | 2.5 |
| 4 | 1 | 1 | 1 | 1.5 | 2 |

**Answer**

a. 28 $\text{ft}^3$

b. 1.75 ft.

8) The depth of a 3-ft by 3-ft hole in the ground, measured at 1-ft intervals, is given in the following table.

a. Estimate the volume of the hole by using a Riemann sum with $m = n = 3$ and the sample points to be the upper left corners of the sub-squares of $R$.

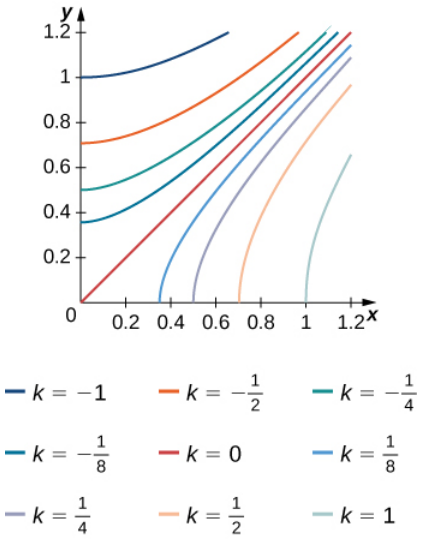
b. Find the average depth of the hole.

| | $y$ | | | |
|---|---|---|---|---|
| $x$ | 0 | 1 | 2 | 3 |
| 0 | 6 | 6.5 | 6.4 | 6 |
| 1 | 6.5 | 7 | 7.5 | 6.5 |
| 2 | 6.5 | 6.7 | 6.5 | 6 |
| 3 | 6 | 6.5 | 5 | 5.6 |

9) The level curves $f(x, y) = k$ of the function $f$ are given in the following graph, where $k$ is a constant.

a. Apply the midpoint rule with $m = n = 2$ to estimate the double integral $\iint_R f(x, y)\, dA$, where $R = [0.2, 1] \times [0, 0.8]$.

b. Estimate the average value of the function $f$ on $R$.



**Answer**

a. Answers will vary somewhat, but should be close to these: $f(0.4, 0.2) \approx 0.125$, $f(0.4, 0.6) \approx -0.2$, $f(0.8, 0.2) \approx 0.6$, and $f(0.8, 0.6) \approx 0.3$.

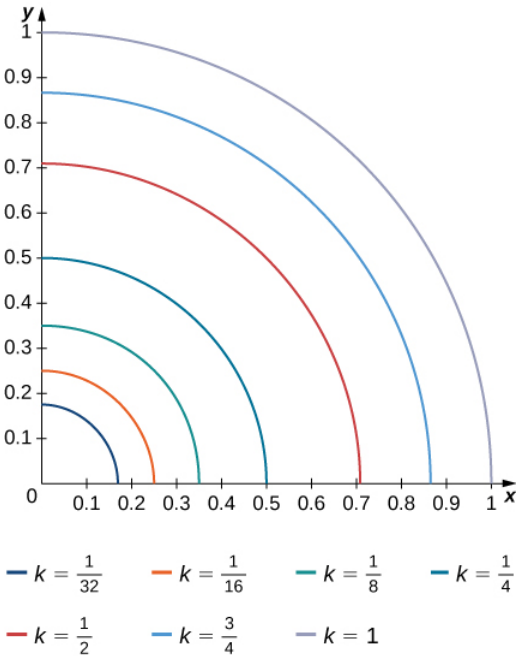
Since the area of each rectangle is $\Delta A_i = (0.4)(0.4) = 0.16 \text{ units}^2$, $\iint_R f(x, y)\, dA = \int_{0.2}^{1} \int_{0}^{0.8} f(x, y)\, dy\, dx \approx f(0.4, 0.2)(0.16) + f(0.4, 0.6)(0.16) + f(0.8, 0.2)(0.16) + f(0.8, 0.6)(0.16) = 0.132$

b. $f_{ave} = \dfrac{\int_{0.2}^{1} \int_{0}^{0.8} f(x, y)\, dy\, dx}{\text{area of } R} \approx \dfrac{\int_{0.2}^{1} \int_{0}^{0.8} f(x, y)\, dy\, dx}{0.64} \approx 0.206$

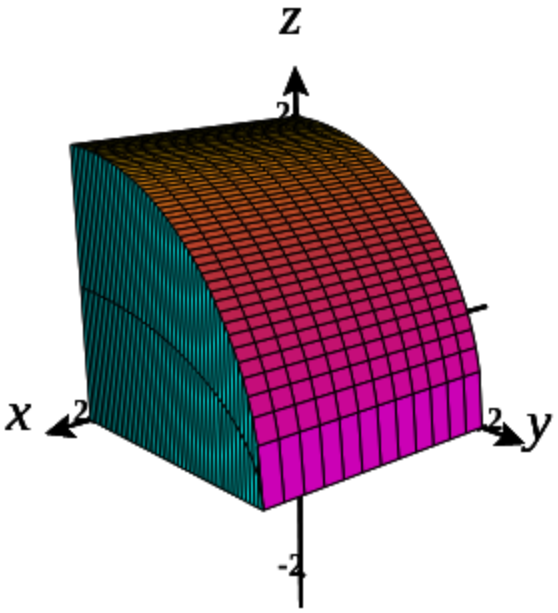
10) The level curves $f(x, y) = k$ of the function $f$ are given in the following graph, where $k$ is a constant.

a. Apply the midpoint rule with $m = n = 2$ to estimate the double integral $\iint_R f(x, y)\, dA$, where $R = [0.1, 0.5] \times [0.1, 0.5]$.

b. Estimate the average value of the function $f$ on $R$.



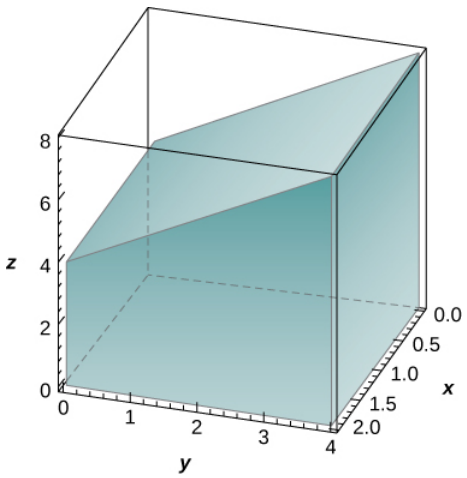
11) The solid lying under the surface $z = \sqrt{4 - y^2}$ and above the rectangular region$R = [0, 2] \times [0, 2]$ is illustrated in the following graph. Evaluate the double integral $\iint_R f(x, y)$, where $f(x, y) = \sqrt{4 - y^2}$ by finding the volume of the corresponding solid.



**Answer**

$2\pi$

12) The solid lying under the plane $z = y + 4$ and above the rectangular region $R = [0, 2] \times [0, 4]$ is illustrated in the following graph. Evaluate the double integral $\iint_R f(x, y)\, dA$, where $f(x, y) = y + 4$, by finding the volume of the corresponding solid.



**In the exercises 13 - 20, calculate the integrals by reversing the order of integration.**

13) $\int_{-1}^{1} \left( \int_{-2}^{2} (2x + 3y + 5)\, dx \right)\, dy$

**Answer**

40

14) $\int_0^2 \left( \int_0^1 (x + 2e^y + 3)\, dx \right)\, dy$

15) $\int_1^{27} \left( \int_1^2 (\sqrt[3]{x} + \sqrt[3]{y})\, dy \right)\, dx$

**Answer**

$\frac{81}{2} + 39\sqrt[3]{2}$

16) $\int_1^{16} \left( \int_1^8 (\sqrt[4]{x} + 2\sqrt[3]{y})\, dy \right)\, dx$

17) $\int_{\ln 2}^{\ln 3} \left( \int_0^1 e^{x+y}\, dy \right)\, dx$

**Answer**

$e - 1$

18) $\int_0^2 \left( \int_0^1 3^{x+y}\, dy \right)\, dx$

19) $\int_1^6 \left( \int_2^9 \frac{\sqrt{y}}{x^2}\, dy \right)\, dx$

**Answer**

$15 - \frac{10\sqrt{2}}{9}$

20) $\int_1^9 \left( \int_4^2 \frac{\sqrt{x}}{y^2}\, dy \right)\, dx$

**In exercises 21 - 34, evaluate the iterated integrals by choosing the order of integration.**

21) $\int_0^{\pi} \int_0^{\pi/2} \sin(2x)\cos(3y)\, dx\, dy$

**Answer**

0

22) $\int_{\pi/12}^{\pi/8} \int_{\pi/4}^{\pi/3} [\cot x + \tan(2y)]\, dx\, dy$

23) $\int_1^e \int_1^e \left[ \frac{1}{x}\sin(\ln x) + \frac{1}{y}\cos(\ln y) \right]\, dx\, dy$

**Answer**

$(e-1)(1 + \sin 1 - \cos 1)$

24) $\int_1^e \int_1^e \frac{\sin(\ln x)\cos(\ln y)}{xy}\, dx\, dy$

25) $\int_1^2 \int_1^2 \left( \frac{\ln y}{x} + \frac{x}{2y+1} \right)\, dy\, dx$

**Answer**

$\frac{3}{4}\ln\left(\frac{5}{3}\right) + 2(\ln 2)^2 - \ln 2$

26) $\int_1^e \int_1^2 x^2 \ln(x)\, dy\, dx$

27) $\int_1^{\sqrt{3}} \int_1^2 y \arctan\left(\frac{1}{x}\right)\, dy\, dx$

**Answer**

$\frac{1}{8}[(2\sqrt{3}-3)\pi+6\ \ln 2]$

28) $\int_0^1 \int_0^{1/2} (\arcsin x + \arcsin y)\, dy\, dx$

29) $\int_0^1 \int_1^2 xe^{x+4y}\, dy\, dx$

**Answer**

$\frac{1}{4}e^4(e^4-1)$

30) $\int_1^2 \int_0^1 xe^{x-y}\, dy\, dx$

31) $\int_1^e \int_1^e \left(\frac{\ln y}{\sqrt{y}} + \frac{\ln x}{\sqrt{x}}\right) dy\, dx$

**Answer**

$4(e-1)(2-\sqrt{e})$

32) $\int_1^e \int_1^e \left(\frac{x\ \ln y}{\sqrt{y}} + \frac{y\ \ln x}{\sqrt{x}}\right) dy\, dx$

33) $\int_0^1 \int_1^2 \left(\frac{x}{x^2+y^2}\right) dy\, dx$

**Answer**

$-\frac{\pi}{4} + \ln\left(\frac{5}{4}\right) - \frac{1}{2}\ln 2 + \arctan 2$

34) $\int_0^1 \int_1^2 \frac{y}{x+y^2}\, dy\, dx$

**In exercises 35 - 38, find the average value of the function over the given rectangles.**

35) $f(x,y) = -x+2y$, $R = [0,1]\times[0,1]$

**Answer**

$\frac{1}{2}$

36) $f(x,y) = x^4+2y^3$, $R = [1,2]\times[2,3]$

37) $f(x,y) = \sinh x + \sinh y$, $R = [0,1]\times[0,2]$

**Answer**

$\frac{1}{2}(2\ \cosh 1 + \cosh 2 - 3)$.

38) $f(x,y) = \arctan(xy)$, $R = [0,1]\times[0,1]$

39) Let $f$ and $g$ be two continuous functions such that $0 \le m_1 \le f(x) \le M_1$ for any $x \in [a,b]$ and $0 \le m_2 \le g(y) \le M_2$ for any $y \in [c,d]$. Show that the following inequality is true:

$$m_1 m_2 (b-a)(c-d) \le \int_a^b \int_c^d f(x)g(y)\, dydx \le M_1 M_2 (b-a)(c-d).$$

**In exercises 40 - 43, use property v. of double integrals and the answer from the preceding exercise to show that the following inequalities are true.**

40) $\frac{1}{e^2} \le \iint_R e^{-x^2-y^2}\, dA \le 1$, where $R = [0,1]\times[0,1]$

41) $\frac{\pi^2}{144} \le \iint_R \sin x \cos y\, dA \le \frac{\pi^2}{48}$, where $R = [\frac{\pi}{6}, \frac{\pi}{3}]\times[\frac{\pi}{6}, \frac{\pi}{3}]$

42) $0 \le \iint_R e^{-y}\ \cos x\, dA \le \frac{\pi}{2}$, where $R = [0, \frac{\pi}{2}]\times[0, \frac{\pi}{2}]$

43) $0 \le \iint_R (\ln x)(\ln y)\, dA \le (e-1)^2$, where $R = [1, e] \times [1, e]$

44) Let $f$ and $g$ be two continuous functions such that $0 \le m_1 \le f(x) \le M_1$ for any $x \in [a, b]$ and $0 \le m_2 \le g(y) \le M_2$ for any $y \in [c, d]$. Show that the following inequality is true:

$$(m_1 + m_2)(b-a)(c-d) \le \int_a^b \int_c^d |f(x) + g(y)|\, dy\, dx \le (M_1 + M_2)(b-a)(c-d)$$

**In exercises 45 - 48, use property v. of double integrals and the answer from the preceding exercise to show that the following inequalities are true.**

45) $\frac{2}{e} \le \iint_R (e^{-x^2} + e^{-y^2})\, dA \le 2$, where $R = [0, 1] \times [0, 1]$

46) $\frac{\pi^2}{36} \iint_R (\sin x + \cos y)\, dA \le \frac{\pi^2\sqrt{3}}{36}$, where $R = [\frac{\pi}{6}, \frac{\pi}{3}] \times [\frac{\pi}{6}, \frac{\pi}{3}]$

47) $\frac{\pi}{2} e^{-\pi/2} \le \iint_R (\cos x + e^{-y})\, dA \le \pi$, where $R = [0, \frac{\pi}{2}] \times [0, \frac{\pi}{2}]$

48) $\frac{1}{e} \le \iint_R (e^{-y} - \ln x)\, dA \le 2$, where $R = [0, 1] \times [0, 1]$

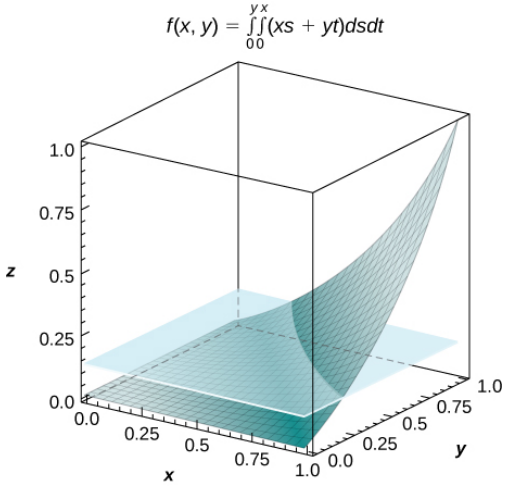
**In exercises 49 - 50, the function $f$ is given in terms of double integrals.**

a. Determine the explicit form of the function $f$.
b. Find the volume of the solid under the surface $z = f(x, y)$ and above the region $R$.
c. Find the average value of the function $f$ on $R$.
d. Use a computer algebra system (CAS) to plot $z = f(x, y)$ and $z = f_{ave}$ in the same system of coordinates.

**49) [T]** $f(x, y) = \int_0^y \int_0^x (xs + yt) ds\, dt$, where $(x, y) \in R = [0, 1] \times [0, 1]$

**Answer**

a. $f(x, y) = \frac{1}{2}xy(x^2 + y^2)$;
b. $V = \int_0^1 \int_0^1 f(x, y)\, dx\, dy = \frac{1}{8}$;
c. $f_{ave} = \frac{1}{8}$;
d.



**50) [T]** $f(x, y) = \int_0^x \int_0^y [\cos(s) + \cos(t)]\, dt\, ds$, where $(x, y) \in R = [0, 3] \times [0, 3]$

51) Show that if $f$ and $g$ are continuous on $[a, b]$ and $[c, d]$, respectively, then

$$\int_a^b \int_c^d |f(x) + g(y)| dy\, dx = (d-c) \int_a^b f(x)\, dx$$
$$+ \int_a^b \int_c^d g(y)\, dy\, dx = (b-a) \int_c^d g(y)\, dy + \int_c^d \int_a^b f(x)\, dx\, dy.$$

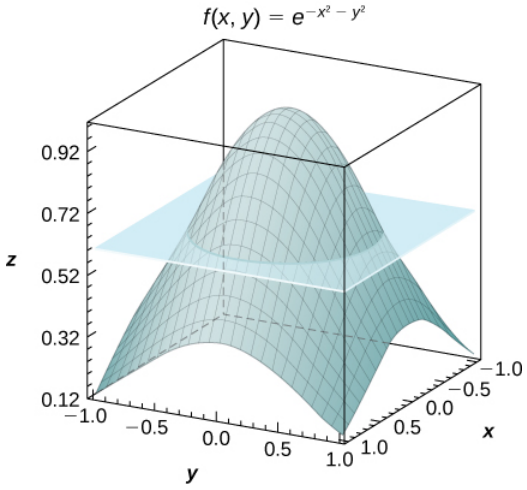
52) Show that $\int_a^b \int_c^d yf(x) + xg(y)\, dy\, dx = \frac{1}{2}(d^2 - c^2)\left(\int_a^b f(x)\, dx\right) + \frac{1}{2}(b^2 - a^2)\left(\int_c^d g(y)\, dy\right)$.

**53) [T]** Consider the function $f(x, y) = e^{-x^2-y^2}$, where $(x, y) \in R = [-1, 1] \times [-1, 1]$.

a. Use the midpoint rule with $m = n = 2, 4, ..., 10$ to estimate the double integral $I = \iint_R e^{-x^2-y^2} dA$. Round your answers to the nearest hundredths.
b. For $m = n = 2$, find the average value of $f$ over the region $R$. Round your answer to the nearest hundredths.
c. Use a CAS to graph in the same coordinate system the solid whose volume is given by $\iint_R e^{-x^2-y^2} dA$ and the plane $z = f_{ave}$.

**Answer**

a. For $m = n = 2$, $I = 4e^{-0.5} \approx 2.43$
b. $f_{ave} = e^{-0.5} \simeq 0.61$;
c.



**54) [T]** Consider the function $f(x, y) = \sin(x^2)\ \cos(y^2)$, where $(x, y \in R = [-1, 1] \times [-1, 1]$.

a. Use the midpoint rule with $m = n = 2, 4, ..., 10$ to estimate the double integral $I = \iint_R \sin(x^2)\cos(y^2)\ dA$. Round your answers to the nearest hundredths.
b. For $m = n = 2$, find the average value of $f$over the region $R$. Round your answer to the nearest hundredths.
c. Use a CAS to graph in the same coordinate system the solid whose volume is given by $\iint_R \sin(x^2)\cos(y^2)\ dA$ and the plane $z = f_{ave}$.

**In exercises 55 - 56, the functions $f_n$ are given, where $n \geq 1$ is a natural number.**

a. Find the volume of the solids $S_n$ under the surfaces $z = f_n(x, y)$ and above the region $R$.
b. Determine the limit of the volumes of the solids $S_n$ as $n$ increases without bound.

55) $f(x, y) = x^n + y^n + xy,\ (x, y) \in R = [0, 1] \times [0, 1]$

**Answer**

a. $\frac{2}{n+1} + \frac{1}{4}$
b. $\frac{1}{4}$

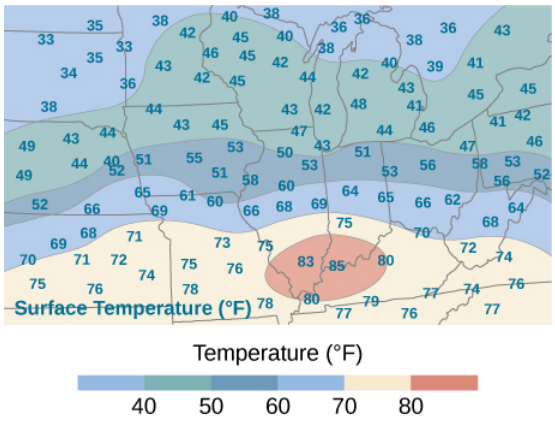
56) $f(x, y) = \frac{1}{x^n} + \frac{1}{y^n},\ (x, y) \in R = [1, 2] \times [1, 2]$

57) Show that the average value of a function $f$ on a rectangular region $R = [a, b] \times [c, d]$ is $f_{ave} \approx \frac{1}{mn} \sum_{i=1}^{m} \sum_{j=1}^{n} f(x_{ij}^*, y_{ij}^*)$,where $(x_{ij}^*, y_{ij}^*)$ are the sample points of the partition of $R$, where $1 \leq i \leq m$ and $1 \leq j \leq n$.

58) Use the midpoint rule with $m = n$ to show that the average value of a function $f$ on a rectangular region $R = [a, b] \times [c, d]$ is approximated by

$$f_{ave} \approx \frac{1}{n^2} \sum_{i,j=1}^{n} f\left(\frac{1}{2}(x_{i=1} + x_i),\ \frac{1}{2}(y_{j=1} + y_j)\right).$$

59) An isotherm map is a chart connecting points having the same temperature at a given time for a given period of time. Use the preceding exercise and apply the midpoint rule with $m = n = 2$ to find the average temperature over the region given in the following figure.



**Answer**

$56.5°$ F; here $f(x_1^*, y_1^*) = 71,\ f(x_2^*, y_1^*) = 72,\ f(x_2^*, y_1^*) = 40,\ f(x_2^*, y_2^*) = 43$, where $x_i^*$ and $y_j^*$ are the midpoints of the subintervals of the partitions of $[a, b]$ and $[c, d]$, respectively.

# 15.3: Double Integrals over General Regions

**Learning Objectives**

- Recognize when a function of two variables is integrable over a general region.
- Evaluate a double integral by computing an iterated integral over a region bounded by two vertical lines and two functions of $x$, or two horizontal lines and two functions of $y$.
- Simplify the calculation of an iterated integral by changing the order of integration.
- Use double integrals to calculate the volume of a region between two surfaces or the area of a plane region.
- Solve problems involving double improper integrals.

Previously, we studied the concept of double integrals and examined the tools needed to compute them. We learned techniques and properties to integrate functions of two variables over rectangular regions. We also discussed several applications, such as finding the volume bounded above by a function over a rectangular region, finding area by integration, and calculating the average value of a function of two variables.

In this section we consider double integrals of functions defined over a general bounded region $D$ on the plane. Most of the previous results hold in this situation as well, but some techniques need to be extended to cover this more general case.

## General Regions of Integration

An example of a general bounded region $D$ on a plane is shown in Figure 15.3.1. Since $D$ is bounded on the plane, there must exist a rectangular region $R$ on the same plane that encloses the region $D$ that is, a rectangular region $R$ exists such that $D$ is a subset of $R (D \subseteq R)$.

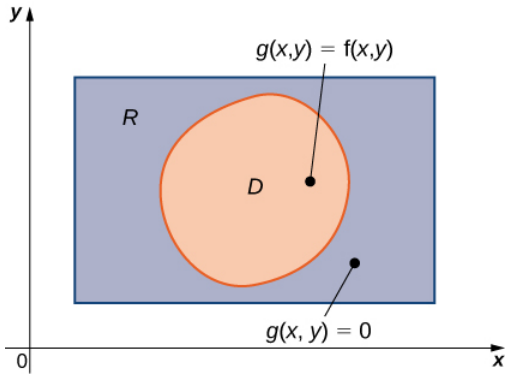

Figure 15.3.1: For a region $D$ that is a subset of $R$, we can define a function $g(x, y)$ to equal $f(x, y)$ at every point in $D$ and 0 at every point of $R$ not in $D$.

Suppose $z = f(x, y)$ is defined on a general planar bounded region $D$ as in Figure 15.3.1. In order to develop double integrals of $f$ over $D$ we extend the definition of the function to include all points on the rectangular region $R$ and then use the concepts and tools from the preceding section. But how do we extend the definition of $f$ to include all the points on $R$? We do this by defining a new function $g(x, y)$ on $R$ as follows:

$$g(x,y) = \begin{cases} f(x,y), & \text{if } (x,y) \text{ is in } D \\ 0, & \text{if } (x,y) \text{ is in } R \text{ but not in } D \end{cases}$$

Note that we might have some technical difficulties if the boundary of $D$ is complicated. So we assume the boundary to be a piecewise smooth and continuous simple closed curve. Also, since all the results developed in the section on Double Integrals over Rectangular Regions used an integrable function $f(x, y)$ we must be careful about $g(x, y)$ and verify that $g(x, y)$ is an integrable function over the rectangular region $R$. This happens as long as the region $D$ is bounded by simple closed curves. For now we will concentrate on the descriptions of the regions rather than the function and extend our theory appropriately for integration.

We consider two types of planar bounded regions.

### Definition: Type I and Type II regions

A region $D$ in the $(x, y)$-plane is of Type I if it lies between two vertical lines and the graphs of two continuous functions $g_1(x)$ and $g_2(x)$. That is (Figure 15.3.2),

$$D = \{(x, y) \mid a \le x \le b,\ g_1(x) \le y \le g_2(x)\}.$$

A region $D$ in the $xy$-plane is of Type II if it lies between two horizontal lines and the graphs of two continuous functions $h_1(y)$ and $h_2(y)$. That is (Figure 15.3.3),

$$D = \{(x, y) \mid c \le y \le d,\ h_1(y) \le x \le h_2(y)\}.$$

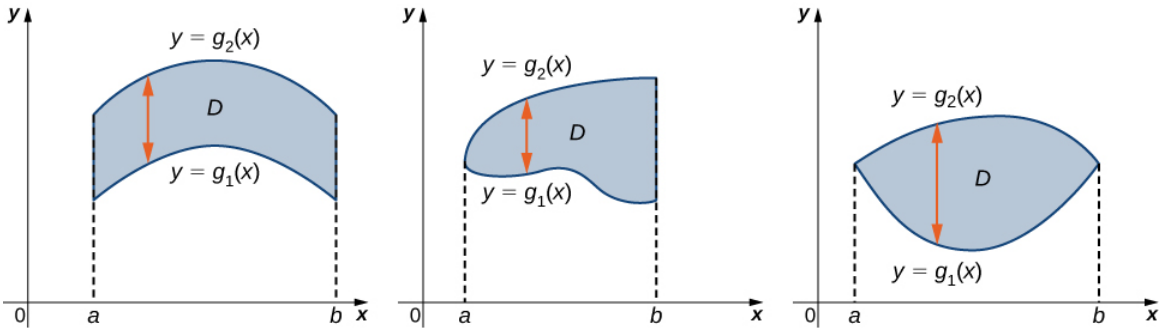

Figure 15.3.2. A Type I region lies between two vertical lines and the graphs of two functions of $x$.

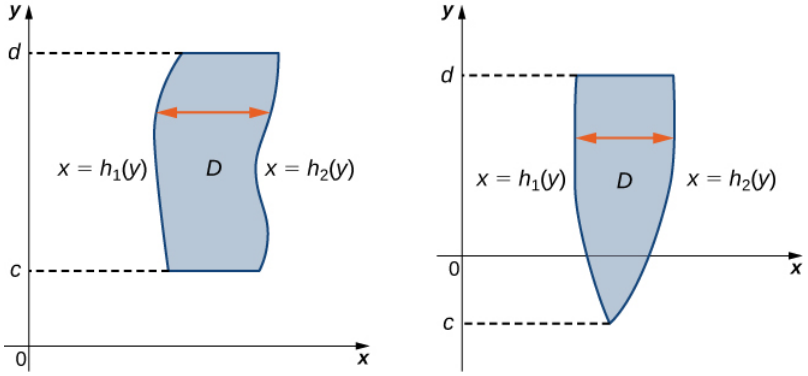

Figure 15.3.3: A Type II region lies between two horizontal lines and the graphs of two functions of $y$.

### Example 15.3.1: Describing a Region as Type I and Also as Type II

Consider the region in the first quadrant between the functions $y = \sqrt{x}$ and $y = x^3$ (Figure 15.3.4). Describe the region first as Type I and then as Type II.

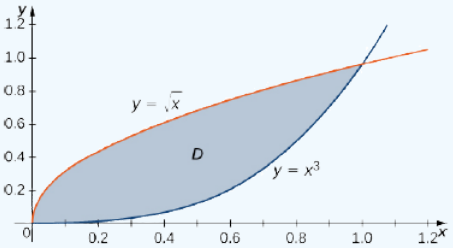

Figure 15.3.4: Region $D$ can be described as Type I or as Type II.

When describing a region as Type I, we need to identify the function that lies above the region and the function that lies below the region. Here, region $D$ is bounded above by $y = \sqrt{x}$ and below by $y = x^3$ in the interval for $x$ in $[0, 1]$. Hence, as Type I, $D$ is described as the set $\{(x, y) \mid 0 \le x \le 1,\ x^3 \le y \le \sqrt[3]{x}\}$.

However, when describing a region as Type II, we need to identify the function that lies on the left of the region and the function that lies on the right of the region. Here, the region $D$ is bounded on the left by $x = y^2$ and on the right by $x = \sqrt[3]{y}$ in

the interval for $y$ in $[0,1]$. Hence, as Type II, $D$ is described as the set $\{(x,y)\,|\,0\le y\le 1,\ y^2\le x\le \sqrt[3]{y}\}$.

**Exercise 15.3.1**

Consider the region in the first quadrant between the functions $y=2x$ and $y=x^2$. Describe the region first as Type I and then as Type II.

**Hint**

Graph the functions, and draw vertical and horizontal lines.

**Answer**

Type I and Type II are expressed as $\{(x,y)\,|\,0\le x\le 2,\ x^2\le y\le 2x\}$ and $\{(x,y)|\,0\le y\le 4,\ \frac{1}{2}y\le x\le \sqrt{y}\}$, respectively.

## Double Integrals over Non-rectangular Regions

To develop the concept and tools for evaluation of a double integral over a general, nonrectangular region, we need to first understand the region and be able to express it as Type I or Type II or a combination of both. Without understanding the regions, we will not be able to decide the limits of integrations in double integrals. As a first step, let us look at the following theorem.

**Theorem: Double Integrals over Nonrectangular Regions**

Suppose $g(x,y)$ is the extension to the rectangle $R$ of the function $f(x,y)$ defined on the regions $D$ and $R$ as shown in Figure 15.3.1 inside $R$. Then $g(x,y)$ is integrable and we define the double integral of $f(x,y)$ over $D$ by

$$\iint_D f(x,y)\,dA=\iint_R g(x,y)\,dA.$$

The right-hand side of this equation is what we have seen before, so this theorem is reasonable because $R$ is a rectangle and $\iint_R g(x,y)dA$ has been discussed in the preceding section. Also, the equality works because the values of $g(x,y)$ are $0$ for any point $(x,y)$ that lies outside $D$ and hence these points do not add anything to the integral. However, it is important that the rectangle $R$ contains the region $D$.

As a matter of fact, if the region $D$ is bounded by smooth curves on a plane and we are able to describe it as Type I or Type II or a mix of both, then we can use the following theorem and not have to find a rectangle $R$ containing the region.

**Theorem: Fubini's Theorem (Strong Form)**

For a function $f(x,y)$ that is continuous on a region $D$ of Type I, we have

$$\iint_D f(x,y)\,dA=\iint_D f(x,y)\,dy\,dx=\int_a^b\left[\int_{g_1(x)}^{g_2(x)} f(x,y)\,dy\right]dx.$$

Similarly, for a function $f(x,y)$ that is continuous on a region $D$ of Type II, we have

$$\iint_D f(x,y)\,dA=\iint_D f(x,y)\,dx\,dy=\int_c^d\left[\int_{h_1(y)}^{h_2(y)} f(x,y)\,dx\right]dy.$$

The integral in each of these expressions is an iterated integral, similar to those we have seen before. Notice that, in the inner integral in the first expression, we integrate $f(x,y)$ with $x$ being held constant and the limits of integration being $g_1(x)$ and $g_2(x)$. In the inner integral in the second expression, we integrate $f(x,y)$ with $y$ being held constant and the limits of integration are $h_1(x)$ and $h_2(x)$.

### Example 15.3.2: Evaluating an Iterated Integral over a Type I Region

Evaluate the integral $\iint_D x^2 e^{xy}\, dA$ where $D$ is shown in Figure 15.3.5.

**Solution**

First construct the region as a Type I region (Figure 15.3.5). Here $D = \{(x,y) \mid 0 \le x \le 2,\ \frac{1}{2}x \le y \le 1\}$. Then we have

$$\iint_D x^2 e^{xy}\, dA = \int_{x=0}^{x=2} \int_{y=1/2x}^{y=1} x^2 e^{xy}\, dy\, dx.$$

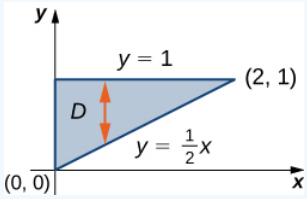

Figure 15.3.5: We can express region $D$ as a Type I region and integrate from $y = \frac{1}{2}x$ to $y = 1$ between the lines $x = 0$ and $x = 2$.

Therefore, we have

$$\begin{aligned}
\int_{x=0}^{x=2} \int_{y=\frac{1}{2}x}^{y=1} x^2 e^{xy}\, dy\, dx &= \int_{x=0}^{x=2} \left[\int_{y=\frac{1}{2}x}^{y=1} x^2 e^{xy}\, dy\right] dx && \text{Iterated integral for a Type I region.} \\
&= \int_{x=0}^{x=2} \left[x^2 \frac{e^{xy}}{x}\right]\Big|_{y=1/2x}^{y=1} dx && \text{Integrate with respect to } y \\
&= \int_{x=0}^{x=2} \left[xe^x - xe^{x^2/2}\right] dx && \text{Integrate with respect to } x \\
&= \left[xe^x - e^x - e^{\frac{1}{2}x^2}\right]\Big|_{x=0}^{x=2} = 2.
\end{aligned}$$

In Example 15.3.2, we could have looked at the region in another way, such as $D = \{(x,y) \mid 0 \le y \le 1,\ 0 \le x \le 2y\}$ (Figure 15.3.6).

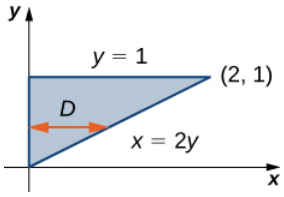

Figure 15.3.6.

This is a Type II region and the integral would then look like

$$\iint_D x^2 e^{xy}\, dA = \int_{y=0}^{y=1} \int_{x=0}^{x=2y} x^2 e^{xy}\, dx\, dy.$$

However, if we integrate first with respect to $x$ this integral is lengthy to compute because we have to use integration by parts twice.

### Example 15.3.3: Evaluating an Iterated Integral over a Type II Region

Evaluate the integral

$$\iint_D (3x^2 + y^2)\, dA$$

where $D = \{(x,y) \mid -2 \le y \le 3,\ y^2 - 3 \le x \le y + 3\}$.

## Solution

Notice that $D$ can be seen as either a Type I or a Type II region, as shown in Figure 15.3.7. However, in this case describing $D$ as Type I is more complicated than describing it as Type II. Therefore, we use $D$ as a Type II region for the integration.

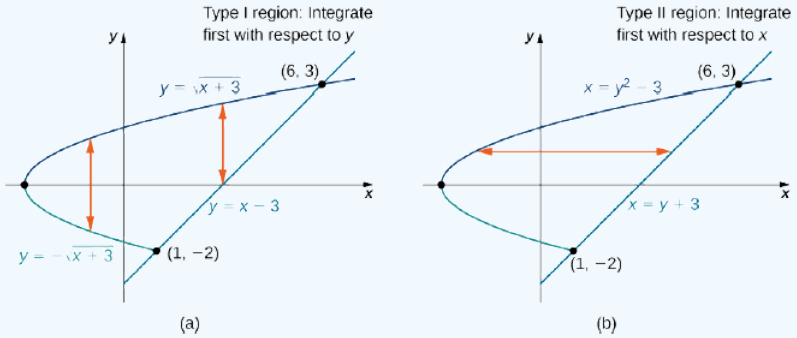

Figure 15.3.7: The region $D$ in this example can be either (a) Type I or (b) Type II.

Choosing this order of integration, we have

$$\begin{aligned}
\iint_D (3x^2 + y^2)\,dA &= \int_{y=-2}^{y=3} \int_{x=y^2-3}^{x=y+3} (3x^2 + y^2)\,dx\,dy \\
&= \int_{y=-2}^{y=3} (x^3 + xy^2)\Big|_{y^2-3}^{y+3}\,dy && \text{Iterated integral, Type II region} \\
&= \int_{y=-2}^{y=3} \big((y+3)^3 + (y+3)y^2 - (y^2-3)^3 \\
&\quad - (y^2-3)y^2\big)\,dy \\
&= \int_{-2}^{3} (54 + 27y - 12y^2 + 2y^3 + 8y^4 \\
&\quad - y^6)\,dy && \text{Integrate with respect to } x. \\
&= \left[54y + \frac{27y^2}{2} - 4y^3 + \frac{y^4}{2} + \frac{8y^5}{5} \right. \\
&\quad \left. - \frac{y^7}{7}\right]_{-2}^{3} \\
&= \frac{2375}{7}.
\end{aligned}$$

### Exercise 15.3.2

Sketch the region $D$ and evaluate the iterated integral

$$\iint_D xy\,dy\,dx$$

where $D$ is the region bounded by the curves $y = \cos\ x$ and $y = \sin\ x$ in the interval $[-3\pi/4,\ \pi/4]$.

**Hint**

Express $D$ as a Type I region, and integrate with respect to $y$ first.

**Answer**

$\frac{\pi}{4}$

Recall from Double Integrals over Rectangular Regions the properties of double integrals. As we have seen from the examples here, all these properties are also valid for a function defined on a non-rectangular bounded region on a plane. In particular,

property 3 states:

If $R = S \cup T$ and $S \cap T = 0$ except at their boundaries, then

$$\iint_R f(x,y)\,dA = \iint_S f(x,y)\,dA + \iint_T f(x,y)\,dA.$$

Similarly, we have the following property of double integrals over a non-rectangular bounded region on a plane.

**Theorem: Decomposing Regions into Smaller Regions**

Suppose the region $D$ can be expressed as $D = D_1 \cup D_2$ where $D_1$ and $D_2$ do not overlap except at their boundaries. Then

$$\iint_D f(x,y)\,dA = \iint_{D_1} f(x,y)\,dA + \iint_{D_2} f(x,y)\,dA.$$

This theorem is particularly useful for non-rectangular regions because it allows us to split a region into a union of regions of Type I and Type II. Then we can compute the double integral on each piece in a convenient way, as in the next example.

**Example 15.3.4: Decomposing Regions**

Express the region $D$ shown in Figure 15.3.8 as a union of regions of Type I or Type II, and evaluate the integral

$$\iint_D (2x + 5y)\,dA.$$

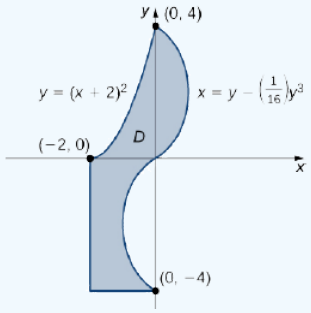

Figure 15.3.8: This region can be decomposed into a union of three regions of Type I or Type II.

### Solution

The region $D$ is not easy to decompose into any one type; it is actually a combination of different types. So we can write it as a union of three regions $D_1$, $D_2$, and $D_3$ where, $D_1 = \{(x,y) \mid -2 \le x \le 0,\ 0 \le y \le (x+2)^2\}$, $D_2 = \{(x,y) \mid 0 \le y \le 4,\ 0 \le x \le \left(y - \frac{1}{16}y^3\right)\}$, and $D_3 = \{(x,y) \mid -4 \le y \le 0,\ -2 \le x \le \left(y - \frac{1}{16}y^3\right)\}$. These regions are illustrated more clearly in Figure 15.3.9.

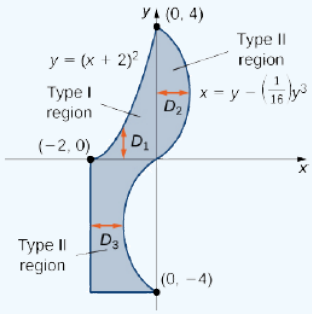

Figure 15.3.9: Breaking the region into three subregions makes it easier to set up the integration.

Here $D_1$ is Type I and $D_2$ and $D_3$ are both of Type II. Hence,

$$\begin{aligned}\iint_D (2x+5y)\,dA &= \iint_{D_1} (2x+5y)\,dA + \iint_{D_2} (2x+5y)\,dA + \iint_{D_3} (2x+5y)\,dA \\ &= \int_{x=-2}^{x=0}\int_{y=0}^{y=(x+2)^2} (2x+5y)\,dy\,dx + \int_{y=0}^{y=4}\int_{x=0}^{x=y-(1/16)y^3} (2x+5y)\,dx\,dy \\ &\quad + \int_{y=-4}^{y=0}\int_{x=-2}^{x=y-(1/16)y^3} (2x+5y)\,dx\,dy \\ &= \int_{x=-2}^{x=0}\left[\frac{1}{2}(2+x)^2(20+24x+5x^2)\right]dx + \int_{y=0}^{y=4}\left[\frac{1}{256}y^6 - \frac{7}{16}y^4 + 6y^2\right]dy \\ &\quad + \int_{y=-4}^{y=0}\left[\frac{1}{256}y^6 - \frac{7}{16}y^4 + 6y^2 + 10y - 4\right]dy \\ &= \frac{40}{3} + \frac{1664}{35} - \frac{1696}{35} = \frac{1304}{105}.\end{aligned}$$

Now we could redo this example using a union of two Type II regions (see Exercise **15.3.4** below).

### ? Exercise 15.3.3

Consider the region bounded by the curves $y = \ln x$ and $y = e^x$ in the interval $[1, 2]$. Decompose the region into smaller regions of Type II.

**Hint**

Sketch the region, and split it into three regions to set it up.

**Answer**

$$\{(x,y)\,|\,0 \le y \le 1,\ 1 \le x \le e^y\} \cup \{(x,y)\,|\,1 \le y \le e,\ 1 \le x \le 2\} \cup \{(x,y)\,|\,e \le y \le e^2,\ \ln y \le x \le 2\}$$

### ? Exercise 15.3.4

Redo Example **15.3.4** using a union of two Type II regions.

**Hint**

$$\{(x,y)\,|\,0 \le y \le 4,\ \sqrt{y} - 2 \le x \le \left(y - \frac{1}{16}y^3\right)\} \cup \{(x,y)\,|\,-4 \le y \le 0,\ -2 \le x \le \left(y - \frac{1}{16}y^3\right)\}$$

**Answer**

Same as in the example shown.

## Changing the Order of Integration

As we have already seen when we evaluate an iterated integral, sometimes one order of integration leads to a computation that is significantly simpler than the other order of integration. Sometimes the order of integration does not matter, but it is important to learn to recognize when a change in order will simplify our work.

### ✓ Example 15.3.5: Changing the Order of Integration

Reverse the order of integration in the iterated integral

$$\int_{x=0}^{x=\sqrt{2}}\int_{y=0}^{y=2-x^2} xe^{x^2}\,dy\,dx.$$

Then evaluate the new iterated integral.

### Solution

The region as presented is of Type I. To reverse the order of integration, we must first express the region as Type II. Refer to Figure 15.3.10.

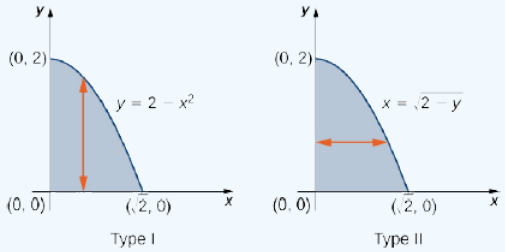

Figure 15.3.10: Converting a region from Type I to Type II.

We can see from the limits of integration that the region is bounded above by $y = 2 - x^2$ and below by $y = 0$ where $x$ is in the interval $[0, \sqrt{2}]$. By reversing the order, we have the region bounded on the left by $x = 0$ and on the right by $x = \sqrt{2 - y}$ where $y$ is in the interval $[0, 2]$. We solved $y = 2 - x^2$ in terms of $x$ to obtain $x = \sqrt{2 - y}$.

Hence

$$\int_0^{\sqrt{2}} \int_0^{2-x^2} xe^{x^2}\, dy\, dx = \int_0^2 \int_0^{\sqrt{2-y}} xe^{x^2}\, dx\, dy \qquad \text{Reverse the order of integration then use substitution.}$$

$$= \int_0^2 \left[ \frac{1}{2} e^{x^2} \Big|_0^{\sqrt{2-y}} \right] dy$$

$$= \int_0^2 \frac{1}{2}(e^{2-y} - 1)\, dy$$

$$= -\frac{1}{2}(e^{2-y} + y)\Big|_0^2$$

$$= \frac{1}{2}(e^2 - 3).$$

### Example 15.3.6: Evaluating an Iterated Integral by Reversing the Order of Integration

Consider the iterated integral

$$\iint_R f(x, y)\, dx\, dy$$

where $z = f(x, y) = x - 2y$ over a triangular region $R$ that has sides on $x = 0$, $y = 0$, and the line $x + y = 1$. Sketch the region, and then evaluate the iterated integral by

a. integrating first with respect to $y$ and then
b. integrating first with respect to $x$.

### Solution

A sketch of the region appears in Figure 15.3.11.

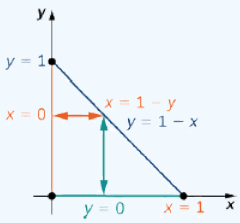

Figure 15.3.11: A triangular region $R$ for integrating in two ways.

We can complete this integration in two different ways.

a. One way to look at it is by first integrating $y$ from $y = 0$ to $y = 1 - x$ vertically and then integrating $x$ from $x = 0$ to $x = 1$:

$$\iint_R f(x,y)\,dx\,dy = \int_{x=0}^{x=1}\int_{y=0}^{y=1-x}(x-2y)\,dy\,dx = \int_{x=0}^{x=1}\left(xy-y^2\right)\Big|_{y=0}^{y=1-x}dx$$
$$= \int_{x=0}^{x=1}\left[x(1-x)-(1-x)^2\right]\,dx = \int_{x=0}^{x=1}[-1+3x-2x^2]dx$$
$$= \left[-x+\frac{3}{2}x^2-\frac{2}{3}x^3\right]\Big|_{x=0}^{x=1} = -\frac{1}{6}.$$

b. The other way to do this problem is by first integrating $x$ from $x=0$ to $x=1-y$ horizontally and then integrating $y$ from $y=0$ to $y=1$:

$$\iint_R f(x,y)\,dx\,dy = \int_{y=0}^{y=1}\int_{x=0}^{x=1-y}(x-2y)\,dx\,dy = \int_{y=0}^{y=1}\left[\frac{1}{2}x^2-2xy\right]_{x=0}^{x=1-y}dy$$
$$= \int_{y=0}^{y=1}\left[\frac{1}{2}(1-y)^2-2y(1-y)\right]dy = \int_{y=0}^{y=1}\left[\frac{1}{2}-3y+\frac{5}{2}y^2\right]\,dy$$
$$= \left[\frac{1}{2}y-\frac{3}{2}y^2+\frac{5}{6}y^3\right]\Big|_{y=0}^{y=1} = -\frac{1}{6}.$$

**? Exercise 15.3.5**

Evaluate the iterated integral $\iint_D (x^2+y^2)\,dA$ over the region $D$ in the first quadrant between the functions $y=2x$ and $y=x^2$.

Evaluate the iterated integral by integrating first with respect to $y$ and then integrating first with resect to $x$.

**Hint**

Sketch the region and follow Example 15.3.6.

**Answer**

$\frac{216}{35}$

## Calculating Volumes, Areas, and Average Values

We can use double integrals over general regions to compute volumes, areas, and average values. The methods are the same as those in Double Integrals over Rectangular Regions, but without the restriction to a rectangular region, we can now solve a wider variety of problems.

**✓ Example 15.3.7: Finding the Volume of a Tetrahedron**

Find the volume of the solid bounded by the planes $x=0,\ y=0,\ z=0$, and $2x+3y+z=6$.

**Solution**

The solid is a tetrahedron with the base on the $xy$-plane and a height $z=6-2x-3y$. The base is the region $D$ bounded by the lines, $x=0$, $y=0$ and $2x+3y=6$ where $z=0$ (Figure 15.3.12). Note that we can consider the region $D$ as Type I or as Type II, and we can integrate in both ways.

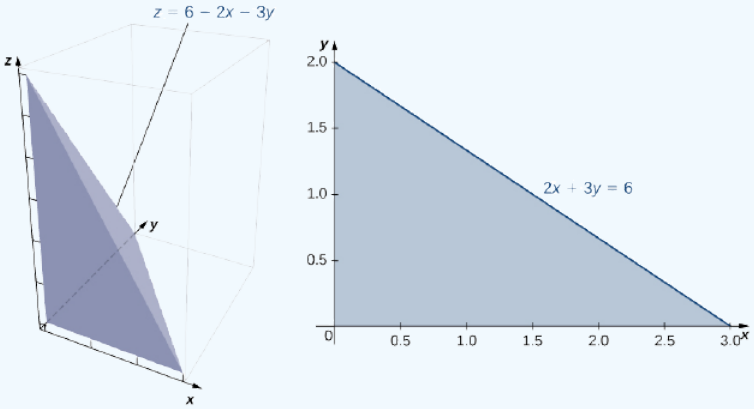

Figure 15.3.12: A tetrahedron consisting of the three coordinate planes and the plane $z = 6 - 2x - 3y$, with the base bound by $x = 0,\ y = 0$, and $2x + 3y = 6$.

First, consider $D$ as a Type I region, and hence $D = \{(x, y) \,|\, 0 \le x \le 3,\ 0 \le y \le 2 - \frac{2}{3}x\}$.

Therefore, the volume is

$$V = \int_{x=0}^{x=3} \int_{y=0}^{y=2-(2x/3)} (6 - 2x - 3y)\, dy\, dx = \int_{x=0}^{x=3} \left[ \left( 6y - 2xy - \frac{3}{2}y^2 \right) \Big|_{y=0}^{y=2-(2x/3)} \right] dx$$

$$= \int_{x=0}^{x=3} \left[ \frac{2}{3}(x-3)^2 \right] dx = 6.$$

Now consider $D$ as a Type II region, so $D = \{(x, y) \,|\, 0 \le y \le 2,\ 0 \le x \le 3 - \frac{3}{2}y\}$. In this calculation, the volume is

$$V = \int_{y=0}^{y=2} \int_{x=0}^{x=3-(3y/2)} (6 - 2x - 3y)\, dx\, dy = \int_{y=0}^{y=2} \left[ (6x - x^2 - 3xy) \Big|_{x=0}^{x=3-(3y/2)} \right] dy$$

$$= \int_{y=0}^{y=2} \left[ \frac{9}{4}(y-2)^2 \right] dy = 6.$$

Therefore, the volume is 6 cubic units.

## Exercise 15.3.6

Find the volume of the solid bounded above by $f(x, y) = 10 - 2x + y$ over the region enclosed by the curves $y = 0$ and $y = e^x$ where $x$ is in the interval $[0, 1]$.

**Hint**

Sketch the region, and describe it as Type I.

**Answer**

$\frac{e^2}{4} + 10e - \frac{49}{4}$ cubic units

Finding the area of a rectangular region is easy, but finding the area of a non-rectangular region is not so easy. As we have seen, we can use double integrals to find a rectangular area. As a matter of fact, this comes in very handy for finding the area of a general non-rectangular region, as stated in the next definition.

## Definition: Double Integrals

The area of a plane-bounded region $D$ is defined as the double integral

$$\iint_D 1\, dA.$$

We have already seen how to find areas in terms of single integration. Here we are seeing another way of finding areas by using double integrals, which can be very useful, as we will see in the later sections of this chapter.

### Example 15.3.8: Finding the Area of a Region

Find the area of the region bounded below by the curve $y = x^2$ and above by the line $y = 2x$ in the first quadrant (Figure 15.3.13).

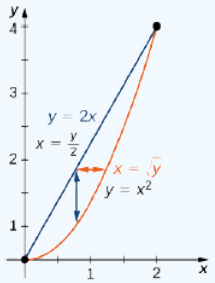

Figure 15.3.13: The region bounded by $y = x^2$ and $y = 2x$.

#### Solution

We just have to integrate the constant function $f(x, y) = 1$ over the region. Thus, the area $A$ of the bounded region is $\int_{x=0}^{x=2} \int_{y=x^2}^{y=2x} dy\, dx$ or $\int_{y=0}^{y=4} \int_{x=y/2}^{x=\sqrt{y}} dx\, dy$ :

$$\begin{aligned} A &= \iint_D 1\, dx\, dy \\ &= \int_{x=0}^{x=2} \int_{y=x^2}^{y=2x} 1\, dy\, dx \\ &= \int_{x=0}^{x=2} \left( y\Big|_{y=x^2}^{y=2x} \right) dx \\ &= \int_{x=0}^{x=2} (2x - x^2)\, dx \\ &= \left( x^2 - \frac{x^3}{3} \right) \Big|_0^2 = \frac{4}{3}. \end{aligned}$$

### Exercise 15.3.7

Find the area of a region bounded above by the curve $y = x^3$ and below by $y = 0$ over the interval $[0, 3]$.

**Hint**

Sketch the region.

**Answer**

$\frac{81}{4}$ square units

We can also use a double integral to find the average value of a function over a general region. The definition is a direct extension of the earlier formula.

### Definition: The Average Value of a Function

If $f(x, y)$ is integrable over a plane-bounded region $D$ with positive area $A(D)$, then the average value of the function is

$$f_{ave} = \frac{1}{A(D)} \iint_D f(x, y)\, dA.$$

Note that the area is $A(D) = \iint_D 1\,dA$.

**Example 15.3.9: Finding an Average Value**

Find the average value of the function $f(x,y) = 7xy^2$ on the region bounded by the line $x = y$ and the curve $x = \sqrt{y}$ (Figure 15.3.14).

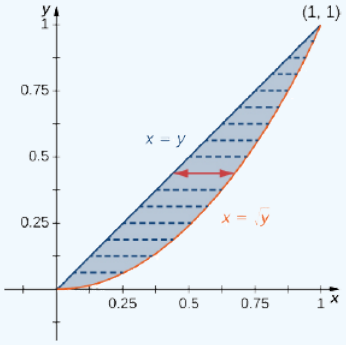

Figure 15.3.14: The region bounded by $x = y$ and $x = \sqrt{y}$.

**Solution**

First find the area $A(D)$ where the region $D$ is given by the figure. We have

$$A(D) = \iint_D 1\,dA = \int_{y=0}^{y=1} \int_{x=y}^{x=\sqrt{y}} 1\,dx\,dy = \int_{y=0}^{y=1} \left[ x \Big|_{x=y}^{x=\sqrt{y}} \right] dy$$
$$= \int_{y=0}^{y=1} (\sqrt{y} - y)\,dy = \frac{2}{3}y^{2/3} - \frac{y^2}{2}\Big|_0^1 = \frac{1}{6}$$

Then the average value of the given function over this region is

$$f_{ave} = \frac{1}{A(D)} \iint_D f(x,y)\,dA = \frac{1}{A(D)} \int_{y=0}^{y=1} \int_{x=y}^{x=\sqrt{y}} 7xy^2\,dx\,dy = \frac{1}{1/6} \int_{y=0}^{y=1} \left[ \frac{7}{2}x^2y^2 \Big|_{x=y}^{x=\sqrt{y}} \right] dy$$
$$= 6\int_{y=0}^{y=1} \left[ \frac{7}{2}y^2(y - y^2) \right] dy = 6\int_{y=0}^{y=1} \left[ \frac{7}{2}(y^3 - y^4) \right] dy = \frac{42}{2}\left( \frac{y^4}{4} - \frac{y^5}{5} \right)\Big|_0^1 = \frac{42}{40} = \frac{21}{20}.$$

**Exercise 15.3.8**

Find the average value of the function $f(x,y) = xy$ over the triangle with vertices $(0,0)$, $(1,0)$ and $(1,3)$.

**Hint**

Express the line joining $(0,0)$ and $(1,3)$ as a function $y = g(x)$.

**Answer**

$\frac{3}{4}$

## Improper Double Integrals

An **improper double integral** is an integral $\iint_D f\,dA$ where either $D$ is an unbounded region or $f$ is an unbounded function. For example, $D = \{(x,y)\,|\,|x - y| \geq 2\}$ is an unbounded region, and the function $f(x,y) = 1/(1 - x^2 - 2y^2)$ over the ellipse $x^2 + 3y^2 \geq 1$ is an unbounded function. Hence, both of the following integrals are improper integrals:

i. $$\iint_D xy\, dA \text{ where } D = \{(x,y) || x-y| \geq 2\};$$

ii. $$\iint_D \frac{1}{1-x^2-2y^2}\, dA \text{ where } D = \{(x,y) | x^2+3y^2 \leq 1\}.$$

In this section we would like to deal with improper integrals of functions over rectangles or simple regions such that f has only finitely many discontinuities. Not all such improper integrals can be evaluated; however, a form of Fubini's theorem does apply for some types of improper integrals.

### Theorem: Fubini's Theorem for Improper Integrals

If $D$ is a bounded rectangle or simple region in the plane defined by

$\{(x,y) : a \leq x \leq b,\ g(x) \leq y \leq h(x)\}$ and also by

$\{(x,y) : c \leq y \leq d,\ j(y) \leq x \leq k(y)\}$ and $f$ is a nonnegative function on $D$ with finitely many discontinuities in the interior of $D$ then

$$\iint_D f\, dA = \int_{x=a}^{x=b} \int_{y=g(x)}^{y=h(x)} f(x,y)\, dy\, dx = \int_{y=c}^{y=d} \int_{x=j(y)}^{x=k(y)} f(x,y)\, dx\, dy$$

It is very important to note that we required that the function be nonnegative on $D$ for the theorem to work. We consider only the case where the function has finitely many discontinuities inside $D$.

### Example 15.3.10: Evaluating a Double Improper Integral

Consider the function $f(x,y) = \frac{e^y}{y}$ over the region $D = \{(x,y) : 0 \leq x \leq 1,\ x \leq y \leq \sqrt{x}\}$.

Notice that the function is nonnegative and continuous at all points on $D$ except $(0,0)$. Use Fubini's theorem to evaluate the improper integral.

#### Solution

First we plot the region $D$ (Figure 15.3.15); then we express it in another way.

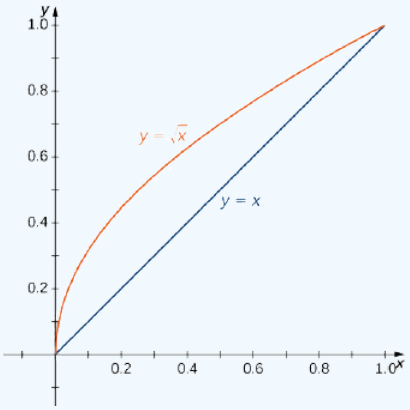

Figure 15.3.15: The function $f$ is continuous at all points of the region $D$ except $(0,0)$.

The other way to express the same region $D$ is

$$D = \{(x,y) : 0 \leq y \leq 1,\ y^2 \leq x \leq y\}.$$

Thus we can use Fubini's theorem for improper integrals and evaluate the integral as

$$\int_{y=0}^{y=1} \int_{x=y^2}^{x=y} \frac{e^y}{y}\, dx\, dy.$$

Therefore, we have

$$\int_{y=0}^{y=1}\int_{x=y^2}^{x=y}\frac{e^y}{y}\,dx\,dy=\int_{y=0}^{y=1}\frac{e^y}{y}x\Big|_{x=y^2}^{x=y}\,dy=\int_{y=0}^{y=1}\frac{e^y}{y}(y-y^2)\,dy=\int_0^1(e^y-ye^y)\,dy=e-2.$$

As mentioned before, we also have an improper integral if the region of integration is unbounded. Suppose now that the function $f$ is continuous in an unbounded rectangle $R$.

**Theorem: Improper Integrals on an Unbounded Region**

If $R$ is an unbounded rectangle such as $R=\{(x,y)\,:\,a\le x\le\infty,\ c\le y\le\infty\}$, then when the limit exists, we have

$$\iint_R f(x,y)\,dA=\lim_{(b,d)\to(\infty,\infty)}\int_a^b\left(\int_c^d f(x,y)\,dy\right)dx=\lim_{(b,d)\to(\infty,\infty)}\int_c^d\left(\int_a^b f(x,y)\,dx\right)dy.$$

The following example shows how this theorem can be used in certain cases of improper integrals.

**Example 15.3.11**

Evaluate the integral $\iint_R xye^{-x^2-y^2}\,dA$ where $R$ is the first quadrant of the plane.

**Solution**

The region $R$ is the first quadrant of the plane, which is unbounded. So

$$\begin{aligned}
\iint_R xye^{-x^2-y^2}\,dA&=\lim_{(b,d)\to(\infty,\infty)}\int_{x=0}^{x=b}\left(\int_{y=0}^{y=d}xye^{-x^2-y^2}dy\right)dx\\
&=\lim_{(b,d)\to(\infty,\infty)}\int_{x=0}^{x=b}\left(-\frac{1}{2}x\int_{y=0}^{y=d}-2ye^{-x^2-y^2}dy\right)dx\\
&=\lim_{(b,d)\to(\infty,\infty)}\int_{x=0}^{x=b}-\frac{1}{2}x\left(e^{-x^2-y^2}\right)\Big|_{y=0}^{y=d}dx\\
&=\lim_{(b,d)\to(\infty,\infty)}\int_{x=0}^{x=b}-\frac{1}{2}x\left(e^{-x^2-d^2}-e^{-x^2}\right)dx\\
&=\lim_{(b,d)\to(\infty,\infty)}\int_{x=0}^{x=b}\frac{1}{2}xe^{-x^2}\left(1-e^{-d^2}\right)dx\\
&=\lim_{(b,d)\to(\infty,\infty)}\left(-\frac{1}{4}\right)\left(1-e^{-d^2}\right)\int_{x=0}^{x=b}-2xe^{-x^2}\,dx\\
&=\lim_{(b,d)\to(\infty,\infty)}\left(-\frac{1}{4}\right)\left(1-e^{-d^2}\right)e^{-x^2}\Big|_{x=0}^{x=b}dx\\
&=\lim_{(b,d)\to(\infty,\infty)}\frac{1}{4}\left(1-e^{-b^2}\right)\left(1-e^{-d^2}\right)\\
&=\lim_{(b,d)\to(\infty,\infty)}\frac{1}{4}\left(1-\cancel{e^{-b^2}}^{\to 0}\right)\left(1-\cancel{e^{-d^2}}^{\to 0}\right)\\
&=\frac{1}{4}
\end{aligned}$$

Thus,

$$\iint_R xye^{-x^2-y^2}\,dA$$

is convergent and the value is $\frac{1}{4}$.

**Exercise 15.3.9**

$$\iint_D \frac{y}{\sqrt{1-x^2-y^2}}\,dA$$

where $D = \{(x,y) : x \geq 0,\ y \geq 0,\ x^2+y^2 \leq 1\}$.

**Hint**

Notice that the integral is nonnegative and discontinuous on $x^2+y^2=1$. Express the region $D$ as $D = \{(x,y) : 0 \leq x \leq 1,\ 0 \leq y \leq \sqrt{1-x^2}\}$ and integrate using the method of substitution.

**Answer**

$\frac{\pi}{4}$

In some situations in probability theory, we can gain insight into a problem when we are able to use double integrals over general regions. Before we go over an example with a double integral, we need to set a few definitions and become familiar with some important properties.

**Definition: Joint Density Function**

Consider a pair of continuous random variables $X$ and $Y$ such as the birthdays of two people or the number of sunny and rainy days in a month. The **joint density function** $f$ of $X$ and $Y$ satisfies the probability that $(X,Y)$ lies in a certain region $D$:

$$P((X,Y) \in D) = \iint_D f(x,y)\,dA.$$

Since the probabilities can never be negative and must lie between 0 and 1 the joint density function satisfies the following inequality and equation:

$$f(x,y) \geq 0 \text{ and } \iint_R f(x,y)\,dA = 1.$$

**Definition: Independent Random Variables**

The variables $X$ and $Y$ are said to be **independent random variables** if their joint density function is the product of their individual density functions:

$$f(x,y) = f_1(x)f_2(y).$$

**Example 15.3.12: Application to Probability**

At Sydney's Restaurant, customers must wait an average of 15 minutes for a table. From the time they are seated until they have finished their meal requires an additional 40 minutes, on average. What is the probability that a customer spends less than an hour and a half at the diner, assuming that waiting for a table and completing the meal are independent events?

**Solution**

Waiting times are mathematically modeled by exponential density functions, with $m$ being the average waiting time, as

$$f(t) = \begin{cases} 0, & \text{if } t < 0 \\ \frac{1}{m}e^{-t/m}, & \text{if } t \geq 0. \end{cases}$$

if $X$ and $Y$ are random variables for 'waiting for a table' and 'completing the meal,' then the probability density functions are, respectively,

$$f_1(x) = \begin{cases} 0, & \text{if } x < 0. \\ \frac{1}{15}e^{-x/15}, & \text{if } x \geq 0. \end{cases} \quad \text{and} \quad f_2(y) = \begin{cases} 0, & \text{if } y < 0 \\ \frac{1}{40}e^{-y/40}, & \text{if } y \geq 0. \end{cases}$$

Clearly, the events are independent and hence the joint density function is the product of the individual functions

$$f(x,y) = f_1(x)f_2(y) = \begin{cases} 0, & \text{if } x < 0 \text{ or } y < 0, \\ \frac{1}{600}e^{-x/15}e^{-y/40}, & \text{if } x, y \geq 0 \end{cases}$$

We want to find the probability that the combined time $X + Y$ is less than 90 minutes. In terms of geometry, it means that the region $D$ is in the first quadrant bounded by the line $x + y = 90$ (Figure 15.3.16).

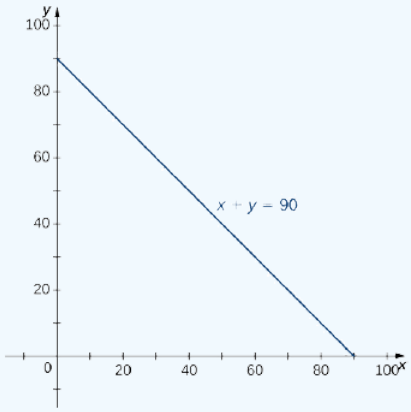

Figure 15.3.16: The region of integration for a joint probability density function.

Hence, the probability that $(X, Y)$ is in the region $D$ is

$$P(X + Y \leq 90) = P((X,Y) \in D) = \iint_D f(x,y)\,dA = \iint_D \frac{1}{600}e^{-x/15}e^{-y/40}\,dA.$$

Since $x + y = 90$ is the same as $y = 90 - x$, we have a region of Type I, so

$$D = \{(x,y) \mid 0 \leq x \leq 90,\ 0 \leq y \leq 90 - x\},$$

$$\begin{aligned} P(X + Y \leq 90) &= \frac{1}{600}\int_{x=0}^{x=90}\int_{y=0}^{y=90-x} e^{-x/15}e^{-y/40}dy\,dx \\ &= -\frac{1}{15}\int_{x=0}^{x=90} e^{-x/15}\int_{y=0}^{y=90-x} -\frac{1}{40}e^{-y/40}dy\,dx \\ &= -\frac{1}{15}\int_{x=0}^{x=90} e^{-x/15}e^{-y/40}\Big|_{y=0}^{y=90-x}\,dx \\ &= \quad \ldots \\ &\approx 0.8328 \end{aligned}$$

Thus, there is an 83.3% chance that a customer spends less than an hour and a half at the restaurant.

Another important application in probability that can involve improper double integrals is the calculation of expected values. First we define this concept and then show an example of a calculation.

**Definition: Expected Values**

In probability theory, we denote the **expected values** $E(X)$ and $E(Y)$ respectively, as the most likely outcomes of the events. The expected values $E(X)$ and $E(Y)$ are given by

$$E(X) = \iint_S x\,f(x,y)\,dA \text{ and } E(Y) = \iint_S y\,f(x,y)\,dA,$$

where $S$ is the sample space of the random variables $X$ and $Y$.

### Example 15.3.13: Finding Expected Value

Find the expected time for the events ‘waiting for a table’ and ‘completing the meal’ in Example **15.3.12**.

**Solution**

Using the first quadrant of the rectangular coordinate plane as the sample space, we have improper integrals for $E(X)$ and $E(Y)$. The expected time for a table is

$$\begin{aligned} E(X) &= \iint_S x\frac{1}{600}e^{-x/15}e^{-y/40}\,dA \\ &= \frac{1}{600}\int_{x=0}^{x=\infty}\int_{y=0}^{y=\infty} xe^{-x/15}e^{-y/40}dA \\ &= \frac{1}{600}\lim_{(a,b)\to(\infty,\infty)}\int_{x=0}^{x=a}\int_{y=0}^{y=b} xe^{-x/15}e^{-y/40}dx\,dy \\ &= \frac{1}{600}\left(\lim_{a\to\infty}\int_{x=0}^{x=a} xe^{-x/15}dx\right)\left(\lim_{b\to\infty}\int_{y=0}^{y=b} e^{-y/40}dy\right) \\ &= \frac{1}{600}\left(\left(\lim_{a\to\infty}(-15e^{-x/15}(x+15))\right)\Big|_{x=0}^{x=a}\right)\left(\left(\lim_{b\to\infty}(-40e^{-y/40})\right)\Big|_{y=0}^{y=b}\right) \\ &= \frac{1}{600}\left(\lim_{a\to\infty}(-15e^{-a/15}(a+15)+225)\right)\left(\lim_{b\to\infty}(-40e^{-b/40}+40)\right) \\ &= \frac{1}{600}(225)(40) = 15. \end{aligned}$$

A similar calculation shows that $E(Y) = 40$. This means that the expected values of the two random events are the average waiting time and the average dining time, respectively.

### Exercise 15.3.10

The joint density function for two random variables $X$ and $Y$ is given by

$$f(x,y) = \begin{cases} \frac{1}{16250}(x^2+y^2), & \text{if } 0 \le x \le 15,\ 0 \le y \le 10 \\ 0, & \text{otherwise} \end{cases}$$

Find the probability that $X$ is at most 10 and $Y$ is at least 5.

**Hint**

Compute the probability

$$P(X \le 10,\ Y \ge 5) = \int_{x=0}^{x=10}\int_{y=5}^{y=10}\frac{1}{16250}(x^2+y^2)dy\,dx.$$

**Answer**

$P(X \le 10,\ Y \ge 5) = \frac{11}{39} \approx 0.28205$

## Key Concepts

- A general bounded region $D$ on the plane is a region that can be enclosed inside a rectangular region. We can use this idea to define a double integral over a general bounded region.
- To evaluate an iterated integral of a function over a general nonrectangular region, we sketch the region and express it as a Type I or as a Type II region or as a union of several Type I or Type II regions that overlap only on their boundaries.
- We can use double integrals to find volumes, areas, and average values of a function over general regions, similarly to calculations over rectangular regions.
- We can use Fubini’s theorem for improper integrals to evaluate some types of improper integrals.

## Key Equations

- **Iterated integral over a Type I region**

$$\iint_D f(x,y)\,dA = \iint_D f(x,y)\,dy\,dx = \int_a^b \left[\int_{g_1(x)}^{g_2(x)} f(x,y)\,dy\right] dx$$

- **Iterated integral over a Type II region**

$$\iint_D f(x,y)\,dA = \iint_D (x,y)\,dx\,dy = \int_c^d \left[\int_{h_1(y)}^{h_2(y)} f(x,y)\,dx\right] dy$$

## Glossary

**improper double integral**

a double integral over an unbounded region or of an unbounded function

**Type I**

a region $D$ in the $xy$- plane is Type I if it lies between two vertical lines and the graphs of two continuous functions $g_1(x)$ and $g_2(x)$

**Type II**

a region $D$ in the $xy$-plane is Type II if it lies between two horizontal lines and the graphs of two continuous functions $h_1(y)$ and $h_2(h)$

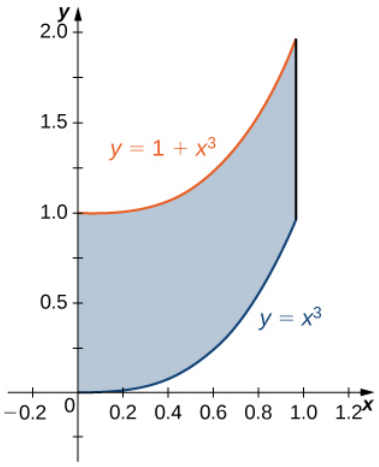
# 15.3E: Exercises for Section 15.2

1) The region $D$ bounded by $y = x^3,\ y = x^3 + 1,\ x = 0$, and $x = 1$ as given in the following figure.



a. Classify this region as vertically simple (Type I) or horizontally simple (Type II).

**Type:**

Type I but not Type II

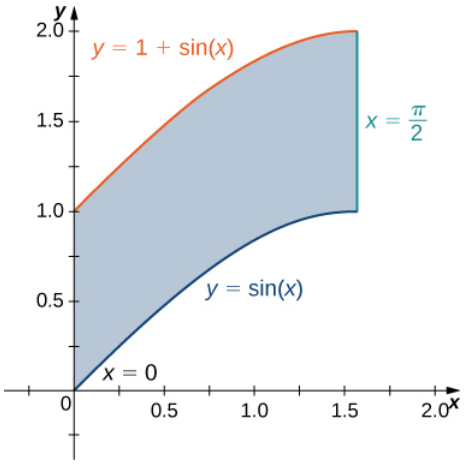
b. Find the area of the region $D$.

c. Find the average value of the function $f(x, y) = 3xy$ on the region graphed in the previous exercise.

**Answer**

$\frac{27}{20}$

2) The region $D$ bounded by $y = \sin x,\ y = 1 + \sin x,\ x = 0$, and $x = \frac{\pi}{2}$ as given in the following figure.



a. Classify this region as vertically simple (Type I) or horizontally simple (Type II).

**Type:**

Type I but not Type II

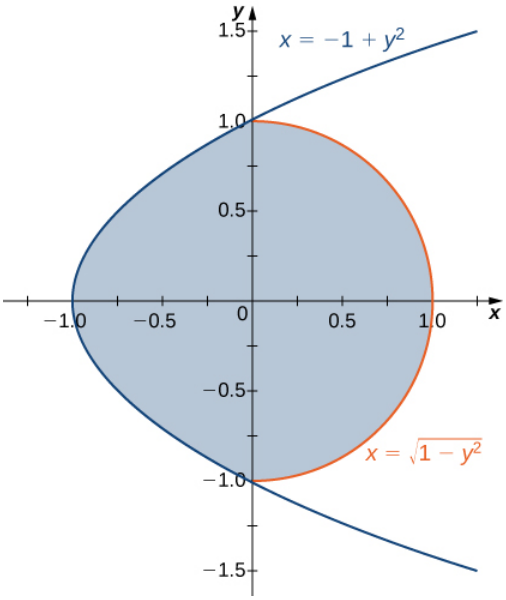
b. Find the area of the region $D$.

**Answer**

$\frac{\pi}{2}$ units$^2$

c. Find the average value of the function $f(x, y) = \cos x$ on the region $D$.

3) The region $D$ bounded by $x = y^2 - 1$ and $x = \sqrt{1 - y^2}$ as given in the following figure.



a. Classify this region as vertically simple (Type I) or horizontally simple (Type II).

**Type:**

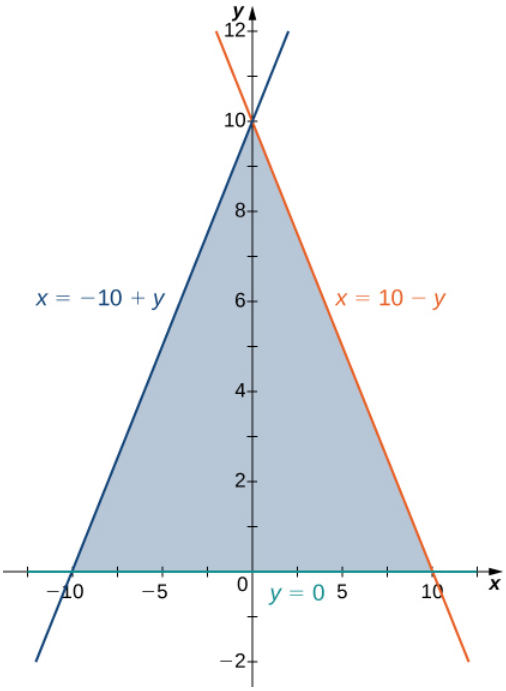
Type II but not Type I

b. Find the volume of the solid under the graph of the function $f(x, y) = xy + 1$ and above the region $D$.

**Answer**

$\frac{1}{6}(8 + 3\pi)$ units$^3$

4) The region $D$ bounded by $y = 0,\ x = -10 + y$, and $x = 10 - y$ as given in the following figure.



a. Classify this region as vertically simple (Type I) or horizontally simple (Type II).

**Type:**

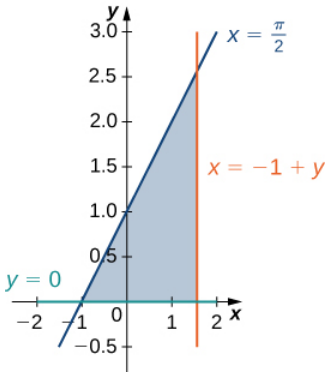
Type II but not Type I

b. Find the volume of the solid under the graph of the function $f(x,y) = x + y$ and above the region in the figure from the previous exercise.

**Answer**

$\frac{1000}{3}$ units$^3$

5) The region $D$ bounded by $y = 0,\ x = y - 1,\ x = \frac{\pi}{2}$ as given in the following figure.

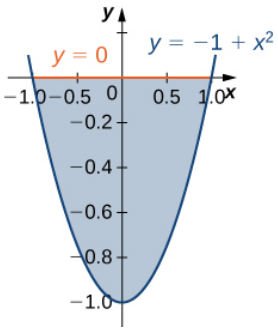


Classify this region as vertically simple (Type I) or horizontally simple (Type II).

**Type:**

Type I and Type II

6) The region $D$ bounded by $y = 0$ and $y = x^2 - 1$ as given in the following figure.



Classify this region as vertically simple (Type I) or horizontally simple (Type II).

**Type:**

Type I and Type II

7) Let $D$ be the region bounded by the curves of equations $y = \cos x$ and $y = 4 - x^2$ and the $x$-axis. Explain why $D$ is neither of Type I nor II.

**Answer**

The region $D$ is not of Type I: it does not lie between two vertical lines and the graphs of two continuous functions $g_1(x)$ and $g_2(x)$. The region is not of Type II: it does not lie between two horizontal lines and the graphs of two continuous functions $h_1(y)$ and $h_2(y)$.

8) Let $D$ be the region bounded by the curves of equations $y = x,\ y = -x$ and $y = 2 - x^2$. Explain why $D$ is neither of Type I nor II.

**In exercises 9 - 14, evaluate the double integral $\iint_D f(x,y)\,dA$ over the region $D$.**

9) $f(x,y) = 1$ and

$D = \{(x,y) | \ 0 \le x \le \frac{\pi}{2},\ \sin x \le y \le 1 + \sin x\}$

**Answer**

$\frac{\pi}{2}$

10) $f(x,y) = 2$ and

$D = \{(x,y) | \ 0 \le y \le 1,\ y - 1 \le x \le \arccos y\}$

11) $f(x,y) = xy$ and

$D = \{(x,y) | \ -1 \le y \le 1,\ y^2 - 1 \le x \le \sqrt{1 - y^2}\}$

**Answer**

**0**

12) $f(x,y) = \sin y$ and $D$ is the triangular region with vertices $(0,0),\ (0,3)$, and $(3,0)$

13) $f(x,y) = -x + 1$ and $D$ is the triangular region with vertices $(0,0),\ (0,2)$, and $(2,2)$

**Answer**

$\frac{2}{3}$

14) $f(x,y) = 2x + 4y$ and

$D = \{(x,y) | \ 0 \le x \le 1,\ x^3 \le y \le x^3 + 1\}$

**In exercises 15 - 20, evaluate the iterated integrals.**

15) $\int_0^1 \int_{2\sqrt{x}}^{2\sqrt{x}+1} (xy+1)\,dy\,dx$

**Answer**

$\frac{41}{20}$

16) $\int_0^3 \int_{2x}^{3x} (x+y^2)\,dy\,dx$

17) $\int_1^2 \int_{-u^2-1}^{-u} (8uv)\,dv\,du$

**Answer**

$-63$

18) $\int_e^{e^2} \int_{\ln u}^{2} (v+\ln u)\,dv\,du$

19) $\int_0^{1/2} \int_{-\sqrt{1-4y^2}}^{\sqrt{1-4y^2}} 4\,dx\,dy$

**Answer**

$\pi$

20) $\int_0^1 \int_{-\sqrt{1-y^2}}^{\sqrt{1-y^2}} (2x+4y^3)\,dx\,dy$

21) Let $D$ be the region bounded by $y=1-x^2,\ y=4-x^2$, and the $x$- and $y$-axes.

a. Show that $\iint_D x\,dA = \int_0^1 \int_{1-x^2}^{4-x^2} x\,dy\,dx + \int_1^2 \int_0^{4-x^2} x\,dy\,dx$ by dividing the region $D$ into two regions of Type I.

b. Evaluate the integral $\iint_D x\,dA$.

22) Let $D$ be the region bounded by $y=1,\ y=x,\ y=\ln x$, and the $x$-axis.

a. Show that $\iint_D y^2\,dA = \int_{-1}^0 \int_{-x}^{2-x^2} y^2 dy\,dx + \int_0^1 \int_x^{2-x^2} y^2 dy\,dx$ by dividing the region $D$ into two regions of Type I, where $D = \{(x,y)\,|\,y \geq x, y \geq -x,\ y \leq 2-x^2\}$.

b. Evaluate the integral $\iint_D y^2\,dA$.

23) Let $D$ be the region bounded by $y=x^2$, $y=x+2$, and $y=-x$.

a. Show that $\iint_D x\,dA = \int_0^1 \int_{-y}^{\sqrt{y}} x\,dx\,dy + \int_1^4 \int_{y-2}^{\sqrt{y}} x\,dx\,dy$ by dividing the region $D$ into two regions of Type II, where $D = \{(x,y)\,|\,y \geq x^2,\ y \geq -x,\ y \leq x+2\}$.

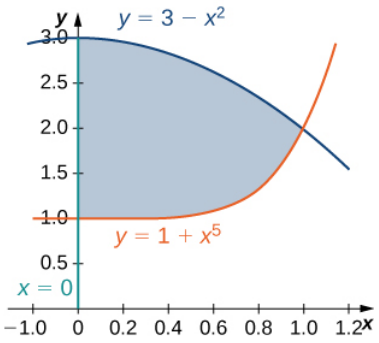
b. Evaluate the integral $\iint_D x\,dA$.

**Answer**

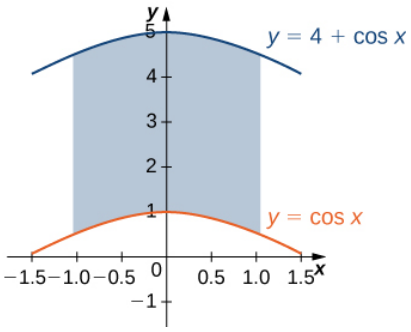
a. Answers may vary;

b. $\frac{7}{3}$

24) The region $D$ bounded by $x=0, y=x^5+1$, and $y=3-x^2$ is shown in the following figure. Find the area $A(D)$ of the region $D$.



25) The region $D$ bounded by $y = \cos x,\ y = 4 + \cos x$, and $x = \pm\frac{\pi}{3}$ is shown in the following figure. Find the area $A(D)$ of the region $D$.



**Answer**

$\frac{8\pi}{3}$

26) Find the area $A(D)$ of the region $D = \{(x,y) | y \geq 1 - x^2, y \leq 4 - x^2,\ y \geq 0,\ x \geq 0\}$.

27) Let $D$ be the region bounded by $y = 1,\ y = x,\ y = \ln x$, and the $x$-axis. Find the area $A(D)$ of the region $D$.

**Answer**

$\left(e - \frac{3}{2}\right)$ units$^2$

28) Find the average value of the function $f(x,y) = \sin y$ on the triangular region with vertices $(0,0),\ (0,3)$, and $(3,0)$.

29) Find the average value of the function $f(x,y) = -x + 1$ on the triangular region with vertices $(0,0),\ (0,2)$, and $(2,2)$.

**Answer**

The average value of $f$ on this triangular region is $\frac{1}{3}$.

**In exercises 30 - 33, change the order of integration and evaluate the integral.**

30) $\int_{-1}^{\pi/2} \int_{0}^{x+1} \sin x \, dy \, dx$

31) $\int_{0}^{1} \int_{x-1}^{1-x} x \, dy \, dx$

**Answer**

$$\int_0^1 \int_{x-1}^{1-x} x \, dy \, dx = \int_{-1}^0 \int_0^{y+1} x \, dx \, dy + \int_0^1 \int_0^{1-y} x \, dx \, dy = \frac{1}{3}$$

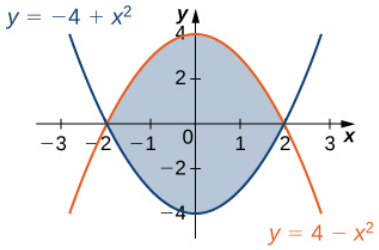
32) $\int_{-1}^{0} \int_{-\sqrt{y+1}}^{\sqrt{y+1}} y^2 dx \, dy$

33) $\int_{-1/2}^{1/2} \int_{-\sqrt{y^2+1}}^{\sqrt{y^2+1}} y \, dx \, dy$

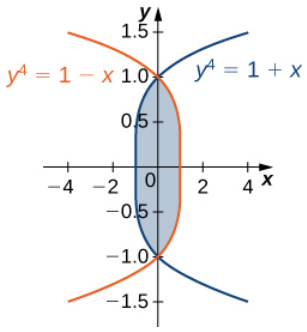
**Answer**

$$\int_{-1/2}^{1/2}\int_{-\sqrt{y^2+1}}^{\sqrt{y^2+1}} y\,dx\,dy = \int_{1}^{2}\int_{-\sqrt{x^2-1}}^{\sqrt{x^2-1}} y\,dy\,dx = 0$$

34) The region $D$ is shown in the following figure. Evaluate the double integral $\iint_D (x^2+y)\,dA$ by using the easier order of integration.



35) The region $D$ is shown in the following figure. Evaluate the double integral $\iint_D (x^2-y^2)\,dA$ by using the easier order of integration.



**Answer**

$$\iint_D (x^2-y^2)dA = \int_{-1}^{1}\int_{y^4-1}^{1-y^4} (x^2-y^2)dx\,dy = \frac{464}{4095}$$

36) Find the volume of the solid under the surface $z = 2x + y^2$ and above the region bounded by $y = x^5$ and $y = x$.

37) Find the volume of the solid under the plane $z = 3x + y$ and above the region determined by $y = x^7$ and $y = x$.

**Answer**

$\frac{4}{5}$ units$^3$

38) Find the volume of the solid under the plane $z = 3x + y$ and above the region bounded by $x = \tan y,\ x = -\tan y$, and $x = 1$.

39) Find the volume of the solid under the surface $z = x^3$ and above the plane region bounded by $x = \sin y,\ x = -\sin y$, and $x = 1$.

**Answer**

$\frac{5\pi}{32}$ units$^3$

40) Let $g$ be a positive, increasing, and differentiable function on the interval $[a, b]$. Show that the volume of the solid under the surface $z = g'(x)$ and above the region bounded by $y = 0,\ y = g(x),\ x = a$, and $x = b$ is given by $\frac{1}{2}(g^2(b) - g^2(a))$.

41) Let $g$ be a positive, increasing, and differentiable function on the interval $[a, b]$ and let $k$ be a positive real number. Show that the volume of the solid under the surface $z = g'(x)$ and above the region bounded by $y = g(x),\ y = g(x) + k,\ x = a$, and $x = b$ is given by $k(g(b) - g(a))$.

42) Find the volume of the solid situated in the first octant and determined by the planes $z = 2,\ z = 0,\ x + y = 1,\ x = 0$, and $y = 0$.

43) Find the volume of the solid situated in the first octant and bounded by the planes $x+2y=1$, $x=0,\ z=4$, and $z=0$.

**Answer**

$1\ \text{units}^3$

44) Find the volume of the solid bounded by the planes $x+y=1,\ x-y=1,\ x=0,\ z=0$, and $z=10$.

45) Find the volume of the solid bounded by the planes $x+y=1,\ x-y=1,\ x+y=-1\ x-y=-1,\ z=1$, and $z=0$

**Answer**

$2\ \text{units}^3$

46) Let $S_1$ and $S_2$ be the solids situated in the first octant under the planes $x+y+z=1$ and $x+y+2z=1$ respectively, and let $S$ be the solid situated between $S_1,\ S_2,\ x=0$, and $y=0$.

a. Find the volume of the solid $S_1$.
b. Find the volume of the solid $S_2$.
c. Find the volume of the solid $S$ by subtracting the volumes of the solids $S_1$ and $S_2$.

47) Let $S_1$ and $S_2$ be the solids situated in the first octant under the planes $2x+2y+z=2$ and $x+y+z=1$ respectively, and let $S$ be the solid situated between $S_1,\ S_2,\ x=0$, and $y=0$.

a. Find the volume of the solid $S_1$.
b. Find the volume of the solid $S_2$.
c. Find the volume of the solid $S$ by subtracting the volumes of the solids $S_1$ and $S_2$.

**Answer**

a. $\frac{1}{3}\ \text{units}^3$
b. $\frac{1}{6}\ \text{units}^3$
c. $\frac{1}{6}\ \text{units}^3$

48) Let $S_1$ and $S_2$ be the solids situated in the first octant under the plane $x+y+z=2$ and under the sphere $x^2+y^2+z^2=4$, respectively. If the volume of the solid $S_2$ is $\frac{4\pi}{3}$ determine the volume of the solid $S$ situated between $S_1$ and $S_2$ by subtracting the volumes of these solids.

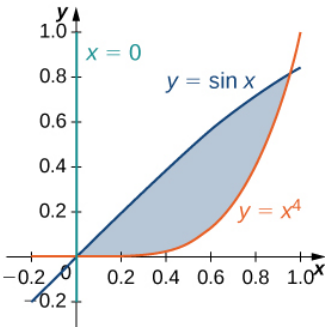
49) Let $S_1$ and $S_2$ be the solids situated in the first octant under the plane $x+y+z=2$ and bounded by the cylinder $x^2+y^2=4$, respectively.

a. Find the volume of the solid $S_1$.
b. Find the volume of the solid $S_2$.
c. Find the volume of the solid $S$ situated between $S_1$ and $S_2$ by subtracting the volumes of the solids $S_1$ and $S_2$.

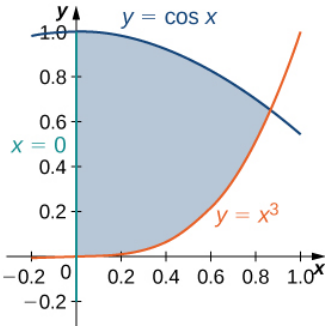
**Answer**

a. $\frac{4}{3}\ \text{units}^3$
b. $2\pi\ \text{units}^3$
c. $\frac{6\pi-4}{3}\ \text{units}^3$

50) [T] The following figure shows the region $D$ bounded by the curves $y=\sin x,\ x=0$, and $y=x^4$. Use a graphing calculator or CAS to find the $x$-coordinates of the intersection points of the curves and to determine the area of the region $D$. Round your answers to six decimal places.



51) [T] The region $D$ bounded by the curves $y = \cos x,\ x = 0$, and $y = x^3$ is shown in the following figure. Use a graphing calculator or CAS to find the $x$-coordinates of the intersection points of the curves and to determine the area of the region $D$. Round your answers to six decimal places.



**Answer**

0 and 0.865474; $A(D) = 0.621135 \text{ units}^3$

52) Suppose that $(X, Y)$ is the outcome of an experiment that must occur in a particular region $S$ in the $xy$-plane. In this context, the region $S$ is called the sample space of the experiment and $X$ and $Y$ are random variables. If $D$ is a region included in $S$, then the probability of $(X, Y)$ being in $D$ is defined as $P[(X, Y) \in D] = \iint_D p(x, y)dx\ dy$, where $p(x, y)$ is the joint probability density of the experiment. Here, $p(x, y)$ is a nonnegative function for which $\iint_S p(x, y)dx\ dy = 1$. Assume that a point $(X, Y)$ is chosen arbitrarily in the square $[0, 3] \times [0, 3]$ with the probability density

$$p(x, y) = \frac{1}{9}(x, y) \in [0, 3] \times [0, 3],$$

$$p(x, y) = 0 \text{ otherwise}$$

Find the probability that the point $(X, Y)$ is inside the unit square and interpret the result.

53) Consider $X$ and $Y$ two random variables of probability densities $p_1(x)$ and $p_2(x)$, respectively. The random variables $X$ and $Y$ are said to be independent if their joint density function is given by $p(x, y) = p_1(x)p_2(y)$. At a drive-thru restaurant, customers spend, on average, 3 minutes placing their orders and an additional 5 minutes paying for and picking up their meals. Assume that placing the order and paying for/picking up the meal are two independent events $X$ and $Y$. If the waiting times are modeled by the exponential probability densities

$$p_1(x) = \frac{1}{3}e^{-x/3}\ x \geq 0,$$

$$p_1(x) = 0 \text{ otherwise}$$

$$p_2(y) = \frac{1}{5}e^{-y/5}\ y \geq 0$$

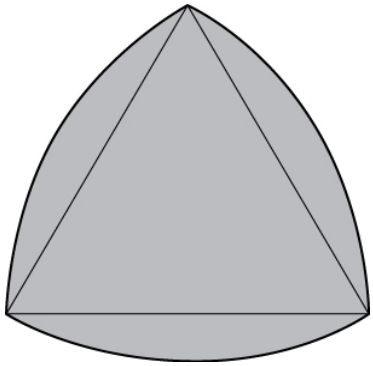
$$p_2(y) = 0 \text{ otherwise}$$

respectively, the probability that a customer will spend less than 6 minutes in the drive-thru line is given by $P[X+Y \leq 6] = \iint_D p(x,y)dx\,dy$, where $D = \{(x,y)|x \geq 0,\ y \geq 0,\ x+y \leq 6\}$. Find $P[X+Y \leq 6]$ and interpret the result.

**Answer**

$P[X+Y \leq 6] = 1 + \frac{3}{2e^2} - \frac{5}{e^{6/5}} \approx 0.45$; there is a $45\%$ chance that a customer will spend $6$ minutes in the drive-thru line.

54) [T] The Reuleaux triangle consists of an equilateral triangle and three regions, each of them bounded by a side of the triangle and an arc of a circle of radius $s$ centered at the opposite vertex of the triangle. Show that the area of the Reuleaux triangle in the following figure of side length $s$ is $\frac{s^2}{2}(\pi - \sqrt{3})$.



55) [T] Show that the area of the lunes of Alhazen, the two blue lunes in the following figure, is the same as the area of the right triangle $ABC$. The outer boundaries of the lunes are semicircles of diameters $AB$ and $AC$ respectively, and the inner boundaries are formed by the circumcircle of the triangle $ABC$.

# 15.4: Double Integrals in Polar Coordinates

**Learning Objectives**

- Recognize the format of a double integral over a polar rectangular region.
- Evaluate a double integral in polar coordinates by using an iterated integral.
- Recognize the format of a double integral over a general polar region.
- Use double integrals in polar coordinates to calculate areas and volumes.

Double integrals are sometimes much easier to evaluate if we change rectangular coordinates to polar coordinates. However, before we describe how to make this change, we need to establish the concept of a double integral in a polar rectangular region.

## Polar Rectangular Regions of Integration

When we defined the double integral for a continuous function in rectangular coordinates—say, $g$ over a region $R$ in the $xy$-plane—we divided $R$ into subrectangles with sides parallel to the coordinate axes. These sides have either constant $x$-values and/or constant $y$-values. In polar coordinates, the shape we work with is a polar rectangle, whose sides have constant $r$-values and/or constant $\theta$-values. This means we can describe a polar rectangle as in Figure 15.4.1$a$, with $R = \{(r, \theta) \mid a \le r \le b,\ \alpha \le \theta \le \beta\}$.

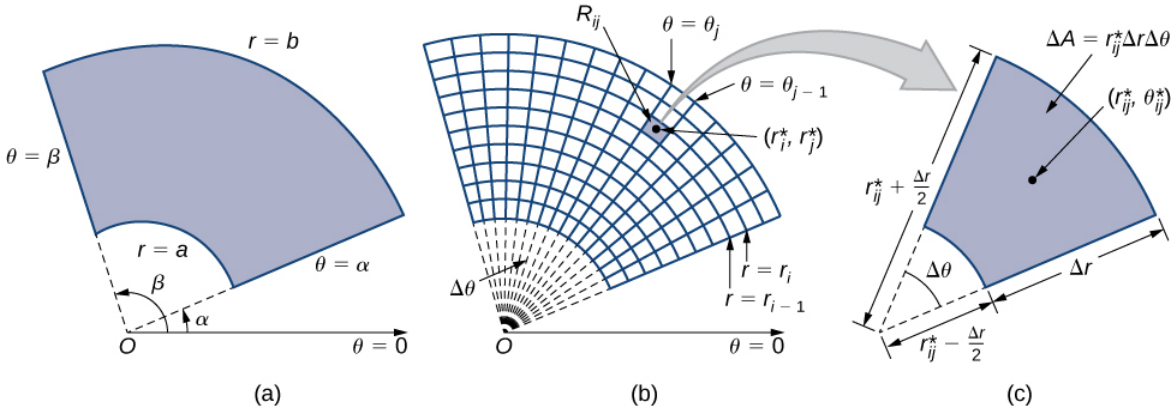

Figure 15.4.1: (a) A polar rectangle $R$ (b) divided into subrectangles $R_{ij}$ (c) Close-up of a subrectangle.

In this section, we are looking to integrate over polar rectangles. Consider a function $f(r, \theta)$ over a polar rectangle $R$. We divide the interval $[a, b]$ into $m$ subintervals $[r_{i-1}, r_i]$ of length $\Delta r = (b - a)/m$ and divide the interval $[\alpha, \beta]$ into $n$ subintervals $[\theta_{i-1}, \theta_i]$ of width $\Delta\theta = (\beta - \alpha)/n$. This means that the circles $r = r_i$ and rays $\theta = \theta_i$ for $1 \le i \le m$ and $1 \le j \le n$ divide the polar rectangle $R$ into smaller polar subrectangles $R_{ij}$ (Figure 15.4.1$b$).

As before, we need to find the area $\Delta A$ of the polar subrectangle $R_{ij}$ and the "polar" volume of the thin box above $R_{ij}$. Recall that, in a circle of radius $r$ the length $s$ of an arc subtended by a central angle of $\theta$ radians is $s = r\theta$. Notice that the polar rectangle $R_{ij}$ looks a lot like a trapezoid with parallel sides $r_{i-1}\Delta\theta$ and $r_i\Delta\theta$ and with a width $\Delta r$. Hence the area of the polar subrectangle $R_{ij}$ is

$$\Delta A = \frac{1}{2}\Delta r(r_{i-1}\Delta\theta + r_i\Delta\theta).$$

Simplifying and letting

$$r_{ij}^* = \frac{1}{2}(r_{i-1} + r_i)$$

we have $\Delta A = r_{ij}^* \Delta r \Delta\theta$.

Therefore, the polar volume of the thin box above $R_{ij}$ (Figure 15.4.2) is

$$f(r_{ij}^*, \theta_{ij}^*)\Delta A = f(r_{ij}^*, \theta_{ij}^*) r_{ij}^* \Delta r \Delta\theta.$$

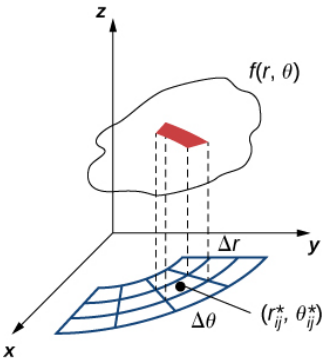

Figure 15.4.2: Finding the volume of the thin box above polar rectangle $R_{ij}$.

Using the same idea for all the subrectangles and summing the volumes of the rectangular boxes, we obtain a double Riemann sum as

$$\sum_{i=1}^{m}\sum_{j=1}^{n} f(r_{ij}^*, \theta_{ij}^*) r_{ij}^* \Delta r \Delta\theta.$$

As we have seen before, we obtain a better approximation to the polar volume of the solid above the region $R$ when we let $m$ and $n$ become larger. Hence, we define the polar volume as the limit of the double Riemann sum,

$$V = \lim_{m,n\to\infty} \sum_{i=1}^{m}\sum_{j=1}^{n} f(r_{ij}^*, \theta_{ij}^*) r_{ij}^* \Delta r \Delta\theta.$$

This becomes the expression for the double integral.

**Definition: The double integral in polar coordinates**

The double integral of the function $f(r, \theta)$ over the polar rectangular region $R$ in the $r\theta$-plane is defined as

$$\iint_R f(r,\theta) dA = \lim_{m,n\to\infty} \sum_{i=1}^{m}\sum_{j=1}^{n} f(r_{ij}^*, \theta_{ij}^*) \Delta A \tag{15.4.1}$$

$$= \lim_{m,n\to\infty} \sum_{i=1}^{m}\sum_{j=1}^{n} f(r_{ij}^*, \theta_{ij}^*) r_{ij}^* \Delta r \Delta\theta. \tag{15.4.2}$$

Again, just as in section on Double Integrals over Rectangular Regions, the double integral over a polar rectangular region can be expressed as an iterated integral in polar coordinates. Hence,

$$\iint_R f(r,\theta)\, dA = \iint_R f(r,\theta)\, r\, dr\, d\theta = \int_{\theta=\alpha}^{\theta=\beta} \int_{r=a}^{r=b} f(r,\theta)\, r\, dr\, d\theta.$$

Notice that the expression for $dA$ is replaced by $r\, dr\, d\theta$ when working in polar coordinates. Another way to look at the polar double integral is to change the double integral in rectangular coordinates by substitution. When the function $f$ is given in terms of $x$ and $y$ using $x = r\cos\theta$, $y = r\sin\theta$, and $dA = r\, dr\, d\theta$ changes it to

$$\iint_R f(x,y)\, dA = \iint_R f(r\cos\theta, r\sin\theta)\, r\, dr\, d\theta.$$

Note that all the properties listed in section on Double Integrals over Rectangular Regions for the double integral in rectangular coordinates hold true for the double integral in polar coordinates as well, so we can use them without hesitation.

**Example 15.4.1.A: Sketching a Polar Rectangular Region**

Sketch the polar rectangular region

$$R = \{(r,\theta) \mid 1 \le r \le 3, 0 \le \theta \le \pi\}.$$

### Solution

As we can see from Figure 15.4.3, $r = 1$ and $r = 3$ are circles of radius 1 and 3 and $0 \le \theta \le \pi$ covers the entire top half of the plane. Hence the region $R$ looks like a semicircular band.

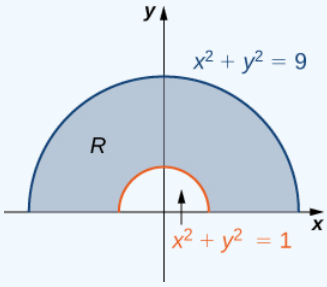

Figure 15.4.3: The polar region $R$ lies between two semicircles.

Now that we have sketched a polar rectangular region, let us demonstrate how to evaluate a double integral over this region by using polar coordinates.

### Example 15.4.1B: Evaluating a Double Integral over a Polar Rectangular Region

Evaluate the integral $\iint_R 3x\,dA$ over the region $R = \{(r,\theta)\,|\,1 \le r \le 2,\ 0 \le \theta \le \pi\}$.

### Solution

First we sketch a figure similar to Figure 15.4.3, but with outer radius $r = 2$. From the figure we can see that we have

$$\begin{aligned}\iint_R 3x\,dA &= \int_{\theta=0}^{\theta=\pi}\int_{r=1}^{r=2} 3r\cos\theta\, r\,dr\,d\theta \quad \text{Use an integral with correct limits of integration.}\\ &= \int_{\theta=0}^{\theta=\pi}\cos\theta\left[r^3\big|_{r=1}^{r=2}\right]d\theta \quad \text{Integrate first with respect to } r.\\ &= \int_{\theta=0}^{\theta=\pi} 7\cos\theta\,d\theta\\ &= 7\sin\theta\Big|_{\theta=0}^{\theta=\pi} = 0.\end{aligned}$$

### Exercise 15.4.1

Sketch the region $D = \{(r,\theta)|1 \le r \le 2, -\frac{\pi}{2} \le \theta \le \frac{\pi}{2}\}$, and evaluate $\iint_R x\,dA$.

**Hint**

Follow the steps in Example 15.4.1A.

**Answer**

$\frac{14}{3}$

### Example 15.4.2A: Evaluating a Double Integral by Converting from Rectangular Coordinates

Evaluate the integral

$$\iint_R (1 - x^2 - y^2)\,dA$$

where $R$ is the unit circle on the $xy$-plane.

### Solution

The region $R$ is a unit circle, so we can describe it as $R = \{(r,\theta)\,|\,0 \le r \le 1,\ 0 \le \theta \le 2\pi\}$.

Using the conversion $x = r\cos\theta$, $y = r\sin\theta$, and $dA = r\,dr\,d\theta$, we have

$$\begin{aligned}\iint_R (1 - x^2 - y^2)\,dA &= \int_0^{2\pi}\int_0^1 (1 - r^2)\,r\,dr\,d\theta \\ &= \int_0^{2\pi}\int_0^1 (r - r^3)\,dr\,d\theta \\ &= \int_0^{2\pi}\left[\frac{r^2}{2} - \frac{r^4}{4}\right]_0^1 d\theta \\ &= \int_0^{2\pi}\frac{1}{4}\,d\theta = \frac{\pi}{2}.\end{aligned}$$

## Example 15.4.2B: Evaluating a Double Integral by Converting from Rectangular Coordinates

Evaluate the integral

$$\iint_R (x + y)\,dA$$

where $R = \{(x, y) \mid 1 \le x^2 + y^2 \le 4,\ x \le 0\}$.

### Solution

We can see that $R$ is an annular region that can be converted to polar coordinates and described as $R = \{(r, \theta) \mid 1 \le r \le 2,\ \frac{\pi}{2} \le \theta \le \frac{3\pi}{2}\}$ (see the following graph).

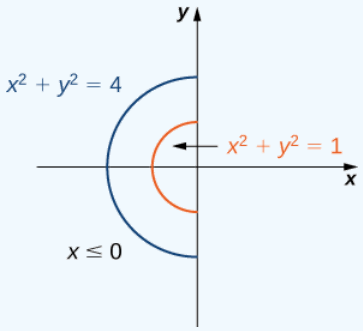

Figure 15.4.4: The annular region of integration $R$.

Hence, using the conversion $x = r\cos\theta$, $y = r\sin\theta$, and $dA = r\,dr\,d\theta$, we have

$$\begin{aligned}\iint_R (x + y)\,dA &= \int_{\theta=\pi/2}^{\theta=3\pi/2}\int_{r=1}^{r=2} (r\cos\theta + r\sin\theta)r\,dr\,d\theta \\ &= \left(\int_{r=1}^{r=2} r^2\,dr\right)\left(\int_{\pi/2}^{3\pi/2} (\cos\theta + \sin\theta)\,d\theta\right) \\ &= \left[\frac{r^3}{3}\right]_1^2 [\sin\theta - \cos\theta]\Big|_{\pi/2}^{3\pi/2} \\ &= -\frac{14}{3}.\end{aligned}$$

## Exercise 15.4.2

Evaluate the integral

$$\iint_R (4 - x^2 - y^2)\,dA$$

where $R$ is the circle of radius 2 on the $xy$-plane.

**Hint**

Follow the steps in the previous example.

**Answer**

$8\pi$

## General Polar Regions of Integration

To evaluate the double integral of a continuous function by iterated integrals over general polar regions, we consider two types of regions, analogous to Type I and Type II as discussed for rectangular coordinates in section on Double Integrals over General Regions. It is more common to write polar equations as $r = f(\theta)$ than $\theta = f(r)$, so we describe a general polar region as $R = \{(r, \theta) \mid \alpha \leq \theta \leq \beta,\ h_1(\theta) \leq r \leq h_2(\theta)\}$ (Figure 15.4.5).

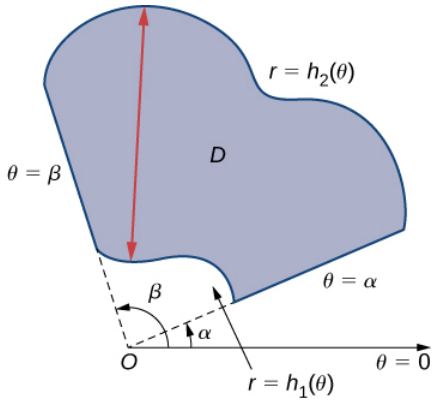

Figure 15.4.5: A general polar region between $\alpha \leq \theta \leq \beta$ and $h_1(\theta) \leq r \leq h_2(\theta)$.

**Theorem: Double Integrals over General Polar Regions**

If $f(r, \theta)$ is continuous on a general polar region $D$ as described above, then

$$\iint_D f(r, \theta)\, r\, dr\, d\theta = \int_{\theta=\alpha}^{\theta=\beta} \int_{r=h_1(\theta)}^{r=h_2(\theta)} f(r, \theta)\, r\, dr\, d\theta.$$

**Example 15.4.3: Evaluating a Double Integral over a General Polar Region**

Evaluate the integral

$$\iint_D r^2 \sin\theta\, r\, dr\, d\theta$$

where $D$ is the region bounded by the polar axis and the upper half of the cardioid $r = 1 + \cos\theta$.

**Solution**

We can describe the region $D$ as $\{(r, \theta) \mid 0 \leq \theta \leq \pi,\ 0 \leq r \leq 1 + \cos\theta\}$ as shown in Figure 15.4.6.

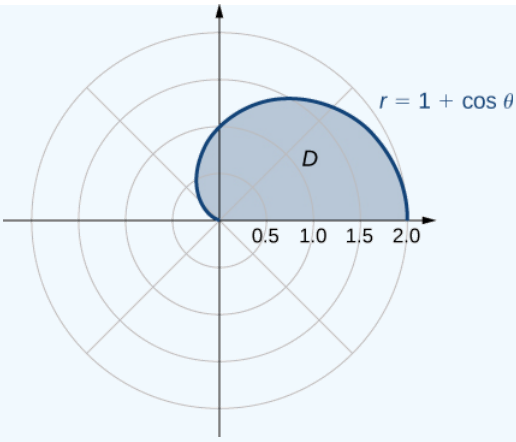

Figure 15.4.6: The region $D$ is the top half of a cardioid.

Hence, we have

$$\begin{aligned}\iint_D r^2 \sin\theta\, r\, dr\, d\theta &= \int_{\theta=0}^{\theta=\pi}\int_{r=0}^{r=1+\cos\theta} (r^2\sin\theta)\, r\, dr\, d\theta \\ &= \frac{1}{4}\int_{\theta=0}^{\theta=\pi} \left[r^4\right]\Big|_{r=0}^{r=1+\cos\theta} \sin\theta\, d\theta \\ &= \frac{1}{4}\int_{\theta=0}^{\theta=\pi} (1+\cos\theta)^4 \sin\theta\, d\theta \\ &= -\frac{1}{4}\left[\frac{(1+\cos\theta)^5}{5}\right]_0^{\pi} = \frac{8}{5}.\end{aligned}$$

## Exercise 15.4.3

Evaluate the integral

$$\iint_D r^2 \sin^2 2\theta\, r\, dr\, d\theta$$

where $D = \left\{(r,\theta)\,|\,0 \le \theta \le \pi,\ 0 \le r \le 2\sqrt{\cos 2\theta}\right\}$.

**Hint**

Graph the region and follow the steps in the previous example.

**Answer**

$\frac{\pi}{8}$

## Polar Areas and Volumes

As in rectangular coordinates, if a solid $S$ is bounded by the surface $z = f(r,\theta)$, as well as by the surfaces $r = a$, $r = b$, $\theta = \alpha$, and $\theta = \beta$, we can find the volume $V$ of $S$ by double integration, as

$$V = \iint_R f(r,\theta)\, r\, dr\, d\theta = \int_{\theta=\alpha}^{\theta=\beta}\int_{r=a}^{r=b} f(r,\theta)\, r\, dr\, d\theta.$$

If the base of the solid can be described as $D = \{(r,\theta)|\alpha \le \theta \le \beta,\ h_1(\theta) \le r \le h_2(\theta)\}$, then the double integral for the volume becomes

$$V = \iint_D f(r,\theta)\, r\, dr\, d\theta = \int_{\theta=\alpha}^{\theta=\beta}\int_{r=h_1(\theta)}^{r=h_2(\theta)} f(r,\theta)\, r\, dr\, d\theta.$$

We illustrate this idea with some examples.

## Example 15.4.4A: Finding a Volume Using a Double Integral

Find the volume of the solid that lies under the paraboloid $z = 1 - x^2 - y^2$ and above the unit circle on the $xy$-plane (Figure 15.4.7).

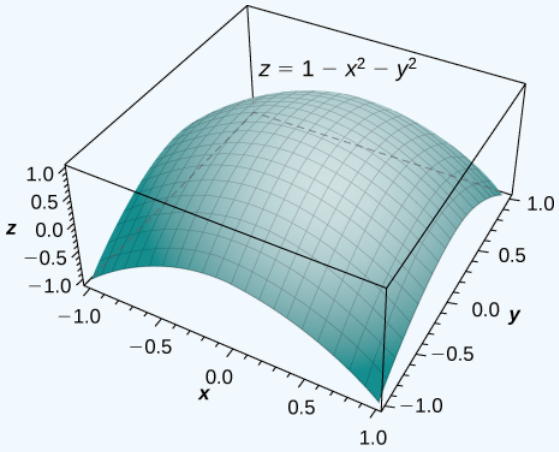

Figure 15.4.7: Finding the volume of a solid under a paraboloid and above the unit circle.

### Solution

By the method of double integration, we can see that the volume is the iterated integral of the form

$$\iint_R (1 - x^2 - y^2)\, dA$$

where $R = \{(r, \theta) \mid 0 \le r \le 1,\ 0 \le \theta \le 2\pi\}$.

This integration was shown before in Example 15.4.2A, so the volume is $\frac{\pi}{2}$ cubic units.

## Example 15.4.4B: Finding a Volume Using Double Integration

Find the volume of the solid that lies under the paraboloid $z = 4 - x^2 - y^2$ and above the disk $(x - 1)^2 + y^2 = 1$ on the $xy$-plane. See the paraboloid in Figure 15.4.8 intersecting the cylinder $(x - 1)^2 + y^2 = 1$ above the $xy$-plane.

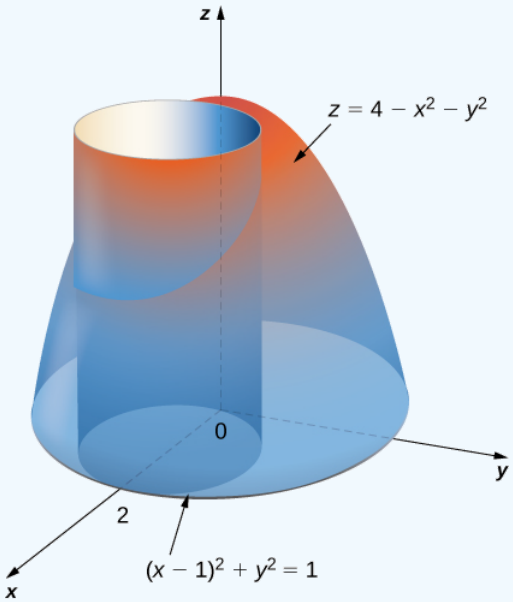

Figure 15.4.8: Finding the volume of a solid with a paraboloid cap and a circular base.

### Solution

First change the disk $(x-1)^2+y^2=1$ to polar coordinates. Expanding the square term, we have $x^2-2x+1+y^2=1$. Then simplify to get $x^2+y^2=2x$, which in polar coordinates becomes $r^2=2r\cos\theta$ and then either $r=0$ or $r=2\cos\theta$. Similarly, the equation of the paraboloid changes to $z=4-r^2$. Therefore we can describe the disk $(x-1)^2+y^2=1$ on the $xy$ -plane as the region

$$D=\{(r,\theta)\,|\,0\le\theta\le\pi,\ 0\le r\le 2\cos\theta\}.$$

Hence the volume of the solid bounded above by the paraboloid $z=4-x^2-y^2$ and below by $r=2\cos\theta$ is

$$\begin{aligned}V&=\iint_D f(r,\theta)\,r\,dr\,d\theta\\&=\int_{\theta=0}^{\theta=\pi}\int_{r=0}^{r=2\cos\theta}(4-r^2)\,r\,dr\,d\theta\\&=\int_{\theta=0}^{\theta=\pi}\left[4\frac{r^2}{2}-\frac{r^4}{4}\Big|_0^{2\cos\theta}\right]d\theta\\&=\int_0^{\pi}[8\cos^2\theta-4\cos^4\theta]\,d\theta\\&=\left[\frac{5}{2}\theta+\frac{5}{2}\sin\theta\cos\theta-\sin\theta\cos^3\theta\right]_0^{\pi}=\frac{5}{2}\pi\ \text{units}^3.\end{aligned}$$

Notice in the next example that integration is not always easy with polar coordinates. Complexity of integration depends on the function and also on the region over which we need to perform the integration. If the region has a more natural expression in polar coordinates or if $f$ has a simpler antiderivative in polar coordinates, then the change in polar coordinates is appropriate; otherwise, use rectangular coordinates.

### Example 15.4.5A: Finding a Volume Using a Double Integral

Find the volume of the region that lies under the paraboloid $z=x^2+y^2$ and above the triangle enclosed by the lines $y=x$, $x=0$, and $x+y=2$ in the $xy$-plane.

### Solution

First examine the region over which we need to set up the double integral and the accompanying paraboloid.

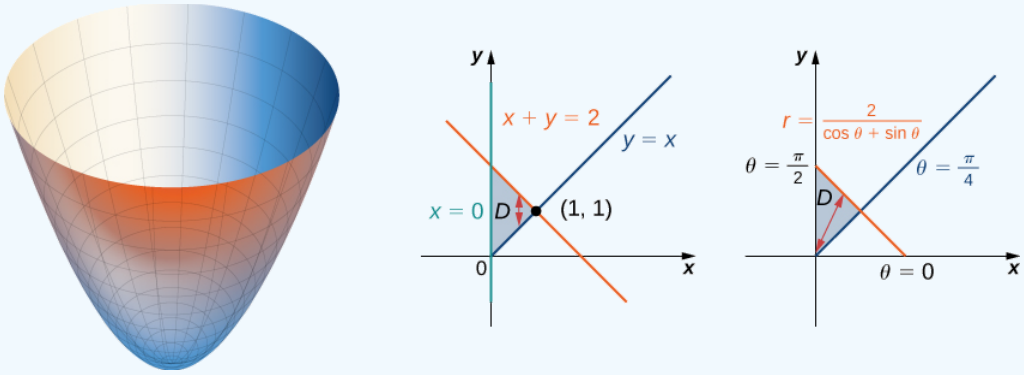

Figure 15.4.9: Finding the volume of a solid under a paraboloid and above a given triangle.

The region $D$ is $\{(x,y)\,|\,0\le x\le 1,\ x\le y\le 2-x\}$. Converting the lines $y=x$, $x=0$, and $x+y=2$ in the $xy$-plane to functions of $r$ and $\theta$ we have $\theta=\pi/4$, $\theta=\pi/2$, and $r=2/(\cos\theta+\sin\theta)$, respectively. Graphing the region on the $xy$- plane, we see that it looks like $D=\{(r,\theta)\,|\,\pi/4\le\theta\le\pi/2,\ 0\le r\le 2/(\cos\theta+\sin\theta)\}$.

Now converting the equation of the surface gives $z=x^2+y^2=r^2$. Therefore, the volume of the solid is given by the double integral

$$
\begin{aligned}
V &= \iint_D f(r,\theta)\, r\, dr\, d\theta \\
&= \int_{\theta=\pi/4}^{\theta=\pi/2} \int_{r=0}^{r=2/(\cos\theta+\sin\theta)} r^2 r\, dr d\theta \\
&= \int_{\pi/4}^{\pi/2} \left[\frac{r^4}{4}\right]_0^{2/(\cos\theta+\sin\theta)} d\theta \\
&= \frac{1}{4}\int_{\pi/4}^{\pi/2} \left(\frac{2}{\cos\theta+\sin\theta}\right)^4 d\theta \\
&= \frac{16}{4}\int_{\pi/4}^{\pi/2} \left(\frac{1}{\cos\theta+\sin\theta}\right)^4 d\theta \\
&= 4\int_{\pi/4}^{\pi/2} \left(\frac{1}{\cos\theta+\sin\theta}\right)^4 d\theta.
\end{aligned}
$$

As you can see, this integral is very complicated. So, we can instead evaluate this double integral in rectangular coordinates as

$$V = \int_0^1 \int_x^{2-x} (x^2+y^2)\, dy\, dx.$$

Evaluating gives

$$
\begin{aligned}
V &= \int_0^1 \int_x^{2-x} (x^2+y^2)\, dy\, dx \\
&= \int_0^1 \left[x^2 y + \frac{y^3}{3}\right]\Big|_x^{2-x} dx \\
&= \int_0^1 \frac{8}{3} - 4x + 4x^2 - \frac{8x^3}{3}\, dx \\
&= \left[\frac{8x}{3} - 2x^2 + \frac{4x^3}{3} - \frac{2x^4}{3}\right]\Big|_0^1 \\
&= \frac{4}{3}\ \text{units}^3.
\end{aligned}
$$

To answer the question of how the formulas for the volumes of different standard solids such as a sphere, a cone, or a cylinder are found, we want to demonstrate an example and find the volume of an arbitrary cone.

### Example 15.4.5$B$: Finding a Volume Using a Double Integral

Use polar coordinates to find the volume inside the cone $z = 2 - \sqrt{x^2+y^2}$ and above the $xy$-plane.

#### Solution

The region $D$ for the integration is the base of the cone, which appears to be a circle on the $xy$-plane (Figure 15.4.10).

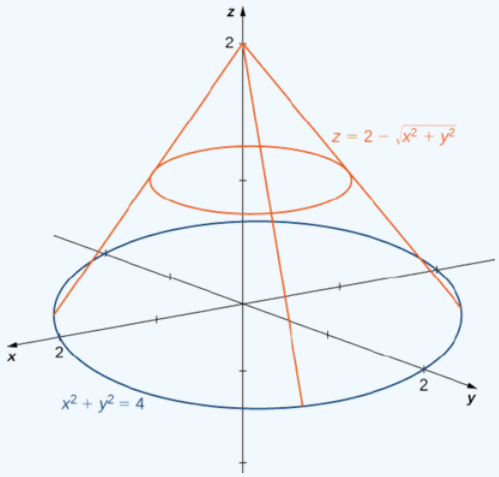

Figure 15.4.10: Finding the volume of a solid inside the cone and above the $xy$-plane.

We find the equation of the circle by setting $z = 0$:

$$\begin{aligned} 0 &= 2 - \sqrt{x^2 + y^2} \\ 2 &= \sqrt{x^2 + y^2} \\ x^2 + y^2 &= 4. \end{aligned}$$

This means the radius of the circle is $2$ so for the integration we have $0 \le \theta \le 2\pi$ and $0 \le r \le 2$. Substituting $x = r\cos\theta$ and $y = r\sin\theta$ in the equation $z = 2 - \sqrt{x^2 + y^2}$ we have $z = 2 - r$. Therefore, the volume of the cone is

$$\int_{\theta=0}^{\theta=2\pi} \int_{r=0}^{r=2} (2 - r)\, r\, dr\, d\theta = 2\pi \frac{4}{3} = \frac{8\pi}{3} \text{ cubic units.}$$

**Analysis**

Note that if we were to find the volume of an arbitrary cone with radius $a$ units and height $h$ units, then the equation of the cone would be $z = h - \frac{h}{a}\sqrt{x^2 + y^2}$.

We can still use Figure 15.4.10 and set up the integral as

$$\int_{\theta=0}^{\theta=2\pi} \int_{r=0}^{r=a} \left(h - \frac{h}{a} r\right) r\, dr\, d\theta.$$

Evaluating the integral, we get $\frac{1}{3}\pi a^2 h$.

## Exercise 15.4.5

Use polar coordinates to find an iterated integral for finding the volume of the solid enclosed by the paraboloids $z = x^2 + y^2$ and $z = 16 - x^2 - y^2$.

**Hint**

Sketching the graphs can help.

**Answer**

$$V = \int_0^{2\pi} \int_0^{2\sqrt{2}} (16 - 2r^2)\, r\, dr\, d\theta = 64\pi \text{ cubic units.}$$

As with rectangular coordinates, we can also use polar coordinates to find areas of certain regions using a double integral. As before, we need to understand the region whose area we want to compute. Sketching a graph and identifying the region can be helpful to realize the limits of integration. Generally, the area formula in double integration will look like

$$\text{Area of } A = \int_\alpha^\beta \int_{h_1(\theta)}^{h_2(\theta)} 1\, r\, dr\, d\theta.$$

## Example 15.4.6A: Finding an Area Using a Double Integral in Polar Coordinates

Evaluate the area bounded by the curve $r = \cos 4\theta$.

### Solution

Sketching the graph of the function $r = \cos 4\theta$ reveals that it is a polar rose with eight petals (see the following figure).

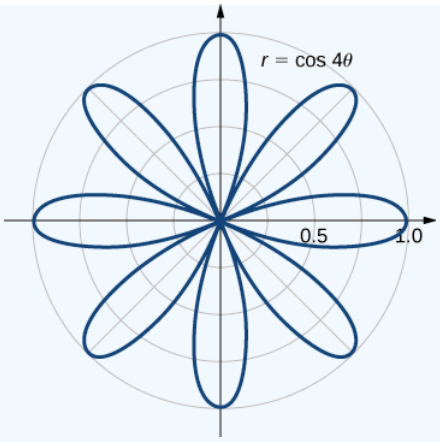

Figure 15.4.11: Finding the area of a polar rose with eight petals.

Using symmetry, we can see that we need to find the area of one petal and then multiply it by 8. Notice that the values of $\theta$ for which the graph passes through the origin are the zeros of the function $\cos\ 4\theta$, and these are odd multiples of $\pi/8$. Thus, one of the petals corresponds to the values of $\theta$ in the interval $[-\pi/8, \pi/8]$. Therefore, the area bounded by the curve $r = \cos\ 4\theta$ is

$$\begin{aligned} A &= 8\int_{\theta=-\pi/8}^{\theta=\pi/8}\int_{r=0}^{r=\cos\ 4\theta} 1\, r\, dr\, d\theta \\ &= 8\int_{\theta=-\pi/8}^{\theta=\pi/8}\left[\frac{1}{2}r^2\Big|_0^{\cos\ 4\theta}\right] d\theta \\ &= 8\int_{-\pi/8}^{\pi/8}\frac{1}{2}\cos^2 4\theta\, d\theta \\ &= 8\left[\frac{1}{4}\theta + \frac{1}{16}\sin\ 4\theta\ \cos\ 4\theta\Big|_{-\pi/8}^{\pi/8}\right] \\ &= 8\left[\frac{\pi}{16}\right] = \frac{\pi}{2}\ \text{units}^2. \end{aligned}$$

## Example 15.4.6$B$: Finding Area Between Two Polar Curves

Find the area enclosed by the circle $r = 3\ \cos\ \theta$ and the cardioid $r = 1 + \cos\ \theta$.

### Solution

First and foremost, sketch the graphs of the region (Figure 15.4.12).

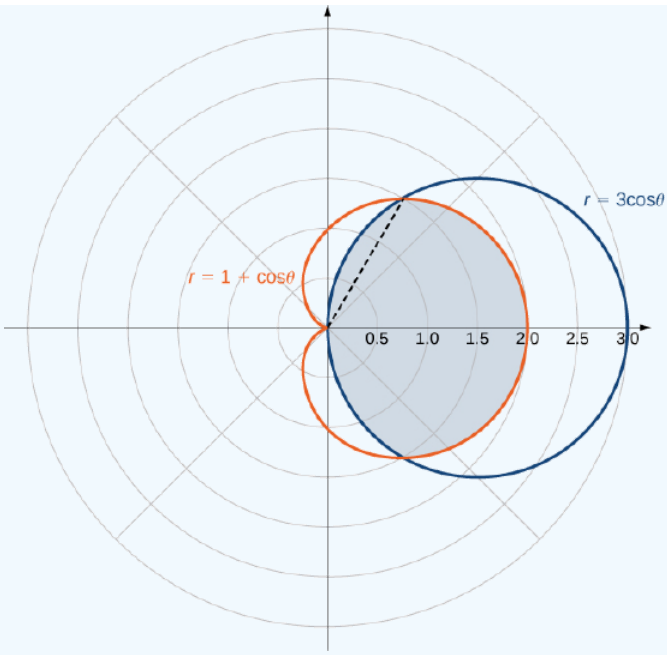

Figure 15.4.12: Finding the area enclosed by both a circle and a cardioid.

We can from see the symmetry of the graph that we need to find the points of intersection. Setting the two equations equal to each other gives

$$3\cos\theta = 1 + \cos\theta.$$

One of the points of intersection is $\theta = \pi/3$. The area above the polar axis consists of two parts, with one part defined by the cardioid from $\theta = 0$ to $\theta = \pi/3$ and the other part defined by the circle from $\theta = \pi/3$ to $\theta = \pi/2$. By symmetry, the total area is twice the area above the polar axis. Thus, we have

$$A = 2\left[\int_{\theta=0}^{\theta=\pi/3}\int_{r=0}^{r=1+\cos\theta} 1\,r\,dr\,d\theta + \int_{\theta=\pi/3}^{\theta=\pi/2}\int_{r=0}^{r=3\cos\theta} 1\,r\,dr\,d\theta\right].$$

Evaluating each piece separately, we find that the area is

$$A = 2\left(\frac{1}{4}\pi + \frac{9}{16}\sqrt{3} + \frac{3}{8}\pi - \frac{9}{16}\sqrt{3}\right) = 2\left(\frac{5}{8}\pi\right) = \frac{5}{4}\pi \text{ square units.}$$

## ? Exercise 15.4.6

Find the area enclosed inside the cardioid $r = 3 - 3\sin\theta$ and outside the cardioid $r = 1 + \sin\theta$.

**Hint**

Sketch the graph, and solve for the points of intersection.

**Answer**

$$A = 2\int_{-\pi/2}^{\pi/6}\int_{1+\sin\theta}^{3-3\sin\theta} r\,dr\,d\theta = \left(8\pi + 9\sqrt{3}\right) \text{ units}^2$$

## ✓ Example 15.4.7: Evaluating an Improper Double Integral in Polar Coordinates

Evaluate the integral

$$\iint_{R^2} e^{-10(x^2+y^2)}\,dx\,dy.$$

**Solution**

This is an improper integral because we are integrating over an unbounded region $R^2$. In polar coordinates, the entire plane $R^2$ can be seen as $0 \le \theta \le 2\pi$, $0 \le r \le \infty$.

Using the changes of variables from rectangular coordinates to polar coordinates, we have

$$\begin{aligned}\iint_{R^2} e^{-10(x^2+y^2)}\,dx\,dy &= \int_{\theta=0}^{\theta=2\pi}\int_{r=0}^{r=\infty} e^{-10r^2}\,r\,dr\,d\theta = \int_{\theta=0}^{\theta=2\pi}\left(\lim_{a\to\infty}\int_{r=0}^{r=a} e^{-10r^2}\,r\,dr\right)d\theta \\ &= \left(\int_{\theta=0}^{\theta=2\pi} d\theta\right)\left(\lim_{a\to\infty}\int_{r=0}^{r=a} e^{-10r^2}\,r\,dr\right) \\ &= 2\pi\left(\lim_{a\to\infty}\int_{r=0}^{r=a} e^{-10r^2}\,r\,dr\right) \\ &= 2\pi\lim_{a\to\infty}\left(-\frac{1}{20}\right)\left(e^{-10r^2}\Big|_0^a\right) \\ &= 2\pi\left(-\frac{1}{20}\right)\lim_{a\to\infty}\left(e^{-10a^2}-1\right) \\ &= \frac{\pi}{10}.\end{aligned}$$

**? Exercise 15.4.7**

Evaluate the integral

$$\iint_{R^2} e^{-4(x^2+y^2)}dx\,dy.$$

**Hint**

Convert to the polar coordinate system.

**Answer**

$\frac{\pi}{4}$

## Key Concepts

- To apply a double integral to a situation with circular symmetry, it is often convenient to use a double integral in polar coordinates. We can apply these double integrals over a polar rectangular region or a general polar region, using an iterated integral similar to those used with rectangular double integrals.
- The area $dA$ in polar coordinates becomes $r\,dr\,d\theta$.
- Use $x = r\cos\theta$, $y = r\sin\theta$, and $dA = r\,dr\,d\theta$ to convert an integral in rectangular coordinates to an integral in polar coordinates.
- Use $r^2 = x^2 + y^2$ and $\theta = tan^{-1}\left(\frac{y}{x}\right)$ to convert an integral in polar coordinates to an integral in rectangular coordinates, if needed.
- To find the volume in polar coordinates bounded above by a surface $z = f(r,\theta)$ over a region on the $xy$-plane, use a double integral in polar coordinates.

## Key Equations

- **Double integral over a polar rectangular region** $R$

$$\iint_R f(r,\theta)dA = \lim_{m,n\to\infty}\sum_{i=1}^{m}\sum_{j=1}^{n} f(r_{ij}^*,\theta_{ij}^*)\Delta A = \lim_{m,n\to\infty}\sum_{i=1}^{m}\sum_{j=1}^{n} f(r_{ij}^*,\theta_{ij}^*)r_{ij}^*\Delta r\Delta\theta$$

- **Double integral over a general polar region**

$$\iint_D f(r,\theta)\,r\,dr\,d\theta = \int_{\theta=\alpha}^{\theta=\beta}\int_{r=h_1(\theta)}^{r_2(\theta)} f(r,\theta)\,r\,dr\,d\theta$$

## Glossary

**polar rectangle**

the region enclosed between the circles $r = a$ and $r = b$ and the angles $\theta = \alpha$ and $\theta = \beta$; it is described as $R = \{(r, \theta) \mid a \leq r \leq b, \alpha \leq \theta \leq \beta\}$

# 15.4E: EXERCISES FOR SECTION 15.3

## TERMS AND CONCEPTS

1. When evaluating $\int\int_R f(x,y)\,dA$ using polar coordinates, $f(x,y)$ is replaced with _____ and $dA$ is replaced with _____.

**Answer**

$f(x,y)$ is replaced with $f(r\cos\theta, r\sin\theta)$ and $dA$ is replaced with $r\,dr\,d\theta$.

2. Why would one be interested in evaluating a double integral with polar coordinates?

## DEFINING POLAR REGIONS

**In exercises 3 - 6, express the region $R$ in polar coordinates.**

3) $R$ is the region of the disk of radius 2 centered at the origin that lies in the first quadrant.

**Answer**

$R = \{(r,\theta)\,|\,0 \le r \le 2,\ 0 \le \theta \le \frac{\pi}{2}\}$

4) $R$ is the region of the disk of radius 3 centered at the origin.

5) $R$ is the region between the circles of radius 4 and radius 5 centered at the origin that lies in the second quadrant.

**Answer**

$R = \{(r,\theta)\,|\,4 \le r \le 5,\ \frac{\pi}{2} \le \theta \le \pi\}$

6) $R$ is the region bounded by the $y$-axis and $x = \sqrt{1-y^2}$.

7) $R$ is the region bounded by the $x$-axis and $y = \sqrt{2-x^2}$.

**Answer**

$R = \{(r,\theta)\,|\,0 \le r \le \sqrt{2},\ 0 \le \theta \le \pi\}$

8) $R = \{(x,y)\,|\,x^2+y^2 \le 4x\}$

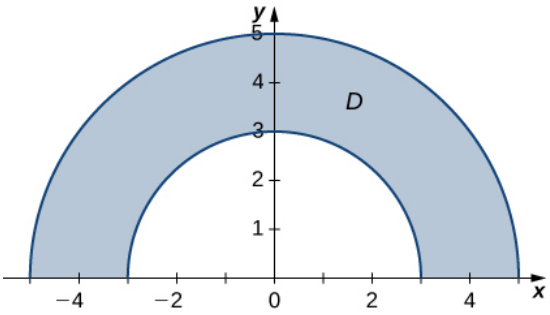
9) $R = \{(x,y)\,|\,x^2+y^2 \le 4y\}$

**Answer**

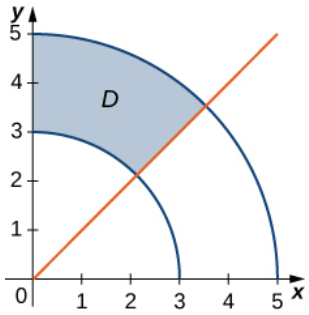
$R = \{(r,\theta)\,|\,0 \le r \le 4\,\sin\theta,\ 0 \le \theta \le \pi\}$

**In exercises 10 - 15, the graph of the polar rectangular region $D$ is given. Express $D$ in polar coordinates. In exercises 10 - 13 the regions are bounded by circles centered at the origin, the coordinate axes, and/or lines of the form $y = \pm x$ (each of which should be able to be identified by inspection).**

10)



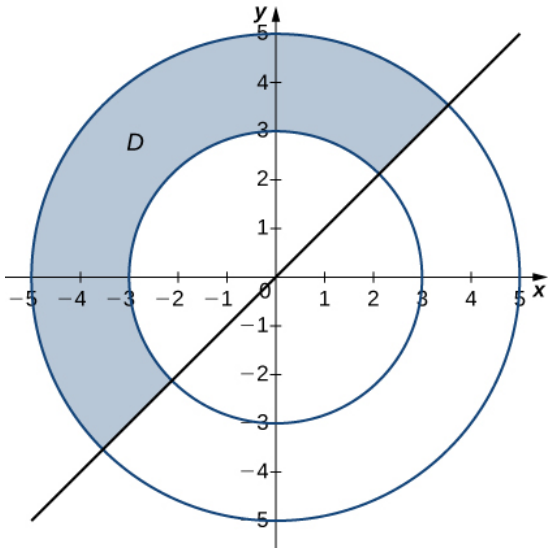
11)



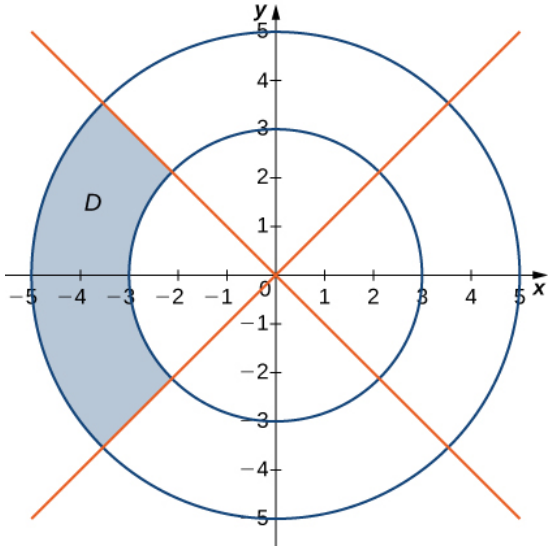
**Answer**

$D = \{(r, \theta) \mid 3 \leq r \leq 5,\ \frac{\pi}{4} \leq \theta \leq \frac{\pi}{2}\}$

12)



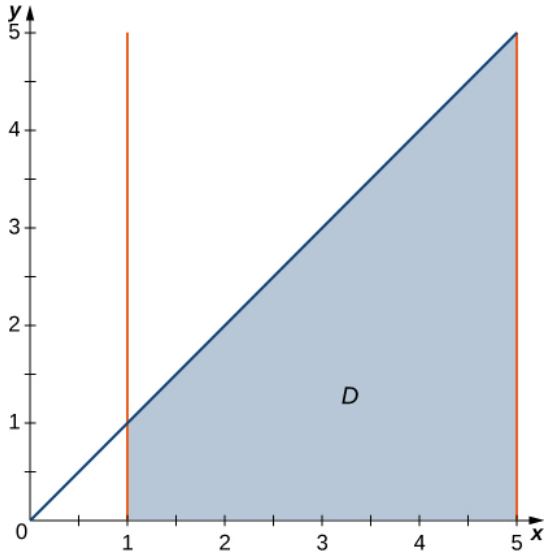
13)



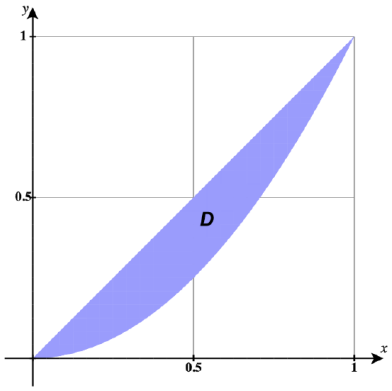
**Answer**

$D = \{(r, \theta) \mid 3 \leq r \leq 5,\ \frac{3\pi}{4} \leq \theta \leq \frac{5\pi}{4}\}$

14) In the following graph, the region $D$ is situated below $y = x$ and is bounded by $x = 1,\ x = 5$, and $y = 0$.



15) In the following graph, the region $D$ is bounded by $y = x$ and $y = x^2$.



**Answer**

$D = \{(r, \theta) \mid 0 \le r \le \tan\theta \sec\theta,\ 0 \le \theta \le \frac{\pi}{4}\}$

## EVALUATING POLAR DOUBLE INTEGRALS

**In exercises 16 - 25, evaluate the double integral $\iint_R f(x, y)\, dA$ over the polar rectangular region $R$.**

16) $f(x, y) = x^2 + y^2$, $R = \{(r, \theta) \mid 3 \le r \le 5,\ 0 \le \theta \le 2\pi\}$

17) $f(x, y) = x + y$, $R = \{(r, \theta) \mid 3 \le r \le 5,\ 0 \le \theta \le 2\pi\}$

**Answer**

0

18) $f(x, y) = x^2 + xy,\ R = \{(r, \theta) \mid 1 \le r \le 2,\ \pi \le \theta \le 2\pi\}$

19) $f(x, y) = x^4 + y^4,\ R = \{(r, \theta) \mid 1 \le r \le 2,\ \frac{3\pi}{2} \le \theta \le 2\pi\}$

**Answer**

$\frac{63\pi}{16}$

20) $f(x, y) = \sqrt[3]{x^2 + y^2}$, where $R = \{(r, \theta) \mid 0 \le r \le 1,\ \frac{\pi}{2} \le \theta \le \pi\}$.

21) $f(x, y) = x^4 + 2x^2y^2 + y^4$, where $R = \{(r, \theta) \mid 3 \le r \le 4,\ \frac{\pi}{3} \le \theta \le \frac{2\pi}{3}\}$.

**Answer**

$\frac{3367\pi}{18}$

22) $f(x,y) = \sin(\arctan\frac{y}{x})$, where $R = \{(r,\theta) \mid 1 \le r \le 2,\ \frac{\pi}{6} \le \theta \le \frac{\pi}{3}\}$

23) $f(x,y) = \arctan\left(\frac{y}{x}\right)$, where $R = \{(r,\theta) \mid 2 \le r \le 3,\ \frac{\pi}{4} \le \theta \le \frac{\pi}{3}\}$

**Answer**

$\frac{35\pi^2}{576}$

24) $\iint_R e^{x^2+y^2}\left[1 + 2\ \arctan\left(\frac{y}{x}\right)\right] dA,\ R = \{(r,\theta) \mid 1 \le r \le 2,\ \frac{\pi}{6} \le \theta \frac{\pi}{3}\}$

25) $\iint_R \left(e^{x^2+y^2} + x^4 + 2x^2y^2 + y^4\right) \arctan\left(\frac{y}{x}\right) dA,\ R = \{(r,\theta) \mid 1 \le r \le 2,\ \frac{\pi}{4} \le \theta \le \frac{\pi}{3}\}$

**Answer**

$\frac{7}{576}\pi^2(21 - e + e^4)$

## CONVERTING DOUBLE INTEGRALS TO POLAR FORM

**In exercises 26 - 29, the integrals have been converted to polar coordinates. Verify that the identities are true and choose the easiest way to evaluate the integrals, in rectangular or polar coordinates.**

26) $\int_1^2 \int_0^x (x^2 + y^2)\, dy\, dx = \int_0^{\frac{\pi}{4}} \int_{\sec\theta}^{2\sec\theta} r^3\, dr\, d\theta$

27) $\int_2^3 \int_0^x \frac{x}{\sqrt{x^2+y^2}}\, dy\, dx = \int_0^{\pi/4} \int_{2\sec\theta}^{3\sec\theta} r\ \cos\theta\, dr\, d\theta$

**Answer**

$\frac{5}{2}\ln(1+\sqrt{2})$

28) $\int_0^1 \int_{x^2}^x \frac{1}{\sqrt{x^2+y^2}}\, dy\, dx = \int_0^{\pi/4} \int_0^{\tan\theta\ \sec\theta} dr\, d\theta$

29) $\int_0^1 \int_{x^2}^x \frac{y}{\sqrt{x^2+y^2}}\, dy\, dx = \int_0^{\pi/4} \int_0^{\tan\theta\ \sec\theta} r\ \sin\theta\, dr\, d\theta$

**Answer**

$\frac{1}{6}(2 - \sqrt{2})$

**In exercises 30 - 37, draw the region of integration, $R$, labeling all limits of integration, convert the integrals to polar coordinates and evaluate them.**

30) $\int_0^3 \int_0^{\sqrt{9-y^2}} (x^2 + y^2)\, dx\, dy$

31) $\int_0^2 \int_{-\sqrt{4-y^2}}^{\sqrt{4-y^2}} (x^2 + y^2)^2\, dx\, dy$

**Answer**

$\int_0^{\pi} \int_0^2 r^5\, dr\, d\theta \quad = \quad \frac{32\pi}{3}$

32) $\int_0^1 \int_0^{\sqrt{1-x^2}} (x + y)\, dy\, dx$

33) $\int_0^4 \int_{-\sqrt{16-x^2}}^{\sqrt{16-x^2}} \sin(x^2 + y^2)\, dy\, dx$

**Answer**

$\int_{-\pi/2}^{\pi/2} \int_0^4 r\ \sin(r^2)\, dr\, d\theta \quad = \quad \pi\ \sin^2 8$

34) $\int_0^5 \int_{-\sqrt{25-x^2}}^{\sqrt{25-x^2}} \sqrt{x^2+y^2}\, dy\, dx$

35) $\int_{-4}^4 \int_{-\sqrt{16-y^2}}^0 (2y - x)\, dx\, dy$

**Answer**

$$\int_{\frac{\pi}{2}}^{\frac{3\pi}{2}} \int_0^4 \left(2r\sin\theta - r\cos\theta\right) r\,dr\,d\theta \quad = \quad \frac{128}{3}$$

36) $\int_0^2 \int_y^{\sqrt{8-y^2}} (x+y)\,dx\,dy$

37) $\int_{-2}^{-1} \int_0^{\sqrt{4-x^2}} (x+5)\,dy\,dx + \int_{-1}^{1} \int_{\sqrt{1-x^2}}^{\sqrt{4-x^2}} (x+5)\,dy\,dx + \int_1^2 \int_0^{\sqrt{4-x^2}} (x+5)\,dy\,dx$

**Answer**

$$\int_0^{\pi} \int_1^2 \left(r\cos\theta + 5\right) r\,dr\,d\theta \quad = \quad \frac{15\pi}{2}$$

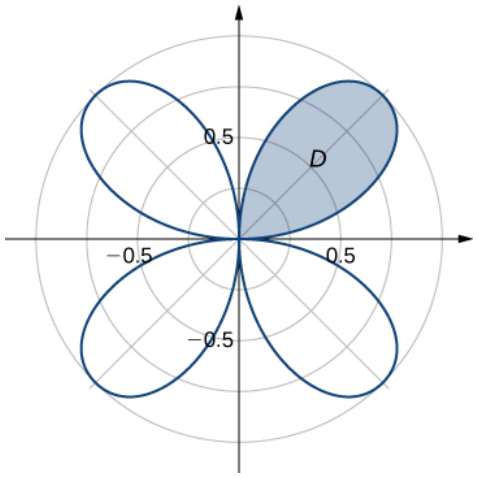
38) Evaluate the integral $\iint_D r\,dA$ where $D$ is the region bounded by the polar axis and the upper half of the cardioid $r = 1 + \cos\theta$.

39) Find the area of the region $D$ bounded by the polar axis and the upper half of the cardioid $r = 1 + \cos\theta$.

**Answer**

$\frac{3\pi}{4}$

40) Evaluate the integral $\iint_D r\,dA$, where $D$ is the region bounded by the part of the four-leaved rose $r = \sin 2\theta$ situated in the first quadrant (see the following figure).



41) Find the total area of the region enclosed by the four-leaved rose $r = \sin 2\theta$ (see the figure in the previous exercise).

**Answer**

$\frac{\pi}{2}$

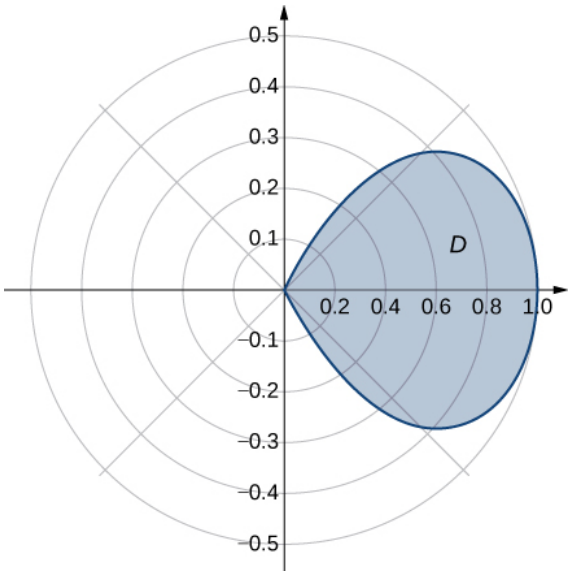
42) Find the area of the region $D$ which is the region bounded by $y = \sqrt{4 - x^2}$, $x = \sqrt{3}$, $x = 2$, and $y = 0$.

43) Find the area of the region $D$, which is the region inside the disk $x^2 + y^2 \leq 4$ and to the right of the line $x = 1$.

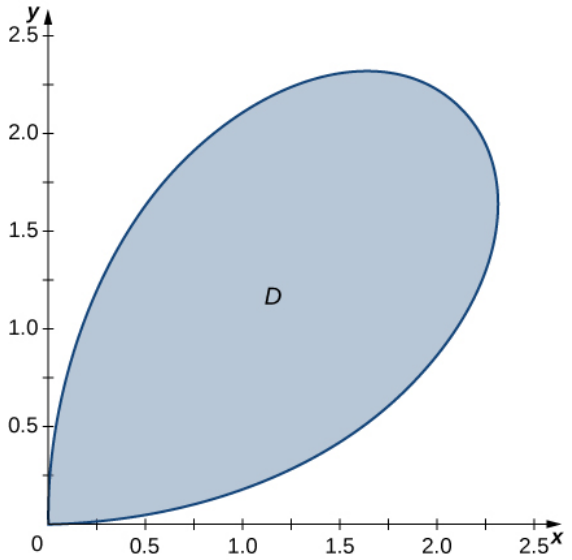
**Answer**

$\frac{1}{3}(4\pi - 3\sqrt{3})$

44) Determine the average value of the function $f(x, y) = x^2 + y^2$ over the region $D$ bounded by the polar curve $r = \cos 2\theta$, where $-\frac{\pi}{4} \leq \theta \leq \frac{\pi}{4}$ (see the following graph).



45) Determine the average value of the function $f(x,y) = \sqrt{x^2+y^2}$ over the region $D$ bounded by the polar curve $r = 3\sin 2\theta$, where $0 \le \theta \le \frac{\pi}{2}$ (see the following graph).



**Answer**

$\frac{16}{3\pi}$

46) Find the volume of the solid situated in the first octant and bounded by the paraboloid $z = 1 - 4x^2 - 4y^2$ and the planes $x = 0,\ y = 0$, and $z = 0$.

47) Find the volume of the solid bounded by the paraboloid $z = 2 - 9x^2 - 9y^2$ and the plane $z = 1$.

**Answer**

$\frac{\pi}{18}$

48)

1. Find the volume of the solid $S_1$ bounded by the cylinder $x^2 + y^2 = 1$ and the planes $z = 0$ and $z = 1$.
2. Find the volume of the solid $S_2$ outside the double cone $z^2 = x^2 + y^2$ inside the cylinder $x^2 + y^2 = 1$, and above the plane $z = 0$.
3. Find the volume of the solid inside the cone $z^2 = x^2 + y^2$ and below the plane $z = 1$ by subtracting the volumes of the solids $S_1$ and $S_2$.

49)

1. Find the volume of the solid $S_1$ inside the unit sphere $x^2 + y^2 + z^2 = 1$ and above the plane $z = 0$.

2. Find the volume of the solid $S_2$ inside the double cone $(z-1)^2 = x^2 + y^2$ and above the plane $z = 0$.
3. Find the volume of the solid outside the double cone $(z-1)^2 = x^2 + y^2$ and inside the sphere $x^2 + y^2 + z^2 = 1$.

**Answer**

a. $\frac{2\pi}{3}$; b. $\frac{\pi}{2}$; c. $\frac{\pi}{6}$

**In Exercises 50-51, special double integrals are presented that are especially well suited for evaluation in polar coordinates.**

50) The surface of a right circular cone with height $h$ and base radius $a$ can be described by the equation $f(x,y) = h - h\sqrt{\frac{x^2}{a^2} + \frac{y^2}{a^2}}$, where the tip of the cone lies at $(0,0,h)$ and the circular base lies in the $xy$-plane, centered at the origin.
Confirm that the volume of a right circular cone with height $h$ and base radius $a$ is $V = \frac{1}{3}\pi a^2 h$ by evaluating $\int\int_R f(x,y)\, dA$ in polar coordinates.

51) Consider $\int\int_R e^{-(x^2+y^2)}\, dA$.
(a) Why is this integral difficult to evaluate in rectangular coordinates, regardless of the region $R$?
(b) Let $R$ be the region bounded by the circle of radius $a$ centered at the origin. Evaluate the double integral using polar coordinates.
(c) Take the limit of your answer from (b), as $a \to \infty$. What does this imply about the volume under the surface of $e^{-(x^2+y^2)}$ over the entire $xy$ -plane?

**For the following two exercises, consider a spherical ring, which is a sphere with a cylindrical hole cut so that the axis of the cylinder passes through the center of the sphere (see the following figure).**

52) If the sphere has radius 4 and the cylinder has radius 2 find the volume of the spherical ring.

53) A cylindrical hole of diameter 6 cm is bored through a sphere of radius 5 cm such that the axis of the cylinder passes through the center of the sphere. Find the volume of the resulting spherical ring.

**Answer**

$\frac{256\pi}{3}$ cm$^3$

54) Find the volume of the solid that lies under the double cone $z^2 = 4x^2 + 4y^2$, inside the cylinder $x^2 + y^2 = x$, and above the plane $z = 0$.

55) Find the volume of the solid that lies under the paraboloid $z = x^2 + y^2$, inside the cylinder $x^2 + y^2 = 1$ and above the plane $z = 0$.

**Answer**

$\frac{3\pi}{32}$

56) Find the volume of the solid that lies under the plane $x + y + z = 10$ and above the disk $x^2 + y^2 = 4x$.

57) Find the volume of the solid that lies under the plane $2x + y + 2z = 8$ and above the unit disk $x^2 + y^2 = 1$.

**Answer**

$4\pi$

58) A radial function $f$ is a function whose value at each point depends only on the distance between that point and the origin of the system of coordinates; that is, $f(x,y) = g(r)$, where $r = \sqrt{x^2 + y^2}$. Show that if $f$ is a continuous radial function, then

$$\iint_D f(x,y)dA = (\theta_2 - \theta_1)[G(R_2) - G(R_1)], \text{ where } G'(r) = rg(r)$$

and $(x,y) \in D = \{(r,\theta) \mid R_1 \le r \le R_2,\ 0 \le \theta \le 2\pi\}$, with $0 \le R_1 < R_2$ and $0 \le \theta_1 < \theta_2 \le 2\pi$.

59) Use the information from the preceding exercise to calculate the integral $\iint_D (x^2+y^2)^3 dA$, where $D$ is the unit disk.

**Answer**

$\frac{\pi}{4}$

60) Let $f(x,y) = \dfrac{F'(r)}{r}$ be a continuous radial function defined on the annular region $D = \{(r,\theta) \mid R_1 \le r \le R_2,\ 0 \le \theta \le 2\pi\}$, where $r = \sqrt{x^2+y^2}$, $0 < R_1 < R_2$, and $F$ is a differentiable function.

Show that $\iint_D f(x,y)\,dA = 2\pi[F(R_2) - F(R_1)]$.

61) Apply the preceding exercise to calculate the integral $\iint_D \dfrac{e^{\sqrt{x^2+y^2}}}{\sqrt{x^2+y^2}}\,dx\,dy$ where $D$ is the annular region between the circles of radii 1 and 2 situated in the third quadrant.

**Answer**

$\frac{1}{2}\pi e(e-1)$

62) Let $f$ be a continuous function that can be expressed in polar coordinates as a function of $\theta$ only; that is, $f(x,y) = h(\theta)$, where $(x,y) \in D = \{(r,\theta) \mid R_1 \le r \le R_2,\ \theta_1 \le \theta \le \theta_2\}$, with $0 \le R_1 < R_2$ and $0 \le \theta_1 < \theta_2 \le 2\pi$.

Show that $\iint_D f(x,y)\,dA = \dfrac{1}{2}(R_2^2 - R_1^2)[H(\theta_2) - H(\theta_1)]$, where $H$ is an antiderivative of $h$.

63) Apply the preceding exercise to calculate the integral $\iint_D \dfrac{y^2}{x^2}\,dA$, where $D = \{(r,\theta) \mid 1 \le r \le 2,\ \frac{\pi}{6} \le \theta \le \frac{\pi}{3}\}$.

**Answer**

$\sqrt{3} - \frac{\pi}{4}$

64) Let $f$ be a continuous function that can be expressed in polar coordinates as a function of $\theta$ only; that is $f(x,y) = g(r)h(\theta)$, where $(x,y) \in \{(r,\theta) \mid R_1 \le r \le R_2,\ \theta_1 \le \theta \le \theta_2\}$ with $0 \le R_1 < R_2$ and $0 \le \theta_1 < \theta_2 \le 2\pi$. Show that

$$\iint_D f(x,y)\,dA = [G(R_2) - G(R_1)]\ [H(\theta_2) - H(\theta_1)],$$

where $G$ and $H$ are antiderivatives of $g$ and $h$, respectively.

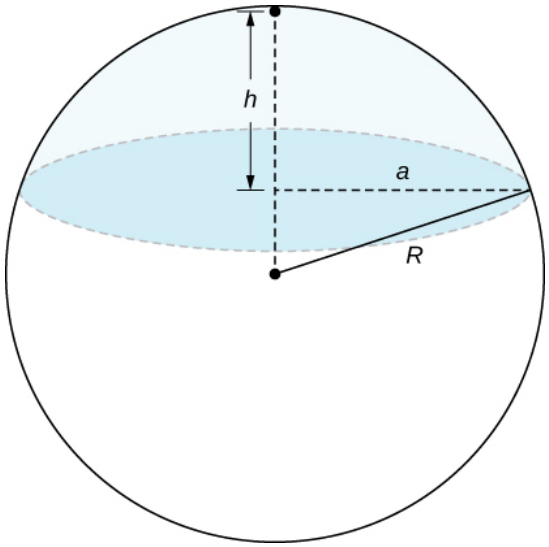
65) Evaluate $\iint_D \arctan\left(\dfrac{y}{x}\right)\sqrt{x^2+y^2}\,dA$, where $D = \{(r,\theta) \mid 2 \le r \le 3,\ \frac{\pi}{4} \le \theta \le \frac{\pi}{3}\}$.

**Answer**

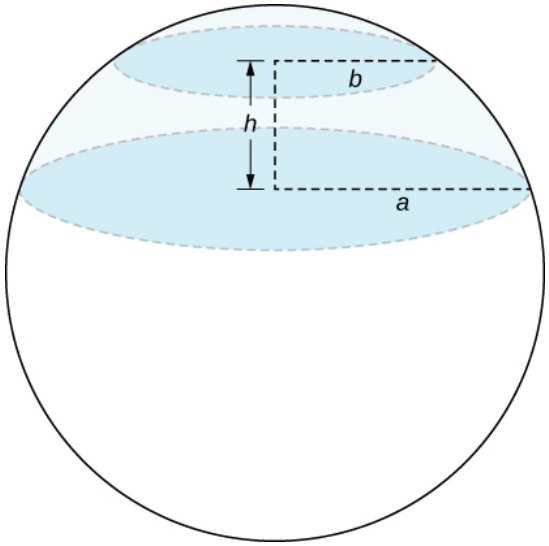
$\frac{133}{864}\pi^2$

66) A spherical cap is the region of a sphere that lies above or below a given plane.

a. Show that the volume of the spherical cap in the figure below is $\frac{1}{6}\pi h(3a^2 + h^2)$.



b. A spherical segment is the solid defined by intersecting a sphere with two parallel planes. If the distance between the planes is $h$ show that the volume of the spherical segment in the figure below is $\frac{1}{6}\pi h(3a^2+3b^2+h^2)$.



67) In statistics, the joint density for two independent, normally distributed events with a mean $\mu=0$ and a standard distribution $\sigma$ is defined by $p(x,y)=\frac{1}{2\pi\sigma^2}e^{-\frac{x^2+y^2}{2\sigma^2}}$. Consider $(X,Y)$, the Cartesian coordinates of a ball in the resting position after it was released from a position on the $z$-axis toward the $xy$-plane. Assume that the coordinates of the ball are independently normally distributed with a mean $\mu=0$ and a standard deviation of $\sigma$ (in feet). The probability that the ball will stop no more than $a$ feet from the origin is given by

$$P[X^2+Y^2\le a^2]=\iint_D p(x,y)dy\,dx,$$

where $D$ is the disk of radius $a$ centered at the origin. Show that

$$P[X^2+Y^2\le a^2]=1-e^{-a^2/2\sigma^2}.$$

68) The double improper integral

$$\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}e^{-x^2+y^2/2}\,dy\,dx$$

may be defined as the limit value of the double integrals $\iint_D e^{-x^2+y^2/2}\,dA$ over disks $D_a$ of radii $a$ centered at the origin, as $a$ increases without bound; that is,

$$\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}e^{-x^2+y^2/2}dy\,dx=\lim_{a\to\infty}\iint_{D_a}e^{-x^2+y^2/2}\,dA.$$

Use polar coordinates to show that $\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} e^{-x^2+y^2/2}\,dy\,dx = 2\pi.$

69) Show that $\int_{-\infty}^{\infty} e^{-x^2/2}\,dx = \sqrt{2\pi}$ by using the relation

$$\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} e^{-x^2+y^2/2}\,dy\,dx = \left(\int_{-\infty}^{\infty} e^{-x^2/2}dx\right)\left(\int_{-\infty}^{\infty} e^{-y^2/2}dy\right).$$

# 15.5: Triple Integrals

**Learning Objectives**

- Recognize when a function of three variables is integrable over a rectangular box.
- Evaluate a triple integral by expressing it as an iterated integral.
- Recognize when a function of three variables is integrable over a closed and bounded region.
- Simplify a calculation by changing the order of integration of a triple integral.
- Calculate the average value of a function of three variables.

Previously, we discussed the double integral of a function $f(x, y)$ of two variables over a rectangular region in the plane. In this section we define the triple integral of a function $f(x, y, z)$ of three variables over a rectangular solid box in space, $\mathbb{R}^3$. Later in this section we extend the definition to more general regions in $\mathbb{R}^3$.

## Integrable Functions of Three Variables

We can define a rectangular box $B$ in $\mathbb{R}^3$ as

$$B = \{(x, y, z) \mid a \le x \le b,\ c \le y \le d,\ e \le z \le f\}.$$

We follow a similar procedure to what we did in previously. We divide the interval $[a, b]$ into $l$ subintervals $[x_{i-1}, x_i]$ of equal length $\Delta x$ with

$$\Delta x = \frac{x_i - x_{i-1}}{l},$$

divide the interval $[c, d]$ into $m$ subintervals $[y_{i-1}, y_i]$ of equal length $\Delta y$ with

$$\Delta y = \frac{y_j - y_{j-1}}{m},$$

and divide the interval $[e, f]$ into $n$ subintervals $[z_{i-1}, z_i]$ of equal length $\Delta z$ with

$$\Delta z = \frac{z_k - z_{k-1}}{n}$$

Then the rectangular box $B$ is subdivided into $lmn$ subboxes:

$$B_{ijk} = [x_{i-1}, x_i] \times [y_{i-1}, y_i] \times [z_{i-1}, z_i],$$

as shown in Figure 15.5.1.

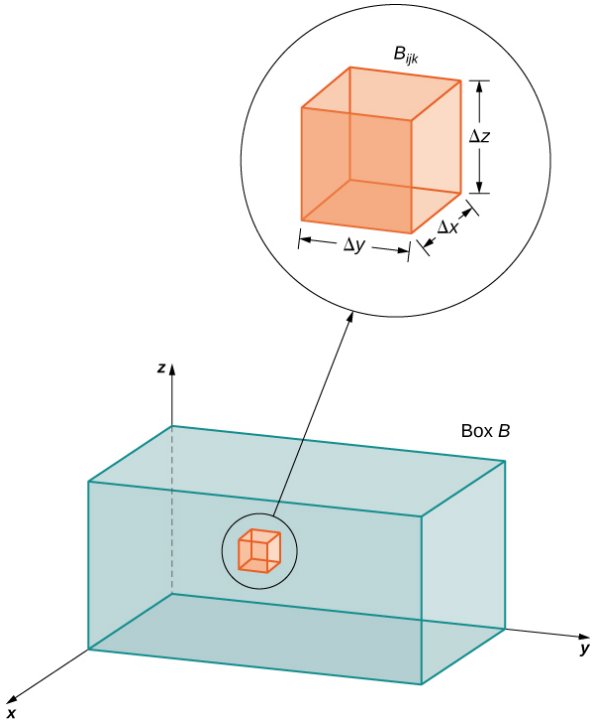

Figure 15.5.1: A rectangular box in $\mathbb{R}^3$ divided into subboxes by planes parallel to the coordinate planes.

For each $i$, $j$, and $k$, consider a sample point $(x^*_{ijk}, y^*_{ijk}, z^*_{ijk})$ in each sub-box $B_{ijk}$. We see that its volume is $\Delta V = \Delta x \Delta y \Delta z$. Form the triple Riemann sum

$$\sum_{i=1}^{l}\sum_{j=1}^{m}\sum_{k=1}^{n} f(x^*_{ijk}, y^*_{ijk}, z^*_{ijk})\,\Delta x \Delta y \Delta z.$$

We define the triple integral in terms of the limit of a triple Riemann sum, as we did for the double integral in terms of a double Riemann sum.

**Definition: The triple integral**

The triple integral of a function $f(x, y, z)$ over a rectangular box $B$ is defined as

$$\lim_{l,m,n\to\infty} \sum_{i=1}^{l}\sum_{j=1}^{m}\sum_{k=1}^{n} f(x^*_{ijk}, y^*_{ijk}, z^*_{ijk})\,\Delta x \Delta y \Delta z = \iiint_B f(x, y, z)\,dV$$

if this limit exists.

When the triple integral exists on $B$ the function $f(x, y, z)$ is said to be integrable on $B$. Also, the triple integral exists if $f(x, y, z)$ is continuous on $B$. Therefore, we will use continuous functions for our examples. However, continuity is sufficient but not necessary; in other words, $f$ is bounded on $B$ and continuous except possibly on the boundary of $B$. The sample point $(x^*_{ijk}, y^*_{ijk}, z^*_{ijk})$ can be any point in the rectangular sub-box $B_{ijk}$ and all the properties of a double integral apply to a triple integral. Just as the double integral has many practical applications, the triple integral also has many applications, which we discuss in later sections.

Now that we have developed the concept of the triple integral, we need to know how to compute it. Just as in the case of the double integral, we can have an iterated triple integral, and consequently, a version of **Fubini's theorem** for triple integrals exists.

**Fubini's Theorem for Triple Integrals**

If $f(x, y, z)$ is continuous on a rectangular box $B = [a, b] \times [c, d] \times [e, f]$, then

$$\iiint_B f(x, y, z)\,dV = \int_e^f \int_c^d \int_a^b f(x, y, z)\,dx\,dy\,dz.$$

This integral is also equal to any of the other five possible orderings for the iterated triple integral.

For $a, b, c, d, e$ and $f$ real numbers, the iterated triple integral can be expressed in six different orderings:

$$\int_e^f \int_c^d \int_a^b f(x,y,z)\,dx\,dy\,dz = \int_e^f \left( \int_c^d \left( \int_a^b f(x,y,z)\,dx \right) dy \right) dz \tag{15.5.1}$$

$$= \int_c^d \left( \int_e^f \left( \int_a^b f(x,y,z)\,dx \right) dz \right) dy \tag{15.5.2}$$

$$= \int_a^b \left( \int_e^f \left( \int_c^d f(x,y,z)\,dy \right) dz \right) dx \tag{15.5.3}$$

$$= \int_e^f \left( \int_a^b \left( \int_c^d f(x,y,z)\,dy \right) dx \right) dz \tag{15.5.4}$$

$$= \int_c^d \left( \int_a^b \left( \int_c^d f(x,y,z)\,dz \right) dx \right) dy \tag{15.5.5}$$

$$= \int_a^b \left( \int_c^d \left( \int_e^f f(x,y,z)\,dz \right) dy \right) dx \tag{15.5.6}$$

For a rectangular box, the order of integration does not make any significant difference in the level of difficulty in computation. We compute triple integrals using Fubini's Theorem rather than using the Riemann sum definition. We follow the order of integration in the same way as we did for double integrals (that is, from inside to outside).

### Example 15.5.1: Evaluating a Triple Integral

Evaluate the triple integral

$$\int_{z=0}^{z=1} \int_{y=2}^{y=4} \int_{x=-1}^{x=5} (x + yz^2)\,dx\,dy\,dz.$$

**Solution**

The order of integration is specified in the problem, so integrate with respect to $x$ first, then $y$, and then $z$.

$$\begin{aligned}
&\int_{z=0}^{z=1} \int_{y=2}^{y=4} \int_{x=-1}^{x=5} (x + yz^2)\,dx\,dy\,dz \\
&= \int_{z=0}^{z=1} \int_{y=2}^{y=4} \left[ \frac{x^2}{2} + xyz^2 \Big|_{x=-1}^{x=5} \right] dy\,dz && \text{Integrate with respect to } x. \\
&= \int_{z=0}^{z=1} \int_{y=2}^{y=4} \left[ 12 + 6yz^2 \right] dy\,dz && \text{Evaluate.} \\
&= \int_{z=0}^{z=1} \left[ 12y + 6\frac{y^2}{2} z^2 \Big|_{y=2}^{y=4} \right] dz && \text{Integrate with respect to } y. \\
&= \int_{z=0}^{z=1} \left[ 24 + 36z^2 \right] dz && \text{Evaluate.} \\
&= \left[ 24z + 36\frac{z^3}{3} \right]_{z=0}^{z=1} && \text{Integrate with respect to } z. \\
&= 36. && \text{Evaluate.}
\end{aligned}$$

### Example 15.5.2: Evaluating a Triple Integral

Evaluate the triple integral

$$\iiint_B x^2 yz\,dV$$

where $B = \{(x,y,z) \mid -2 \le x \le 1,\ 0 \le y \le 3,\ 1 \le z \le 5\}$ as shown in Figure 15.5.2.

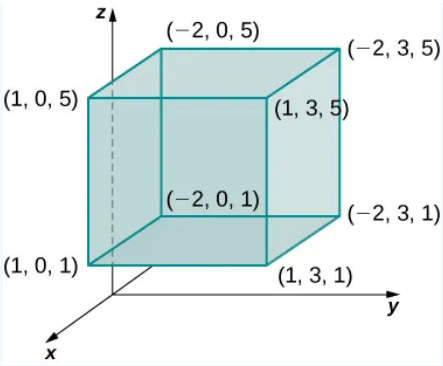

Figure 15.5.2: Evaluating a triple integral over a given rectangular box.

### Solution

The order is not specified, but we can use the iterated integral in any order without changing the level of difficulty. Choose, say, to integrate $y$ first, then $x$, and then $z$.

$$\begin{aligned}\iiint_B x^2yz\,dV &= \int_1^5\int_{-2}^1\int_0^3 [x^2yz]\,dy\,dx\,dz \\ &= \int_1^5\int_{-2}^1 \left[x^2\frac{y^2}{2}z\Big|_0^3\right] dx\,dz \\ &= \int_1^5\int_{-2}^1 \frac{9}{2}x^2z\,dx\,dz \\ &= \int_1^5 \left[\frac{9}{2}\frac{x^3}{3}z\Big|_{-2}^1\right] dz \\ &= \int_1^5 \frac{27}{2}z\,dz \\ &= \frac{27}{2}\frac{z^2}{2}\Big|_1^5 = \frac{27}{4}(25-1) = 162.\end{aligned}$$

Now try to integrate in a different order just to see that we get the same answer. Choose to integrate with respect to $x$ first, then $z$, then $y$

$$\begin{aligned}\iiint_B x^2yz\,dV &= \int_0^3\int_1^5\int_{-2}^1 [x^2yz]\,dx\,dz\,dy \\ &= \int_0^3\int_1^5 \left[\frac{x^3}{3}yz\Big|_{-2}^1\right] dz\,dy \\ &= \int_0^3\int_1^5 3yz\,dz\,dy \\ &= \int_0^3 \left[3y\frac{z^2}{2}\Big|_1^5\right] dy \\ &= \int_0^3 36y\,dy \\ &= 36\frac{y^2}{2}\Big|_0^3 = 18(9-0) = 162.\end{aligned}$$

**? Exercise 15.5.1**

Evaluate the triple integral

$$\iiint_B z\sin x\cos y\,dV$$

where $B = \{(x,y,z)\,|\,0 \le x \le \pi,\ \frac{3\pi}{2} \le y \le 2\pi,\ 1 \le z \le 3\}$.

**Hint**

Follow the steps in the previous example.

**Answer**

$$\iiint_B z \sin x \cos y \, dV = 8$$

## Triple Integrals over a General Bounded Region

We now expand the definition of the triple integral to compute a triple integral over a more **general bounded region** $E$ in $\mathbb{R}^3$. The general bounded regions we will consider are of three types. First, let $D$ be the bounded region that is a projection of $E$ onto the $xy$-plane. Suppose the region $E$ in $\mathbb{R}^3$ has the form

$$E = \{(x, y, z) \mid (x, y) \in D, u_1(x, y) \leq z \leq u_2(x, y)\}.$$

For two functions $z = u_1(x, y)$ and $u_2(x, y)$, such that $u_1(x, y) \leq u_2(x, y)$ for all $(x, y)$ in $D$ as shown in the following figure.

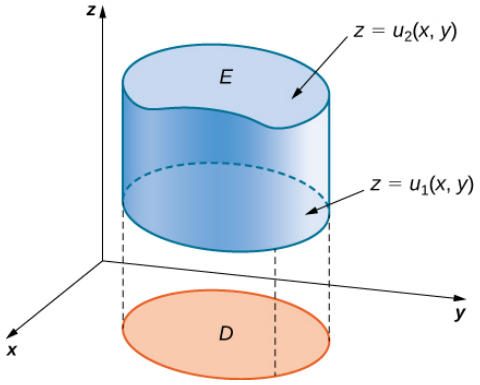

Figure **15.5.3**: We can describe region $E$ as the space between $u_1(x, y)$ and $u_2(x, y)$ above the projection $D$ of $E$ onto the $xy$-plane.

### Triple Integral over a General Region

The triple integral of a continuous function $f(x, y, z)$ over a general three-dimensional region

$$E = \{(x, y, z) \mid (x, y) \in D, \, u_1(x, y) \leq z \leq u_2(x, y)\}$$

in $\mathbb{R}^3$, where $D$ is the projection of $E$ onto the $xy$-plane, is

$$\iiint_E f(x, y, z) \, dV = \iint_D \left[ \int_{u_1(x,y)}^{u_2(x,y)} f(x, y, z) \, dz \right] dA.$$

Similarly, we can consider a general bounded region $D$ in the $xy$-plane and two functions $y = u_1(x, z)$ and $y = u_2(x, z)$ such that $u_1(x, z) \leq u_2(x, z)$ for all $(x, z)$ in $D$. Then we can describe the solid region $E$ in $\mathbb{R}^3$ as

$$E = \{(x, y, z) \mid (x, z) \in D, \, u_1(x, z) \leq z \leq u_2(x, z)\}$$

where $D$ is the projection of $E$ onto the $xy$-plane and the triple integral is

$$\iiint_E f(x, y, z) \, dV = \iint_D \left[ \int_{u_1(x,z)}^{u_2(x,z)} f(x, y, z) \, dy \right] dA.$$

Finally, if $D$ is a general bounded region in the $xy$-plane and we have two functions $x = u_1(y, z)$ and $x = u_2(y, z)$ such that $u_1(y, z) \leq u_2(y, z)$ for all $(y, z)$ in $D$, then the solid region $E$ in $\mathbb{R}^3$ can be described as

$$E = \{(x, y, z) \mid (y, z) \in D, \, u_1(y, z) \leq z \leq u_2(y, z)\}$$

where $D$ is the projection of $E$ onto the $xy$-plane and the triple integral is

$$\iiint_E f(x, y, z) \, dV = \iint_D \left[ \int_{u_1(y,z)}^{u_2(y,z)} f(x, y, z) \, dx \right] dA.$$

Note that the region $D$ in any of the planes may be of Type I or Type II as described in previously. If $D$ in the $xy$-plane is of Type I (Figure 15.5.4), then

$$E = \{(x, y, z) \mid a \le x \le b,\ g_1(x) \le y \le g_2(x),\ u_1(x, y) \le z \le u_2(x, y)\}.$$

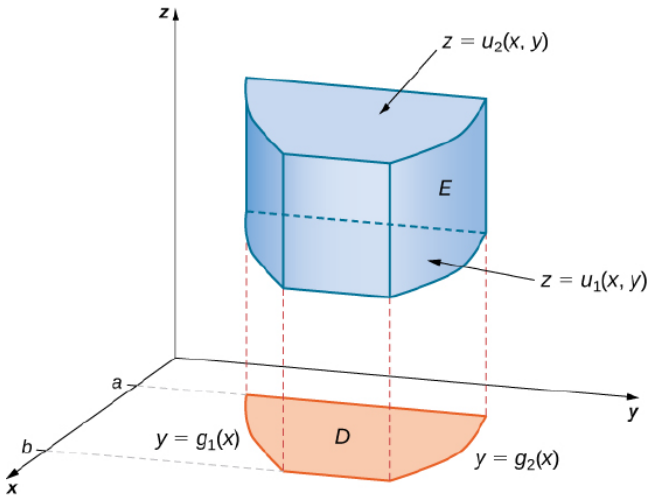

Figure 15.5.4: A box $E$ where the projection $D$ in the $xy$-plane is of Type I.

Then the triple integral becomes

$$\iiint_E f(x, y, z)\, dV = \int_a^b \int_{g_1(x)}^{g_2(x)} \int_{u_1(x,y)}^{u_2(x,y)} f(x, y, z)\, dz\, dy\, dx.$$

If $D$ in the $xy$-plane is of Type II (Figure 15.5.5), then

$$E = \{(x, y, z) \mid c \le x \le d, h_1(x) \le y \le h_2(x),\ u_1(x, y) \le z \le u_2(x, y)\}.$$

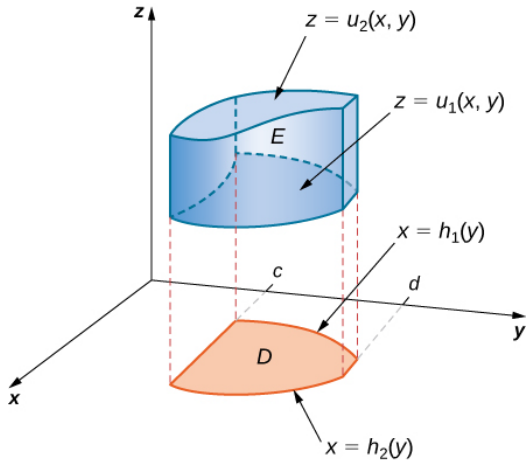

Figure 15.5.5: A box $E$ where the projection $D$ in the $xy$-plane is of Type II.

Then the triple integral becomes

$$\iiint_E f(x, y, z)\, dV = \int_{y=c}^{y=d} \int_{x=h_1(y)}^{x=h_2(y)} \int_{z=u_1(x,y)}^{z=u_2(x,y)} f(x, y, z)\, dz\, dx\, dy.$$

### Example 15.5.3A: Evaluating a Triple Integral over a General Bounded Region

Evaluate the triple integral of the function $f(x, y, z) = 5x - 3y$ over the solid tetrahedron bounded by the planes $x = 0$, $y = 0$, $z = 0$, and $x + y + z = 1$.

**Solution**

Figure 15.5.6 shows the solid tetrahedron $E$ and its projection $D$ on the $xy$-plane.

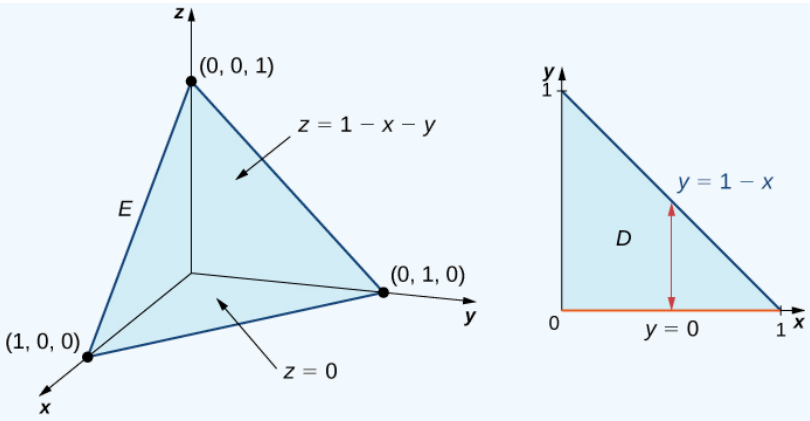

Figure 15.5.6: The solid $E$ has a projection $D$ on the $xy$-plane of Type I.

We can describe the solid region tetrahedron as

$$E = \{(x, y, z) \,|\, 0 \le x \le 1,\ 0 \le y \le 1 - x,\ 0 \le z \le 1 - x - y\}.$$

Hence, the triple integral is

$$\iiint_E f(x, y, z)\, dV = \int_{x=0}^{x=1} \int_{y=0}^{y=1-x} \int_{z=0}^{z=1-x-y} (5x - 3y)\, dz\, dy\, dx.$$

To simplify the calculation, first evaluate the integral $\int_{z=0}^{z=1-x-y} (5x - 3y)\, dz$. We have

$$\int_{z=0}^{z=1-x-y} (5x - 3y)\, dz = (5x - 3y)z \Big|_{z=0}^{z=1-x-y} = (5x - 3y)(1 - x - y).$$

Now evaluate the integral

$$\int_{y=0}^{y=1-x} (5x - 3y)(1 - x - y)\, dy,$$

obtaining

$$\int_{y=0}^{y=1-x} (5x - 3y)(1 - x - y)\, dy = \frac{1}{2}(x - 1)^2(6x - 1).$$

Finally evaluate

$$\int_{x=0}^{x=1} \frac{1}{2}(x - 1)^2(6x - 1)\, dx = \frac{1}{12}.$$

Putting it all together, we have

$$\iiint_E f(x, y, z)\, dV = \int_{x=0}^{x=1} \int_{y=0}^{y=1-x} \int_{z=0}^{z=1-x-y} (5x - 3y)\, dz\, dy\, dx = \frac{1}{12}.$$

Just as we used the double integral

$$\iint_D 1\, dA$$

to find the area of a general bounded region $D$ we can use

$$\iiint_E 1\, dV$$

to find the volume of a general solid bounded region $E$. The next example illustrates the method.

## Example 15.5.3B: Finding a Volume by Evaluating a Triple Integral

Find the volume of a right pyramid that has the square base in the $xy$-plane $[-1,1] \times [-1,1]$ and vertex at the point $(0,0,1)$ as shown in the following figure.

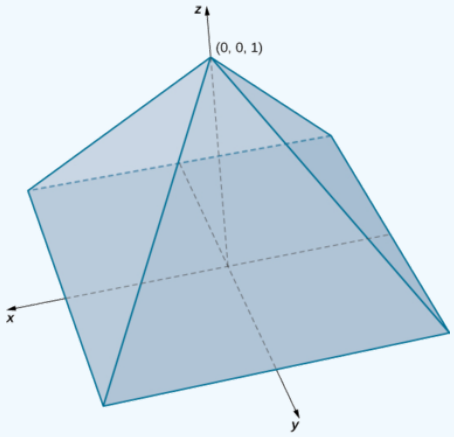

Figure 15.5.7: Finding the volume of a pyramid with a square base.

### Solution

In this pyramid the value of $z$ changes from 0 to 1 and at each height $z$ the cross section of the pyramid for any value of $z$ is the square

$$[-1+z,\, 1-z] \times [-1+z,\, 1-z].$$

Hence, the volume of the pyramid is

$$\iiint_E 1\, dV$$

where

$$E = \{(x,y,z) \,|\, 0 \le z \le 1,\, -1+z \le y \le 1-z,\, -1+z \le x \le 1-z\}.$$

Thus, we have

$$\begin{aligned} \iiint_E 1\, dV &= \int_{z=0}^{z=1} \int_{y=-1+z}^{y=1-z} \int_{x=-1+z}^{x=1-z} 1\, dx\, dy\, dz \\ &= \int_{z=0}^{z=1} \int_{y=-1+z}^{y=1-z} (2-2z)\, dy\, dz \\ &= \int_{z=0}^{z=1} (2-2z)^2\, dz = \frac{4}{3}. \end{aligned}$$

Hence, the volume of the pyramid is $\frac{4}{3}$ cubic units.

## Exercise 15.5.3

Consider the solid sphere $E = \{(x,y,z) \,|\, x^2+y^2+z^2 = 9\}$. Write the triple integral

$$\iiint_E f(x,y,z)\, dV$$

for an arbitrary function $f$ as an iterated integral. Then evaluate this triple integral with $f(x,y,z) = 1$. Notice that this gives the volume of a sphere using a triple integral.

**Hint**

Follow the steps in the previous example. Use symmetry.

**Answer**

$$\iiint_E 1\,dV = 8\int_{x=-3}^{x=3}\int_{y=-\sqrt{9-z^2}}^{y=\sqrt{9-z^2}}\int_{z=-\sqrt{9-x^2-y^2}}^{z=\sqrt{9-x^2-y^2}} 1\,dz\,dy\,dx$$
$$= 36\pi \text{ cubic units.}$$

## Changing the Order of Integration

As we have already seen in double integrals over general bounded regions, changing the order of the integration is done quite often to simplify the computation. With a triple integral over a rectangular box, the order of integration does not change the level of difficulty of the calculation. However, with a triple integral over a general bounded region, choosing an appropriate order of integration can simplify the computation quite a bit. Sometimes making the change to polar coordinates can also be very helpful. We demonstrate two examples here.

### Example 15.5.4: Changing the Order of Integration

Consider the iterated integral

$$\int_{x=0}^{x=1}\int_{y=0}^{y=x^2}\int_{z=0}^{z=y} f(x,y,z)\,dz\,dy\,dx.$$

The order of integration here is first with respect to $z$, then $y$, and then $x$. Express this integral by changing the order of integration to be first with respect to $x$, then $z$, and then $y$. Verify that the value of the integral is the same if we let $f(x,y,z) = xyz$.

**Solution**

The best way to do this is to sketch the region $E$ and its projections onto each of the three coordinate planes. Thus, let

$$E = \{(x,y,z)\,|\,0 \le x \le 1,\ 0 \le y \le x^2,\ 0 \le z \le y\}.$$

and

$$\int_{x=0}^{x=1}\int_{y=0}^{y=x^2}\int_{z=0}^{z=x^2} f(x,y,z)\,dz\,dy\,dx = \iiint_E f(x,y,z)\,dV.$$

We need to express this triple integral as

$$\int_{y=c}^{y=d}\int_{z=v_1(y)}^{z=v_2(y)}\int_{x=u_1(y,z)}^{x=u_2(y,z)} f(x,y,z)\,dx\,dz\,dy.$$

Knowing the region $E$ we can draw the following projections (Figure 15.5.8):

on the $xy$-plane is $D_1 = \{(x,y)\,|\,0 \le x \le 1,\ 0 \le y \le x^2\} = \{(x,y)\,|\,0 \le y \le 1,\ \sqrt{y} \le x \le 1\}$,

on the $yz$-plane is $D_2 = \{(y,z)\,|\,0 \le y \le 1,\ 0 \le z \le y^2\}$, and

on the $xz$-plane is $D_3 = \{(x,z)\,|\,0 \le x \le 1,\ 0 \le z \le x^2\}$.

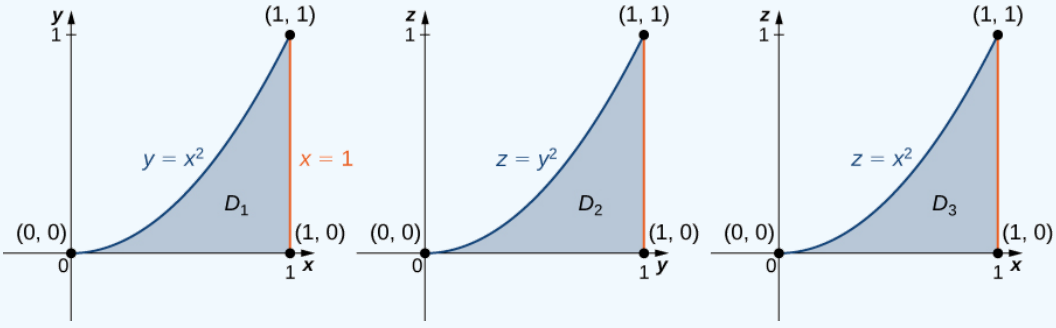

Figure 15.5.8. The three cross sections of $E$ on the three coordinate planes.

Now we can describe the same region $E$ as $\{(x,y,z)\,|\,0 \le y \le 1,\ 0 \le z \le y^2,\ \sqrt{y} \le x \le 1\}$, and consequently, the triple integral becomes

$$\int_{y=c}^{y=d}\int_{z=v_1(y)}^{z=v_2(y)}\int_{x=u_1(y,z)}^{x=u_2(y,z)} f(x,y,z)\,dx\,dz\,dy = \int_{y=0}^{y=1}\int_{z=0}^{z=x^2}\int_{x=\sqrt{y}}^{x=1} f(x,y,z)\,dx\,dz\,dy$$

Now assume that $f(x,y,z) = xyz$ in each of the integrals. Then we have

$$\begin{aligned}\int_{x=0}^{x=1}\int_{y=0}^{y=x^2}\int_{z=0}^{z=y^2} xyz\,dz\,dy\,dx &= \int_{x=0}^{x=1}\int_{y=0}^{y=x^2}\left[xy\frac{z^2}{2}\Big|_{z=0}^{z=y^2}\right]dy\,dx\\ &= \int_{x=0}^{x=1}\int_{y=0}^{y=x^2}\left(x\frac{y^5}{2}\right)dy\,dx\\ &= \int_{x=0}^{x=1}\left[x\frac{y^6}{12}\Big|_{y=0}^{y=x^2}\right]dx\\ &= \int_{x=0}^{x=1}\frac{x^{13}}{12}dx = \frac{x^{14}}{168}\Big|_{x=0}^{x=1}\\ &= \frac{1}{168},\end{aligned}$$

$$\begin{aligned}\int_{y=0}^{y=1}\int_{z=0}^{z=y^2}\int_{x=\sqrt{y}}^{x=1} xyz\,dx\,dz\,dy &= \int_{y=0}^{y=1}\int_{z=0}^{z=y^2}\left[yz\frac{x^2}{2}\Big|_{\sqrt{y}}^{1}\right]dz\,dy\\ &= \int_{y=0}^{y=1}\int_{z=0}^{z=y^2}\left(\frac{yz}{2}-\frac{y^2z}{2}\right)dz\,dy\\ &= \int_{y=0}^{y=1}\left[\frac{yz^2}{4}-\frac{y^2z^2}{4}\Big|_{z=0}^{z=y^2}\right]dy\\ &= \int_{y=0}^{y=1}\left(\frac{y^5}{4}-\frac{y^6}{4}\right)dy\\ &= \left(\frac{y^6}{24}-\frac{y^7}{28}\right)\Big|_{y=0}^{y=1}\\ &= \frac{1}{168}.\end{aligned}$$

The answers match.

## ? Exercise 15.5.4

Write five different iterated integrals equal to the given integral

$$\int_{z=0}^{z=4}\int_{y=0}^{y=4-z}\int_{x=0}^{x=\sqrt{y}} f(x,y,z)\,dx\,dy\,dz.$$

**Hint**

Follow the steps in the previous example, using the region $E$ as $\{(x,y,z)\mid 0\le z\le 4,\ 0\le y\le 4-z,\ 0\le x\le\sqrt{y}\}$, and describe and sketch the projections onto each of the three planes, five different times.

**Answer**

$$(i)\ \int_{z=0}^{z=4}\int_{x=0}^{x=\sqrt{4-z}}\int_{y=x^2}^{y=4-z} f(x,y,z)\,dy\,dx\,dz,\ (ii)\ \int_{y=0}^{y=4}\int_{z=0}^{z=4-y}\int_{x=0}^{x=\sqrt{y}} f(x,y,z)\,dx\,dz\,dy,\ (iii)\ \int_{y=0}^{y=4}\int_{x=0}^{x=\sqrt{y}}\int_{z=0}^{Z=4-y} f(x,y,z)\,dz\,dx\,dy,$$

$$(iv)\ \int_{x=0}^{x=2}\int_{y=x^2}^{y=4}\int_{z=0}^{z=4-y} f(x,y,z)\,dz\,dy\,dx,\ (v)\ \int_{x=0}^{x=2}\int_{z=0}^{z=4-x^2}\int_{y=x^2}^{y=4-z} f(x,y,z)\,dy\,dz\,dx$$

## ✓ Example 15.5.5: Changing Integration Order and Coordinate Systems

Evaluate the triple integral

$$\iiint_E \sqrt{x^2+z^2}\,dV,$$

where $E$ is the region bounded by the paraboloid $y=x^2+z^2$ (Figure 15.5.9) and the plane $y=4$.

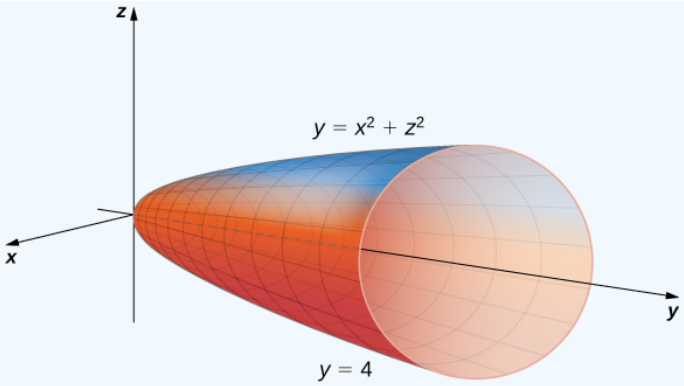

Figure 15.5.9. Integrating a triple integral over a paraboloid.

### Solution

The projection of the solid region $E$ onto the $xy$-plane is the region bounded above by $y = 4$ and below by the parabola $y = x^2$ as shown.

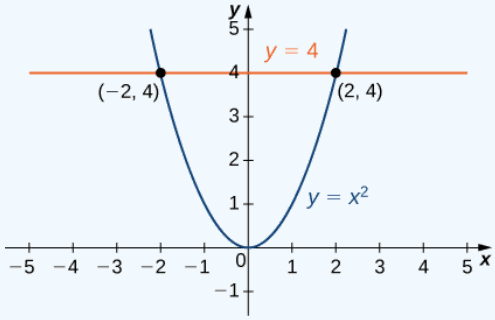

Figure 15.5.10. Cross section in the $xy$-plane of the paraboloid in Figure 15.5.9.

Thus, we have

$$E = \{(x, y, z) \mid -2 \le x \le 2,\ x^2 \le y \le 4,\ -\sqrt{y - x^2} \le z \le \sqrt{y - x^2}\}.$$

The triple integral becomes

$$\iiint_E \sqrt{x^2 + z^2}\, dV = \int_{x=-2}^{x=2} \int_{y=x^2}^{y=4} \int_{z=-\sqrt{y-x^2}}^{z=\sqrt{y-x^2}} \sqrt{x^2 + z^2}\, dz\, dy\, dx.$$

This expression is difficult to compute, so consider the projection of $E$ onto the $xz$-plane. This is a circular disc $x^2 + z^2 \le 4$. So we obtain

$$\begin{aligned} \iiint_E \sqrt{x^2 + z^2}\, dV &= \int_{x=-2}^{x=2} \int_{y=x^2}^{y=4} \int_{z=-\sqrt{y-x^2}}^{z=\sqrt{y-x^2}} \sqrt{x^2 + z^2}\, dz\, dy\, dx \\ &= \int_{x=-2}^{x=2} \int_{z=-\sqrt{4-x^2}}^{z=\sqrt{4-x^2}} \int_{y=x^2+z^2}^{y=4} \sqrt{x^2 + z^2}\, dy\, dz\, dx. \end{aligned}$$

Here the order of integration changes from being first with respect to $z$ then $y$ and then $x$ to being first with respect to $y$ then to $z$ and then to $x$. It will soon be clear how this change can be beneficial for computation. We have

$$\int_{x=-2}^{x=2} \int_{z=-\sqrt{4-x^2}}^{z=\sqrt{4-x^2}} \int_{y=x^2+z^2}^{y=4} \sqrt{x^2 + z^2}\, dy\, dz\, dx = \int_{x=-2}^{x=2} \int_{z=-\sqrt{4-x^2}}^{z=\sqrt{4-x^2}} (4 - x^2 - z^2)\sqrt{x^2 + z^2}\, dz\, dx.$$

Now use the polar substitution $x = r\cos\theta$, $z = r\sin\theta$, and $dz\, dx = r\, dr\, d\theta$ in the $xz$-plane. This is essentially the same thing as when we used polar coordinates in the $xy$-plane, except we are replacing $y$ by $z$. Consequently the limits of integration change and we have, by using $r^2 = x^2 + z^2$,

$$\int_{x=-2}^{x=2}\int_{z=-\sqrt{4-x^2}}^{z=\sqrt{4-x^2}}(4-x^2-z^2)\sqrt{x^2+z^2}\,dz\,dx=\int_{\theta=0}^{\theta=2\pi}\int_{r=0}^{r=2}(4-r^2)r\,r\,dr\,d\theta$$
$$=\int_0^{2\pi}\left[\frac{4r^3}{3}-\frac{r^5}{5}\Big|_0^2\right]d\theta=\int_0^{2\pi}\frac{64}{15}\,d\theta=\frac{128\pi}{15}$$

## Average Value of a Function of Three Variables

Recall that we found the average value of a function of two variables by evaluating the double integral over a region on the plane and then dividing by the area of the region. Similarly, we can find the average value of a function in three variables by evaluating the triple integral over a solid region and then dividing by the volume of the solid.

### Average Value of a Function of Three Variables

If $f(x,y,z)$ is integrable over a solid bounded region $E$ with positive volume $V(E)$, then the average value of the function is

$$f_{ave}=\frac{1}{V(E)}\iiint_E f(x,y,z)\,dV.$$

Note that the volume is

$$V(E)=\iiint_E 1\,dV.$$

### Example 15.5.6: Finding an Average Temperature

The temperature at a point $(x,y,z)$ of a solid $E$ bounded by the coordinate planes and the plane $x+y+z=1$ is $T(x,y,z)=(xy+8z+20)$ °C. Find the average temperature over the solid.

**Solution**

Use the theorem given above and the triple integral to find the numerator and the denominator. Then do the division. Notice that the plane $x+y+z=1$ has intercepts $(1,0,0)$, $(0,1,0)$, and $(0,0,1)$. The region $E$ looks like

$$E=\{(x,y,z)\,|\,0\le x\le 1,\ 0\le y\le 1-x,\ 0\le z\le 1-x-y\}.$$

Hence the triple integral of the temperature is

$$\iiint_E f(x,y,z)\,dV=\int_{x=0}^{x=1}\int_{y=0}^{y=1-x}\int_{z=0}^{z=1-x-y}(xy+8z+20)\,dz\,dy\,dx=\frac{147}{40}.$$

The volume evaluation is

$$V(E)=\iiint_E 1\,dV=\int_{x=0}^{x=1}\int_{y=0}^{y=1-x}\int_{z=0}^{z=1-x-y}1\,dz\,dy\,dx=\frac{1}{6}.$$

Hence the average value is

$$T_{ave}=\frac{147/40}{1/6}=\frac{6(147)}{40}=\frac{441}{20}\ ^\circ\text{C}$$

.

### Exercise 15.5.6

Find the average value of the function $f(x,y,z)=xyz$ over the cube with sides of length 4 units in the first octant with one vertex at the origin and edges parallel to the coordinate axes.

**Hint**

Follow the steps in the previous example.

**Answer**

$f_{ave} = 8$

## Key Concepts

- To compute a triple integral we use Fubini's theorem, which states that if $f(x, y, z)$ is continuous on a rectangular box $B = [a, b] \times [c, d] \times [e, f]$, then

$$\iiint_B f(x, y, z)\, dV = \int_e^f \int_c^d \int_a^b f(x, y, z)\, dx\, dy\, dz$$

  and is also equal to any of the other five possible orderings for the iterated triple integral.
- To compute the volume of a general solid bounded region $E$ we use the triple integral

$$V(E) = \iiint_E 1\, dV.$$

- Interchanging the order of the iterated integrals does not change the answer. As a matter of fact, interchanging the order of integration can help simplify the computation.
- To compute the average value of a function over a general three-dimensional region, we use

$$f_{ave} = \frac{1}{V(E)} \iiint_E f(x, y, z)\, dV.$$

## Key Equations

- **Triple integral**

$$\lim_{l,m,n\to\infty} \sum_{i=1}^{l} \sum_{j=1}^{m} \sum_{k=1}^{n} f(x^*_{ijk}, y^*_{ijk}, z^*_{ijk})\, \Delta x \Delta y \Delta z = \iiint_B f(x, y, z)\, dV$$

## Glossary

**triple integral**

the triple integral of a continuous function $f(x, y, z)$ over a rectangular solid box $B$ is the limit of a Riemann sum for a function of three variables, if this limit exists

# 15.5E: Exercises for Section 15.4

**In exercises 1 - 4, evaluate the triple integrals over the rectangular solid box $B$.**

1. $\iiint_B (2x + 3y^2 + 4z^3)\, dV$, where $B = \{(x, y, z) \mid 0 \le x \le 1,\ 0 \le y \le 2,\ 0 \le z \le 3\}$

**Answer**

192

2. $\iiint_B (xy + yz + xz)\, dV$, where $B = \{(x, y, z) \mid 1 \le x \le 2,\ 0 \le y \le 2,\ 1 \le z \le 3\}$
3. $\iiint_B (x \cos y + z)\, dV$, where $B = \{(x, y, z) \mid 0 \le x \le 1,\ 0 \le y \le \pi,\ -1 \le z \le 1\}$

**Answer**

0

4. $\iiint_B (z \sin x + y^2)\, dV$, where $B = \{(x, y, z) \mid 0 \le x \le \pi,\ 0 \le y \le 1,\ -1 \le z \le 2\}$

**In exercises 5 - 8, change the order of integration by integrating first with respect to $z$, then $x$, then $y$.**

5. $\int_0^1 \int_1^2 \int_2^3 (x^2 + \ln y + z)\, dx\, dy\, dz$

**Answer**

$$\int_0^1 \int_1^2 \int_2^3 (x^2 + \ln y + z)\, dx\, dy\, dz = \frac{35}{6} + 2 \ln 2$$

6. $\int_0^1 \int_{-1}^1 \int_0^3 (ze^x + 2y)\, dx\, dy\, dz$
7. $\int_{-1}^2 \int_1^3 \int_0^4 \left(x^2 z + \frac{1}{y}\right) dx\, dy\, dz$

**Answer**

$$\int_{-1}^2 \int_1^3 \int_0^4 \left(x^2 z + \frac{1}{y}\right) dx\, dy\, dz = 64 + 12 \ln 3$$

8. $\int_1^2 \int_{-2}^{-1} \int_0^1 \frac{x + y}{z}\, dx\, dy\, dz$

9. Let $F$, $G$, and $H$ be continuous functions on $[a, b]$, $[c, d]$, and $[e, f]$, respectively, where $a$, $b$, $c$, $d$, $e$, and $f$ are real numbers such that $a < b$, $c < d$, and $e < f$. Show that

$$\int_a^b \int_c^d \int_e^f F(x)\, G(y)\, H(z)\, dz\, dy\, dx = \left(\int_a^b F(x)\, dx\right) \left(\int_c^d G(y)\, dy\right) \left(\int_e^f H(z)\, dz\right).$$

10. Let $F$, $G$, and $H$ be differential functions on $[a, b]$, $[c, d]$, and $[e, f]$, respectively, where $a$, $b$, $c$, $d$, $e$, and $f$ are real numbers such that $a < b$, $c < d$, and $e < f$. Show that

$$\int_a^b \int_c^d \int_e^f F'(x)\, G'(y)\, H'(z)\, dz\, dy\, dx = [F(b) - F(a)]\, [G(d) - G(c)]\, H(f) - H(e)].$$

**In exercises 11 - 14, evaluate the triple integrals over the bounded region**

$E = \{(x, y, z) \mid a \le x \le b,\ h_1(x) \le y \le h_2(x),\ e \le z \le f\}$.

11. $\iiint_E (2x + 5y + 7z)\, dV$, where $E = \{(x, y, z) \mid 0 \le x \le 1,\ 0 \le y \le -x + 1,\ 1 \le z \le 2\}$

**Answer**

$\frac{77}{12}$

12. $\iiint_E (y \ln x + z)\, dV$, where $E = \{(x, y, z) \mid 1 \le x \le e,\ 0 \le y \ln x,\ 0 \le z \le 1\}$

13. $\iiint_E (\sin x + \sin y)\, dV$, where $E = \{(x, y, z) \mid 0 \le x \le \frac{\pi}{2},\ -\cos x \le y \cos x,\ -1 \le z \le 1\}$

**Answer**

**2**

14. $\iiint_E (xy + yz + xz)\, dV$ where $E = \{(x, y, z) \mid 0 \le x \le 1,\ -x^2 \le y \le x^2,\ 0 \le z \le 1\}$

**In exercises 15 - 18, evaluate the triple integrals over the indicated bounded region $E$.**

15. $\iiint_E (x + 2yz)\, dV$, where $E = \{(x, y, z) \mid 0 \le x \le 1,\ 0 \le y \le x,\ 0 \le z \le 5 - x - y\}$

**Answer**

$\frac{430}{120}$

16. $\iiint_E (x^3 + y^3 + z^3)\, dV$, where $E = \{(x, y, z) \mid 0 \le x \le 2,\ 0 \le y \le 2x,\ 0 \le z \le 4 - x - y\}$

17. $\iiint_E y\, dV$, where $E = \{(x, y, z) \mid -1 \le x \le 1,\ -\sqrt{1 - x^2} \le y \le \sqrt{1 - x^2},\ 0 \le z \le 1 - x^2 - y^2\}$

**Answer**

**0**

18. $\iiint_E x\, dV$, where $E = \{(x, y, z) \mid -2 \le x \le 2,\ -4\sqrt{1 - x^2} \le y \le \sqrt{4 - x^2},\ 0 \le z \le 4 - x^2 - y^2\}$

**In exercises 19 - 22, evaluate the triple integrals over the bounded region $E$ of the form**

$E = \{(x, y, z) \mid g_1(y) \le x \le g_2(y),\ c \le y \le d,\ e \le z \le f\}$.

19. $\iiint_E x^2\, dV$, where $E = \{(x, y, z) \mid 1 - y^2 \le x \le y^2 - 1,\ -1 \le y \le 1,\ 1 \le z \le 2\}$

**Answer**

$-\frac{64}{105}$

20. $\iiint_E (y + \sin x)\, dV$, where $E = \{(x, y, z) \mid -y^4 \le x \le y^4,\ 0 \le y \le 2,\ 0 \le z \le 4\}$

21. $\iiint_E (x - yz)\, dV$, where $E = \{(x, y, z) \mid -y^6 \le x \le \sqrt{y},\ 0 \le y \le 1x,\ -1 \le z \le 1\}$

**Answer**

$\frac{11}{26}$

22. $\iiint_E z\, dV$, where $E = \{(x, y, z) \mid 2 - 2y \le x \le 2 + \sqrt{y},\ 0 \le y \le 1x,\ 2 \le z \le 3\}$

**In exercises 23 - 26, evaluate the triple integrals over the bounded region**

$E = \{(x, y, z) \mid g_1(y) \le x \le g_2(y),\ c \le y \le d,\ u_1(x, y) \le z \le u_2(x, y)\}$

23. $\iiint_E z\, dV$, where $E = \{(x, y, z) \mid -y \le x \le y,\ 0 \le y \le 1,\ 0 \le z \le 1 - x^4 - y^4\}$

**Answer**

$\frac{113}{450}$

24. $\iiint_E (xz + 1)\, dV$, where $E = \{(x, y, z) \mid 0 \le x \le \sqrt{y},\ 0 \le y \le 2,\ 0 \le z \le 1 - x^2 - y^2\}$

25. $\iiint_E (x - z)\, dV$, where $E = \{(x, y, z) \mid -\sqrt{1 - y^2} \le x \le y,\ 0 \le y \le \frac{1}{2}x,\ 0 \le z \le 1 - x^2 - y^2\}$

**Answer**

$\frac{1}{160}(6\sqrt{3}-41)$

26. $\iiint_E (x+y)\,dV$, where $E=\{(x,y,z)\,|\,0\le x\le\sqrt{1-y^2},\ 0\le y\le 1x,\ 0\le z\le 1-x\}$

**In exercises 27 - 30, evaluate the triple integrals over the bounded region**

**$E=\{(x,y,z)\,|\,(x,y)\in D,\ u_1(x,y)x\le z\le u_2(x,y)\}$, where $D$ is the projection of $E$ onto the $xy$-plane.**

27. $\iint_D \left(\int_1^2 (x+y)\,dz\right)\,dA$, where $D=\{(x,y)\,|\,x^2+y^2\le 1\}$

**Answer**

$\frac{3\pi}{2}$

28. $\iint_D \left(\int_1^3 x(z+1)\,dz\right)\,dA$, where $D=\{(x,y)\,|\,x^2-y^2\ge 1,\ x\le\sqrt{5}\}$

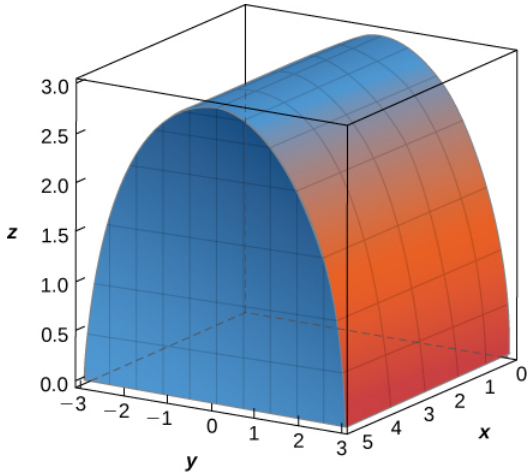
29. $\iint_D \left(\int_0^{10-x-y} (x+2z)\,dz\right)\,dA$, where $D=\{(x,y)\,|\,y\ge 0,\ x\ge 0,\ x+y\le 10\}$

**Answer**

1250

30. $\iint_D \left(\int_0^{4x^2+4y^2} y\,dz\right)\,dA$, where $D=\{(x,y)\,|\,x^2+y^2\le 4,\ y\ge 1,\ x\ge 0\}$

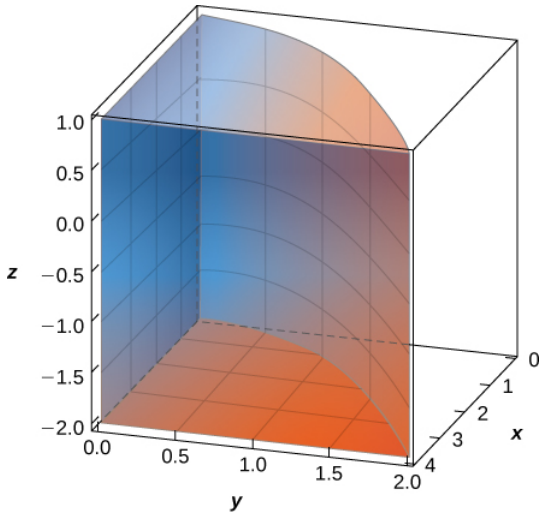
31. The solid $E$ bounded by $y^2+z^2=9$, $z=0$, and $x=5$ is shown in the following figure. Evaluate the integral $\iiint_E z\,dV$ by integrating first with respect to $z$, then $y$, and then $x$.



**Answer**

$\int_0^5\int_{-3}^3\int_0^{\sqrt{9-y^2}} z\,dz\,dy\,dx=90$

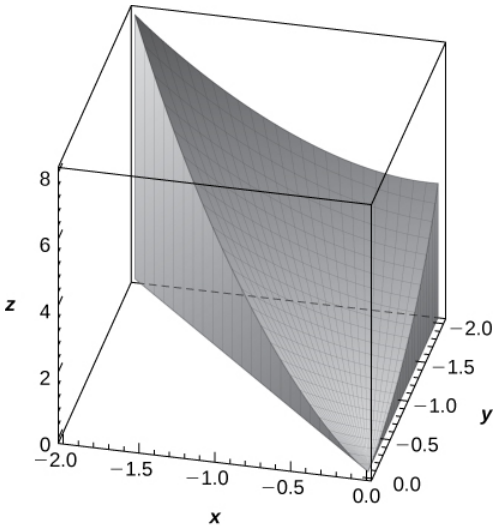
32. The solid $E$ bounded by $y=\sqrt{x}$, $x=4$, $y=0$, and $z=1$ is given in the following figure. Evaluate the integral $\iiint_E xyz\,dV$ by integrating first with respect to $x$, then $y$, and then $z$.



33. [T] The volume of a solid $E$ is given by the integral $\int_{-2}^{0}\int_{x}^{0}\int_{0}^{x^2+y^2} dz\,dy\,dx$. Use a computer algebra system (CAS) to graph $E$ and find its volume. Round your answer to two decimal places.

**Answer**

$V \approx 5.33$ units$^3$



34. [T] The volume of a solid $E$ is given by the integral $\int_{-1}^{0}\int_{-x^3}^{0}\int_{0}^{1+\sqrt{x^2+y^2}} dz\,dy\,dx$. Use a CAS to graph $E$ and find its volume $V$. Round your answer to two decimal places.

**In exercises 35 - 38, use two circular permutations of the variables $x$, $y$, and $z$ to write new integrals whose values equal the value of the original integral. A circular permutation of $x$, $y$, and $z$ is the arrangement of the numbers in one of the following orders: $y$, $z$, and $x$ or $z$, $x$, and $y$.**

35. $\int_{0}^{1}\int_{1}^{3}\int_{2}^{4}(x^2z^2+1)\,dx\,dy\,dz$

**Answer**

$\int_{0}^{1}\int_{1}^{3}\int_{2}^{4}(y^2z^2+1)\,dz\,dx\,dy;$
$\int_{0}^{1}\int_{1}^{3}\int_{2}^{4}(x^2y^2+1)\,dy\,dz\,dx$

36. $\int_0^3 \int_0^1 \int_0^{-x+1} (2x+5y+7z)dy\,dx\,dz$

37. $\int_0^1 \int_{-y}^{y} \int_0^{1-x^4-y^4} \ln x\; dz\,dx\,dy$

38. $\int_{-1}^1 \int_0^1 \int_{-y^6}^{\sqrt{y}} (x+yz)\,dx\,dy\,dz$

39. Set up the integral that gives the volume of the solid $E$ bounded by $y^2 = x^2 + z^2$ and $y = a^2$, where $a > 0$.

**Answer**

$$V = \int_{-a}^{a} \int_{-\sqrt{a^2-z^2}}^{\sqrt{a^2-z^2}} \int_{\sqrt{x^2+z^2}}^{a^2} dy\,dx\,dz$$

40. Set up the integral that gives the volume of the solid $E$ bounded by $x = y^2 + z^2$ and $x = a^2$, where $a > 0$.

## Average Value of a Function

41. Find the average value of the function $f(x, y, z) = x + y + z$ over the parallelepiped determined by $x + 0$, $x = 1$, $y = 0$, $y = 3$, $z = 0$, and $z = 5$.

**Answer**

$\frac{9}{2}$

42. Find the average value of the function $f(x, y, z) = xyz$ over the solid $E = [0, 1] \times [0, 1] \times [0, 1]$ situated in the first octant.

## Finding Volumes using Triple Integrals

43. Find the volume of the solid $E$ that lies under the plane $x + y + z = 9$ and whose projection onto the $xy$-plane is bounded by $x = sqrty - 1$, $x = 0$, and $x + y = 7$.

**Answer**

$\frac{156}{5}$ $\text{units}^3$

44. Find the volume of the solid $E$ that lies under the plane $2x + y + z = 8$ and whose projection onto the $xy$-plane is bounded by $x = sin^{-1}y$, $y = 0$, and $x = \frac{\pi}{2}$.

45. Consider the pyramid with the base in the $xy$-plane of $[-2, 2] \times [-2, 2]$ and the vertex at the point $(0, 0, 8)$.

a. Show that the equations of the planes of the lateral faces of the pyramid are $4y + z = 8$, $4y - z = -8$, $4x + z = 8$, and $-4x + z = 8$.

b. Find the volume of the pyramid.

**Answer**

a. Answers may vary;

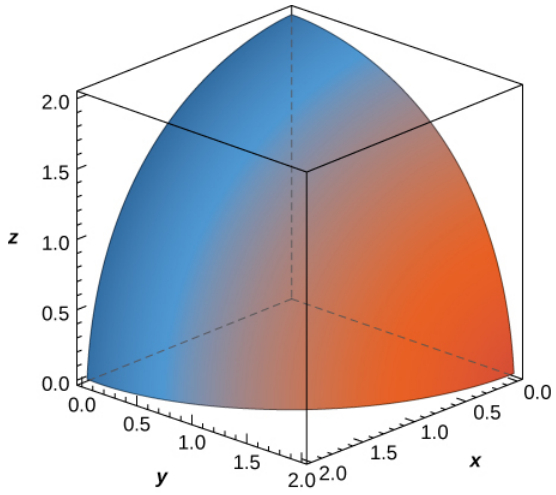
b. $\frac{128}{3}$ $\text{units}^3$

46. Consider the pyramid with the base in the $xy$-plane of $[-3, 3] \times [-3, 3]$ and the vertex at the point $(0, 0, 9)$.

a. Show that the equations of the planes of the side faces of the pyramid are $3y + z = 9$, $3y + z = 9$, $y = 0$ and $x = 0$.

b. Find the volume of the pyramid.

47. The solid $E$ bounded by the sphere of equation $x^2 + y^2 + z^2 = r^2$ with $r > 0$ and located in the first octant is represented in the following figure.



a. Write the triple integral that gives the volume of $E$ by integrating first with respect to $z$, then with $y$, and then with $x$.

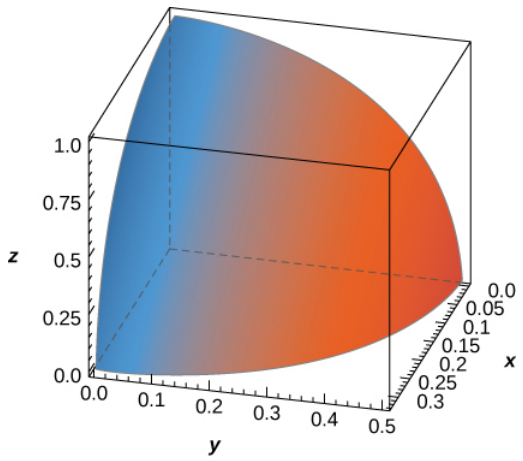
b. Rewrite the integral in part a. as an equivalent integral in five other orders.

**Answer**

a. $\int_0^4 \int_0^{\sqrt{r^2-x^2}} \int_0^{\sqrt{r^2-x^2-y^2}} dz\,dy\,dx$

b. $\int_0^2 \int_0^{\sqrt{r^2-x^2}} \int_0^{\sqrt{r^2-x^2-y^2}} dz\,dx\,dy$,
$\int_0^r \int_0^{\sqrt{r^2-x^2}} \int_0^{\sqrt{r^2-x^2-y^2}} dy\,dx\,dz$,
$\int_0^r \int_0^{\sqrt{r^2-x^2}} \int_0^{\sqrt{r^2-x^2-y^2}} dy\,dz\,dx$,
$\int_0^r \int_0^{\sqrt{r^2-x^2}} \int_0^{\sqrt{r^2-x^2-y^2}} dx\,dy\,dz$,
$\int_0^r \int_0^{\sqrt{r^2-x^2}} \int_0^{\sqrt{r^2-x^2-y^2}} dx\,dz\,dy$

48. The solid $E$ bounded by the sphere of equation $9x^2 + 4y^2 + z^2 = 1$ and located in the first octant is represented in the following figure.



a. Write the triple integral that gives the volume of $E$ by integrating first with respect to $z$ then with $y$ and then with $x$.

b. Rewrite the integral in part a. as an equivalent integral in five other orders.

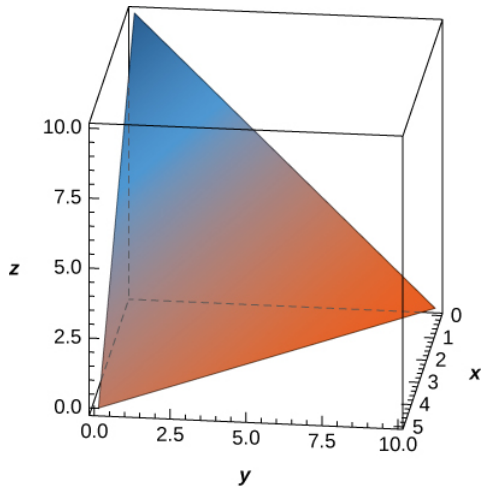
49. Find the volume of the prism with vertices $(0,0,0)$, $(2,0,0)$, $(2,3,0)$, $(0,3,0)$, $(0,0,1)$, and $(2,0,1)$.

**Answer**

$3$ units$^3$

50. Find the volume of the prism with vertices $(0,0,0)$, $(4,0,0)$, $(4,6,0)$, $(0,6,0)$, $(0,0,1)$, and $(4,0,1)$.

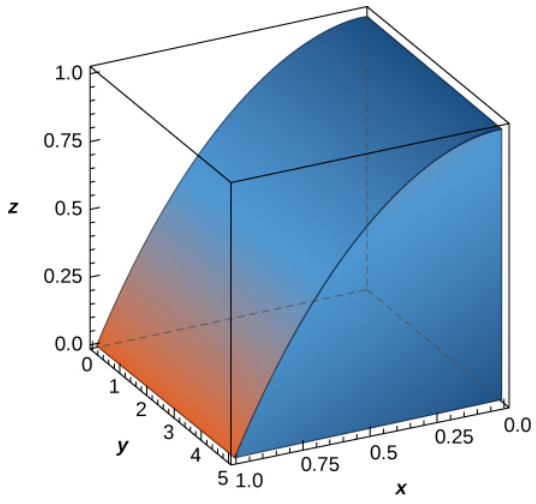
51. The solid $E$ bounded by $z = 10 - 2x - y$ and situated in the first octant is given in the following figure. Find the volume of the solid.



**Answer**

$\frac{250}{3}$ units$^3$

52. The solid $E$ bounded by $z = 1 - x^2$ and situated in the first octant is given in the following figure. Find the volume of the solid.



## Approximating Triple Integrals

53. The midpoint rule for the triple integral $\iiint_B f(x,y,z)\,dV$ over the rectangular solid box $B$ is a generalization of the midpoint rule for double integrals. The region $B$ is divided into subboxes of equal sizes and the integral is approximated by the triple Riemann sum

$$\sum_{i=1}^{l}\sum_{j=1}^{m}\sum_{k=1}^{n} f(\bar{x}_i, \bar{y}_j, \bar{z}_k)\Delta V,$$

where $(\bar{x}_i, \bar{y}_j, \bar{z}_k)$ is the center of the box $B_{ijk}$ and $\Delta V$ is the volume of each subbox. Apply the midpoint rule to approximate

$$\iiint_B x^2\,dV$$

over the solid $B = \{(x, y, z) \mid 0 \le x \le 1,\ 0 \le y \le 1,\ 0 \le z \le 1\}$ by using a partition of eight cubes of equal size. Round your answer to three decimal places.

**Answer**

$\iiint_B f(x, y, z)\,dV \approx \frac{5}{16} \approx 0.313$ units$^3$

54. [T]

a. Apply the midpoint rule to approximate $\iiint_B e^{-x^2}\,dV$ over the solid $B = \{(x, y, z) \mid 0 \le x \le 1,\ 0 \le y \le 1,\ 0 \le z \le 1\}$ by using a partition of eight cubes of equal size. Round your answer to three decimal places.

b. Use a CAS to improve the above integral approximation in the case of a partition of $n^3$ cubes of equal size, where $n = 3, 4, \ldots, 10$.

## Applications

55. Suppose that the temperature in degrees Celsius at a point $(x, y, z)$ of a solid $E$ bounded by the coordinate planes and the plane $x + y + z = 5$ is given by:

$$T(x, y, z) = xz + 5z + 10$$

Find the average temperature over the solid.

**Answer**

$17.5°$ C

56. Suppose that the temperature in degrees Fahrenheit at a point $(x, y, z)$ of a solid $E$ bounded by the coordinate planes and the plane $x + y + z = 5$ is given by:

$$T(x, y, z) = x + y + xy$$

Find the average temperature over the solid.

57. Show that the volume of a right square pyramid of height $h$ and side length $a$ is $v = \dfrac{ha^2}{3}$ by using triple integrals.

58. Show that the volume of a regular right hexagonal prism of edge length $a$ is $\dfrac{3a^3\sqrt{3}}{2}$ by using triple integrals.

59. Show that the volume of a regular right hexagonal pyramid of edge length $a$ is $\dfrac{a^3\sqrt{3}}{2}$ by using triple integrals.

60. If the charge density at an arbitrary point $(x, y, z)$ of a solid $E$ is given by the function $\rho(x, y, z)$, then the total charge inside the solid is defined as the triple integral $\iiint_E \rho(x, y, z)\,dV$. Assume that the charge density of the solid $E$ enclosed by the paraboloids $x = 5 - y^2 - z^2$ and $x = y^2 + z^2 - 5$ is equal to the distance from an arbitrary point of $E$ to the origin. Set up the integral that gives the total charge inside the solid $E$.

**Answer**

Total Charge inside the Solid $E$ $= \int_{-\sqrt{5}}^{\sqrt{5}} \int_{-\sqrt{5-y^2}}^{\sqrt{5-y^2}} \int_{y^2+z^2-5}^{5-y^2-z^2} \sqrt{x^2 + y^2 + z^2}\,dx\,dz\,dy$

# 15.6: Triple Integrals in Cylindrical and Spherical Coordinates

**Learning Objectives**

- Evaluate a triple integral by changing to cylindrical coordinates.
- Evaluate a triple integral by changing to spherical coordinates.

Earlier in this chapter we showed how to convert a double integral in rectangular coordinates into a double integral in polar coordinates in order to deal more conveniently with problems involving circular symmetry. A similar situation occurs with triple integrals, but here we need to distinguish between cylindrical symmetry and spherical symmetry. In this section we convert triple integrals in rectangular coordinates into a triple integral in either cylindrical or spherical coordinates.

Also recall the chapter prelude, which showed the opera house l'Hemisphèric in Valencia, Spain. It has four sections with one of the sections being a theater in a five-story-high sphere (ball) under an oval roof as long as a football field. Inside is an IMAX screen that changes the sphere into a planetarium with a sky full of 9000 twinkling stars. Using triple integrals in spherical coordinates, we can find the volumes of different geometric shapes like these.

## Review of Cylindrical Coordinates

As we have seen earlier, in two-dimensional space $\mathbb{R}^2$ a point with rectangular coordinates $(x, y)$ can be identified with $(r, \theta)$ in polar coordinates and vice versa, where $x = r\cos\theta$, $y = r\sin\theta$, $r^2 = x^2 + y^2$ and $\tan\theta = \frac{y}{x}$ are the relationships between the variables.

In three-dimensional space $\mathbb{R}^3$ a point with rectangular coordinates $(x, y, z)$ can be identified with cylindrical coordinates $(r, \theta, z)$ and vice versa. We can use these same conversion relationships, adding $z$ as the vertical distance to the point from the $(xy$-plane as shown in 15.6.1.

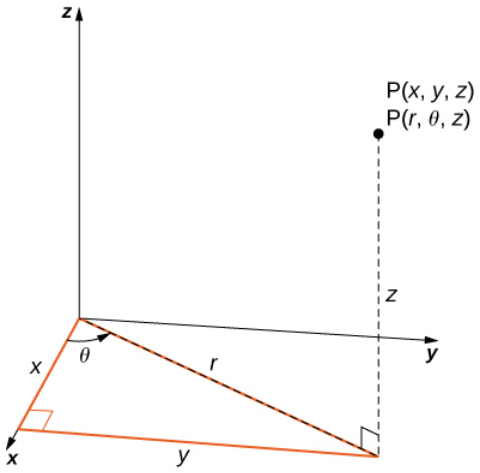

Figure 15.6.1: Cylindrical coordinates are similar to polar coordinates with a vertical $z$ coordinate added.

To convert from rectangular to cylindrical coordinates, we use the conversion

- $x = r\cos\theta$
- $y = r\sin\theta$
- $z = z$

To convert from cylindrical to rectangular coordinates, we use

- $r^2 = x^2 + y^2$ and
- $\theta = \tan^{-1}\left(\frac{y}{x}\right)$
- $z = z$

Note that that $z$-coordinate remains the same in both cases.

In the two-dimensional plane with a rectangular coordinate system, when we say $x = k$ (constant) we mean an unbounded vertical line parallel to the $y$-axis and when $y = l$ (constant) we mean an unbounded horizontal line parallel to the $x$-axis. With the polar coordinate system, when we say $r = c$ (constant), we mean a circle of radius $c$ units and when $\theta = \alpha$ (constant) we mean an infinite ray making an angle $\alpha$ with the positive $x$-axis.

Similarly, in three-dimensional space with rectangular coordinates $(x, y, z)$ the equations $x = k$, $y = l$ and $z = m$ where $k$, $l$ and $m$ are constants, represent unbounded planes parallel to the $yz$-plane, $xz$-plane and $xy$-plane, respectively. With cylindrical coordinates $(r, \theta, z)$, by $r = c$, $\theta = \alpha$, and $z = m$, where $c, \alpha$, and $m$ are constants, we mean an unbounded vertical cylinder with the z-axis as its radial axis; a plane making a constant angle $\alpha$ with the $xy$-plane; and an unbounded horizontal plane parallel to the $xy$-plane, respectively. This means that the circular cylinder $x^2 + y^2 = c^2$ in rectangular coordinates can be represented simply as $r = c$ in cylindrical coordinates. (Refer to Cylindrical and Spherical Coordinates for more review.)

## Integration in Cylindrical Coordinates

Triple integrals can often be more readily evaluated by using cylindrical coordinates instead of rectangular coordinates. Some common equations of surfaces in rectangular coordinates along with corresponding equations in cylindrical coordinates are listed in Table 15.6.1. These equations will become handy as we proceed with solving problems using triple integrals.

Table 15.6.1: Equations of Some Common Shapes

| | Circular cylinder | Circular cone | Sphere | Paraboloid |
|---|---|---|---|---|
| *Rectangular* | $x^2 + y^2 = c^2$ | $z^2 = c^2(x^2 + y^2)$ | $x^2 + y^2 + z^2 = c^2$ | $z = c(x^2 + y^2)$ |
| *Cylindrical* | $r = c$ | $z = cr$ | $r^2 + z^2 = c^2$ | $z = cr^2$ |

As before, we start with the simplest bounded region $B$ in $\mathbb{R}^3$ to describe in cylindrical coordinates, in the form of a cylindrical box, $B = \{(r, \theta, z) | a \le r \le b, \alpha \le \theta \le \beta, c \le z \le d\}$ (Figure 15.6.2). Suppose we divide each interval into $l$, $m$, and $n$ subdivisions such that $\Delta r = \frac{b-a}{l}$, $\Delta\theta = \frac{\beta-\alpha}{m}$, and $\Delta z = \frac{d-c}{n}$. Then we can state the following definition for a triple integral in cylindrical coordinates.

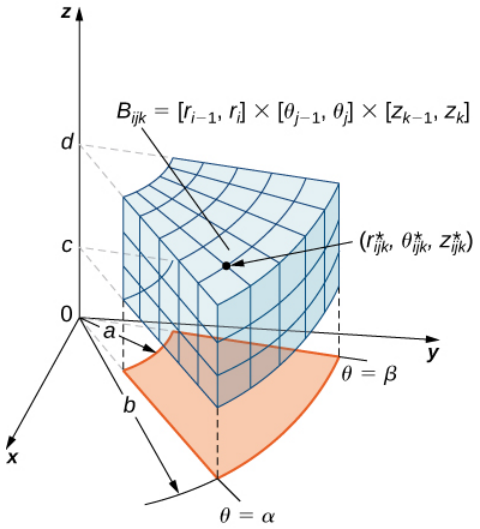

Figure 15.6.2: A cylindrical box $B$ described by cylindrical coordinates.

**DEFINITION: triple integral in cylindrical coordinates**

Consider the cylindrical box (expressed in cylindrical coordinates)

$$B = \{(r, \theta, z) | a \le r \le b, \alpha \le \theta \le \beta, c \le z \le d\}.$$

If the function $f(r, \theta, z)$ is continuous on $B$ and if $(r^*_{ijk}, \theta^*_{ijk}, z^*_{ijk})$ is any sample point in the cylindrical subbox $B_{ijk} = |r_{i-1}, r_i| \times |\theta_{j-1}, \theta_j| \times |z_{k-1}, k_i|$ (Figure 15.6.2), then we can define the *triple integral in cylindrical coordinates* as the limit of a triple Riemann sum, provided the following limit exists:

$$\lim_{l,m,n\to\infty}\sum_{i=1}^{l}\sum_{j=1}^{m}\sum_{k=1}^{n} f(r^*_{ijk},\theta^*_{ijk},z^*_{ijk})\,\Delta r\Delta\theta\Delta z.$$

Note that if $g(x,y,z)$ is the function in rectangular coordinates and the box $B$ is expressed in rectangular coordinates, then the triple integral

$$\iiint_B g(x,y,z)\,dV$$

is equal to the triple integral

$$\iiint_B g(r\,\cos\theta,\,r\,\sin\,\theta,\,z)r\,dr\,d\theta\,dz$$

and we have

$$\iiint_B g(x,y,z)\,dV=\iiint_B g(r\,\cos\theta,\,r\,\sin\,\theta,\,z)\,r\,dr\,d\theta\,dz=\iiint_B f(r,\theta\,z)\,r\,dr\,d\theta\,dz.$$

As mentioned in the preceding section, all the properties of a double integral work well in triple integrals, whether in rectangular coordinates or cylindrical coordinates. They also hold for iterated integrals. To reiterate, in cylindrical coordinates, Fubini's theorem takes the following form:

**Theorem: Fubini's Theorem in Cylindrical Coordinates**

Suppose that $g(x,y,z)$ is continuous on a rectangular box $B$ which when described in cylindrical coordinates looks like $B=\{(r,\theta,z)|a\le r\le b,\,\alpha\le\theta\le\beta,\,c\le z\le d\}$.

Then $g(x,y,z)=g(r\,\cos\theta,r\,\sin\,\theta,z)=f(r,\theta,z)$ and

$$\iiint_B g(x,y,z)\,dV=\int_c^d\int_\beta^\alpha\int_a^b f(r,\theta,z)\,r\,dr\,d\theta\,dz.$$

The iterated integral may be replaced equivalently by any one of the other five iterated integrals obtained by integrating with respect to the three variables in other orders.

Cylindrical coordinate systems work well for solids that are symmetric around an axis, such as cylinders and cones. Let us look at some examples before we define the triple integral in cylindrical coordinates on general cylindrical regions.

**Example 15.6.1: Evaluating a Triple Integral over a Cylindrical Box**

Evaluate the triple integral

$$\iiint_B (zr\,\sin\,\theta)r\,dr\,d\theta\,dz$$

where the cylindrical box $B$ is $B=\{(r,\theta,z)|0\le r\le 2,\,0\le\theta\le\pi/2,\,0,\le z\le 4\}$.

**Solution**

As stated in Fubini's theorem, we can write the triple integral as the iterated integral

$$\iiint_B (zr\,\sin\,\theta)r\,dr\,d\theta\,dz=\int_{\theta=0}^{\theta=\pi/2}\int_{r=0}^{r=2}\int_{z=0}^{z=4}(zr\,\sin\,\theta)\,r\,dz\,dr\,d\theta.$$

The evaluation of the iterated integral is straightforward. Each variable in the integral is independent of the others, so we can integrate each variable separately and multiply the results together. This makes the computation much easier:

$$\int_{\theta=0}^{\theta=\pi/2}\int_{r=0}^{r=2}\int_{z=0}^{z=4}(zr\,\sin\,\theta)\,r\,dz\,dr\,d\theta=\left(\int_0^{\pi/2}\sin\,\theta\,d\theta\right)\left(\int_0^2 r^2dr\right)\left(\int_0^4 z\,dz\right)$$
$$=\left(-\cos\theta\big|_0^{\pi/2}\right)\left(\frac{r^3}{3}\bigg|_0^2\right)\left(\frac{z^2}{2}\bigg|_0^4\right)=\frac{64}{3}.$$

**? Exercise 15.6.1:**

Evaluate the triple integral

$$\int_{\theta=0}^{\theta=\pi}\int_{r=0}^{r=1}\int_{z=0}^{z=4}(rz\,\sin\,\theta)\,r\,dz\,dr\,d\theta.$$

**Hint**

Follow the same steps as in the previous example.

**Answer**

8

If the cylindrical region over which we have to integrate is a general solid, we look at the projections onto the coordinate planes. Hence the triple integral of a continuous function $f(r,\theta,z)$ over a general solid region $E=\{(r,\theta,z)|(r,\theta)\in D, u_1(r,\theta)\le z\le u_2(r,\theta)\}$ in $\mathbb{R}^3$ where $D$ is the projection of $E$ onto the $r\theta$-plane, is

$$\iiint_E f(r,\theta,z)\,r\,dr\,d\theta\,dz=\iint_D\left[\int_{u_1(r,\theta)}^{u_2(r,\theta)}f(r,\theta,z)dz\right]r\,dr\,d\theta.$$

In particular, if $D=\{(r,\theta)|g_1(\theta)\le r\le g_2(\theta),\alpha\le\theta\le\beta\}$, then we have

$$\iiint_E f(r,\theta,z)\,r\,dr\,d\theta=\int_{\theta=\alpha}^{\theta=\beta}\int_{r=g_1(\theta)}^{r=g_2(\theta)}\int_{z=u_1(r,\theta)}^{z=u_2(r,\theta)}f(r,\theta,z)\,r\,dz\,dr\,d\theta.$$

Similar formulas exist for projections onto the other coordinate planes. We can use polar coordinates in those planes if necessary.

**✓ Example 15.6.2: Setting up a Triple Integral in Cylindrical Coordinates over a General Region**

Consider the region $E$ inside the right circular cylinder with equation $r=2\,\sin\,\theta$, bounded below by the $r\theta$-plane and bounded above by the sphere with radius 4 centered at the origin (Figure 15.5.3). Set up a triple integral over this region with a function $f(r,\theta,z)$ in cylindrical coordinates.

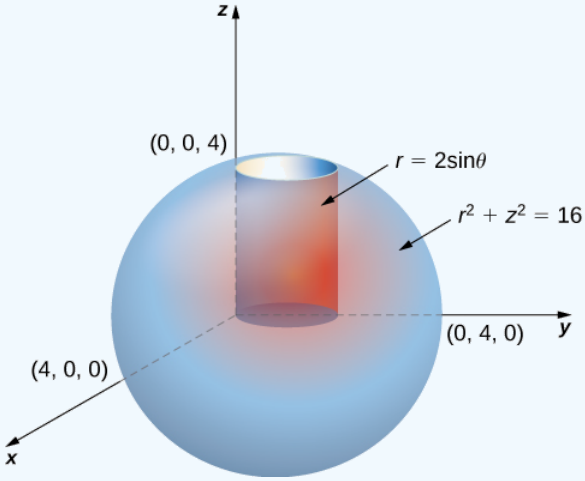

Figure 15.6.3: Setting up a triple integral in cylindrical coordinates over a cylindrical region.

**Solution**

First, identify that the equation for the sphere is $r^2 + z^2 = 16$. We can see that the limits for $z$ are from $0$ to $z = \sqrt{16 - r^2}$. Then the limits for $r$ are from $0$ to $r = 2 \sin \theta$. Finally, the limits for $\theta$ are from $0$ to $\pi$. Hence the region is $E = \{(r, \theta, z) | 0 \leq \theta \leq \pi,\ 0 \leq r \leq 2 \sin \theta,\ 0 \leq z \leq \sqrt{16 - r^2}\}$. Therefore, the triple integral is

$$\iiint_E f(r, \theta, z)\, r\, dz\, dr\, d\theta = \int_{\theta=0}^{\theta=\pi} \int_{r=0}^{r=2 \sin \theta} \int_{z=0}^{z=\sqrt{16-r^2}} f(r, \theta, z)\, r\, dz\, dr\, d\theta.$$

**? Exercise 15.6.2:**

Consider the region inside the right circular cylinder with equation $r = 2 \sin \theta$ bounded below by the $r\theta$-plane and bounded above by $z = 4 - y$. Set up a triple integral with a function $f(r, \theta, z)$ in cylindrical coordinates.

**Hint**

Analyze the region, and draw a sketch.

**Answer**

$$\iiint_E f(r, \theta, z) r\, dz\, dr\, d\theta = \int_{\theta=0}^{\theta=\pi} \int_{r=0}^{r=2 \sin \theta} \int_{z=0}^{z=4-r \sin \theta} f(r, \theta, z) r\, dz\, dr\, d\theta.$$

**✓ Example 15.6.3: Setting up a Triple Integral in Two Ways**

Let $E$ be the region bounded below by the cone $z = \sqrt{x^2 + y^2}$ and above by the paraboloid $z = 2 - x^2 - y^2$. (Figure 15.5.4). Set up a triple integral in cylindrical coordinates to find the volume of the region, using the following orders of integration:

a. $dz\, dr\, d\theta$

b. $dr\, dz\, d\theta$

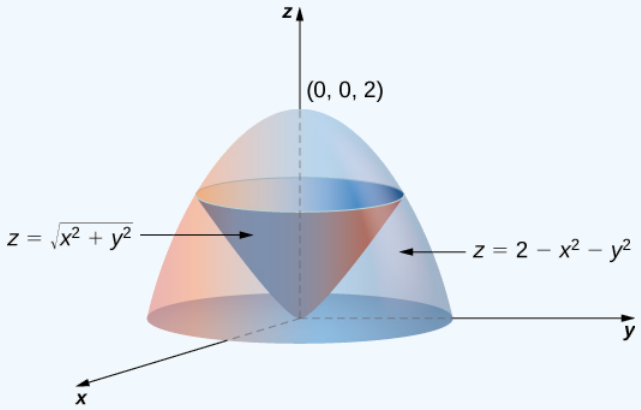

Figure 15.6.4: Setting up a triple integral in cylindrical coordinates over a conical region.

**Solution**

a. The cone is of radius 1 where it meets the paraboloid. Since $z = 2 - x^2 - y^2 = 2 - r^2$ and $z = \sqrt{x^2 + y^2} = r^2$ (assuming $r$ is nonnegative), we have $2 - r^2 = r$. Solving, we have $r^2 + r - 2 = (r + 2)(r - 1) = 0$. Since $r \geq 0$, we have $r = 1$. Therefore $z = 1$. So the intersection of these two surfaces is a circle of radius $1$ in the plane $z = 1$. The cone is the lower bound for $z$ and the paraboloid is the upper bound. The projection of the region onto the $xy$-plane is the circle of radius $1$ centered at the origin.

Thus, we can describe the region as $E = \{(r, \theta, z) | 0 \leq \theta \leq 2\pi,\ 0 \leq r \leq 1,\ r \leq z \leq 2 - r^2\}$.

Hence the integral for the volume is

$$V = \int_{\theta=0}^{\theta=2\pi} \int_{r=0}^{r=1} \int_{z=r}^{z=2-r^2} r\, dz\, dr\, d\theta.$$

b. We can also write the cone surface as $r = z$ and the paraboloid as $r^2 = 2 - z$. The lower bound for $r$ is zero, but the upper bound is sometimes the cone and the other times it is the paraboloid. The plane $z = 1$ divides the region into two regions. Then the region can be described as

$$E = \{(r, \theta, z) | 0 \leq \theta \leq 2\pi,\ 0 \leq z \leq 1,\ 0 \leq r \leq z\}$$
$$\cup \{(r, \theta, z) | 0 \leq \theta \leq 2\pi,\ 1 \leq z \leq 2,\ 0 \leq r \leq \sqrt{2 - z}\}.$$

Now the integral for the volume becomes

$$V = \int_{\theta=0}^{\theta=2\pi} \int_{z=0}^{z=1} \int_{r=0}^{r=z} r\, dr\, dz\, d\theta + \int_{\theta=0}^{\theta=2\pi} \int_{z=1}^{z=2} \int_{r=0}^{r=\sqrt{2-z}} r\, dr\, dz\, d\theta.$$

## ? Exercise 15.6.3:

Redo the previous example with the order of integration $d\theta\, dz\, dr$.

**Hint**

Note that $\theta$ is independent of $r$ and $z$.

**Answer**

$E = \{(r, \theta, z) | 0 \leq \theta \leq 2\pi,\ 0 \leq z \leq 1,\ 0 \leq r \leq 2 - z^2\}$ and

$$V = \int_{r=0}^{r=1} \int_{z=0}^{z=2-r^2} \int_{\theta=0}^{\theta=2\pi} r\, d\theta\, dz\, dr.$$

## ✓ Example 15.6.4: Finding a Volume with Triple Integrals in Two Ways

Let $E$ be the region bounded below by the $r\theta$-plane, above by the sphere $x^2 + y^2 + z^2 = 4$, and on the sides by the cylinder $x^2 + y^2 = 1$ (Figure 15.5.5). Set up a triple integral in cylindrical coordinates to find the volume of the region using the following orders of integration, and in each case find the volume and check that the answers are the same:

a. $dz\, dr\, d\theta$
b. $dr\, dz\, d\theta$.

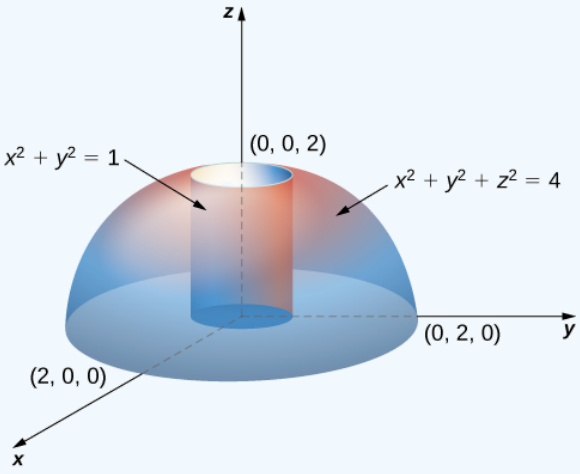

Figure 15.6.5: Finding a cylindrical volume with a triple integral in cylindrical coordinates.

### Solution

a. Note that the equation for the sphere is

$$x^2 + y^2 + z^2 = 4 \text{ or } r^2 + z^2 = 4$$

and the equation for the cylinder is

$$x^2 + y^2 = 1 \text{ or } r^2 = 1.$$

Thus, we have for the region $E$

$$E = \{(r, \theta, z) | 0 \leq z \leq \sqrt{4 - r^2},\ 0 \leq r \leq 1,\ 0 \leq \theta \leq 2\pi\}$$

Hence the integral for the volume is

$$\begin{aligned} V(E) &= \int_{\theta=0}^{\theta=2\pi} \int_{r=0}^{r=1} \int_{z=0}^{z=\sqrt{4-r^2}} r\, dz\, dr\, d\theta \\ &= \int_{\theta=0}^{\theta=2\pi} \int_{r=0}^{r=1} \left[ rz \Big|_{z=0}^{z=\sqrt{4-r^2}} \right] dr\, d\theta \\ &= \int_{\theta=0}^{\theta=2\pi} \int_{r=0}^{r=1} \left( r\sqrt{4 - r^2} \right) dr\, d\theta \\ &= \int_0^{2\pi} \left( \frac{8}{3} - \sqrt{3} \right) d\theta = 2\pi \left( \frac{8}{3} - \sqrt{3} \right) \text{ cubic units.} \end{aligned}$$

b. Since the sphere is $x^2 + y^2 + z^2 = 4$, which is $r^2 + z^2 = 4$, and the cylinder is $x^2 + y^2 = 1$, which is $r^2 = 1$, we have $1 + z^2 = 4$, that is, $z^2 = 3$. Thus we have two regions, since the sphere and the cylinder intersect at $(1, \sqrt{3})$ in the $rz$-plane

$$E_1 = \{(r, \theta, z) | 0 \leq r \leq \sqrt{4 - r^2},\ \sqrt{3} \leq z \leq 2,\ 0 \leq \theta \leq 2\pi\}$$

and

$$E_2 = \{(r, \theta, z) | 0 \leq r \leq 1,\ 0 \leq z \leq \sqrt{3},\ 0 \leq \theta \leq 2\pi\}.$$

Hence the integral for the volume is

$$\begin{aligned} V(E) &= \int_{\theta=0}^{\theta=2\pi} \int_{z=\sqrt{3}}^{z=2} \int_{r=0}^{r=\sqrt{4-r^2}} r\, dr\, dz\, d\theta + \int_{\theta=0}^{\theta=2\pi} \int_{z=0}^{z=\sqrt{3}} \int_{r=0}^{r=1} r\, dr\, dz\, d\theta \\ &= \sqrt{3}\pi + \left( \frac{16}{3} - 3\sqrt{3} \right) \pi \\ &= 2\pi \left( \frac{8}{3} - \sqrt{3} \right) \text{ cubic units.} \end{aligned}$$

**? Exercise 15.6.4**

Redo the previous example with the order of integration $d\theta\, dz\, dr$.

**Hint**

A figure can be helpful. Note that $\theta$ is independent of $r$ and $z$.

**Answer**

$E_2 = \{(r, \theta, z) | 0 \leq \theta \leq 2\pi,\ 0 \leq r \leq 1,\ r \leq z \leq \sqrt{4 - r^2}\}$ and

$$V = \int_{r=0}^{r=1} \int_{z=r}^{z=\sqrt{4-r^2}} \int_{\theta=0}^{\theta=2\pi} r\, d\theta\, dz\, dr.$$

## Review of Spherical Coordinates

In three-dimensional space $\mathbb{R}^3$ in the spherical coordinate system, we specify a point $P$ by its distance $\rho$ from the origin, the polar angle $\theta$ from the positive $x$-axis (same as in the cylindrical coordinate system), and the angle $\varphi$ from the positive $z$-axis and the line $OP$ (Figure 15.6.6). Note that $\rho > 0$ and $0 \leq \varphi \leq \pi$. (Refer to Cylindrical and Spherical Coordinates for a review.) Spherical coordinates are useful for triple integrals over regions that are symmetric with respect to the origin.

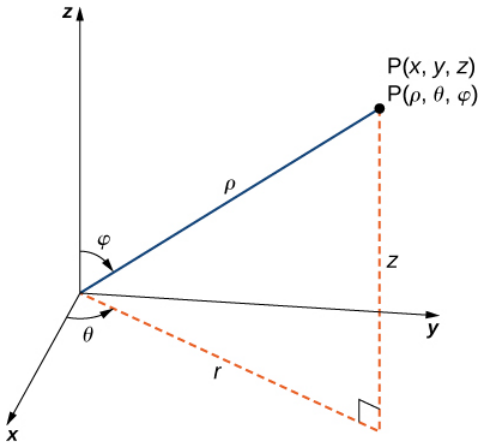

Figure 15.6.6: The spherical coordinate system locates points with two angles and a distance from the origin.

Recall the relationships that connect rectangular coordinates with spherical coordinates.

From spherical coordinates to rectangular coordinates:

$$x = \rho \sin \varphi \cos \theta,\ y = \rho \sin \varphi \sin \theta,\ and\ z = \rho \cos \varphi.$$

From rectangular coordinates to spherical coordinates:

$$\rho^2 = x^2 + y^2 + z^2,\ \tan \theta = \frac{y}{x},\ \varphi = \arccos\left(\frac{z}{\sqrt{x^2 + y^2 + z^2}}\right).$$

Other relationships that are important to know for conversions are

- $r = \rho \sin \varphi$
- $\theta = \theta$ These equations are used to convert from spherical coordinates to cylindrical coordinates.
- $z = \rho \cos \varphi$

and

- $\rho = \sqrt{r^2 + z^2}$
- $\theta = \theta$ These equations are used to convert from cylindrical coordinates to spherical coordinates.
- $\varphi = \arccos\left(\frac{z}{\sqrt{r^2+z^2}}\right)$

15.6.7 shows a few solid regions that are convenient to express in spherical coordinates.

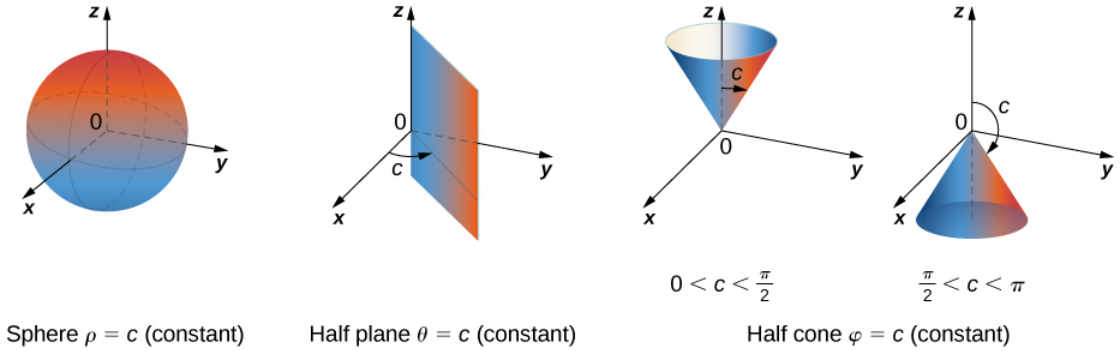

Figure 15.6.7: Spherical coordinates are especially convenient for working with solids bounded by these types of surfaces. (The letter $c$ indicates a constant.)

## Integration in Spherical Coordinates

We now establish a triple integral in the spherical coordinate system, as we did before in the cylindrical coordinate system. Let the function $f(\rho, \theta, \varphi)$ be continuous in a bounded spherical box, $B = \{(\rho, \theta, \varphi) | a \le \rho \le b,\ \alpha \le \theta \le \beta,\ \gamma \le \varphi \le \psi\}$. We then divide each interval into $l, m, n$ and $n$ subdivisions such that $\Delta\rho = \frac{b-a}{l}$, $\Delta\theta = \frac{\beta-\alpha}{m}$. $\Delta\varphi = \frac{\psi-\gamma}{n}$. Now we can illustrate the following theorem for

triple integrals in spherical coordinates with $(\rho^*_{ijk}, \theta^*_{ijk}, \varphi^*_{ijk})$ being any sample point in the spherical subbox $B_{ijk}$. For the volume element of the subbox $\Delta V$ in spherical coordinates, we have $\Delta V = (\Delta\rho)\,(\rho\Delta\varphi)\,(\rho\,\sin\,\varphi\,\Delta\theta)$, as shown in the following figure.

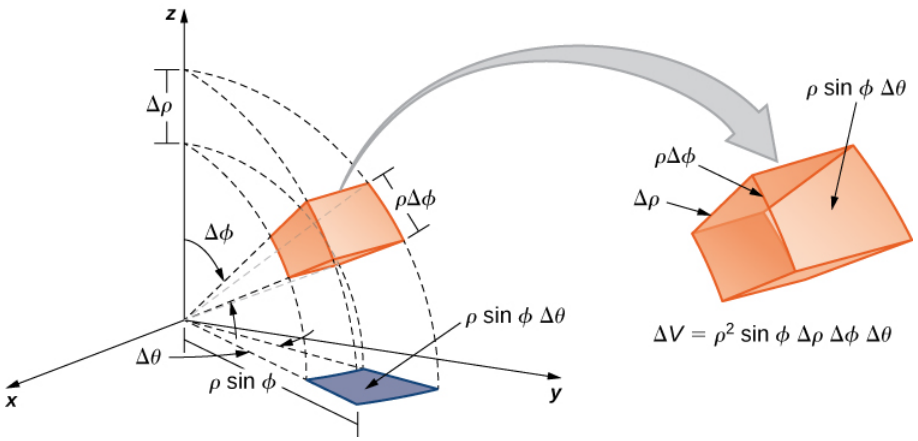

Figure 15.6.8: The volume element of a box in spherical coordinates.

**Definition: triple integral in spherical coordinates**

The **triple integral in spherical coordinates** is the limit of a triple Riemann sum,

$$\lim_{l,m,n\to\infty} \sum_{i=1}^{l}\sum_{j=1}^{m}\sum_{k=1}^{n} f(\rho^*_{ijk}, \theta^*_{ijk}, \varphi^*_{ijk})(\rho^*_{ijk})^2 \sin\,\varphi\Delta\rho\,\Delta\theta\Delta\varphi$$

provided the limit exists.

As with the other multiple integrals we have examined, all the properties work similarly for a triple integral in the spherical coordinate system, and so do the iterated integrals. Fubini's theorem takes the following form.

**Theorem: Fubini's Theorem for Spherical Coordinates**

If $f(\rho, \theta, \varphi)$ is continuous on a spherical solid box $B = [a, b] \times [\alpha, \beta] \times [\gamma, \psi]$, then

$$\iiint_B f(\rho, \theta, \varphi)\,\rho^2 \sin\,\varphi\,d\rho\,d\varphi\,d\theta = \int_{\varphi=\gamma}^{\varphi=\psi}\int_{\theta=\alpha}^{\theta=\beta}\int_{\rho=a}^{\rho=b} f(\rho, \theta, \varphi)\,\rho^2 \sin\,\varphi\,d\rho\,d\varphi\,d\theta.$$

This iterated integral may be replaced by other iterated integrals by integrating with respect to the three variables in other orders.

As stated before, spherical coordinate systems work well for solids that are symmetric around a point, such as spheres and cones. Let us look at some examples before we consider triple integrals in spherical coordinates on general spherical regions.

**Example 15.6.5: Evaluating a Triple Integral in Spherical Coordinates**

Evaluate the iterated triple integral

$$\int_{\theta=0}^{\theta=2\pi}\int_{\varphi=0}^{\varphi=\pi/2}\int_{\rho=0}^{\rho=1} \rho^2 \sin\,\varphi\,d\rho\,d\varphi\,d\theta.$$

**Solution**

As before, in this case the variables in the iterated integral are actually independent of each other and hence we can integrate each piece and multiply:

$$\int_0^{2\pi}\int_0^{\pi/2}\int_0^1 \rho^2 \sin\,\varphi\,d\rho\,d\varphi\,d\theta = \int_0^{2\pi} d\theta \int_0^{\pi/2} \sin\,\varphi\,d\varphi \int_0^1 \rho^2 d\rho = (2\pi)\,(1)\left(\frac{1}{3}\right) = \frac{2\pi}{3}$$

The concept of triple integration in spherical coordinates can be extended to integration over a general solid, using the projections onto the coordinate planes. Note that $dV$ and $dA$ mean the increments in volume and area, respectively. The variables $V$ and $A$ are used as the variables for integration to express the integrals.

The triple integral of a continuous function $f(\rho, \theta, \varphi)$ over a general solid region

$$E = \{(\rho, \theta, \varphi) | (\rho, \theta) \in D, u_1(\rho, \theta) \leq \varphi \leq u_2(\rho, \theta)\}$$

in $\mathbb{R}^3$, where $D$ is the projection of $E$ onto the $\rho\theta$-plane, is

$$\iiint_E f(\rho, \theta, \varphi)\, dV = \iint_D \left[ \int_{u_1(\rho,\theta)}^{u_2(\rho,\theta)} f(\rho, \theta, \varphi)\, d\varphi \right] dA.$$

In particular, if $D = \{(\rho, \theta) | g_1(\theta) \leq \rho \leq g_2(\theta),\ \alpha \leq \theta \leq \beta\}$, the we have

$$\iiint_E f(\rho, \theta, \varphi)\, dV = \int_\alpha^\beta \int_{g_1(\theta)}^{g_2(\theta)} \int_{u_1(\rho,\theta)}^{u_2(\rho,\theta)} f(\rho, \theta, \varphi) \rho^2 \sin\varphi\, d\varphi\, d\rho\, d\theta.$$

Similar formulas occur for projections onto the other coordinate planes.

### Example 15.6.6: Setting up a Triple Integral in Spherical Coordinates

Set up an integral for the volume of the region bounded by the cone $z = \sqrt{3(x^2 + y^2)}$ and the hemisphere $z = \sqrt{4 - x^2 - y^2}$ (see the figure below).

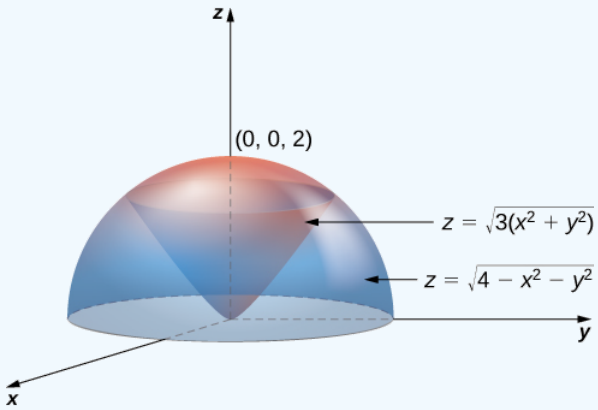

Figure 15.6.9: A region bounded below by a cone and above by a hemisphere.

#### Solution

Using the conversion formulas from rectangular coordinates to spherical coordinates, we have:

For the cone: $z = \sqrt{3(x^2 + y^2)}$ or $\rho \cos\varphi = \sqrt{3}\rho \sin\varphi$ or $\tan\varphi = \frac{1}{\sqrt{3}}$ or $\varphi = \frac{\pi}{6}$.

For the sphere: $z = \sqrt{4 - x^2 - y^2}$ or $z^2 + x^2 + y^2 = 4$ or $\rho^2 = 4$ or $\rho = 2$.

Thus, the triple integral for the volume is

$$V(E) = \int_{\theta=0}^{\theta=2\pi} \int_{\varphi=0}^{\varphi=\pi/6} \int_{\rho=0}^{\rho=2} \rho^2 \sin\varphi\, d\rho\, d\varphi\, d\theta.$$

### Exercise 15.6.5

Set up a triple integral for the volume of the solid region bounded above by the sphere $\rho = 2$ and bounded below by the cone $\varphi = \pi/3$.

**Hint**

Follow the steps of the previous example.

**Answer**

$$V(E) = \int_{\theta=0}^{\theta=2\pi} \int_{\varphi=0}^{\varphi=\pi/3} \int_{\rho=0}^{\rho=2} \rho^2 \sin\,\varphi \, d\rho \, d\varphi \, d\theta$$

### Example 15.6.7: Interchanging Order of Integration in Spherical Coordinates

Let $E$ be the region bounded below by the cone $z = \sqrt{x^2 + y^2}$ and above by the sphere $z = x^2 + y^2 + z^2$ (Figure 15.5.10). Set up a triple integral in spherical coordinates and find the volume of the region using the following orders of integration:

a. $d\rho \, d\phi \, d\theta$
b. $d\varphi \, d\rho \, d\theta$

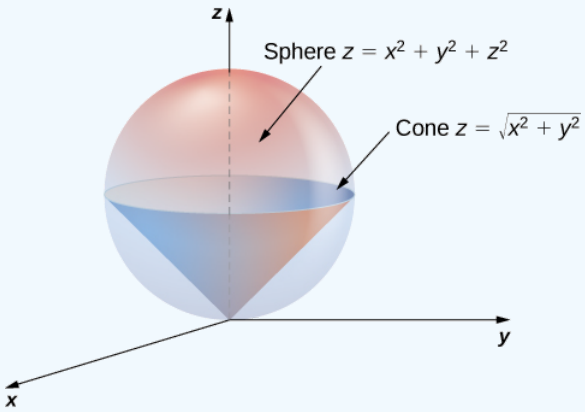

Figure 15.6.10:. A region bounded below by a cone and above by a sphere.

**Solution**

a. Use the conversion formulas to write the equations of the sphere and cone in spherical coordinates.

For the sphere:

$$\begin{aligned} x^2 + y^2 + z^2 &= z \\ \rho^2 &= \rho \cos\,\varphi \\ \rho &= \cos\,\varphi. \end{aligned}$$

For the cone:

$$\begin{aligned} z &= \sqrt{x^2 + y^2} \\ \rho \cos\,\varphi &= \sqrt{\rho^2 \sin^2\,\varphi \cos^2\theta + \rho^2 \sin^2\,\varphi \sin^2\theta} \\ \rho \cos\,\varphi &= \sqrt{\rho^2 \sin^2\,\varphi\,(\cos^2\theta + \sin^2\theta)} \\ \rho \cos\,\varphi &= \rho \sin\,\varphi \\ \cos\,\varphi &= \sin\,\varphi \\ \varphi &= \pi/4. \end{aligned}$$

Hence the integral for the volume of the solid region $E$ becomes

$$V(E) = \int_{\theta=0}^{\theta=2\pi} \int_{\varphi=0}^{\varphi=\pi/4} \int_{\rho=0}^{\rho=\cos\,\varphi} \rho^2 \sin\,\varphi \, d\rho \, d\varphi \, d\theta.$$

b. Consider the $\varphi\rho$-plane. Note that the ranges for $\varphi$ and $\rho$ (from part a.) are

$$\begin{aligned} 0 \le \varphi &\le \pi/4 \\ 0 \le \rho &\le \cos\varphi \end{aligned}$$

The curve $\rho = \cos\,\varphi$ meets the line $\varphi = \pi/4$ at the point $(\pi/4, \sqrt{2}/2)$. Thus, to change the order of integration, we need to use two pieces:

$$0 \le \rho \le \sqrt{2}/2,\ 0 \le \varphi \le \pi/4$$

and

$$\sqrt{2}/2 \leq \rho \leq 1,\ 0 \leq \varphi \leq \cos^{-1}\rho.$$

Hence the integral for the volume of the solid region $E$ becomes

$$V(E) = \int_{\theta=0}^{\theta=2\pi}\int_{\rho=0}^{\rho=\sqrt{2}/2}\int_{\varphi=0}^{\varphi=\pi/4}\rho^2\sin\,\varphi\,d\varphi\,d\rho\,d\theta + \int_{\theta=0}^{\theta=2\pi}\int_{\rho=\sqrt{2}/2}^{\rho=1}\int_{\varphi=0}^{\varphi=\cos^{-1}\rho}\rho^2\sin\,\varphi\,d\varphi\,d\rho\,d\theta$$

In each case, the integration results in $V(E) = \frac{\pi}{8}$.

Before we end this section, we present a couple of examples that can illustrate the conversion from rectangular coordinates to cylindrical coordinates and from rectangular coordinates to spherical coordinates.

### Example 15.6.8: Converting from Rectangular Coordinates to Cylindrical Coordinates

Convert the following integral into cylindrical coordinates:

$$\int_{y=-1}^{y=1}\int_{x=0}^{x=\sqrt{1-y^2}}\int_{z=x^2+y^2}^{z=\sqrt{x^2+y^2}} xyz\,dz\,dx\,dy.$$

**Solution**

The ranges of the variables are

$$\begin{aligned} -1 &\leq y \leq y \\ 0 &\leq x \leq \sqrt{1-y^2} \\ x^2+y^2 &\leq z \leq \sqrt{x^2+y^2}. \end{aligned}$$

The first two inequalities describe the right half of a circle of radius 1. Therefore, the ranges for $\theta$ and $r$ are

$$-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2} \text{ and } 0 \leq r \leq 1.$$

The limits of $z$ are $r^2 \leq z \leq r$, hence

$$\int_{y=-1}^{y=1}\int_{x=0}^{x=\sqrt{1-y^2}}\int_{z=x^2+y^2}^{z=\sqrt{x^2+y^2}} xyz\,dz\,dx\,dy = \int_{\theta=-\pi/2}^{\theta=\pi/2}\int_{r=0}^{r=1}\int_{z=r^2}^{z=r} r(r\,\cos\theta)\,(r\,\sin\,\theta)\,z\,dz\,dr\,d\theta.$$

### Example 15.6.9: Converting from Rectangular Coordinates to Spherical Coordinates

Convert the following integral into spherical coordinates:

$$\int_{y=0}^{y=3}\int_{x=0}^{x=\sqrt{9-y^2}}\int_{z=\sqrt{x^2+y^2}}^{z=\sqrt{18-x^2-y^2}} (x^2+y^2+z^2)\,dz\,dx\,dy.$$

**Solution**

The ranges of the variables are

$$\begin{aligned} 0 &\leq y \leq 3 \\ 0 &\leq x \leq \sqrt{9-y^2} \\ \sqrt{x^2+y^2} &\leq z \leq \sqrt{18-x^2-y^2}. \end{aligned}$$

The first two ranges of variables describe a quarter disk in the first quadrant of the $xy$-plane. Hence the range for $\theta$ is $0 \leq \theta \leq \frac{\pi}{2}$.

The lower bound $z = \sqrt{x^2+y^2}$ is the upper half of a cone and the upper bound $z = \sqrt{18-x^2-y^2}$ is the upper half of a sphere. Therefore, we have $0 \leq \rho \leq \sqrt{18}$, which is $0 \leq \rho \leq 3\sqrt{2}$.

For the ranges of $\varphi$ we need to find where the cone and the sphere intersect, so solve the equation

$$\begin{aligned} r^2 + z^2 &= 18 \\ \left(\sqrt{x^2+y^2}\right)^2 + z^2 &= 18 \\ z^2 + z^2 &= 18 \\ 2z^2 &= 18 \\ z^2 &= 9 \\ z &= 3. \end{aligned}$$

This gives

$$\begin{aligned} 3\sqrt{2}\cos\varphi &= 3 \\ \cos\varphi &= \frac{1}{\sqrt{2}} \\ \varphi &= \frac{\pi}{4}. \end{aligned}$$

Putting this together, we obtain

$$\int_{y=0}^{y=3}\int_{x=0}^{x=\sqrt{9-y^2}}\int_{z=\sqrt{x^2+y^2}}^{z=\sqrt{18-x^2-y^2}}(x^2+y^2+z^2)\,dz\,dx\,dy = \int_{\varphi=0}^{\varphi=\pi/4}\int_{\theta=0}^{\theta=\pi/2}\int_{\rho=0}^{\rho=3\sqrt{2}}\rho^4\sin\varphi\,d\rho\,d\theta\,d\varphi.$$

**? Exercise 15.6.6:**

Use rectangular, cylindrical, and spherical coordinates to set up triple integrals for finding the volume of the region inside the sphere $x^2+y^2+z^2=4$ but outside the cylinder $x^2+y^2=1$.

**Answer: Rectangular**

$$\int_{x=-2}^{x=2}\int_{y=-\sqrt{4-x^2}}^{y=\sqrt{4-x^2}}\int_{z=-\sqrt{4-x^2-y^2}}^{z=\sqrt{4-x^2-y^2}}dz\,dy\,dx - \int_{x=-1}^{x=1}\int_{y=-\sqrt{1-x^2}}^{y=\sqrt{1-x^2}}\int_{z=-\sqrt{4-x^2-y^2}}^{z=\sqrt{4-x^2-y^2}}dz\,dy\,dx.$$

**Answer: Cylindrical**

$$\int_{\theta=0}^{\theta=2\pi}\int_{r=1}^{r=2}\int_{z=-\sqrt{4-r^2}}^{z=\sqrt{4-r^2}}r\,dz\,dr\,d\theta.$$

**Answer: Spherical**

$$\int_{\varphi=\pi/6}^{\varphi=5\pi/6}\int_{\theta=0}^{\theta=2\pi}\int_{\rho=\csc\varphi}^{\rho=2}\rho^2\sin\varphi\,d\rho\,d\theta\,d\varphi.$$

Now that we are familiar with the spherical coordinate system, let's find the volume of some known geometric figures, such as spheres and ellipsoids.

**✓ Example 15.6.10: Chapter Opener: Finding the Volume of l'Hemisphèric**

Find the volume of the spherical planetarium in l'Hemisphèric in Valencia, Spain, which is five stories tall and has a radius of approximately 50 ft, using the equation $x^2+y^2+z^2=r^2$.

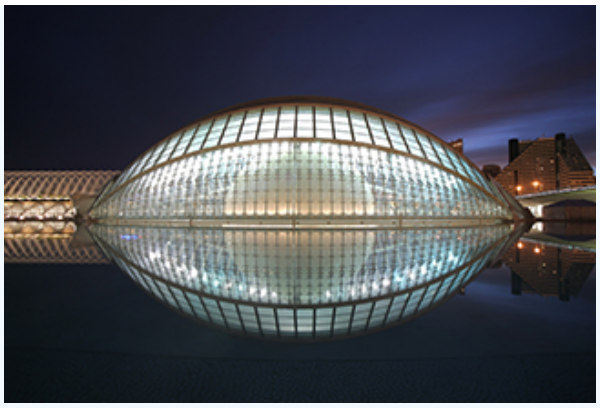

Figure 15.6.11: (credit: modification of work by Javier Yaya Tur, Wikimedia Commons)

### Solution

We calculate the volume of the ball in the first octant, where $x \leq 0$, $y \leq 0$, and $z \leq 0$, using spherical coordinates, and then multiply the result by 8 for symmetry. Since we consider the region $D$ as the first octant in the integral, the ranges of the variables are

$$0 \leq \varphi \leq \frac{\pi}{2}, 0 \leq \rho \leq r, 0 \leq \theta \leq \frac{\pi}{2}.$$

Therefore,

$$\begin{aligned} V = \iiint_D dx\, dy\, dz &= 8 \int_{\theta=0}^{\theta=\pi/2} \int_{\rho=0}^{\rho=\pi} \int_{\varphi=0}^{\varphi=\pi/2} \rho^2 \sin\theta \, d\varphi \, d\rho \, d\varphi \\ &= 8 \int_{\varphi=0}^{\varphi=\pi/2} d\varphi \int_{\rho=0}^{\rho=r} \rho^2 d\rho \int_{\theta=0}^{\theta=\pi/2} \sin\theta \, d\theta \\ &= 8 \left(\frac{\pi}{2}\right) \left(\frac{r^3}{3}\right) (1) \\ &= \frac{4}{3}\pi r^3. \end{aligned}$$

This exactly matches with what we knew. So for a sphere with a radius of approximately 50 ft, the volume is $\frac{4}{3}\pi(50)^3 \approx 523,600\ ft^3$.

For the next example we find the volume of an ellipsoid.

### Example 15.6.11: Finding the Volume of an Ellipsoid

Find the volume of the ellipsoid $\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$.

### Solution

We again use symmetry and evaluate the volume of the ellipsoid using spherical coordinates. As before, we use the first octant $x \leq 0$, $y \leq 0$, and $z \leq 0$ and then multiply the result by 8.

In this case the ranges of the variables are

$$0 \leq \varphi \leq \frac{\pi}{2}\, 0 \leq \rho \leq 1, \text{ and } 0 \leq \theta \leq \frac{\pi}{2}.$$

Also, we need to change the rectangular to spherical coordinates in this way:

$$x = a\rho \cos\varphi \sin\theta,\ y = b\rho \sin\varphi \sin\theta, \text{ and } z = cp \cos\theta.$$

Then the volume of the ellipsoid becomes

$$
\begin{aligned}
V &= \iiint_D dx\,dy\,dz \\
&= 8\int_{\theta=0}^{\theta=\pi/2}\int_{\rho=0}^{\rho=1}\int_{\varphi=0}^{\varphi=\pi/2} abc\,\rho^2\sin\theta\,d\varphi\,d\rho\,d\theta \\
&= 8abc\int_{\varphi=0}^{\varphi=\pi/2} d\varphi\int_{\rho=0}^{\rho=1}\rho^2 d\rho\int_{\theta=0}^{\theta=\pi/2}\sin\theta\,d\theta \\
&= 8abc\left(\frac{\pi}{2}\right)\left(\frac{1}{3}\right)(1) \\
&= \frac{4}{3}\pi abc.
\end{aligned}
$$

### Example 15.6.12: Finding the Volume of the Space Inside an Ellipsoid and Outside a Sphere

Find the volume of the space inside the ellipsoid $\frac{x^2}{75^2}+\frac{y^2}{80^2}+\frac{z^2}{90^2}=1$ and outside the sphere $x^2+y^2+z^2=50^2$.

**Solution**

This problem is directly related to the l'Hemisphèric structure. The volume of space inside the ellipsoid and outside the sphere might be useful to find the expense of heating or cooling that space. We can use the preceding two examples for the volume of the sphere and ellipsoid and then substract.

First we find the volume of the ellipsoid using $a=75$ ft, $b=80$ ft, and $c=90$ ft in the result from Example. Hence the volume of the ellipsoid is

$$V_{ellipsoid}=\frac{4}{3}\pi(75)(80)(90)\approx 2,262,000\ ft^3.$$

From Example, the volume of the sphere is

$$V_{sphere}\approx 523,600\ ft^3.$$

Therefore, the volume of the space inside the ellipsoid $\frac{x^2}{75^2}+\frac{y^2}{80^2}+\frac{z^2}{90^2}=1$ and outside the sphere $x^2+y^2+z^2=50^2$ is approximately

$$V_{Hemispheric}=V_{ellipsoid}-V_{sphere}=1,738,400\ ft^3.$$

### Student Project: Hot air balloons

Hot air ballooning is a relaxing, peaceful pastime that many people enjoy. Many balloonist gatherings take place around the world, such as the Albuquerque International Balloon Fiesta. The Albuquerque event is the largest hot air balloon festival in the world, with over 500 balloons participating each year.

Figure 15.6.12: Balloons lift off at the 2001 Albuquerque International Balloon Fiesta. (credit: David Herrera, Flickr)

As the name implies, hot air balloons use hot air to generate lift. (Hot air is less dense than cooler air, so the balloon floats as long as the hot air stays hot.) The heat is generated by a propane burner suspended below the opening of the basket. Once the balloon takes off, the pilot controls the altitude of the balloon, either by using the burner to heat the air and ascend or by using a vent near the top of the balloon to release heated air and descend. The pilot has very little control over where the balloon goes, however—balloons are at the mercy of the winds. The uncertainty over where we will end up is one of the reasons balloonists are attracted to the sport.

In this project we use triple integrals to learn more about hot air balloons. We model the balloon in two pieces. The top of the balloon is modeled by a half sphere of radius 28

feet. The bottom of the balloon is modeled by a frustum of a cone (think of an ice cream cone with the pointy end cut off). The radius of the large end of the frustum is $28$ feet and the radius of the small end of the frustum is $28$ feet. A graph of our balloon model and a cross-sectional diagram showing the dimensions are shown in the following figure.

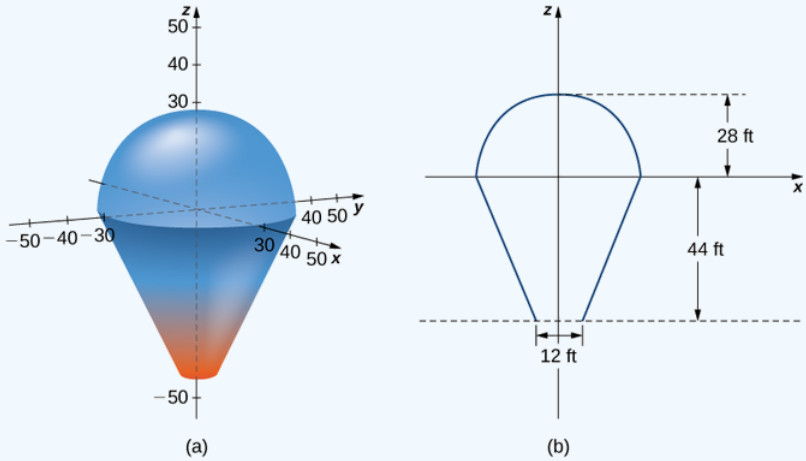

Figure 15.6.13: (a) Use a half sphere to model the top part of the balloon and a frustum of a cone to model the bottom part of the balloon. (b) A cross section of the balloon showing its dimensions.

We first want to find the volume of the balloon. If we look at the top part and the bottom part of the balloon separately, we see that they are geometric solids with known volume formulas. However, it is still worthwhile to set up and evaluate the integrals we would need to find the volume. If we calculate the volume using integration, we can use the known volume formulas to check our answers. This will help ensure that we have the integrals set up correctly for the later, more complicated stages of the project.

1. Find the volume of the balloon in two ways.

a. Use triple integrals to calculate the volume. Consider each part of the balloon separately. (Consider using spherical coordinates for the top part and cylindrical coordinates for the bottom part.)

b. Verify the answer using the formulas for the volume of a sphere, $V = \frac{4}{3}\pi r^3$, and for the volume of a cone, $V = \frac{1}{3}\pi r^2 h$.

In reality, calculating the temperature at a point inside the balloon is a tremendously complicated endeavor. In fact, an entire branch of physics (thermodynamics) is devoted to studying heat and temperature. For the purposes of this project, however, we are going to make some simplifying assumptions about how temperature varies from point to point within the balloon. Assume that just prior to liftoff, the temperature (in degrees Fahrenheit) of the air inside the balloon varies according to the function

$$T_0(r, \theta, z) = \frac{z - r}{10} + 210.$$

2. What is the average temperature of the air in the balloon just prior to liftoff? (Again, look at each part of the balloon separately, and do not forget to convert the function into spherical coordinates when looking at the top part of the balloon.)

Now the pilot activates the burner for $10$ seconds. This action affects the temperature in a $12$-foot-wide column $20$ feet high, directly above the burner. A cross section of the balloon depicting this column in shown in the following figure

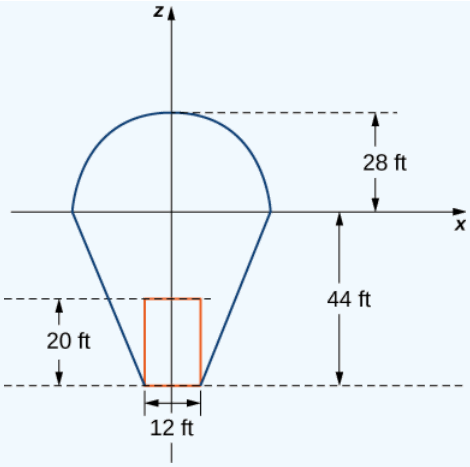

Figure 15.6.14: Activating the burner heats the air in a 20-foot-high, 12-foot-wide column directly above the burner.

Assume that after the pilot activates the burner for 10 seconds, the temperature of the air in the column described above *increases* according to the formula

$$H(r,\theta,z) = -2z - 48.$$

Then the temperature of the air in the column is given by

$$T_1(r,\theta,z) = \frac{z-r}{10} + 210 + (-2z - 48),$$

while the temperature in the remainder of the balloon is still given by

$$T_0(r,\theta,z) = \frac{z-r}{10} + 210.$$

3. Find the average temperature of the air in the balloon after the pilot has activated the burner for 10 seconds.

## Key Concepts

- To evaluate a triple integral in cylindrical coordinates, use the iterated integral

$$\int_{\theta=\alpha}^{\theta=\beta} \int_{r=g_1(\theta)}^{r=g_2(\theta)} \int_{z=u_1(r,\theta)}^{u_2(r,\theta)} f(r,\theta,z) r \, dz \, dr \, d\theta.$$

- To evaluate a triple integral in spherical coordinates, use the iterated integral

$$\int_{\theta=\alpha}^{\theta=\beta} \int_{\rho=g_1(\theta)}^{\rho=g_2(\theta)} \int_{\varphi=u_1(r,\theta)}^{u_2(r,\theta)} f(\rho,\theta,\varphi)\, \rho^2 \sin\varphi \, d\varphi \, d\rho \, d\theta.$$

### Key Equations

- **Triple integral in cylindrical coordinates**

$$\iiint_B g(s,y,z)dV = \iiint_B g(r\cos\theta,\, r\sin\theta,\, z) r \, dr \, d\theta \, dz = \iiint_B f(r,\theta,z) r \, dr \, d\theta \, dz$$

- **Triple integral in spherical coordinates**

$$\iiint_B f(\rho,\theta,\varphi)\rho^2 \sin\varphi \, d\rho \, d\varphi \, d\theta = \int_{\varphi=\gamma}^{\varphi=\psi} \int_{\theta=\alpha}^{\theta=\beta} \int_{\rho=a}^{\rho=b} f(\rho,\theta,\varphi)\rho^2 \sin\varphi \, d\rho \, d\varphi \, d\theta$$

## Glossary

**triple integral in cylindrical coordinates**

the limit of a triple Riemann sum, provided the following limit exists:

$$lim_{l,m,n\to\infty}\sum_{i=1}^{l}\sum_{j=1}^{m}\sum_{k=1}^{n}f(r^*_{ijk},\theta^*_{ijk},s^*_{ijk})r^*_{ijk}\Delta r\Delta\theta\Delta z$$

**triple integral in spherical coordinates**

the limit of a triple Riemann sum, provided the following limit exists:

$$lim_{l,m,n\to\infty}\sum_{i=1}^{l}\sum_{j=1}^{m}\sum_{k=1}^{n}f(\rho^*_{ijk},\theta^*_{ijk},\varphi^*_{ijk})(\rho^*_{ijk})^2\sin\,\varphi\Delta\rho\Delta\theta\Delta\varphi$$

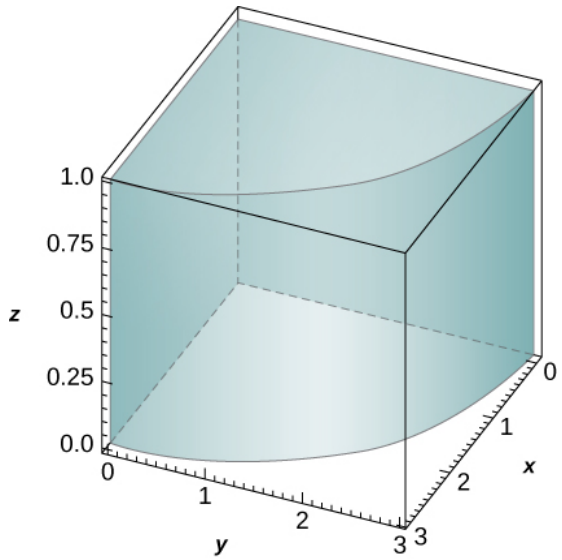
# 15.6E: EXERCISES FOR SECTION 15.5

**In exercises 1 - 8, evaluate the triple integrals $\iiint_E f(x,y,z)\,dV$ over the solid $E$.**

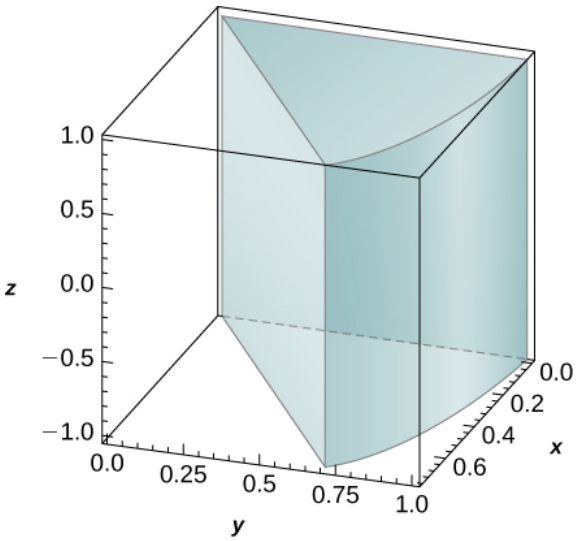
1. $f(x,y,z)=z,\quad B=\{(x,y,z)\,|\,x^2+y^2\le 9,\quad x\le 0,\quad y\le 0,\quad 0\le z\le 1\}$



**Answer**

$\frac{9\pi}{8}$

2. $f(x,y,z)=xz^2,\ B=\{(x,y,z)\,|\,x^2+y^2\le 16,\ x\ge 0,\ y\le 0,\ -1\le z\le 1\}$
3. $f(x,y,z)=xy,\ B=\{(x,y,z)\,|\,x^2+y^2\le 1,\ x\ge 0,\ x\ge y,\ -1\le z\le 1\}$



**Answer**

$\frac{1}{8}$

4. $f(x,y,z)=x^2+y^2,\ B=\{(x,y,z)\,|\,x^2+y^2\le 4,\ x\ge 0,\ x\le y,\ 0\le z\le 3\}$
5. $f(x,y,z)=e^{\sqrt{x^2+y^2}},\ B=\{(x,y,z)\,|\,1\le x^2+y^2\le 4,\ y\le 0,\ x\le y\sqrt{3},\ 2\le z\le 3\}$

**Answer**

$\frac{\pi e^2}{6}$

6. $f(x,y,z)=\sqrt{x^2+y^2},\ B=\{(x,y,z)\,|\,1\le x^2+y^2\le 9,\ y\le 0,\ 0\le z\le 1\}$

7. a. Let $B$ be a cylindrical shell with inner radius $a$ outer radius $b$, and height $c$ where $0<a<b$ and $c>0$. Assume that a function $F$ defined on $B$ can be expressed in cylindrical coordinates as $F(x,y,z)=f(r)+h(z)$, where $f$ and $h$ are differentiable functions. If $\int_a^b \bar{f}(r)\,dr=0$ and $\bar{h}(0)=0$, where $\bar{f}$ and $\bar{h}$ are antiderivatives of $f$ and $h$, respectively, show that $\iiint_B F(x,y,z)\,dV=2\pi c(b\bar{f}(b)-a\bar{f}(a))+\pi(b^2-a^2)\bar{h}(c)$.

b. Use the previous result to show that $\iiint_B \left(z+\sin\sqrt{x^2+y^2}\right)\,dx\,dy\,dz=6\pi^2(\pi-2)$, where $B$ is a cylindrical shell with inner radius $\pi$ outer radius $2\pi$, and height $2$.

8. a. Let $B$ be a cylindrical shell with inner radius $a$ outer radius $b$ and height $c$ where $0<a<b$ and $c>0$. Assume that a function $F$ defined on $B$ can be expressed in cylindrical coordinates as $F(x,y,z)=f(r)g(\theta)f(z)$, where $f,\ g$, and $h$ are differentiable functions. If $\int_a^b \tilde{f}(r)\,dr=0$, where $\tilde{f}$ is an antiderivative of $f$, show that $\iiint_B F(x,y,z)\,dV=[b\tilde{f}(b)-a\tilde{f}(a)][\tilde{g}(2\pi)-\tilde{g}(0)][\tilde{h}(c)-\tilde{h}(0)]$, where $\tilde{g}$ and $\tilde{h}$ are antiderivatives of $g$ and $h$, respectively.

b. Use the previous result to show that $\iiint_B z\sin\sqrt{x^2+y^2}\,dx\,dy\,dz=-12\pi^2$, where $B$ is a cylindrical shell with inner radius $\pi$ outer radius $2\pi$, and height $2$.

**In exercises 9 - 12, the boundaries of the solid $E$ are given in cylindrical coordinates.**

a. Express the region $E$ in cylindrical coordinates.

b. Convert the integral $\iiint_E f(x,y,z)\,dV$ to cylindrical coordinates.

9. $E$ is bounded by the right circular cylinder $r=4\sin\theta$, the $r\theta$-plane, and the sphere $r^2+z^2=16$.

**Answer**

a. $E=\{(r,\theta,z)\,|\,0\le\theta\le\pi,\ 0\le r\le 4\sin\theta,\ 0\le z\le\sqrt{16-r^2}\}$

b. $\int_0^{\pi}\int_0^{4\sin\theta}\int_0^{\sqrt{16-r^2}} f(r,\theta,z)r\,dz\,dr\,d\theta$

10. $E$ is bounded by the right circular cylinder $r=\cos\theta$, the $r\theta$-plane, and the sphere $r^2+z^2=9$.

11. $E$ is located in the first octant and is bounded by the circular paraboloid $z=9-3r^2$, the cylinder $r=\sqrt{3}$, and the plane $r(\cos\theta+\sin\theta)=20-z$.

**Answer**

a. $E=\{(r,\theta,z)\,|\,0\le\theta\le\frac{\pi}{2},\ 0\le r\le\sqrt{3},\ 9-r^2\le z\le 10-r(\cos\theta+\sin\theta)\}$

b. $\int_0^{\pi/2}\int_0^{\sqrt{3}}\int_{9-r^2}^{10-r(\cos\theta+\sin\theta)} f(r,\theta,z)r\,dz\,dr\,d\theta$

12. $E$ is located in the first octant outside the circular paraboloid $z=10-2r^2$ and inside the cylinder $r=\sqrt{5}$ and is bounded also by the planes $z=20$ and $\theta=\frac{\pi}{4}$.

**In exercises 13 - 16, the function $f$ and region $E$ are given.**

a. Express the region $E$ and the function $f$ in cylindrical coordinates.

b. Convert the integral $\iiint_B f(x,y,z)\,dV$ into cylindrical coordinates and evaluate it.

13. $f(x,y,z)=x^2+y^2,\ E=\{(x,y,z)\,|\,0\le x^2+y^2\le 9,\ x\ge 0,\ y\ge 0,\ 0\le z\le x+3\}$

**Answer**

a. $E=\{(r,\theta,z)\,|\,0\le r\le 3,\ 0\le\theta\le\frac{\pi}{2},\ 0\le z\le r\ \cos\theta+3\}$,
$f(r,\theta,z)=\frac{1}{r\ \cos\theta+3}$

b. $\int_0^3\int_0^{\pi/2}\int_0^{r\ \cos\theta+3}\frac{r}{r\ \cos\theta+3}\,dz\,d\theta\,dr=\frac{9\pi}{4}$

14. $f(x,y,z)=x^2+y^2,\ E=\{(x,y,z)|0\le x^2+y^2\le 4,\ y\ge 0,\ 0\le z\le 3-x\}$

15. $f(x,y,z)=x,\ E=\{(x,y,z)\,|\,1\le y^2+z^2\le 9,\ 0\le x\le 1-y^2-z^2\}$

**Answer**

a. $y = r\ \cos\theta,\ z = r\ \sin\theta,\ x = z,\ E = \{(r,\theta,z)\,|\,1 \le r \le 3,\ 0 \le \theta \le 2\pi,\ 0 \le z \le 1 - r^2\},\ f(r,\theta,z) = z;$

b. $\int_1^3 \int_0^{2\pi} \int_0^{1-r^2} zr\ dz\ d\theta\ dr = \dfrac{356\pi}{3}$

16. $f(x,y,z) = y,\ E = \{(x,y,z)\,|\,1 \le x^2 + z^2 \le 9,\ 0 \le y \le 1 - x^2 - z^2\}$

**In exercises 17 - 24, find the volume of the solid $E$ whose boundaries are given in rectangular coordinates.**

17. $E$ is above the $xy$-plane, inside the cylinder $x^2 + y^2 = 1$, and below the plane $z = 1$.

**Answer**

$\pi$

18. $E$ is below the plane $z = 1$ and inside the paraboloid $z = x^2 + y^2$.

19. $E$ is bounded by the circular cone $z = \sqrt{x^2 + y^2}$ and $z = 1$.

**Answer**

$\frac{\pi}{3}$

20. $E$ is located above the $xy$-plane, below $z = 1$, outside the one-sheeted hyperboloid $x^2 + y^2 - z^2 = 1$, and inside the cylinder $x^2 + y^2 = 2$.

21. $E$ is located inside the cylinder $x^2 + y^2 = 1$ and between the circular paraboloids $z = 1 - x^2 - y^2$ and $z = x^2 + y^2$.

**Answer**

$\pi$

22. $E$ is located inside the sphere $x^2 + y^2 + z^2 = 1$, above the $xy$-plane, and inside the circular cone $z = \sqrt{x^2 + y^2}$.

23. $E$ is located outside the circular cone $x^2 + y^2 = (z-1)^2$ and between the planes $z = 0$ and $z = 2$.

**Answer**

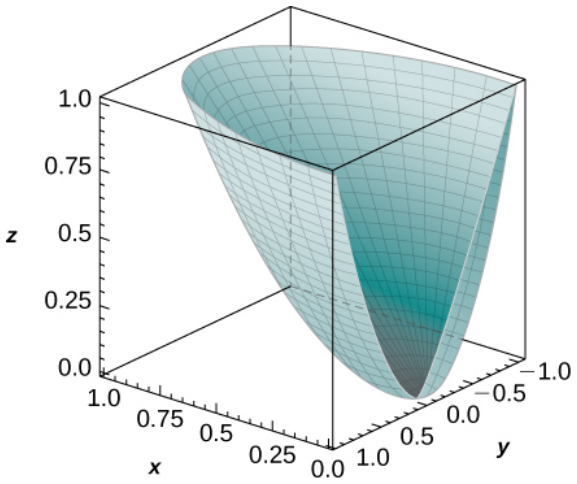
$\frac{4\pi}{3}$

24. $E$ is located outside the circular cone $z = 1 - \sqrt{x^2 + y^2}$, above the $xy$-plane, below the circular paraboloid, and between the planes $z = 0$ and $z = 2$.

25. [T] Use a computer algebra system (CAS) to graph the solid whose volume is given by the iterated integral in cylindrical coordinates $\int_{-\pi/2}^{\pi/2} \int_0^1 \int_{r^2}^{r} r\ dz\ dr\ d\theta$. Find the volume $V$ of the solid. Round your answer to four decimal places.

**Answer**

$V = \frac{pi}{12} \approx 0.2618$



26. [T] Use a CAS to graph the solid whose volume is given by the iterated integral in cylindrical coordinates $\int_0^{\pi/2} \int_0^1 \int_{r^4}^{r} r\ dz\ dr\ d\theta$. Find the volume $E$ of the solid. Round your answer to four decimal places.

27. Convert the integral $\int_0^1 \int_{-\sqrt{1-y^2}}^{\sqrt{1-y^2}} \int_{x^2+y^2}^{\sqrt{x^2+y^2}} xz\ dz\ dx\ dy$ into an integral in cylindrical coordinates.

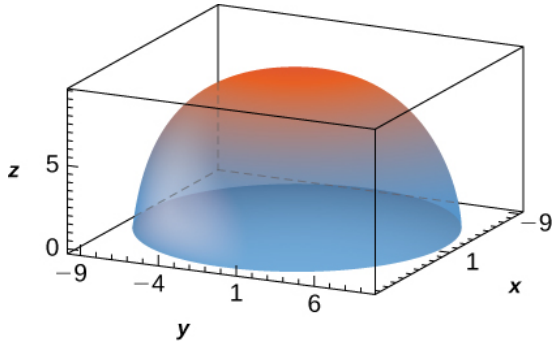
**Answer**

$$\int_0^1 \int_0^{\pi} \int_{r^2}^{r} zr^2\ \cos\theta\, dz\ d\theta\ dr$$

28. Convert the integral $\int_0^2 \int_0^y \int_0^1 (xy+z)\, dz\ dx\ dy$ into an integral in cylindrical coordinates.

**In exercises 29 - 32, evaluate the triple integral $\iiint_B f(x,y,z)\, dV$ over the solid $B$.**

29. $f(x,y,z)=1,\ B=\{(x,y,z)\,|\,x^2+y^2+z^2\le 90,\ z\ge 0\}$

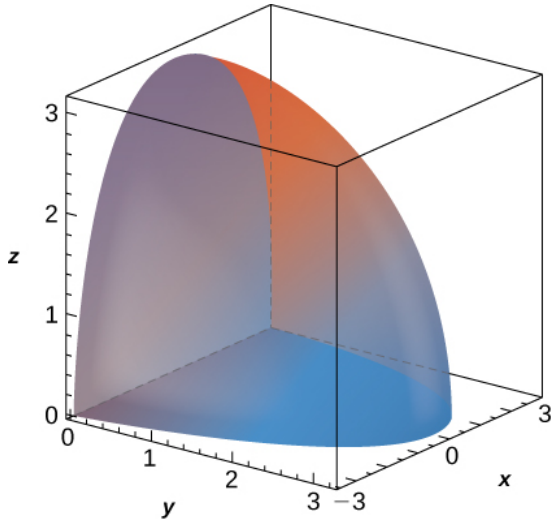


[Hide Solution]

**Answer**

$180\pi\sqrt{10}$

30. $f(x,y,z)=1-\sqrt{x^2+y^2+z^2},\ B=\{(x,y,z)\,|\,x^2+y^2+z^2\le 9,\ y\ge 0,\ z\ge 0\}$



31. $f(x,y,z)=\sqrt{x^2+y^2},\ B$ is bounded above by the half-sphere $x^2+y^2+z^2=9$ with $z\ge 0$ and below by the cone $2z^2=x^2+y^2$.

**Answer**

$\frac{81\pi(\pi-2)}{16}$

32. $f(x,y,z)=\sqrt{x^2+y^2},\ B$ is bounded above by the half-sphere $x^2+y^2+z^2=16$ with $z\ge 0$ and below by the cone $2z^2=x^2+y^2$.

33. Show that if $F(\rho,\theta,\varphi)=f(\rho)g(\theta)h(\varphi)$ is a continuous function on the spherical box $B=\{(\rho,\theta,\varphi)\,|\,a\le\rho\le b,\ \alpha\le\theta\le\beta,\ \gamma\le\varphi\le\psi\}$, then $\iiint_B F\ dV=\left(\int_a^b \rho^2 f(\rho)\ dr\right)\left(\int_\alpha^\beta g(\theta)\ d\theta\right)\left(\int_\gamma^\psi h(\varphi)\ \sin\varphi\ d\varphi\right)$.

34. A function $F$ is said to have spherical symmetry if it depends on the distance to the origin only, that is, it can be expressed in spherical coordinates as $F(x,y,z) = f(\rho)$, where $\rho = \sqrt{x^2+y^2+z^2}$. Show that $\iiint_B F(x,y,z)\,dV = 2\pi \int_a^b \rho^2 f(\rho)\,d\rho$, where $B$ is the region between the upper concentric hemispheres of radii $a$ and $b$ centered at the origin, with $0 < a < b$ and $F$ a spherical function defined on $B$.

Use the previous result to show that $\iiint_B (x^2+y^2+z^2)\sqrt{x^2+y^2+z^2}\,dV = 21\pi$, where $B = \{(x,y,z) \mid 1 \le x^2+y^2+z^2 \le 2,\ z \ge 0\}$.

35. Let $B$ be the region between the upper concentric hemispheres of radii $a$ and $b$ centered at the origin and situated in the first octant, where $0 < a < b$. Consider $F$ a function defined on $B$ whose form in spherical coordinates $(\rho,\theta,\varphi)$ is $F(x,y,z) = f(\rho)\cos\varphi$. Show that if $g(a) = g(b) = 0$ and $\int_a^b h(\rho)\,d\rho = 0$, then $\iiint_B F(x,y,z)\,dV = \frac{\pi^2}{4}[ah(a) - bh(b)]$, where $g$ is an antiderivative of $f$ and $h$ is an antiderivative of $g$.

Use the previous result to show that $\iiint_B = \frac{z\cos\sqrt{x^2+y^2+z^2}}{\sqrt{x^2+y^2+z^2}}\,dV = \frac{3\pi^2}{2}$, where $B$ is the region between the upper concentric hemispheres of radii $\pi$ and $2\pi$ centered at the origin and situated in the first octant.

**In exercises 36 - 39, the function $f$ and region $E$ are given.**

a. Express the region $E$ and function $f$ in cylindrical coordinates.

b. Convert the integral $\iiint_B f(x,y,z)\,dV$ into cylindrical coordinates and evaluate it.

36. $f(x,y,z) = z;\ E = \{(x,y,z) \mid 0 \le x^2+y^2+z^2 \le 1,\ z \ge 0\}$

37. $f(x,y,z) = x+y;\ E = \{(x,y,z) \mid 1 \le x^2+y^2+z^2 \le 2,\ z \ge 0,\ y \ge 0\}$

**Answer**

a. $f(\rho,\theta,\varphi) = \rho\ \sin\varphi\ (\cos\theta + \sin\theta),\ E = \{(\rho,\theta,\varphi) \mid 1 \le \rho \le 2,\ 0 \le \theta \le \pi,\ 0 \le \varphi \le \frac{\pi}{2}\}$;

b. $\int_0^{\pi}\int_0^{\pi/2}\int_1^2 \rho^3 \cos\varphi\ \sin\varphi\ d\rho\ d\varphi\ d\theta = \frac{15\pi}{8}$

38. $f(x,y,z) = 2xy;\ E = \{(x,y,z) \mid \sqrt{x^2+y^2} \le z \le \sqrt{1-x^2-y^2},\ x \ge 0,\ y \ge 0\}$

39. $f(x,y,z) = z;\ E = \{(x,y,z) \mid x^2+y^2+z^2-2x \le 0,\ \sqrt{x^2+y^2} \le z\}$

**Answer**

a. $f(\rho,\theta,\varphi) = \rho\ \cos\varphi;\ E = \{(\rho,\theta,\varphi) \mid 0 \le \rho \le 2\ \cos\varphi,\ 0 \le \theta \le \frac{\pi}{2},\ 0 \le \varphi \le \frac{\pi}{4}\}$;

b. $\int_0^{\pi/2}\int_0^{\pi/4}\int_0^{2\ \cos\varphi} \rho^3 \sin\varphi\ \cos\varphi\ d\rho\ d\varphi\ d\theta = \frac{7\pi}{24}$

**In exercises 40 - 41, find the volume of the solid $E$ whose boundaries are given in rectangular coordinates.**

40. $E = \{(x,y,z) \mid \sqrt{x^2+y^2} \le z \le \sqrt{16-x^2-y^2},\ x \ge 0,\ y \ge 0\}$

41. $E = \{(x,y,z) \mid x^2+y^2+z^2-2z \le 0,\ \sqrt{x^2+y^2} \le z\}$

**Answer**

$\frac{\pi}{4}$

42. Use spherical coordinates to find the volume of the solid situated outside the sphere $\rho = 1$ and inside the sphere $\rho = \cos\varphi$, with $\varphi \in [0, \frac{\pi}{2}]$.

43. Use spherical coordinates to find the volume of the ball $\rho \le 3$ that is situated between the cones $\varphi = \frac{\pi}{4}$ and $\varphi = \frac{\pi}{3}$.

**Answer**

$9\pi(\sqrt{2}-1)$

44. Convert the integral $\int_{-4}^{4}\int_{-\sqrt{16-y^2}}^{\sqrt{16-y^2}}\int_{-\sqrt{16-x^2-y^2}}^{\sqrt{16-x^2-y^2}} (x^2+y^2+z^2)\,dz\,dx\,dy$ into an integral in spherical coordinates.

45. Convert the integral $\int_0^4\int_0^{\sqrt{16-x^2}}\int_{-\sqrt{16-x^2-y^2}}^{\sqrt{16-x^2-y^2}} (x^2+y^2+z^2)^2\,dz\,dy\,dx$ into an integral in spherical coordinates.

**Answer**

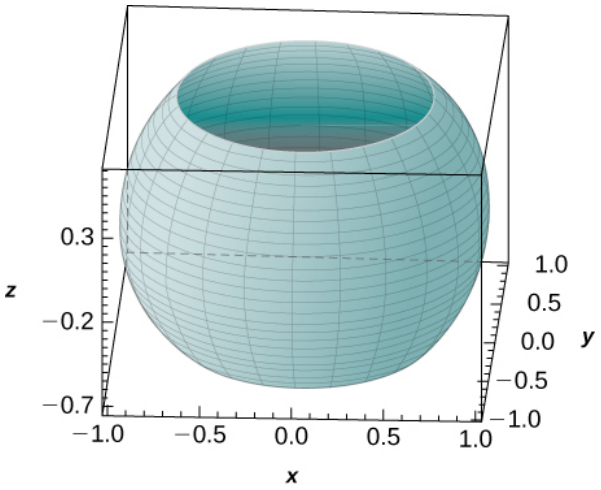
$\int_0^{\pi/2}\int_0^{\pi/2}\int_0^4 \rho^6 \sin\varphi\,d\rho\,d\phi\,d\theta$

46. Convert the integral $\int_{-2}^{2}\int_{-\sqrt{4-x^2}}^{\sqrt{4-x^2}}\int_{\sqrt{x^2+y^2}}^{\sqrt{16-x^2-y^2}} dz\,dy\,dx$ into an integral in spherical coordinates and evaluate it.

47. [T] Use a CAS to graph the solid whose volume is given by the iterated integral in spherical coordinates $\int_{\pi/2}^{\pi}\int_{5\pi}^{\pi/6}\int_{0}^{2}\rho^2\sin\varphi\,d\rho\,d\varphi\,d\theta$. Find the volume $V$ of the solid. Round your answer to three decimal places.

**Answer**

$V=\frac{4\pi\sqrt{3}}{3}\approx 7.255$



48. [T] Use a CAS to graph the solid whose volume is given by the iterated integral in spherical coordinates as $\int_{0}^{2\pi}\int_{3\pi/4}^{\pi/4}\int_{0}^{1}\rho^2\sin\varphi\,d\rho\,d\varphi\,d\theta$. Find the volume $V$ of the solid. Round your answer to three decimal places.

49. [T] Use a CAS to evaluate the integral $\iiint_E (x^2+y^2)\,dV$ where $E$ lies above the paraboloid $z=x^2+y^2$ and below the plane $z=3y$.

**Answer**

$\frac{343\pi}{32}$

50. [T]

a. Evaluate the integral $\iiint_E e^{\sqrt{x^2+y^2+z^2}}\,dV$, where $E$ is bounded by spheres $4x^2+4y^2+4z^2=1$ and $x^2+y^2+z^2=1$.

b. Use a CAS to find an approximation of the previous integral. Round your answer to two decimal places.

51. Express the volume of the solid inside the sphere $x^2+y^2+z^2=16$ and outside the cylinder $x^2+y^2=4$ as triple integrals in cylindrical coordinates and spherical coordinates, respectively.

**Answer**

$\int_{0}^{2\pi}\int_{2}^{4}\int_{-\sqrt{16-r^2}}^{\sqrt{16-r^2}} r\,dz\,dr\,d\theta$ and $\int_{\pi/6}^{5\pi/6}\int_{0}^{2\pi}\int_{2\csc\phi}^{4}\rho^2\sin\rho\,d\rho\,d\theta\,d\phi$

52. Express the volume of the solid inside the sphere $x^2+y^2+z^2=16$ and outside the cylinder $x^2+y^2=4$ that is located in the first octant as triple integrals in cylindrical coordinates and spherical coordinates, respectively.

53. The power emitted by an antenna has a power density per unit volume given in spherical coordinates by $p(\rho,\theta,\varphi)=\frac{P_0}{\rho^2}\cos^2\theta\,\sin^4\varphi$, where $P_0$ is a constant with units in watts. The total power within a sphere $B$ of radius $r$ meters is defined as $P=\iiint_B p(\rho,\theta,\varphi)\,dV$. Find the total power $P$.

**Answer**

$P=\frac{32P_0\pi}{3}$ watts

54. Use the preceding exercise to find the total power within a sphere $B$ of radius 5 meters when the power density per unit volume is given by $p(\rho,\theta,\varphi)=\frac{30}{\rho^2}\cos^2\theta\sin^4\varphi$.

55. A charge cloud contained in a sphere $B$ of radius $r$ centimeters centered at the origin has its charge density given by $q(x,y,z) = k\sqrt{x^2+y^2+z^2}\,\frac{\mu C}{cm^3}$, where $k>0$. The total charge contained in $B$ is given by $Q = \iiint_B q(x,y,z)\,dV$. Find the total charge $Q$.

**Answer**

$Q = kr^4\pi\mu C$

56. Use the preceding exercise to find the total charge cloud contained in the unit sphere if the charge density is $q(x,y,z) = 20\sqrt{x^2+y^2+z^2}\,\frac{\mu C}{cm^3}$.

# 15.7: Calculating Centers of Mass and Moments of Inertia

**Learning Objectives**

- Use double integrals to locate the center of mass of a two-dimensional object.
- Use double integrals to find the moment of inertia of a two-dimensional object.
- Use triple integrals to locate the center of mass of a three-dimensional object.

We have already discussed a few applications of multiple integrals, such as finding areas, volumes, and the average value of a function over a bounded region. In this section we develop computational techniques for finding the center of mass and moments of inertia of several types of physical objects, using double integrals for a lamina (flat plate) and triple integrals for a three-dimensional object with variable density. The density is usually considered to be a constant number when the lamina or the object is homogeneous; that is, the object has uniform density.

## Center of Mass in Two Dimensions

The center of mass is also known as the center of gravity if the object is in a uniform gravitational field. If the object has uniform density, the center of mass is the geometric center of the object, which is called the centroid. Figure **15.7.1** shows a point $P$ as the center of mass of a lamina. The lamina is perfectly balanced about its center of mass.

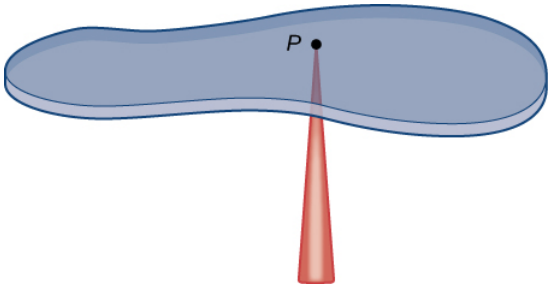

Figure **15.7.1**: A lamina is perfectly balanced on a spindle if the lamina's center of mass sits on the spindle.

To find the coordinates of the center of mass $P(\bar{x},\bar{y})$ of a lamina, we need to find the moment $M_x$ of the lamina about the $x$-axis and the moment $M_y$ about the $y$-axis. We also need to find the mass $m$ of the lamina. Then

$$\bar{x}=\frac{M_y}{m}$$

and

$$\bar{y}=\frac{M_x}{m}.$$

Refer to Moments and Centers of Mass for the definitions and the methods of single integration to find the center of mass of a one-dimensional object (for example, a thin rod). We are going to use a similar idea here except that the object is a two-dimensional lamina and we use a double integral.

If we allow a constant density function, then $\bar{x}=\frac{M_y}{m}$ and $\bar{y}=\frac{M_x}{m}$ give the *centroid* of the lamina.

Suppose that the lamina occupies a region $R$ in the $xy$-plane and let $\rho(x,y)$ be its density (in units of mass per unit area) at any point $(x,y)$. Hence,

$$\rho(x,y)=\lim_{\Delta A\to 0}\frac{\Delta m}{\Delta A}$$

where $\Delta m$ and $\Delta A$ are the mass and area of a small rectangle containing the point $(x,y)$ and the limit is taken as the dimensions of the rectangle go to $0$ (see the following figure).

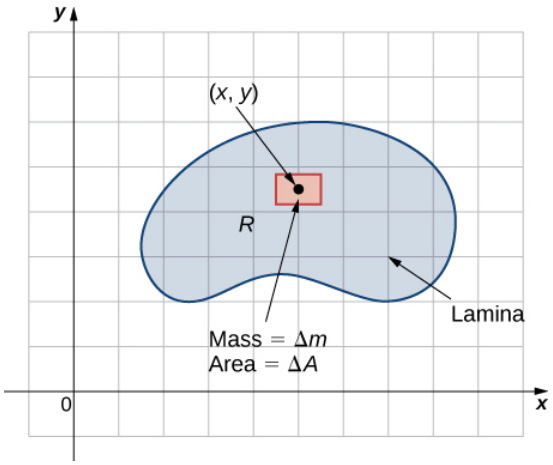

Figure 15.7.2: The density of a lamina at a point is the limit of its mass per area in a small rectangle about the point as the area goes to zero.

Just as before, we divide the region $R$ into tiny rectangles $R_{ij}$ with area $\Delta A$ and choose $(x_{ij}^*, y_{ij}^*)$ as sample points. Then the mass $m_{ij}$ of each $R_{ij}$ is equal to $\rho(x_{ij}^*, y_{ij}^*)\Delta A$ (Figure 15.7.2). Let $k$ and $l$ be the number of subintervals in $x$ and $y$ respectively. Also, note that the shape might not always be rectangular but the limit works anyway, as seen in previous sections.

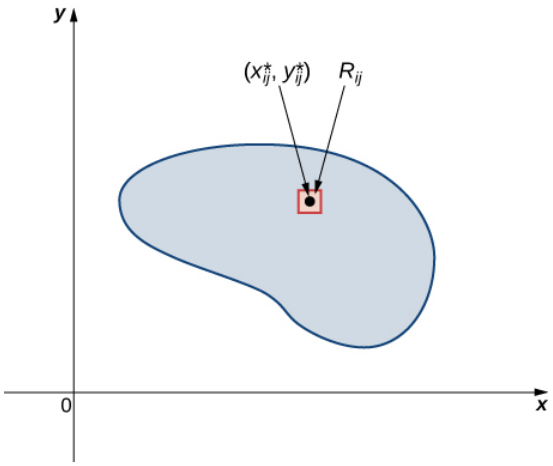

Figure 15.7.3: Subdividing the lamina into tiny rectangles $R_{ij}$ each containing a sample point $(x_{ij}^*, y_{ij}^*)$.

Hence, the mass of the lamina is

$$m = \lim_{k,l\to\infty} \sum_{i=1}^{k} \sum_{j=1}^{l} m_{ij} = \lim_{k,l\to\infty} \sum_{i=1}^{k} \sum_{j=1}^{l} \rho(x_{ij}^*, y_{ij}^*)\Delta A = \iint_R \rho(x,y)dA.$$

Let's see an example now of finding the total mass of a triangular lamina.

**Example 15.7.1: Finding the Total Mass of a Lamina**

Consider a triangular lamina $R$ with vertices $(0,0)$, $(0,3)$, $(3,0)$ and with density $\rho(x,y) = xy\, kg/m^2$. Find the total mass.

**Solution**

A sketch of the region $R$ is always helpful, as shown in the following figure.

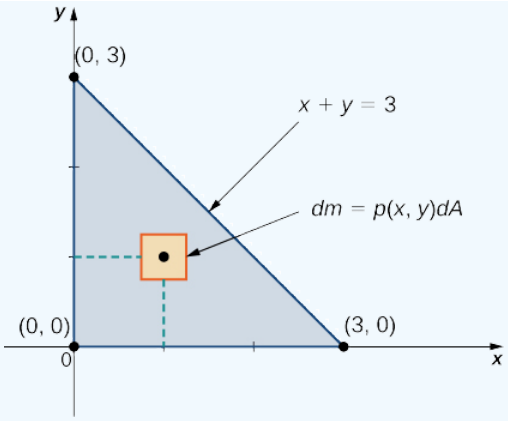

Figure 15.7.4: A lamina in the $xy$-plane with density $\rho(x,y) = xy$.

Using the expression developed for mass, we see that

$$m = \iint_R dm = \iint_R \rho(x,y)dA = \int_{x=0}^{x=3}\int_{y=0}^{y=3-x} xy\,dy\,dx = \int_{x=0}^{x=3}\left[x\frac{y^2}{2}\Big|_{y=0}^{y=3}\right]dx$$
$$= \int_{x=0}^{x=3}\frac{1}{2}x(3-x)^2dx = \left[\frac{9x^2}{4} - x^3 + \frac{x^4}{8}\right]\Big|_{x=0}^{x=3} = \frac{27}{8}.$$

The computation is straightforward, giving the answer $m = \frac{27}{8}\ kg$.

**? Exercise 15.7.1**

Consider the same region $R$ as in the previous example, and use the density function $\rho(x,y) = \sqrt{xy}$. Find the total mass.

**Answer**

$\frac{9\pi}{8}\ kg$

Now that we have established the expression for mass, we have the tools we need for calculating moments and centers of mass. The moment $M_z$ about the $x$-axis for $R$ is the limit of the sums of moments of the regions $R_{ij}$ about the $x$-axis. Hence

$$M_x = \lim_{k,l\to\infty}\sum_{i=1}^{k}\sum_{j=1}^{l}(y_{ij}^*)m_{ij} = \lim_{k,l\to\infty}\sum_{i=1}^{k}\sum_{j=1}^{l}(y_{ij}^*)\rho(x_{ij}^*, y_{ij}^*)\,\Delta A = \iint_R y\rho(x,y)\,dA$$

Similarly, the moment $M_y$ about the $y$-axis for $R$ is the limit of the sums of moments of the regions $R_{ij}$ about the $y$-axis. Hence

$$M_y = \lim_{k,l\to\infty}\sum_{i=1}^{k}\sum_{j=1}^{l}(x_{ij}^*)m_{ij} = \lim_{k,l\to\infty}\sum_{i=1}^{k}\sum_{j=1}^{l}(x_{ij}^*)\rho(x_{ij}^*, y_{ij}^*)\,\Delta A = \iint_R x\rho(x,y)\,dA$$

**✓ Example 15.7.2: Finding Moments**

Consider the same triangular lamina $R$ with vertices $(0,0)$, $(0,3)$, $(3,0)$ and with density $\rho(x,y) = xy$. Find the moments $M_x$ and $M_y$.

**Solution**

Use double integrals for each moment and compute their values:

$$M_x = \iint_R y\rho(x,y)\,dA = \int_{x=0}^{x=3}\int_{y=0}^{y=3-x} xy^2\,dy\,dx = \frac{81}{20},$$

$$M_y = \iint_R x\rho(x,y)\,dA = \int_{x=0}^{x=3}\int_{y=0}^{y=3-x} x^2y\,dy\,dx = \frac{81}{20},$$

The computation is quite straightforward.

**Exercise 15.7.2**

Consider the same lamina $R$ as above and use the density function $\rho(x,y)=\sqrt{xy}$. Find the moments $M_x$ and $M_y$.

**Answer**

$M_x=\frac{81\pi}{64}$ and $M_y=\frac{81\pi}{64}$

Finally we are ready to restate the expressions for the center of mass in terms of integrals. We denote the $x$-coordinate of the center of mass by $\bar{x}$ and the $y$-coordinate by $\bar{y}$. Specifically,

$$\bar{x}=\frac{M_y}{m}=\frac{\iint_R x\rho(x,y)\,dA}{\iint_R \rho(x,y)\,dA}$$

and

$$\bar{y}=\frac{M_x}{m}=\frac{\iint_R y\rho(x,y)\,dA}{\iint_R \rho(x,y)\,dA}$$

**Example 15.7.3: center of mass**

Again consider the same triangular region $R$ with vertices $(0,0)$, $(0,3)$, $(3,0)$ and with density function $\rho(x,y)=xy$. Find the center of mass.

**Solution**

Using the formulas we developed, we have

$$\bar{x}=\frac{M_y}{m}=\frac{\iint_R x\rho(x,y)\,dA}{\iint_R \rho(x,y)\,dA}=\frac{81/20}{27/8}=\frac{6}{5},$$

$$\bar{y}=\frac{M_x}{m}=\frac{\iint_R y\rho(x,y)\,dA}{\iint_R \rho(x,y)\,dA}=\frac{81/20}{27/8}=\frac{6}{5}.$$

Therefore, the center of mass is the point $\left(\frac{6}{5},\frac{6}{5}\right)$.

**Analysis**

If we choose the density $\rho(x,y)$ instead to be uniform throughout the region (i.e., constant), such as the value 1 (any constant will do), then we can compute the centroid,

$$x_c=\frac{M_y}{m}=\frac{\iint_R x\,dA}{\iint_R dA}=\frac{9/2}{9/2}=1,$$

$$y_c=\frac{M_x}{m}=\frac{\iint_R y\,dA}{\iint_R dA}=\frac{9/2}{9/2}=1.$$

Notice that the center of mass $\left(\frac{6}{5},\frac{6}{5}\right)$ is not exactly the same as the centroid $(1,1)$ of the triangular region. This is due to the variable density of $R$ If the density is constant, then we just use $\rho(x,y)=c$ (constant). This value cancels out from the formulas, so for a constant density, the center of mass coincides with the centroid of the lamina.

**Exercise 15.7.3**

Again use the same region $R$ as above and use the density function $\rho(x,y)=\sqrt{xy}$. Find the center of mass.

**Answer**

$$\bar{x} = \frac{M_y}{m} = \frac{81\pi/64}{9\pi/8} = \frac{9}{8} \text{ and } \bar{y} = \frac{M_x}{m} = \frac{81\pi}{9\pi/8} = \frac{0}{8}.$$

Once again, based on the comments at the end of Example 15.7.3, we have expressions for the centroid of a region on the plane:

$$x_c = \frac{M_y}{m} = \frac{\iint_R x\,dA}{\iint_R dA} \text{ and } y_c = \frac{M_x}{m} = \frac{\iint_R y\,dA}{\iint_R dA}.$$

We should use these formulas and verify the centroid of the triangular region referred to in the last three examples.

### Example 15.7.4: Finding Mass, Moments, and Center of Mass

Find the mass, moments, and the center of mass of the lamina of density $\rho(x,y) = x + y$ occupying the region $R$ under the curve $y = x^2$ in the interval $0 \le x \le 2$ (see the following figure).

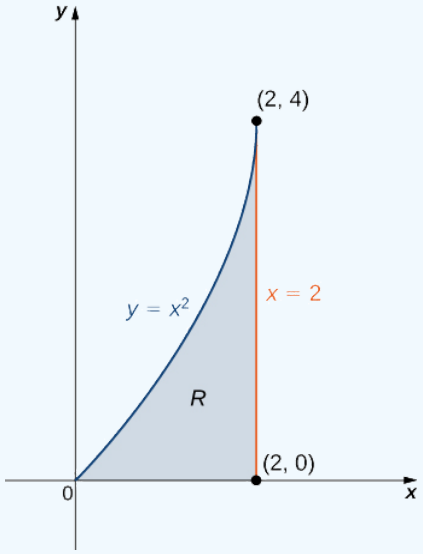

Figure 15.7.5: Locating the center of mass of a lamina $R$ with density $\rho(x,y) = x + y$.

**Solution**

First we compute the mass $m$. We need to describe the region between the graph of $y = x^2$ and the vertical lines $x = 0$ and $x = 2$:

$$m = \iint_R dm = \iint_R \rho(x,y)\,dA = \int_{x=0}^{x=2} \int_{y=0}^{y=x^2} (x+y)\,dy\,dx = \int_{x=0}^{x=2} \left[ xy + \frac{y^2}{2} \Big|_{y=0}^{y=x^2} \right] dx$$

$$= \int_{x=0}^{x=2} \left[ x^3 + \frac{x^4}{2} \right] dx = \left[ \frac{x^4}{4} + \frac{x^5}{10} \right] \Big|_{x=0}^{x=2} = \frac{36}{5}.$$

Now compute the moments $M_x$ and $M_y$:

$$M_x = \iint_R y\rho(x,y)\,dA = \int_{x=0}^{x=2} \int_{y=0}^{y=x^2} y(x+y)\,dy\,dx = \frac{80}{7},$$

$$M_y = \iint_R x\rho(x,y)\,dA = \int_{x=0}^{x=2} \int_{y=0}^{y=x^2} x(x+y)\,dy\,dx = \frac{176}{15}.$$

Finally, evaluate the center of mass,

$$\bar{x} = \frac{M_y}{m} = \frac{\iint_R x\rho(x,y)\,dA}{\iint_R \rho(x,y)\,dA} = \frac{176/15}{36/5} = \frac{44}{27},$$

$$\bar{y} = \frac{M_x}{m} = \frac{\iint_R y\rho(x,y)\,dA}{\iint_R \rho(x,y)\,dA} = \frac{80/7}{36/5} = \frac{100}{63}.$$

Hence the center of mass is $(\bar{x}, \bar{y}) = \left(\frac{44}{27}, \frac{100}{63}\right)$.

## Exercise 15.7.4

Calculate the mass, moments, and the center of mass of the region between the curves $y = x$ and $y = x^2$ with the density function $\rho(x, y) = x$ in the interval $0 \le x \le 1$.

**Answer**

$$\bar{x} = \frac{M_y}{m} = \frac{1/20}{1/12} = \frac{3}{5} \text{ and } \bar{y} = \frac{M_x}{m} = \frac{1/24}{1/12} = \frac{1}{2}$$

## Example 15.7.5: Finding a Centroid

Find the centroid of the region under the curve $y = e^x$ over the interval $1 \le x \le 3$ (Figure 15.7.6).

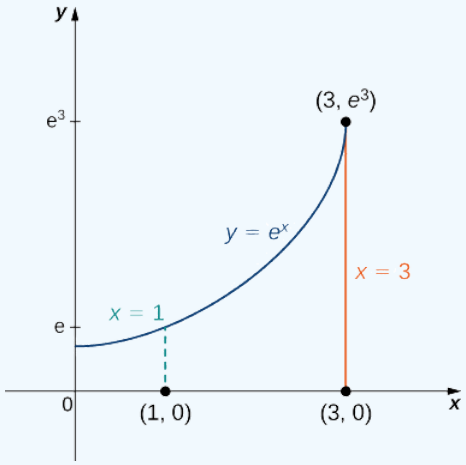

Figure 15.7.6: Finding a centroid of a region below the curve $y = e^x$.

### Solution

To compute the centroid, we assume that the density function is constant and hence it cancels out:

$$x_c = \frac{M_y}{m} = \frac{\iint_R x\,dA}{\iint_R dA} \text{ and } y_c = \frac{M_x}{m} = \frac{\iint_R y\,dA}{\iint_R dA},$$

$$x_c = \frac{M_y}{m} = \frac{\iint_R x\,dA}{\iint_R dA} = \frac{\int_{x=1}^{x=3}\int_{y=0}^{y=e^x} x\,dy\,dx}{\int_{x=1}^{x=3}\int_{y=0}^{y=e^x} dy\,dx} = \frac{\int_{x=1}^{x=3} xe^x dx}{\int_{x=1}^{x=3} e^x dx} = \frac{2e^3}{e^3 - e} = \frac{2e^2}{e^2 - 1},$$

$$y_c = \frac{M_x}{m} = \frac{\iint_R y\,dA}{\iint_R dA} = \frac{\int_{x=1}^{x=3}\int_{y=0}^{y=e^x} y\,dy\,dx}{\int_{x=1}^{x=3}\int_{y=0}^{y=e^x} dy\,dx} = \frac{\int_{x=1}^{x=3} \frac{e^{2x}}{2} dx}{\int_{x=1}^{x=3} e^x dx} = \frac{\frac{1}{4}e^2(e^4 - 1)}{e(e^2 - 1)} = \frac{1}{4}e(e^2 + 1).$$

Thus the centroid of the region is

$$(x_c, y_c) = \left(\frac{2e^2}{e^2 - 1}, \frac{1}{4}e(e^2 + 1)\right).$$

## Exercise 15.7.5

Calculate the centroid of the region between the curves $y = x$ and $y = \sqrt{x}$ with uniform density in the interval $0 \le x \le 1$.

**Answer**

$$x_c = \frac{M_y}{m} = \frac{1/15}{1/6} = \frac{2}{5} \text{ and } y_c = \frac{M_x}{m} = \frac{1/12}{1/6} = \frac{1}{2}$$

## Moments of Inertia

For a clear understanding of how to calculate moments of inertia using double integrals, we need to go back to the general definition in Section 6.6. The moment of inertia of a particle of mass $m$ about an axis is $mr^2$ where $r$ is the distance of the particle from the axis. We can see from Figure 15.7.3 that the moment of inertia of the subrectangle $R_{ij}$ about the $x$-axis is $(y_{ij}^*)^2\rho(x_{ij}^*, y_{ij}^*)\Delta A$. Similarly, the moment of inertia of the subrectangle $R_{ij}$ about the $y$-axis is $(x_{ij}^*)^2\rho(x_{ij}^*, y_{ij}^*)\Delta A$. The moment of inertia is related to the rotation of the mass; specifically, it measures the tendency of the mass to resist a change in rotational motion about an axis.

The moment of inertia $I_x$ about the $x$-axis for the region $R$ is the limit of the sum of moments of inertia of the regions $R_{ij}$ about the $x$-axis. Hence

$$I_x = \lim_{k,l\to\infty} \sum_{i=1}^{k}\sum_{j=1}^{l} (y_{ij}^*)^2 m_{ij} = \lim_{k,l\to\infty} \sum_{i=1}^{k}\sum_{j=1}^{l} (y_{ij}^*)^2 \rho(x_{ij}^*, y_{ij}^*)\,\Delta A = \iint_R y^2\rho(x,y)\,dA.$$

Similarly, the moment of inertia $I_y$ about the $y$-axis for $R$ is the limit of the sum of moments of inertia of the regions $R_{ij}$ about the $y$ -axis. Hence

$$I_y = \lim_{k,l\to\infty} \sum_{i=1}^{k}\sum_{j=1}^{l} (x_{ij}^*)^2 m_{ij} = \lim_{k,l\to\infty} \sum_{i=1}^{k}\sum_{j=1}^{l} (x_{ij}^*)^2 \rho(x_{ij}^*, y_{ij}^*)\,\Delta A = \iint_R x^2\rho(x,y)\,dA.$$

Sometimes, we need to find the moment of inertia of an object about the origin, which is known as the polar moment of inertia. We denote this by $I_0$ and obtain it by adding the moments of inertia $I_x$ and $I_y$. Hence

$$I_0 = I_x + I_y = \iint_R (x^2 + y^2)\rho(x,y)\,dA.$$

All these expressions can be written in polar coordinates by substituting $x = r\cos\theta$, $y = r\sin\theta$, and $dA = r\,dr\,d\theta$. For example, $I_0 = \iint_R r^2\rho(r\cos\theta, r\sin\theta)\,dA$.

### Example 15.7.6: Finding Moments of Inertia for a Triangular Lamina

Use the triangular region $R$ with vertices $(0,0)$, $(2,2)$, and $(2,0)$ and with density $\rho(x,y) = xy$ as in previous examples. Find the moments of inertia.

**Solution**

Using the expressions established above for the moments of inertia, we have

$$I_x = \iint_R y^2\rho(x,y)\,dA = \int_{x=0}^{x=2}\int_{y=0}^{y=x} xy^3\,dy\,dx = \frac{8}{3},$$

$$I_y = \iint_R x^2\rho(x,y)\,dA = \int_{x=0}^{x=2}\int_{y=0}^{y=x} x^3y\,dy\,dx = \frac{16}{3},$$

$$I_0 = \iint_R (x^2+y^2)\rho(x,y)\,dA = \int_0^2\int_0^x (x^2+y^2)xy\,dy\,dx = I_x + I_y = 8$$

### Exercise 15.7.6

Again use the same region $R$ as above and the density function $\rho(x,y) = \sqrt{xy}$. Find the moments of inertia.

**Answer**

$$I_x = \int_{x=0}^{x=2}\int_{y=0}^{y=x} y^2\sqrt{xy}\,dy\,dx = \frac{64}{35}$$

and

$$I_y = \int_{x=0}^{x=2} \int_{y=0}^{y=x} x^2 \sqrt{xy}\, dy\, dx = \frac{64}{35}.$$

Also,

$$I_0 = \int_{x=0}^{x=2} \int_{y=0}^{y=x} (x^2 + y^2) \sqrt{xy}\, dy\, dx = \frac{128}{21}$$

As mentioned earlier, the moment of inertia of a particle of mass $m$ about an axis is $mr^2$ where $r$ is the distance of the particle from the axis, also known as the **radius of gyration**.

Hence the radii of gyration with respect to the $x$-axis, the $y$-axis and the origin are

$$R_x = \sqrt{\frac{I_x}{m}},\ R_y = \sqrt{\frac{I_y}{m}},\ \text{and}\ R_0 = \sqrt{\frac{I_0}{m}},$$

respectively. In each case, the radius of gyration tells us how far (perpendicular distance) from the axis of rotation the entire mass of an object might be concentrated. The moments of an object are useful for finding information on the balance and torque of the object about an axis, but radii of gyration are used to describe the distribution of mass around its centroidal axis. There are many applications in engineering and physics. Sometimes it is necessary to find the radius of gyration, as in the next example.

### Example 15.7.7: Finding the Radius of Gyration for a Triangular Lamina

Consider the same triangular lamina $R$ with vertices $(0,0)$, $(2,2)$, and $(2,0)$ and with density $\rho(x,y) = xy$ as in previous examples. Find the radii of gyration with respect to the $x$-axis the $y$-axis and the origin.

#### Solution

If we compute the mass of this region we find that $m = 2$. We found the moments of inertia of this lamina in Example 15.7.4. From these data, the radii of gyration with respect to the $x$-axis, $y$-axis and the origin are, respectively,

$$R_x = \sqrt{\frac{I_x}{m}} = \sqrt{\frac{8/3}{2}} = \sqrt{\frac{8}{6}} = \frac{2\sqrt{3}}{3}, \tag{15.7.1}$$

$$R_y = \sqrt{\frac{I_y}{m}} = \sqrt{\frac{16/3}{2}} = \sqrt{\frac{8}{3}} = \frac{2\sqrt{6}}{3}, \tag{15.7.2}$$

$$R_0 = \sqrt{\frac{I_0}{m}} = \sqrt{\frac{8}{2}} = \sqrt{4} = 2. \tag{15.7.3}$$

### Exercise 15.7.7

Use the same region $R$ from Example 15.7.7 and the density function $\rho(x,y) = \sqrt{xy}$. Find the radii of gyration with respect to the $x$-axis, the $y$-axis, and the origin.

**Hint**

Follow the steps shown in the previous example.

**Answer**

$R_x = \frac{6\sqrt{35}}{35}$, $R_y = \frac{6\sqrt{15}}{15}$, and $R_0 = \frac{4\sqrt{42}}{7}$.

## Center of Mass and Moments of Inertia in Three Dimensions

All the expressions of double integrals discussed so far can be modified to become triple integrals.

## Definition

If we have a solid object $Q$ with a density function $\rho(x,y,z)$ at any point $(x,y,z)$ in space, then its mass is

$$m = \iiint_Q \rho(x,y,z)\,dV.$$

Its moments about the $xy$-plane the $xz$-plane and the $yz$-plane are

$$M_{xy} = \iiint_Q z\rho(x,y,z)\,dV,\ M_{xz} = \iiint_Q y\rho(x,y,z)\,dV,\ M_{yz} = \iiint_Q x\rho(x,y,z)\,dV.$$

If the center of mass of the object is the point $(\bar{x},\bar{y},\bar{z})$, then

$$\bar{x} = \frac{M_{yz}}{m},\ \bar{y} = \frac{M_{xz}}{m},\ \bar{z} = \frac{M_{xy}}{m}.$$

Also, if the solid object is homogeneous (with constant density), then the center of mass becomes the centroid of the solid. Finally, the moments of inertia about the $yz$-plane, $xz$-plane, and the $xy$-plane are

$$I_x = \iiint_Q (y^2+z^2)\,\rho(x,y,z)\,dV,$$

$$I_y = \iiint_Q (x^2+z^2)\,\rho(x,y,z)\,dV,$$

$$I_z = \iiint_Q (x^2+y^2)\,\rho(x,y,z)\,dV.$$

## Example 15.7.8: Finding the Mass of a Solid

Suppose that $Q$ is a solid region bounded by $x+2y+3z=6$ and the coordinate planes and has density $\rho(x,y,z) = x^2yz$. Find the total mass.

### Solution

The region $Q$ is a tetrahedron (Figure 15.7.7) meeting the axes at the points $(6,0,0)$, $(0,3,0)$, and $(0,0,2)$. To find the limits of integration, let $z=0$ in the slanted plane $z = \frac{1}{3}(6-x-2y)$. Then for $x$ and $y$ find the projection of $Q$ onto the $xy$-plane, which is bounded by the axes and the line $x+2y=6$. Hence the mass is

$$m = \iiint_Q \rho(x,y,z)\,dV = \int_{x=0}^{x=6}\int_{y=0}^{y=1/2(6-x)}\int_{z=0}^{z=1/3(6-x-2y)} x^2yz\,dz\,dy\,dx = \frac{108}{35}$$

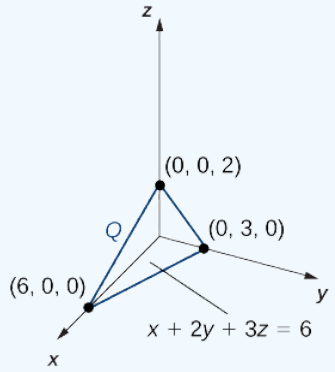

Figure 15.7.7: Finding the mass of a three-dimensional solid $Q$.

**Exercise 15.7.8**

Consider the same region $Q$ (Figure 15.7.7), and use the density function $\rho(x,y,z)=xy^2z$. Find the mass.

**Hint**

Follow the steps in the previous example.

**Answer**

$\frac{54}{35}=1.543$

**Example 15.7.9: Finding the Center of Mass of a Solid**

Suppose $Q$ is a solid region bounded by the plane $x+2y+3z=6$ and the coordinate planes with density $\rho(x,y,z)=x^2yz$ (see Figure 15.7.7). Find the center of mass using decimal approximation.

**Solution**

We have used this tetrahedron before and know the limits of integration, so we can proceed to the computations right away. First, we need to find the moments about the $xy$-plane, the $xz$-plane, and the $yz$-plane:

$$M_{xy}=\iiint_Q z\rho(x,y,z)\,dV=\int_{x=0}^{x=6}\int_{y=0}^{y=\frac{1}{2}(6-x)}\int_{z=0}^{z=\frac{1}{3}(6-x-2y)}x^2yz^2\,dz\,dy\,dx=\frac{54}{35}\approx 1.543,$$

$$M_{xz}=\iiint_Q y\rho(x,y,z)\,dV=\int_{x=0}^{x=6}\int_{y=0}^{y=\frac{1}{2}(6-x)}\int_{z=0}^{z=\frac{1}{3}(6-x-2y)}x^2y^2z\,dz\,dy\,dx=\frac{81}{35}\approx 2.314,$$

$$M_{yz}=\iiint_Q x\rho(x,y,z)\,dV=\int_{x=0}^{x=6}\int_{y=0}^{y=\frac{1}{2}(6-x)}\int_{z=0}^{z=\frac{1}{3}(6-x-2y)}x^3yz\,dz\,dy\,dx=\frac{243}{35}\approx 6.943.$$

Hence the center of mass is

$$\bar{x}=\frac{M_{yz}}{m},\ \bar{y}=\frac{M_{xz}}{m},\ \bar{z}=\frac{M_{xy}}{m},$$

$$\bar{x}=\frac{M_{yz}}{m}=\frac{243/35}{108/35}=\frac{243}{108}=2.25,$$

$$\bar{y}=\frac{M_{xz}}{m}=\frac{81/35}{108/35}=\frac{81}{108}=0.75,$$

$$\bar{z}=\frac{M_{xy}}{m}=\frac{54/35}{108/35}=\frac{54}{108}=0.5$$

The center of mass for the tetrahedron $Q$ is the point $(2.25,0.75,0.5)$.

**Exercise 15.7.9**

Consider the same region $Q$ (Figure 15.7.7) and use the density function $\rho(x,y,z)=xy^2z$. Find the center of mass.

**Hint**

Check that $M_{xy}=\frac{27}{35}$, $M_{xz}=\frac{243}{140}$, and $M_{yz}=\frac{81}{35}$. Then use $m$ from a previous checkpoint question.

**Answer**

$\left(\frac{3}{2},\frac{9}{8},\frac{1}{2}\right)$

We conclude this section with an example of finding moments of inertia $I_x$, $I_y$, and $I_z$.

### Example 15.7.10: Finding the Moments of Inertia of a Solid

Suppose that $Q$ is a solid region and is bounded by $x+2y+3z=6$ and the coordinate planes with density $\rho(x,y,z)=x^2yz$ (see Figure 15.7.7). Find the moments of inertia of the tetrahedron $Q$ about the $yz$-plane, the $xz$-plane, and the $xy$-plane.

**Solution**

Once again, we can almost immediately write the limits of integration and hence we can quickly proceed to evaluating the moments of inertia. Using the formula stated before, the moments of inertia of the tetrahedron $Q$ about the $yz$-plane, the $xz$-plane, and the $xy$-plane are

$$I_x=\iiint_Q (y^2+z^2)\rho(x,y,z)\,dV,$$

$$I_y=\iiint_Q (x^2+z^2)\rho(x,y,z)\,dV,$$

and

$$I_z=\iiint_Q (x^2+y^2)\rho(x,y,z)\,dV \text{ with } \rho(x,y,z)=x^2yz.$$

Proceeding with the computations, we have

$$I_x=\iiint_Q (y^2+z^2)x^2\rho(x,y,z)\,dV$$

$$=\int_{x=0}^{x=6}\int_{y=0}^{y=\frac{1}{2}(6-x)}\int_{z=0}^{z=\frac{1}{3}(6-x-2y)}(y^2+z^2)x^2yz\,dz\,dy\,dx=\frac{117}{35}\approx 3.343,$$

$$I_y=\iiint_Q (x^2+z^2)x^2\rho(x,y,z)\,dV$$

$$=\int_{x=0}^{x=6}\int_{y=0}^{y=\frac{1}{2}(6-x)}\int_{z=0}^{z=\frac{1}{3}(6-x-2y)}(x^2+z^2)x^2yz\,dz\,dy\,dx=\frac{684}{35}\approx 19.543,$$

$$I_z=\iiint_Q (x^2+y^2)x^2\rho(x,y,z)\,dV$$

$$=\int_{x=0}^{x=6}\int_{y=0}^{y=\frac{1}{2}(6-x)}\int_{z=0}^{z=\frac{1}{3}(6-x-2y)}(x^2+y^2)x^2yz\,dz\,dy\,dx=\frac{729}{35}\approx 20.829.$$

Thus, the moments of inertia of the tetrahedron $Q$ about the $yz$-plane, the $xz$-plane, and the $xy$-plane are $117/35$, $684/35$, and $729/35$, respectively.

### Exercise 15.7.10

Consider the same region $Q$ (Figure 15.7.7), and use the density function $\rho(x,y,z)=xy^2z$. Find the moments of inertia about the three coordinate planes.

**Answer**

The moments of inertia of the tetrahedron $Q$ about the $yz$-plane, the $xz$-plane, and the $xy$-plane are $99/35$, $36/7$ and $243/35$, respectively.

## Key Concepts

Finding the mass, center of mass, moments, and moments of inertia in double integrals:

- For a lamina $R$ with a density function $\rho(x,y)$ at any point $(x,y)$ in the plane, the mass is

$$m=\iint_R \rho(x,y)\,dA.$$

- The moments about the $x$-axis and $y$-axis are

$$M_x = \iint_R y\rho(x,y)\,dA \text{ and } M_y = \iint_R x\rho(x,y)\,dA.$$

- The center of mass is given by $\bar{x} = \dfrac{M_y}{m}$, $\bar{y} = \dfrac{M_x}{m}$.
- The center of mass becomes the centroid of the plane when the density is constant.
- The moments of inertia about the $x$-axis, $y$-axis, and the origin are

$$I_x = \iint_R y^2\rho(x,y)\,dA,\ I_y = \iint_R x^2\rho(x,y)\,dA,\ \text{and } I_0 = I_x + I_y = \iint_R (x^2+y^2)\rho(x,y)\,dA.$$

Finding the mass, center of mass, moments, and moments of inertia in triple integrals:

- For a solid object $Q$ with a density function $\rho(x,y,z)$ at any point $(x,y,z)$ in space, the mass is

$$m = \iiint_Q \rho(x,y,z)\,dV.$$

- The moments about the $xy$-plane, the $xz$-plane, and the $yz$-plane are

$$M_{xy} = \iiint_Q z\rho(x,y,z)\,dV,\ M_{xz} = \iiint_Q y\rho(x,y,z)\,dV,\ M_{yz} = \iiint_Q x\rho(x,y,z)\,dV$$

- The center of mass is given by $\bar{x} = \dfrac{M_{yz}}{m}$, $\bar{y} = \dfrac{M_{xz}}{m}$, $\bar{z} = \dfrac{M_{xy}}{m}$.
- The center of mass becomes the centroid of the solid when the density is constant.
- The moments of inertia about the $yz$-plane, the $xz$-plane, and the $xy$-plane are

$$I_x = \iiint_Q (y^2+z^2)\,\rho(x,y,z)\,dV,\ I_y = \iiint_Q (x^2+z^2)\,\rho(x,y,z)\,dV,$$
$$I_z = \iiint_Q (x^2+y^2)\,\rho(x,y,z)\,dV.$$

## Key Equations

- **Mass of a lamina**

$$m = \lim_{k,l\to\infty} \sum_{i=1}^{k}\sum_{j=1}^{l} m_{ij} = \lim_{k,l\to\infty} \sum_{i=1}^{k}\sum_{j=1}^{l} \rho(x_{ij}^*, y_{ij}^*)\,\Delta A = \iint_R \rho(x,y)\,dA$$

- **Moment about the $x$-axis**

$$M_x = \lim_{k,l\to\infty} \sum_{i=1}^{k}\sum_{j=1}^{l} (y_{ij}^*) m_{ij} = \lim_{k,l\to\infty} \sum_{i=1}^{k}\sum_{j=1}^{l} (y_{ij}^*)\rho(x_{ij}^*, y_{ij}^*)\,\Delta A = \iint_R y\rho(x,y)\,dA$$

- **Moment about the $y$-axis**

$$M_y = \lim_{k,l\to\infty} \sum_{i=1}^{k}\sum_{j=1}^{l} (x_{ij}^*) m_{ij} = \lim_{k,l\to\infty} \sum_{i=1}^{k}\sum_{j=1}^{l} (x_{ij}^*)\rho(x_{ij}^*, y_{ij}^*)\,\Delta A = \iint_R x\rho(x,y)\,dA$$

- **Center of mass of a lamina**

$$\bar{x} = \frac{M_y}{m} = \frac{\iint_R x\rho(x,y)\,dA}{\iint_R \rho(x,y)\,dA} \text{ and } \bar{y} = \frac{M_x}{m} = \frac{\iint_R y\rho(x,y)\,dA}{\iint_R \rho(x,y)\,dA}$$

## Glossary

**radius of gyration**

the distance from an object's center of mass to its axis of rotation

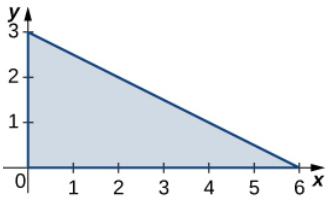
# 15.7E: Exercises for Section 15.6

**In exercises 1 - 12, the region $R$ occupied by a lamina is shown in a graph. Find the mass of $R$ with the density function $\rho$.**

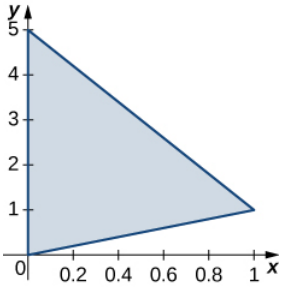
1. $R$ is the triangular region with vertices $(0,0)$, $(0,3)$, and $(6,0)$; $\rho(x,y)=xy$.



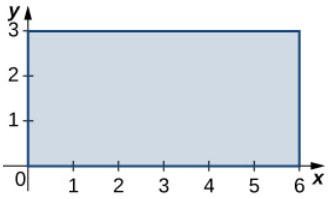
**Answer**

$\frac{27}{2}$

2. $R$ is the triangular region with vertices $(0,0)$, $(1,1)$, and $(0,5)$; $\rho(x,y)=x+y$.



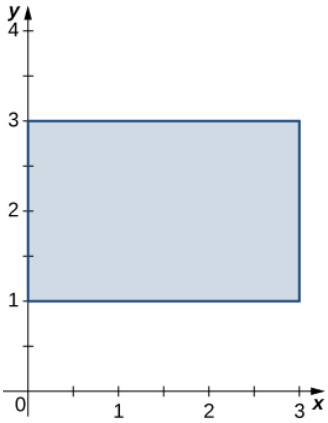
3. $R$ is the rectangular region with vertices $(0,0)$, $(0,3)$, $(6,3)$ and $(6,0)$; $\rho(x,y)=\sqrt{xy}$.



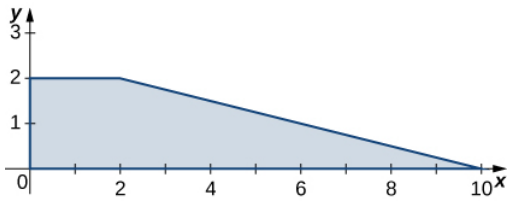
**Answer**

$24\sqrt{2}$

4. $R$ is the rectangular region with vertices $(0,1)$, $(0,3)$, $(3,3)$ and $(3,1)$; $\rho(x,y)=x^2y$.



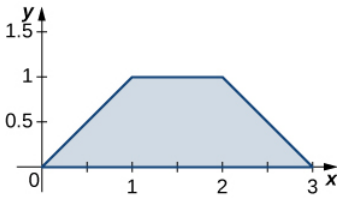
5. $R$ is the trapezoidal region determined by the lines $y=-\frac{1}{4}x+\frac{5}{2}$, $y=0$, $y=2$, and $x=0$; $\rho(x,y)=3xy$.



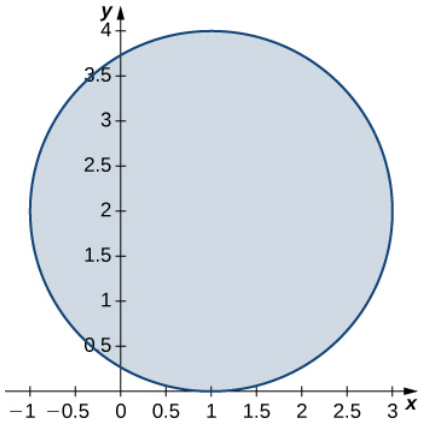
**Answer**

**76**

6. $R$ is the trapezoidal region determined by the lines $y = 0,\ y = 1,\ y = x$ and $y = -x + 3;\ \rho(x, y) = 2x + y$.



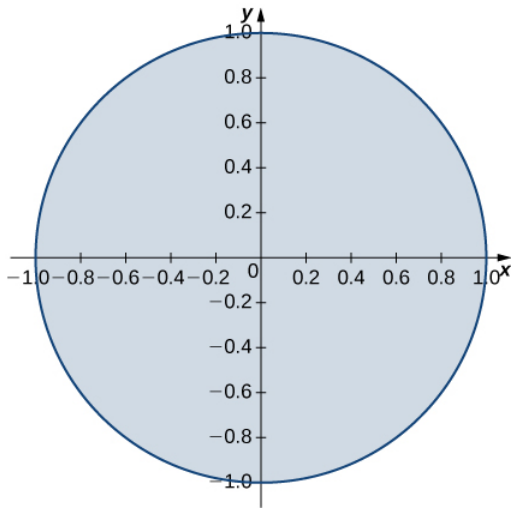
7. $R$ is the disk of radius $2$ centered at $(1, 2);\ \rho(x, y) = x^2 + y^2 - 2x - 4y + 5$.



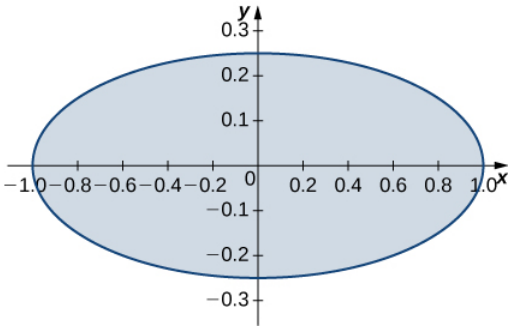
**Answer**

$8\pi$

8. $R$ is the unit disk; $\rho(x, y) = 3x^4 + 6x^2y^2 + 3y^4$.



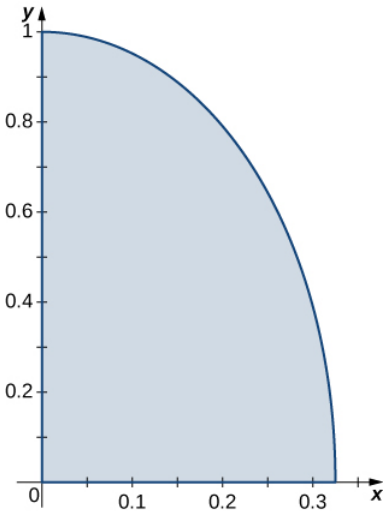
9. $R$ is the region enclosed by the ellipse $x^2 + 4y^2 = 1;\ \rho(x, y) = 1$.



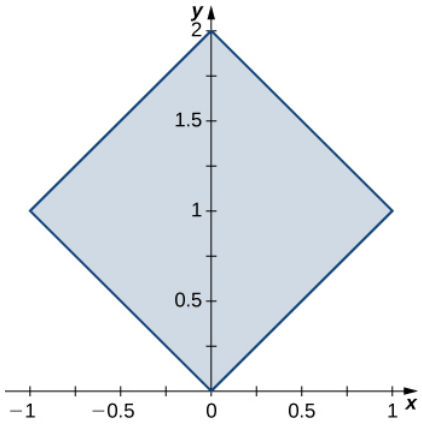
**Answer**

$\frac{\pi}{2}$

10. $R = \{(x, y) \mid 9x^2 + y^2 \leq 1,\ x \geq 0,\ y \geq 0\};\ \rho(x, y) = \sqrt{9x^2 + y^2}$.



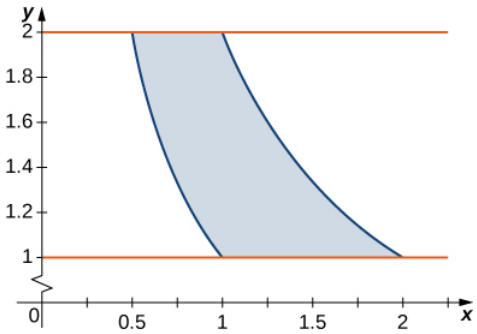
11. $R$ is the region bounded by $y = x,\ y = -x,\ y = x + 2,\ y = -x + 2;\ \rho(x, y) = 1$.



**Answer**

2

12. $R$ is the region bounded by $y = \frac{1}{x},\ y = \frac{2}{x},\ y = 1$, and $y = 2;\ \rho(x, y) = 4(x + y)$.



**In exercises 13 - 24, consider a lamina occupying the region $R$ and having the density function $\rho$ given in the preceding group of exercises. Use a computer algebra system (CAS) to answer the following questions.**

**a. Find the moments $M_x$ and $M_y$ about the $x$-axis and $y$-axis, respectively.**

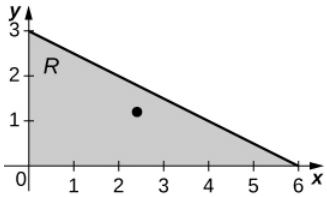
**b. Calculate and plot the center of mass of the lamina.**

**c. [T] Use a CAS to locate the center of mass on the graph of $R$.**

13. [T] $R$ is the triangular region with vertices $(0,0)$, $(0,3)$, and $(6,0)$; $\rho(x,y)=xy$.

**Answer**

a. $M_x=\frac{81}{5}$, $M_y=\frac{162}{5}$;
b. $\bar{x}=\frac{12}{5}$, $\bar{y}=\frac{6}{5}$;
c.

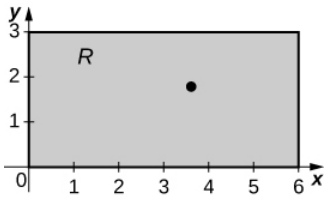


14. [T] $R$ is the triangular region with vertices $(0,0)$, $(1,1)$, and $(0,5)$; $\rho(x,y)=x+y$.

15. [T] $R$ is the rectangular region with vertices $(0,0)$, $(0,3)$, $(6,3)$, and $(6,0)$; $\rho(x,y)=\sqrt{xy}$.

**Answer**

a. $M_x=\frac{216\sqrt{2}}{5}$, $M_y=\frac{432\sqrt{2}}{5}$;
b. $\bar{x}=\frac{18}{5}$, $\bar{y}=\frac{9}{5}$;
c.



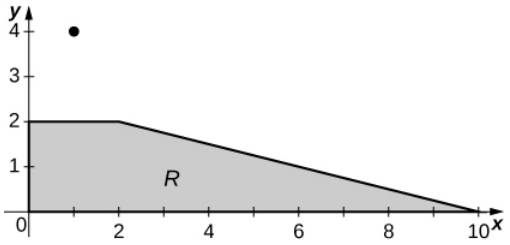
16. [T] $R$ is the rectangular region with vertices $(0,1)$, $(0,3)$, $(3,3)$, and $(3,1)$; $\rho(x,y)=x^2y$.

17. [T] $R$ is the trapezoidal region determined by the lines $y=-\frac{1}{4}x+\frac{5}{2}$, $y=0$, $y=2$, and $x=0$; $\rho(x,y)=3xy$.

**Answer**

a. $M_x=\frac{368}{5}$, $M_y=\frac{1552}{5}$;
b. $\bar{x}=\frac{92}{95}$, $\bar{y}=\frac{388}{95}$;

c.



18. [T] $R$ is the trapezoidal region determined by the lines $y = 0,\ y = 1,\ y = x$, and $y = -x + 3;\ \rho(x, y) = 2x + y$.

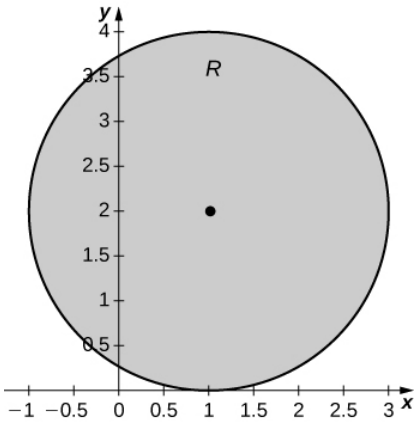
19. [T] $R$ is the disk of radius $2$ centered at $(1, 2);\ \rho(x, y) = x^2 + y^2 - 2x - 4y + 5$.

**Answer**

a. $M_x = 16\pi,\ M_y = 8\pi$;

b. $\bar{x} = 1,\ \bar{y} = 2$;

c.



20. [T] $R$ is the unit disk; $\rho(x, y) = 3x^4 + 6x^2y^2 + 3y^4$.

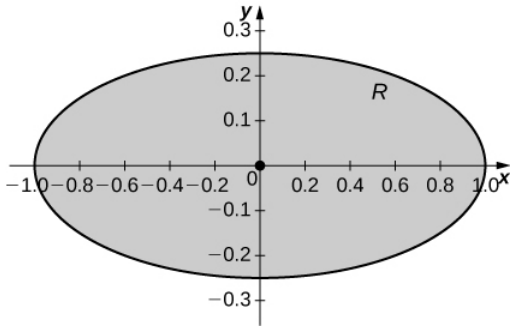
21. [T] $R$ is the region enclosed by the ellipse $x^2 + 4y^2 = 1;\ \rho(x, y) = 1$.

**Answer**

a. $M_x = 0,\ M_y = 0)$;

b. $\bar{x} = 0,\ \bar{y} = 0$;

c.

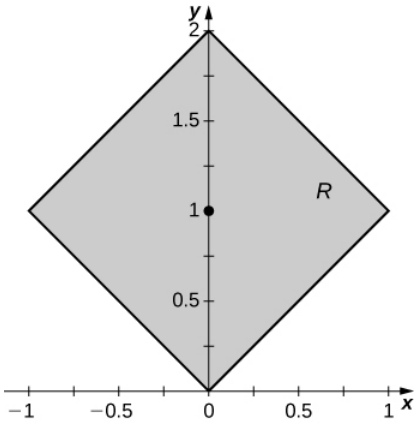


22. [T] $R = \{(x, y) \mid 9x^2 + y^2 \le 1,\ x \ge 0,\ y \ge 0\};\ \rho(x, y) = \sqrt{9x^2 + y^2}$.

23. [T] $R$ is the region bounded by $y = x,\ y = -x,\ y = x + 2$, and $y = -x + 2;\ \rho(x, y) = 1$.

**Answer**

a. $M_x = 2,\ M_y = 0$);
b. $\bar{x} = 0,\ \bar{y} = 1$;
c.



24. [T] $R$ is the region bounded by $y = \frac{1}{x},\ y = \frac{2}{x},\ y = 1$, and $y = 2;\ \rho(x, y) = 4(x + y)$.

**In exercises 25 - 36, consider a lamina occupying the region $R$ and having the density function $\rho$ given in the first two groups of Exercises.**

**a. Find the moments of inertia $I_x$, $I_y$ and $I_0$ about the $x$-axis, $y$-axis, and origin, respectively.**

**b. Find the radii of gyration with respect to the $x$-axis, $y$-axis, and origin, respectively.**

25. $R$ is the triangular region with vertices $(0, 0),\ (0, 3)$, and $(6, 0);\ \rho(x, y) = xy$.

**Answer**

a. $I_x = \frac{243}{10},\ I_y = \frac{486}{5}$, and $I_0 = \frac{243}{2}$;
b. $R_x = \frac{3\sqrt{5}}{5},\ R_y = \frac{6\sqrt{5}}{5}$, and $R_0 = 3$

26. $R$ is the triangular region with vertices $(0, 0),\ (1, 1)$, and $(0, 5);\ \rho(x, y) = x + y$.

27. $R$ is the rectangular region with vertices $(0, 0),\ (0, 3),\ (6, 3)$, and $(6, 0);\ \rho(x, y) = \sqrt{xy}$.

**Answer**

a. $I_x = \frac{2592\sqrt{2}}{7},\ I_y = \frac{648\sqrt{2}}{7}$, and $I_0 = \frac{3240\sqrt{2}}{7}$;
b. $R_x = \frac{6\sqrt{21}}{7},\ R_y = \frac{3\sqrt{21}}{7}$, and $R_0 = \frac{3\sqrt{106}}{7}$

28. $R$ is the rectangular region with vertices $(0, 1),\ (0, 3),\ (3, 3)$, and $(3, 1);\ \rho(x, y) = x^2 y$.

29. $R$ is the trapezoidal region determined by the lines $y = -\frac{1}{4}x + \frac{5}{2},\ y = 0,\ y = 2$, and x = 0; \space \rho (x,y) = 3xy\).

**Answer**

a. $I_x = 88,\ I_y = 1560$, and $I_0 = 1648$;
b. $R_x = \frac{\sqrt{418}}{19},\ R_y = \frac{\sqrt{7410}}{10}$, and $R_0 = \frac{2\sqrt{1957}}{19}$

30. $R$ is the trapezoidal region determined by the lines $y = 0,\ y = 1,\ y = x$, and y = -x + 3; \space \rho (x,y) = 2x + y\).

31. $R$ is the disk of radius $2$ centered at $(1, 2);\ \rho(x, y) = x^2 + y^2 - 2x - 4y + 5$.

**Answer**

a. $I_x = \frac{128\pi}{3},\ I_y = \frac{56\pi}{3}$, and $I_0 = \frac{184\pi}{3}$;
b. $R_x = \frac{4\sqrt{3}}{3},\ R_y = \frac{\sqrt{21}}{2}$, and $R_0 = \frac{\sqrt{69}}{3}$

32. $R$ is the unit disk; $\rho(x,y) = 3x^4 + 6x^2y^2 + 3y^4$.

33. $R$ is the region enclosed by the ellipse $x^2 + 4y^2 = 1;\ \rho(x,y) = 1$.

**Answer**

a. $I_x = \frac{\pi}{32},\ I_y = \frac{\pi}{8}$, and $I_0 = \frac{5\pi}{32}$;
b. $R_x = \frac{1}{4},\ R_y = \frac{1}{2}$, and $R_0 = \frac{\sqrt{5}}{4}$

34. $R = \{(x,y) \mid 9x^2 + y^2 \le 1,\ x \ge 0,\ y \ge 0\};\ \rho(x,y) = \sqrt{9x^2 + y^2}$.

35. $R$ is the region bounded by $y = x,\ y = -x,\ y = x + 2$, and $y = -x + 2;\ \rho(x,y) = 1$.

**Answer**

a. $I_x = \frac{7}{3},\ I_y = \frac{1}{3}$, and $I_0 = \frac{8}{3}$;
b. $R_x = \frac{\sqrt{42}}{6},\ R_y = \frac{\sqrt{6}}{6}$, and $R_0 = \frac{2\sqrt{3}}{3}$

36. $R$ is the region bounded by $y = \frac{1}{x},\ y = \frac{2}{x},\ y = 1$, and $y = 2;\ \rho(x,y) = 4(x + y)$.

37. Let $Q$ be the solid unit cube. Find the mass of the solid if its density $\rho$ is equal to the square of the distance of an arbitrary point of $Q$ to the $xy$-plane.

**Answer**

$m = \frac{1}{3}$

38. Let $Q$ be the solid unit hemisphere. Find the mass of the solid if its density $\rho$ is proportional to the distance of an arbitrary point of $Q$ to the origin.

39. The solid $Q$ of constant density $1$ is situated inside the sphere $x^2 + y^2 + z^2 = 16$ and outside the sphere $x^2 + y^2 + z^2 = 1$. Show that the center of mass of the solid is not located within the solid.

40. Find the mass of the solid $Q = \{(x,y,z) \mid 1 \le x^2 + z^2 \le 25,\ y \le 1 - x^2 - z^2\}$ whose density is $\rho(x,y,z) = k$, where $k > 0$.

41. [T] The solid $Q = \{(x,y,z) \mid x^2 + y^2 \le 9,\ 0 \le z \le 1,\ x \ge 0,\ y \ge 0\}$ has density equal to the distance to the $xy$-plane. Use a CAS to answer the following questions.

a. Find the mass of $Q$.

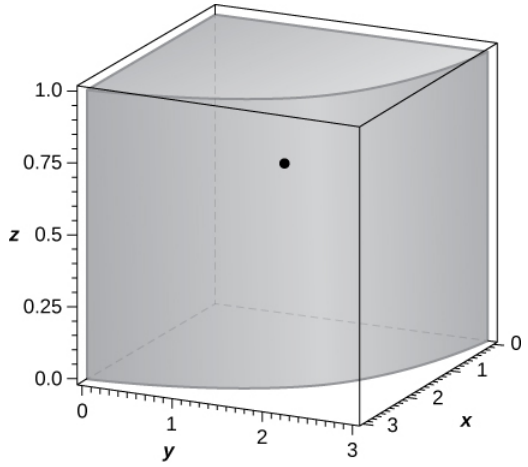
b. Find the moments $M_{xy},\ M_{xz}$ and $M_{yz}$ about the $xy$-plane, $xz$-plane, and $yz$-plane, respectively.

c. Find the center of mass of $Q$.

d. Graph $Q$ and locate its center of mass.

**Answer**

a. $m = \frac{9\pi}{4}$;
b. $M_{xy} = \frac{3\pi}{2},\ M_{xz} = \frac{81}{8},\ M_{yz} = \frac{81}{8}$;
c. $\bar{x} = \frac{9}{2\pi},\ \bar{y} = \frac{9}{2\pi},\ \bar{z} = \frac{2}{3}$;
d.



42. Consider the solid $Q = \{(x, y, z) \,|\, 0 \le x \le 1,\ 0 \le y \le 2,\ 0 \le z \le 3\}$ with the density function $\rho(x, y, z) = x + y + 1$.

a. Find the mass of $Q$.

b. Find the moments $M_{xy},\ M_{xz}$ and $M_{yz}$ about the $xy$-plane, $xz$-plane, and $yz$-plane, respectively.

c. Find the center of mass of $Q$.

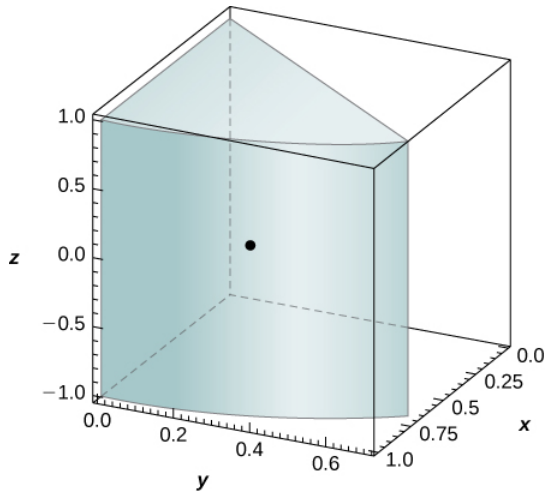
43. [T] The solid $Q$ has the mass given by the triple integral $\int_{-1}^{1} \int_{0}^{\pi/4} \int_{0}^{1} r^2 \, dr \, d\theta \, dz$.

Use a CAS to answer the following questions.

- Show that the center of mass of $Q$ is located in the $xy$-plane.
- Graph $Q$ and locate its center of mass.

**Answer**

$\bar{x} = \frac{3\sqrt{2}}{2\pi}$, $\bar{y} = \frac{3(2-\sqrt{2})}{2\pi}$, $\bar{z} = 0$; 2. the solid $Q$ and its center of mass are shown in the following figure.



44. The solid $Q$ is bounded by the planes $x + 4y + z = 8,\ x = 0,\ y = 0$, and $z = 0$. Its density at any point is equal to the distance to the $xz$-plane. Find the moments of inertia of the solid about the $xz$-plane.

45. The solid $Q$ is bounded by the planes $x + y + z = 3,\ x = 0,\ y = 0$, and $z = 0$. Its density is $\rho(x, y, z) = x + ay$, where $a > 0$. Show that the center of mass of the solid is located in the plane $z = \frac{3}{5}$ for any value of $a$.

46. Let $Q$ be the solid situated outside the sphere $x^2 + y^2 + z^2 = z$ and inside the upper hemisphere $x^2 + y^2 + z^2 = R^2$, where $R > 1$. If the density of the solid is $\rho(x, y, z) = \frac{1}{\sqrt{x^2+y^2+z^2}}$, find $R$ such that the mass of the solid is $\frac{7\pi}{2}$.

47. The mass of a solid $Q$ is given by $\int_0^2 \int_0^{\sqrt{4-x^2}} \int_{\sqrt{x^2+y^2}}^{\sqrt{16-x^2-y^2}} (x^2+y^2+z^2)^n \, dz \, dy \, dx$, where $n$ is an integer. Determine $n$ such the mass of the solid is $(2-\sqrt{2})\pi$.

**Answer**

$n = -2$

48. Let $Q$ be the solid bounded above the cone $x^2+y^2=z^2$ and below the sphere $x^2+y^2+z^2-4z=0$. Its density is a constant $k > 0$. Find $k$ such that the center of mass of the solid is situated $7$ units from the origin.

49. The solid $Q = \{(x,y,z) \mid 0 \le x^2+y^2 \le 16,\ x \ge 0,\ y \ge 0,\ 0 \le z \le x\}$ has the density $\rho(x,y,z) = k$. Show that the moment $M_{xy}$ about the $xy$-plane is half of the moment $M_{yz}$ about the $yz$-plane.

50. The solid $Q$ is bounded by the cylinder $x^2+y^2=a^2$, the paraboloid $b^2 - z = x^2+y^2$, and the $xy$-plane, where $0 < a < b$. Find the mass of the solid if its density is given by $\rho(x,y,z) = \sqrt{x^2+y^2}$.

51. Let $Q$ be a solid of constant density $k$, where $k > 0$, that is located in the first octant, inside the circular cone $x^2+y^2 = 9(z-1)^2$, and above the plane $z=0$. Show that the moment $M_{xy}$ about the $xy$-plane is the same as the moment $M_{yz}$ about the $xz$-plane.

52. The solid $Q$ has the mass given by the triple integral $\int_0^1 \int_0^{\pi/2} \int_0^{r^3} (r^4+r) \, dz \, d\theta \, dr$.

a. Find the density of the solid in rectangular coordinates.

b. Find the moment $M_{xy}$ about the $xy$-plane.

53. The solid $Q$ has the moment of inertia $I_x$ about the $yz$-plane given by the triple integral $\int_0^2 \int_{-\sqrt{4-y^2}}^{\sqrt{4-y^2}} \int_{\frac{1}{2}(x^2+y^2)}^{\sqrt{x^2+y^2}} (y^2+z^2)(x^2+y^2) \, dz \, dx \, dy$.

a. Find the density of $Q$.

b. Find the moment of inertia $I_z$ about the $xy$-plane.

**Answer**

a. $\rho(x,y,z) = x^2+y^2$;
b. $\frac{16\pi}{7}$

54. The solid $Q$ has the mass given by the triple integral $\int_0^{\pi/4} \int_0^{2\sec\theta} \int_0^1 (r^3 \cos\theta \sin\theta + 2r) \, dz \, dr \, d\theta$.

a. Find the density of the solid in rectangular coordinates.

b. Find the moment $M_{xz}$ about the $xz$-plane.

55. Let $Q$ be the solid bounded by the $xy$-plane, the cylinder $x^2+y^2=a^2$, and the plane $z=1$, where $a > 1$ is a real number. Find the moment $M_{xy}$ of the solid about the $xy$-plane if its density given in cylindrical coordinates is $\rho(x,y,z) = \frac{d^2f}{dr^2}(r)$, where $f$ is a differentiable function with the first and second derivatives continuous and differentiable on $(0,a)$.

**Answer**

$M_{xy} = \pi(f(0) - f(a) + af'(a))$

56. A solid $Q$ has a volume given by $\iint_D \int_a^b dA \, dz$, where $D$ is the projection of the solid onto the $xy$-plane and $a < b$ are real numbers, and its density does not depend on the variable $z$. Show that its center of mass lies in the plane $z = \frac{a+b}{2}$.

57. Consider the solid enclosed by the cylinder $x^2+z^2=a^2$ and the planes $y=b$ and $y=c$, where $a > 0$ and $b < c$ are real numbers. The density of $Q$ is given by $\rho(x,y,z) = f'(y)$, where $f$ is a differential function whose derivative is continuous on $(b,c)$. Show that if $f(b) = f(c)$, then the moment of inertia about the $xz$-plane of $Q$ is null.

58. [T] The average density of a solid $Q$ is defined as $\rho_{ave} = \frac{1}{V(Q)} \iiint_Q \rho(x,y,z)\, dV = \frac{m}{V(Q)}$, where $V(Q)$ and $m$ are the volume and the mass of $Q$, respectively. If the density of the unit ball centered at the origin is $\rho(x,y,z) = e^{-x^2-y^2-z^2}$, use a CAS to find its average density. Round your answer to three decimal places.

59. Show that the moments of inertia $I_x$, $I_y$, and $I_z$ about the $yz$-plane, $xz$-plane, and $xy$-plane, respectively, of the unit ball centered at the origin whose density is $\rho(x,y,z) = e^{-x^2-y^2-z^2}$ are the same. Round your answer to two decimal places.

**Answer**

$I_x = I_y = I_z \approx 0.84$

# 15.8: Change of Variables in Multiple Integrals

**Learning Objectives**

- Determine the image of a region under a given transformation of variables.
- Compute the Jacobian of a given transformation.
- Evaluate a double integral using a change of variables.
- Evaluate a triple integral using a change of variables.

Recall from Substitution Rule the method of integration by substitution. When evaluating an integral such as

$$\int_2^3 x(x^2-4)^5 dx,$$

we substitute $u = g(x) = x^2 - 4$. Then $du = 2x\,dx$ or $x\,dx = \frac{1}{2}du$ and the limits change to $u = g(2) = 2^2 - 4 = 0$ and $u = g(3) = 9 - 4 = 5$. Thus the integral becomes

$$\int_0^5 \frac{1}{2}u^5 du$$

and this integral is much simpler to evaluate. In other words, when solving integration problems, we make appropriate substitutions to obtain an integral that becomes much simpler than the original integral.

We also used this idea when we transformed double integrals in rectangular coordinates to polar coordinates and transformed triple integrals in rectangular coordinates to cylindrical or spherical coordinates to make the computations simpler. More generally,

$$\int_a^b f(x)dx = \int_c^d f(g(u))g'(u)du,$$

Where $x = g(u)$, $dx = g'(u)du$, and $u = c$ and $u = d$ satisfy $c = g(a)$ and $d = g(b)$.

A similar result occurs in double integrals when we substitute

- $x = f(r,\theta) = r\,\cos\,\theta$
- $y = g(r,\theta) = r\,\sin\,\theta$, and
- $dA = dx\,dy = r\,dr\,d\theta$.

Then we get

$$\iint_R f(x,y)dA = \iint_S (r\,\cos\,\theta,\, r\,\sin\,\theta)r\,dr\,d\theta$$

where the domain $R$ is replaced by the domain $S$ in polar coordinates. Generally, the function that we use to change the variables to make the integration simpler is called a transformation or mapping.

## Planar Transformations

A planar transformation $T$ is a function that transforms a region $G$ in one plane into a region $R$ in another plane by a change of variables. Both $G$ and $R$ are subsets of $R^2$. For example, Figure 15.8.1 shows a region $G$ in the $uv$-plane transformed into a region $R$ in the $xy$-plane by the change of variables $x = g(u,v)$ and $y = h(u,v)$, or sometimes we write $x = x(u,v)$ and $y = y(u,v)$. We shall typically assume that each of these functions has continuous first partial derivatives, which means $g_u$, $g_v$, $h_u$, and $h_v$ exist and are also continuous. The need for this requirement will become clear soon.

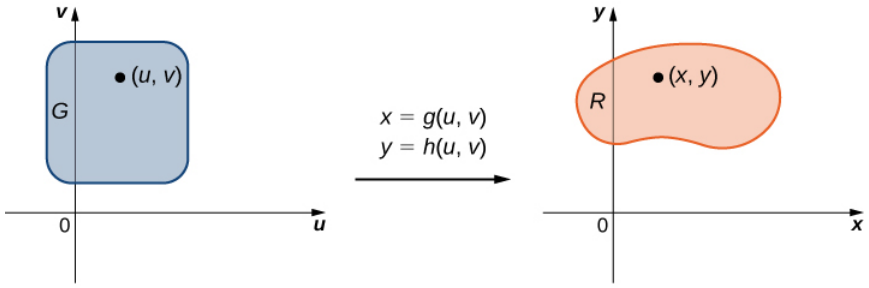

Figure 15.8.1: The transformation of a region $G$ in the $uv$-plane into a region $R$ in the $xy$-plane.

**Definition: one-to-one transformation**

A transformation $T: G \to R$, defined as $T(u,v) = (x,y)$, is said to be a one-to-one transformation if no two points map to the same image point.

To show that $T$ s a one-to-one transformation, we assume $T(u_1, v_1) = T(u_2, v_2)$ and show that as a consequence we obtain$(u_1, v_1) = (u_2, v_2)$. If the transformation $T$ is one-to-one in the domain $G$, then the inverse $T^{-1}$ exists with the domain $R$ such that $T^{-1} \circ T$ and $T \circ T^{-1}$ are identity functions.

Figure 15.8.2 shows the mapping $T(u,v) = (x,y)$ where $x$ and $y$ are related to $u$ and $v$ by the equations $x = g(u,v)$ and $y = h(u,v)$. The region $G$ is the domain of $T$ and the region $R$ is the range of $T$, also known as the *image* of $G$ under the transformation $T$.

**Example 15.8.1.A: Determining How the Transformation Works**

Suppose a transformation $T$ is defined as $T(r,\theta) = (x,y)$ where $x = r\cos\theta$, $y = r\sin\theta$. Find the image of the polar rectangle $G = \{(r,\theta) | 0 \le r \le 1,\ 0 \le \theta \le \pi/2\}$ in the $r\theta$-plane to a region $R$ in the $xy$-plane. Show that $T$ is a one-to-one transformation in $G$ and find $T^{-1}(x,y)$.

### Solution

Since $r$ varies from 0 to 1 in the $r\theta$-plane, we have a circular disc of radius 0 to 1 in the $xy$-plane. Because $\theta$ varies from 0 to $\pi/2$ in the $r\theta$-plane, we end up getting a quarter circle of radius 1 in the first quadrant of the $xy$-plane (Figure 15.8.2). Hence $R$ is a quarter circle bounded by $x^2 + y^2 = 1$ in the first quadrant.

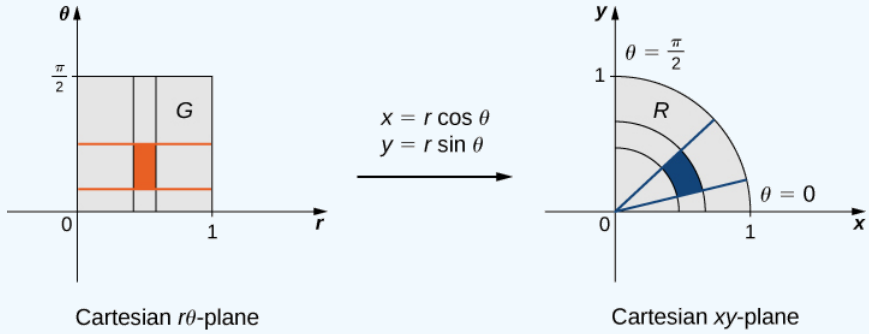

Figure 15.8.2: A rectangle in the $r\theta$-plane is mapped into a quarter circle in the $xy$-plane.

In order to show that $T$ is a one-to-one transformation, assume $T(r_1, \theta_1) = T(r_2, \theta_2)$ and show as a consequence that $(r_1, \theta_1) = (r_2, \theta_2)$. In this case, we have

$$T(r_1, \theta_1) = T(r_2, \theta_2),$$

$$(x_1, y_1) = (x_1, y_1),$$

$$(r_1 \cos\theta_1, r_1 \sin\theta_1) = (r_2 \cos\theta_2, r_2 \sin\theta_2),$$

$$r_1 \cos\theta_1 = r_2 \cos\theta_2,\ r_1 \sin\theta_1 = r_2 \sin\theta_2.$$

Dividing, we obtain

$$\frac{r_1 \cos \theta_1}{r_1 \sin \theta_1} = \frac{r_2 \cos \theta_2}{r_2 \sin \theta_2}$$

$$\frac{\cos \theta_1}{\sin \theta_1} = \frac{\cos \theta_2}{\sin \theta_2}$$

$$\tan \theta_1 = \tan \theta_2$$

$$\theta_1 = \theta_2$$

since the tangent function is one-one function in the interval $0 \le \theta \le \pi/2$. Also, since $0 \le r \le 1$, we have $r_1 = r_2$, $\theta_1 = \theta_2$. Therefore, $(r_1, \theta_1) = (r_2, \theta_2)$ and $T$ is a one-to-one transformation from $G$ to $R$.

To find $T^{-1}(x, y)$ solve for $r, \theta$ in terms of $x, y$. We already know that $r^2 = x^2 + y^2$ and $\tan \theta = \frac{y}{x}$. Thus $T^{-1}(x, y) = (r, \theta)$ is defined as $r = \sqrt{x^2 + y^2}$ and $\tan^{-1}\left(\frac{y}{x}\right)$.

### Example 15.8.1$B$: Finding the Image under $T$

Let the transformation $T$ be defined by $T(u, v) = (x, y)$ where $x = u^2 - v^2$ and $y = uv$. Find the image of the triangle in the $uv$-plane with vertices $(0, 0)$, $(0, 1)$, and $(1, 1)$.

#### Solution

The triangle and its image are shown in Figure 15.8.3. To understand how the sides of the triangle transform, call the side that joins $(0, 0)$ and $(0, 1)$ side $A$, the side that joins $(0, 0)$ and $(1, 1)$ side $B$, and the side that joins $(1, 1)$ and $(0, 1)$ side $C$.

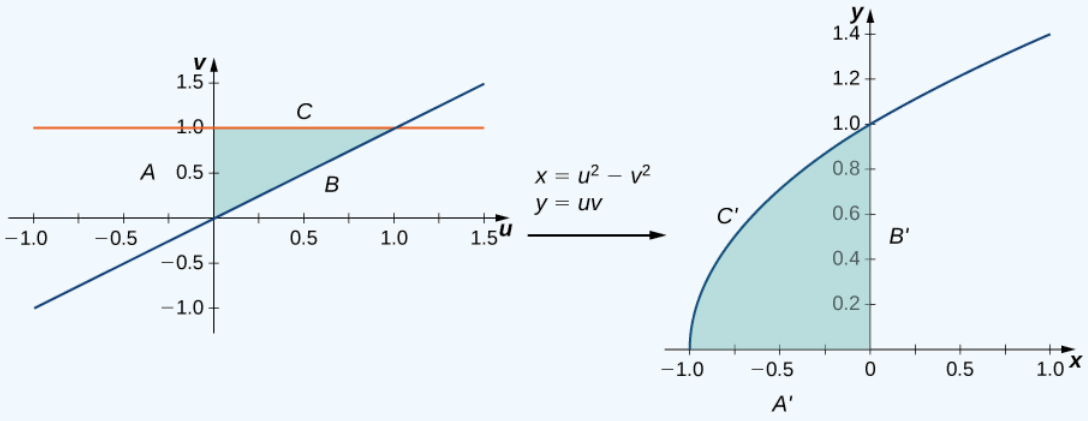

Figure 15.8.3: A triangular region in the $uv$-plane is transformed into an image in the $xy$-plane.

- For the side $A: u = 0,\ 0 \le v \le 1$ transforms to $x = -v^2,\ y = 0$ so this is the side $A'$ that joins $(-1, 0)$ and $(0, 0)$.
- For the side $B: u = v,\ 0 \le u \le 1$ transforms to $x = 0,\ y = u^2$ so this is the side $B'$ that joins $(0, 0)$ and $(0, 1)$.
- For the side $C: 0 \le u \le 1,\ v = 1$ transforms to $x = u^2 - 1,\ y = u$ (hence $x = y^2 - 1$ so this is the side $C'$ that makes the upper half of the parabolic arc joining $(-1, 0)$ and $(0, 1)$.

All the points in the entire region of the triangle in the $uv$-plane are mapped inside the parabolic region in the $xy$-plane.

### Exercise 15.8.1

Let a transformation $T$ be defined as $T(u, v) = (x, y)$ where $x = u + v,\ y = 3v$. Find the image of the rectangle $G = \{(u, v) : 0 \le u \le 1,\ 0 \le v \le 2\}$ from the $uv$-plane after the transformation into a region $R$ in the $xy$-plane. Show that $T$ is a one-to-one transformation and find $T^{-1}(x, y)$.

**Hint**

Follow the steps of Example 15.8.1$B$.

**Answer**

$T^{-1}(x,y) = (u,v)$ where $u = \frac{3x-y}{3}$ and $v = \frac{y}{3}$

## Jacobians

Recall that we mentioned near the beginning of this section that each of the component functions must have continuous first partial derivatives, which means that $g_u, g_v, h_u$ and $h_v$ exist and are also continuous. A transformation that has this property is called a $C^1$ transformation (here $C$ denotes continuous). Let $T(u,v) = (g(u,v),\ h(u,v))$, where $x = g(u,v)$ and $y = h(u,v)$ be a one-to-one $C^1$ transformation. We want to see how it transforms a small rectangular region $S$, $\Delta u$ units by $\Delta v$ units, in the $uv$-plane (Figure 15.8.4).

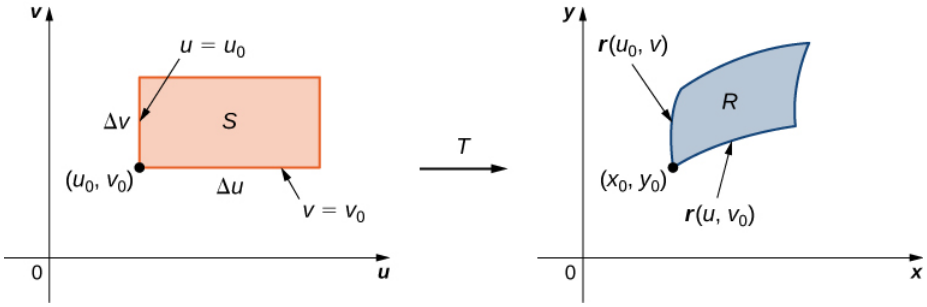

Figure 15.8.4: A small rectangle $S$ in the $uv$-plane is transformed into a region $R$ in the $xy$-plane.

Since $x = g(u,v)$ and $y = h(u,v)$, we have the position vector $r(u,v) = g(u,v)i + h(u,v)j$ of the image of the point $(u,v)$. Suppose that $(u_0, v_0)$is the coordinate of the point at the lower left corner that mapped to $(x_0, y_0) = T(u_0, v_0)$ The line $v = v_0$ maps to the image curve with vector function $r(u, v_0)$, and the tangent vector at $(x_0, y_0)$ to the image curve is

$$r_u = g_u(u_0, v_0)i + h_v(u_0, v_0)j = \frac{\partial x}{\partial u}i + \frac{\partial y}{\partial u}j.$$

Similarly, the line $u = u_0$ maps to the image curve with vector function $r(u_0, v)$, and the tangent vector at $(x_0, y_0)$ to the image curve is

$$r_v = g_v(u_0, v_0)i + h_u(u_0, v_0)j = \frac{\partial x}{\partial v}i + \frac{\partial y}{\partial v}j.$$

Now, note that

$$r_u = \lim_{\Delta u \to 0} \frac{r(u_0 + \Delta u, v_0) - r(u_0, v_0)}{\Delta u} \; so \; r(u_0 + \Delta u, v_0) - r(u_0, v_0) \approx \Delta u r_u.$$

Similarly,

$$r_v = \lim_{\Delta v \to 0} \frac{r(u_0, v_0 + \Delta v) - r(u_0, v_0)}{\Delta v} \; so \; r(u_0, v_0 + \Delta v) - r(u_0, v_0) \approx \Delta v r_v.$$

This allows us to estimate the area $\Delta A$ of the image $R$ by finding the area of the parallelogram formed by the sides $\Delta v r_v$ and $\Delta u r_u$. By using the cross product of these two vectors by adding the $\mathbf{k}$th component as $\mathbf{0}$, the area $\Delta A$ of the image $R$ (refer to The Cross Product) is approximately $|\Delta u r_u \times \Delta v r_v| = |r_u \times r_v| \Delta u \Delta v$. In determinant form, the cross product is

$$r_u \times r_v = \begin{vmatrix} i & j & k \\ \frac{\partial x}{\partial u} & \frac{\partial y}{\partial u} & 0 \\ \frac{\partial x}{\partial v} & \frac{\partial y}{\partial v} & 0 \end{vmatrix} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial y}{\partial u} \\ \frac{\partial x}{\partial v} & \frac{\partial y}{\partial v} \end{vmatrix} k = \left( \frac{\partial x}{\partial u}\frac{\partial y}{\partial v} - \frac{\partial x}{\partial v}\frac{\partial y}{\partial u} \right) k$$

Since $|k| = 1$, we have

$\Delta A \approx |r_u \times r_v| \Delta u \Delta v = \left( \frac{\partial x}{\partial u}\frac{\partial y}{\partial v} - \frac{\partial x}{\partial v}\frac{\partial y}{\partial u} \right) \Delta u \Delta v.$

**Definition: Jacobian**

The *Jacobian* of the $C^1$ transformation $T(u,v) = (g(u,v),\ h(u,v))$ is denoted by $J(u,v)$ and is defined by the $2 \times 2$ determinant

$$J(u,v)=\left|\frac{\partial(x,y)}{\partial(u,v)}\right|=\begin{vmatrix}\frac{\partial x}{\partial u} & \frac{\partial y}{\partial u}\\ \frac{\partial x}{\partial v} & \frac{\partial y}{\partial v}\end{vmatrix}=\left(\frac{\partial x}{\partial u}\frac{\partial y}{\partial v}-\frac{\partial x}{\partial v}\frac{\partial y}{\partial u}\right).$$

Using the definition, we have

$$\Delta A\approx J(u,v)\Delta u\Delta v=\left|\frac{\partial(x,y)}{\partial(u,v)}\right|\Delta u\Delta v.$$

Note that the Jacobian is frequently denoted simply by

$$J(u,v)=\frac{\partial(x,y)}{\partial(u,v)}.$$

Note also that

$$\begin{vmatrix}\frac{\partial x}{\partial u} & \frac{\partial y}{\partial u}\\ \frac{\partial x}{\partial v} & \frac{\partial y}{\partial v}\end{vmatrix}=\left(\frac{\partial x}{\partial u}\frac{\partial y}{\partial v}-\frac{\partial x}{\partial v}\frac{\partial y}{\partial u}\right)=\begin{vmatrix}\frac{\partial x}{\partial u} & \frac{\partial x}{\partial v}\\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v}\end{vmatrix}.$$

Hence the notation $J(u,v)=\frac{\partial(x,y)}{\partial(u,v)}$ suggests that we can write the Jacobian determinant with partials of $x$ in the first row and partials of $y$ in the second row.

### Example 15.8.2$A$: Finding the Jacobian

Find the Jacobian of the transformation given in Example 15.8.1$A$.

**Solution**

The transformation in the example is $T(r,\theta)=(r\cos\theta,\ r\sin\theta)$ where $x=r\cos\theta$ and $y=r\sin\theta$. Thus the Jacobian is

$$J(r,\theta)=\frac{\partial(x,y)}{\partial(r,\theta)}=\begin{vmatrix}\frac{\partial x}{\partial r} & \frac{\partial x}{\partial\theta}\\ \frac{\partial y}{\partial r} & \frac{\partial y}{\partial\theta}\end{vmatrix}=\begin{vmatrix}\cos\theta & -r\sin\theta\\ \sin\theta & r\cos\theta\end{vmatrix}=r\cos^2\theta+r\sin^2\theta=r(\cos^2\theta+\sin^2\theta)=r.$$

### Example 15.8.2$B$: Finding the Jacobian

Find the Jacobian of the transformation given in Example 15.8.1$B$.

**Solution**

The transformation in the example is $T(u,v)=(u^2-v^2,uv)$ where $x=u^2-v^2$ and $y=uv$. Thus the Jacobian is

$$J(u,v)=\frac{\partial(x,y)}{\partial(u,v)}=\begin{vmatrix}\frac{\partial x}{\partial u} & \frac{\partial x}{\partial v}\\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v}\end{vmatrix}=\begin{vmatrix}2u & -2v\\ v & u\end{vmatrix}=2u^2+2v^2.$$

### Exercise 15.8.2

Find the Jacobian of the transformation given in the previous checkpoint: $T(u,v)=(u+v,2v)$.

**Hint**

Follow the steps in the previous two examples.

**Answer**

$$J(u,v) = \frac{\partial(x,y)}{\partial(u,v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} 1 & 1 \\ 0 & 2 \end{vmatrix} = 2$$

## Change of Variables for Double Integrals

We have already seen that, under the change of variables $T(u,v) = (x,y)$ where $x = g(u,v)$ and $y = h(u,v)$, a small region $\Delta A$ in the $xy$-plane is related to the area formed by the product $\Delta u \Delta v$ in the $uv$-plane by the approximation

$$\Delta A \approx J(u,v)\Delta u,\ \Delta v.$$

Now let's go back to the definition of double integral for a minute:

$$\iint_R f(x,y) fA = \lim_{m,n\to\infty} \sum_{i=1}^{m}\sum_{j=1}^{n} f(x_{ij}, y_{ij})\Delta A.$$

Referring to Figure 15.8.5, observe that we divided the region $S$ in the $uv$-plane into small subrectangles $S_{ij}$ and we let the subrectangles $R_{ij}$ in the $xy$-plane be the images of $S_{ij}$ under the transformation $T(u,v) = (x,y)$.

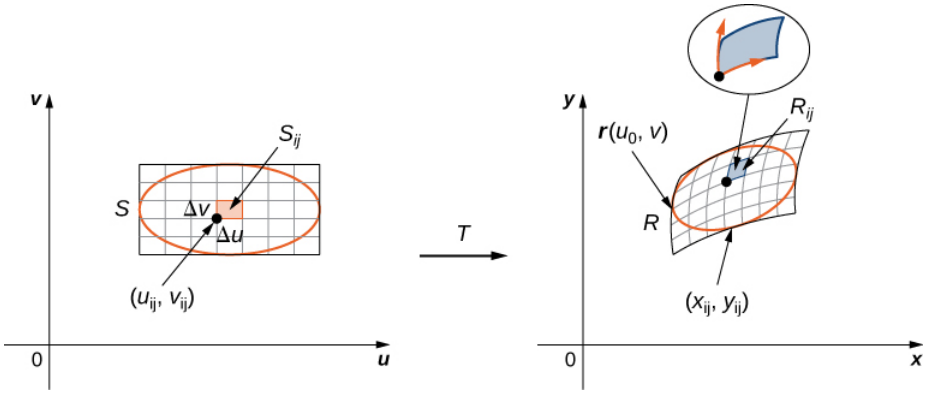

Figure 15.8.5: The subrectangles $S_{ij}$ in the $uv$-plane transform into subrectangles $R_{ij}$ in the $xy$-plane.

Then the double integral becomes

$$\iint_R = f(x,y)dA = \lim_{m,n\to\infty} \sum_{i=1}^{m}\sum_{j=1}^{n} f(x_{ij}, y_{ij})\Delta A$$
$$= \lim_{m,n\to\infty} \sum_{i=1}^{m}\sum_{j=1}^{n} f(g(u_{ij}, v_{ij}),\ h(u_{ij}, v_{ij}))|J(u_{ij}, v_{ij})|\Delta u \Delta v.$$

Notice this is exactly the double Riemann sum for the integral

$$\iint_S f(g(u,v),\ h(u,v)) \left|\frac{\partial(x,y)}{\partial(u,v)}\right| du\, dv.$$

**Change of Variables for Double Integrals**

Let $T(u,v) = (x,y)$ where $x = g(u,v)$ and $y = h(u,v)$ be a one-to-one $C^1$ transformation, with a nonzero Jacobian on the interior of the region $S$ in the $uv$-plane it maps $S$ into the region $R$ in the $xy$-plane. If $f$ is continuous on $R$, then

$$\iint_R f(x,y)dA = \iint_S f(g(u,v),\ h(u,v)) \left|\frac{\partial(x,y)}{\partial(u,v)}\right| du\, dv.$$

With this theorem for double integrals, we can change the variables from $(x,y)$ to $(u,v)$ in a double integral simply by replacing

$$dA = dx\, dy = \left|\frac{\partial(x,y)}{\partial(u,v)}\right| du\, dv$$

when we use the substitutions $x = g(u, v)$ and $y = h(u, v)$ and then change the limits of integration accordingly. This change of variables often makes any computations much simpler.

### Example 15.8.3: Changing Variables from Rectangular to Polar Coordinates

Consider the integral

$$\int_0^2 \int_0^{\sqrt{2x-x^2}} \sqrt{x^2+y^2}\, dy\, dx.$$

Use the change of variables $x = r\cos\theta$ and $y = r\sin\theta$, and find the resulting integral.

**Solution**

First we need to find the region of integration. This region is bounded below by $y = 0$ and above by $y = \sqrt{2x - x^2}$ (Figure 15.8.6).

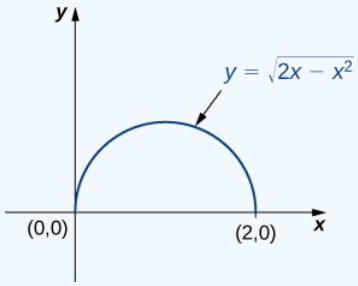

Figure 15.8.6: Changing a region from rectangular to polar coordinates.

Squaring and collecting terms, we find that the region is the upper half of the circle $x^2 + y^2 - 2x = 0$, that is $y^2 + (x-1)^2 = 1$. In polar coordinates, the circle is $r = 2\cos\theta$ so the region of integration in polar coordinates is bounded by $0 \le r \le \cos\theta$ and $0 \le \theta \le \frac{\pi}{2}$.

The Jacobian is $J(r, \theta) = r$, as shown in Example 15.8.2A. Since $r \ge 0$, we have $|J(r, \theta)| = r$.

The integrand $\sqrt{x^2+y^2}$ changes to $r$ in polar coordinates, so the double iterated integral is

$$\int_0^2 \int_0^{\sqrt{2x-x^2}} \sqrt{x^2+y^2}\, dy\, dx = \int_0^{\pi/2} \int_0^{2\cos\theta} r|j(r,\theta)|\, dr\, d\theta = \int_0^{\pi/2} \int_0^{2\cos\theta} r^2\, dr\, d\theta.$$

### Exercise 15.8.3

Considering the integral $\int_0^1 \int_0^{\sqrt{1-x^2}} (x^2+y^2)\, dy\, dx$, use the change of variables $x = r\cos\theta$ and $y = r\sin\theta$ and find the resulting integral.

**Hint**

Follow the steps in the previous example.

**Answer**

$$\int_0^{\pi/2} \int_0^1 r^3\, dr\, d\theta$$

Notice in the next example that the region over which we are to integrate may suggest a suitable transformation for the integration. This is a common and important situation.

## Example 15.8.4: Changing Variables

Consider the integral

$$\iint_R (x-y)\,dy\,dx,$$

where $R$ is the parallelogram joining the points $(1,2)$, $(3,4)$, $(4,3)$, and $(6,5)$ (Figure 15.8.7). Make appropriate changes of variables, and write the resulting integral.

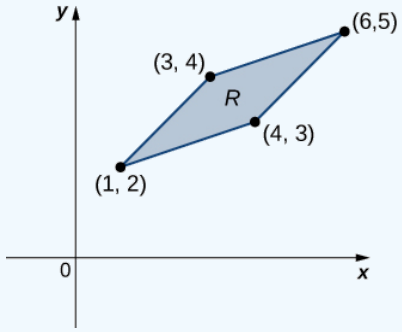

Figure 15.8.7: The region of integration for the given integral.

### Solution

First, we need to understand the region over which we are to integrate. The sides of the parallelogram are $x-y+1$, $x-y-1=0$, $x-3y+5=0$ and $x-3y+9=0$ (Figure 15.8.8). Another way to look at them is $x-y=-1$, $x-y=1$, $x-3y=-5$, and $x-3y=9$.

Clearly the parallelogram is bounded by the lines $y=x+1$, $y=x-1$, $y=\frac{1}{3}(x+5)$, and $y=\frac{1}{3}(x+9)$.

Notice that if we were to make $u=x-y$ and $v=x-3y$, then the limits on the integral would be $-1\le u\le 1$ and $-9\le v\le -5$.

To solve for $x$ and $y$, we multiply the first equation by 3 and subtract the second equation, $3u-v=(3x-3y)-(x-3y)=2x$. Then we have $x=\frac{3u-v}{2}$. Moreover, if we simply subtract the second equation from the first, we get $u-v=(x-y)-(x-3y)=2y$ and $y=\frac{u-v}{2}$.

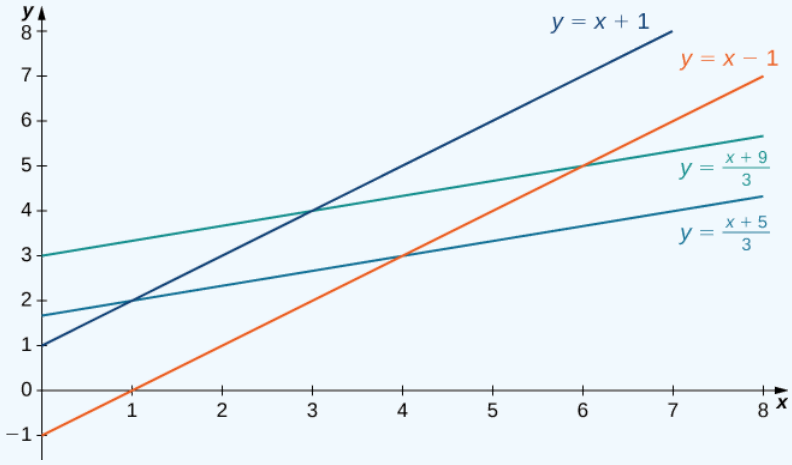

Figure 15.8.8: A parallelogram in the $xy$-plane that we want to transform by a change in variables.

Thus, we can choose the transformation

$$T(u,v)=\left(\frac{3u-v}{2},\frac{u-v}{2}\right)$$

and compute the Jacobian $J(u,v)$. We have

$$J(u,v)=\frac{\partial(x,y)}{\partial(u,v)}=\begin{vmatrix}\frac{\partial x}{\partial u} & \frac{\partial x}{\partial v}\\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v}\end{vmatrix}=\begin{vmatrix}3/2 & -1/2\\ 1/2 & -1/2\end{vmatrix}=-\frac{3}{4}+\frac{1}{4}=-\frac{1}{2}$$

Therefore, $|J(u,v)|=\frac{1}{2}$. Also, the original integrand becomes

$$x-y=\frac{1}{2}[3u-v-u+v]=\frac{1}{2}[3u-u]=\frac{1}{2}[2u]=u.$$

Therefore, by the use of the transformation $T$, the integral changes to

$$\iint_R (x-y)\,dy\,dx=\int_{-9}^{-5}\int_{-1}^{1} J(u,v)u\,du\,dv=\int_{-9}^{-5}\int_{-1}^{1}\left(\frac{1}{2}\right)u\,du\,dv,$$

which is much simpler to compute.

## Exercise 15.8.4

Make appropriate changes of variables in the integral

$$\iint_R \frac{4}{(x-y)^2}\,dy\,dx,$$

where $R$ is the trapezoid bounded by the lines $x-y=2$, $x-y=4$, $x=0$, and $y=0$. Write the resulting integral.

**Hint**

Follow the steps in the previous example.

**Answer**

$x=\frac{1}{2}(v+u)$ and $y=\frac{1}{2}(v-u)$

and

$$\int_2^4\int_{-u}^{u}\left(\frac{1}{2}\right)\cdot\frac{4}{u^2}\,dv\,du.$$

We are ready to give a problem-solving strategy for change of variables.

### Problem-Solving Strategy: Change of Variables

1. Sketch the region given by the problem in the $xy$-plane and then write the equations of the curves that form the boundary.
2. Depending on the region or the integrand, choose the transformations $x=g(u,v)$ and $y=h(u,v)$.
3. Determine the new limits of integration in the $uv$-plane.
4. Find the Jacobian $J(u,v)$.
5. In the integrand, replace the variables to obtain the new integrand.
6. Replace $dy\,dx$ or $dx\,dy$, whichever occurs, by $J(u,v)du\,dv$.

In the next example, we find a substitution that makes the integrand much simpler to compute.

## Example 15.8.5: Evaluating an Integral

Using the change of variables $u=x-y$ and $v=x+y$, evaluate the integral

$$\iint_R (x-y)e^{x^2-y^2}\,dA,$$

where $R$ is the region bounded by the lines $x+y=1$ and $x+y=3$ and the curves $x^2-y^2=-1$ and $x^2-y^2=1$ (see the first region in Figure 15.8.9).

**Solution**

As before, first find the region $R$ and picture the transformation so it becomes easier to obtain the limits of integration after the transformations are made (Figure 15.8.9).

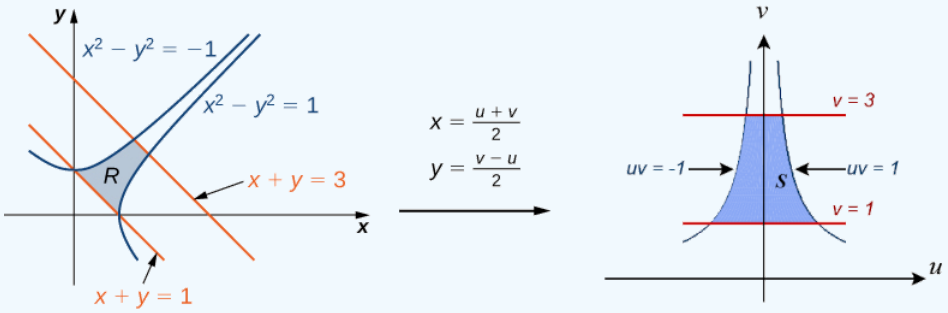

Figure 15.8.9: Transforming the region $R$ into the region $S$ to simplify the computation of an integral.

Given $u = x - y$ and $v = x + y$, we have $x = \frac{u+v}{2}$ and $y = \frac{v-u}{2}$ and hence the transformation to use is $T(u,v) = \left(\frac{u+v}{2}, \frac{v-u}{2}\right)$. The lines $x + y = 1$ and $x + y = 3$ become $v = 1$ and $v = 3$, respectively. The curves $x^2 - y^2 = 1$ and $x^2 - y^2 = -1$ become $uv = 1$ and $uv = -1$, respectively.

Thus we can describe the region $S$ (see the second region Figure 15.8.9) as

$$S = \left\{(u,v) | 1 \le v \le 3, \frac{-1}{v} \le u \le \frac{1}{v}\right\}.$$

The Jacobian for this transformation is

$$J(u,v) = \frac{\partial(x,y)}{\partial(u,v)} = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} 1/2 & 1/2 \\ -1/2 & 1/2 \end{vmatrix} = \frac{1}{2}.$$

Therefore, by using the transformation $T$, the integral changes to

$$\iint_R (x-y)e^{x^2-y^2}\,dA = \frac{1}{2}\int_1^3 \int_{-1/v}^{1/v} ue^{uv}\,du\,dv.$$

Doing the evaluation, we have

$$\frac{1}{2}\int_1^3 \int_{-1/v}^{1/v} ue^{uv}\,du\,dv = \frac{2}{3e} \approx 0.245.$$

**? Exercise 15.8.5**

Using the substitutions $x = v$ and $y = \sqrt{u+v}$, evaluate the integral $\iint_R y\,\sin(y^2 - x)\,dA$, where $R$ is the region bounded by the lines $y = \sqrt{x}$, $x = 2$ and $y = 0$.

**Hint**

Sketch a picture and find the limits of integration.

**Answer**

$\frac{1}{2}(\sin 2 - 2)$

## Change of Variables for Triple Integrals

Changing variables in triple integrals works in exactly the same way. Cylindrical and spherical coordinate substitutions are special cases of this method, which we demonstrate here.

Suppose that $G$ is a region in $uvw$-space and is mapped to $D$ in $xyz$-space (Figure 15.8.10) by a one-to-one $C^1$ transformation $T(u,v,w) = (x,y,z)$ where $x = g(u,v,w)$, $y = h(u,v,w)$, and $z = k(u,v,w)$.

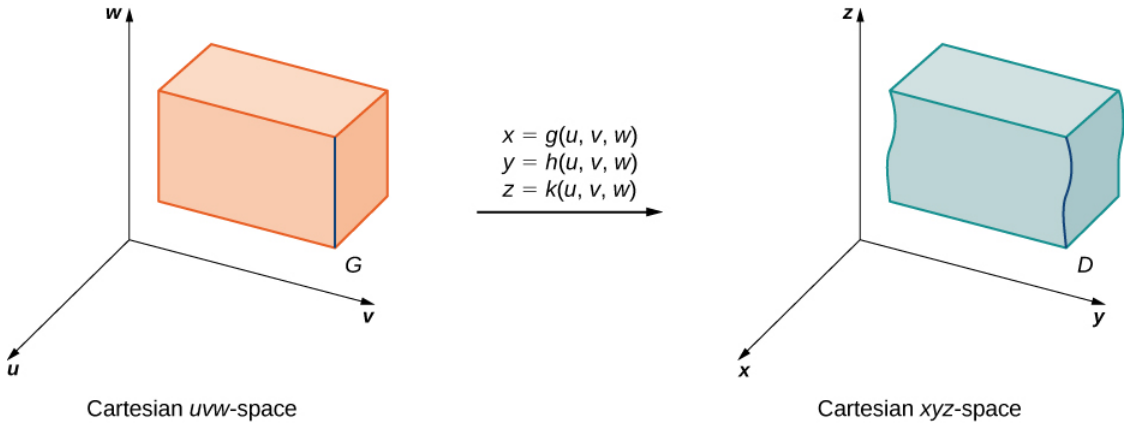

Figure 15.8.10: A region $G$ in $uvw$-space mapped to a region $D$ in $xyz$-space.

Then any function $F(x,y,z)$ defined on $D$ can be thought of as another function $H(u,v,w)$ that is defined on $G$:

$$F(x,y,z) = F(g(u,v,w),\, h(u,v,w),\, k(u,v,w)) = H(u,v,w).$$

Now we need to define the Jacobian for three variables.

**Definition: Jacobian determinant**

The *Jacobian determinant* $J(u,v,w)$ in three variables is defined as follows:

$$J(u,v,w) = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial y}{\partial u} & \frac{\partial z}{\partial u} \\ \frac{\partial x}{\partial v} & \frac{\partial y}{\partial v} & \frac{\partial z}{\partial v} \\ \frac{\partial x}{\partial w} & \frac{\partial y}{\partial w} & \frac{\partial z}{\partial w} \end{vmatrix}.$$

This is also the same as

$$J(u,v,w) = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} & \frac{\partial x}{\partial w} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} & \frac{\partial y}{\partial w} \\ \frac{\partial z}{\partial u} & \frac{\partial z}{\partial v} & \frac{\partial z}{\partial w} \end{vmatrix}.$$

The Jacobian can also be simply denoted as $\frac{\partial(x,y,z)}{\partial(u,v,w)}$.

With the transformations and the Jacobian for three variables, we are ready to establish the theorem that describes change of variables for triple integrals.

**Change of Variables for Triple Integrals**

Let $T(u,v,w) = (x,y,z)$ where $x = g(u,v,w)$, $y = h(u,v,w)$, and $z = k(u,v,w)$, be a one-to-one $C^1$ transformation, with a nonzero Jacobian, that maps the region $G$ in the $uvw$-space into the region $D$ in the $xyz$-space. As in the two-dimensional case, if $F$ is continuous on $D$, then

$$\iiint_D F(x,y,z)\,dV = \iiint_G f(g(u,v,w)\, h(u,v,w),\, k(u,v,w)) \left|\frac{\partial(x,y,z)}{\partial(u,v,w)}\right| du\,dv\,dw \tag{15.8.1}$$

$$= \iiint_G H(u,v,w)|J(u,v,w)|du\,dv\,dw. \tag{15.8.2}$$

Let us now see how changes in triple integrals for cylindrical and spherical coordinates are affected by this theorem. We expect to obtain the same formulas as in Triple Integrals in Cylindrical and Spherical Coordinates.

### Example 15.8.6A: Obtaining Formulas in Triple Integrals for Cylindrical and Spherical Coordinates

Derive the formula in triple integrals for

a. cylindrical and
b. spherical coordinates.

**Solution**

A.

For cylindrical coordinates, the transformation is $T(r,\theta,z)=(x,y,z)$ from the Cartesian $r\theta z$-space to the Cartesian $xyz$-space (Figure 15.8.11). Here $x=r\cos\theta$, $y=r\sin\theta$ and $z=z$. The Jacobian for the transformation is

$$J(r,\theta,z)=\frac{\partial(x,y,z)}{\partial(r,\theta,z)}=\begin{vmatrix}\frac{\partial x}{\partial r} & \frac{\partial x}{\partial\theta} & \frac{\partial x}{\partial z}\\ \frac{\partial y}{\partial r} & \frac{\partial y}{\partial\theta} & \frac{\partial y}{\partial z}\\ \frac{\partial z}{\partial r} & \frac{\partial z}{\partial\theta} & \frac{\partial z}{\partial z}\end{vmatrix}$$

$$\begin{vmatrix}\cos\theta & -r\sin\theta & 0\\ \sin\theta & r\cos\theta & 0\\ 0 & 0 & 1\end{vmatrix}=r\cos^2\theta+r\sin^2\theta=r.$$

We know that $r\geq 0$, so $|J(r,\theta,z)|=r$. Then the triple integral is

$$\iiint_D f(x,y,z)\,dV=\iiint_G f(r\cos\theta,\,r\sin\theta,\,z)\,r\,dr\,d\theta\,dz.$$

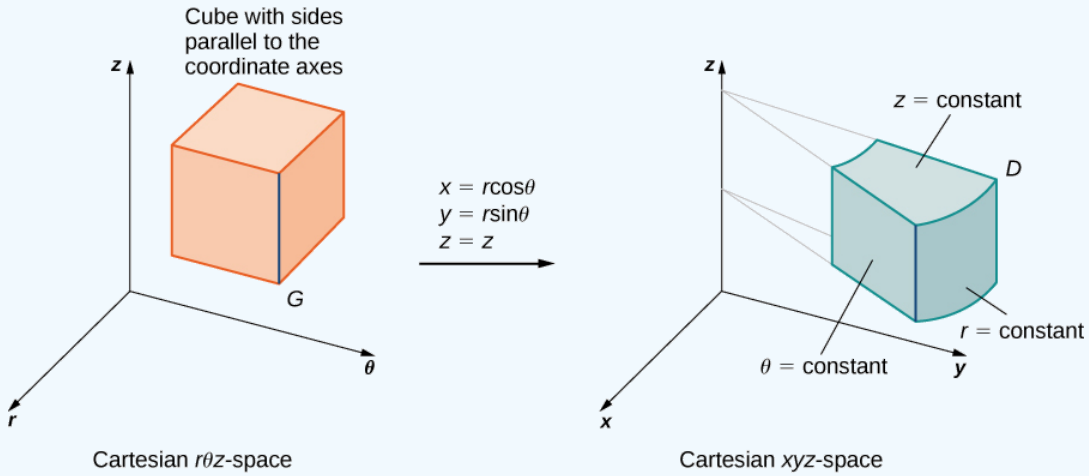

Figure 15.8.11: The transformation from rectangular coordinates to cylindrical coordinates can be treated as a change of variables from region $G$ in $r\theta z$-space to region $D$ in $xyz$-space.

B.

For spherical coordinates, the transformation is $T(\rho,\theta,\varphi)$ from the Cartesian $\rho\theta\varphi$-space to the Cartesian $xyz$-space (Figure 15.8.12). Here $x=\rho\sin\varphi\cos\theta$, $y=\rho\sin\varphi\sin\theta$, and $z=\rho\cos\varphi$. The Jacobian for the transformation is

$$J(\rho,\theta,\varphi)=\frac{\partial(x,y,z)}{\partial(\rho,\theta,\varphi)}=\begin{vmatrix}\frac{\partial x}{\partial\rho} & \frac{\partial x}{\partial\theta} & \frac{\partial x}{\partial\varphi}\\ \frac{\partial y}{\partial\rho} & \frac{\partial y}{\partial\theta} & \frac{\partial y}{\partial\varphi}\\ \frac{\partial z}{\partial\rho} & \frac{\partial z}{\partial\theta} & \frac{\partial z}{\partial\varphi}\end{vmatrix}=\begin{vmatrix}\sin\varphi\cos\theta & -\rho\sin\varphi\sin\theta & \rho\cos\varphi\cos\theta\\ \sin\varphi\sin\theta & \rho\sin\varphi\cos\theta & \rho\cos\varphi\sin\theta\\ \cos\varphi & 0 & -\rho\sin\varphi\end{vmatrix}.$$

Expanding the determinant with respect to the third row:

$$= \cos\varphi \begin{vmatrix} -\rho\sin\varphi\sin\theta & \rho\cos\varphi\cos\theta \\ \rho\sin\varphi\cos\theta & \rho\cos\varphi\sin\theta \end{vmatrix} - \rho\sin\varphi \begin{vmatrix} \sin\varphi\cos\theta & -\rho\sin\varphi\sin\theta \\ \sin\varphi\sin\theta & \rho\sin\varphi\cos\theta \end{vmatrix}$$

$$= \cos\varphi(-\rho^2\sin\varphi\cos\varphi\sin^2\theta - \rho^2\sin\varphi\cos\varphi\cos^2\theta)$$
$$-\rho\sin\varphi(\rho\sin^2\varphi\cos^2\theta + \rho\sin^2\varphi\sin^2\theta)$$

$$= -\rho^2\sin\varphi\cos^2\varphi(\sin^2\theta + \cos^2\theta) - \rho^2\sin\varphi\sin^2\varphi(\sin^2\theta + \cos^2\theta)$$

$$= -\rho^2\sin\varphi\cos^2\varphi - \rho^2\sin\varphi\sin^2\varphi$$

$$= -\rho\sin\varphi(\cos^2\varphi + \sin^2\varphi) = -\rho^2\sin\varphi.$$

Since $0 \le \varphi \le \pi$, we must have $\sin\varphi \ge 0$. Thus $|J(\rho,\theta,\varphi)| = |-\rho^2\sin\varphi| = \rho^2\sin\varphi$.

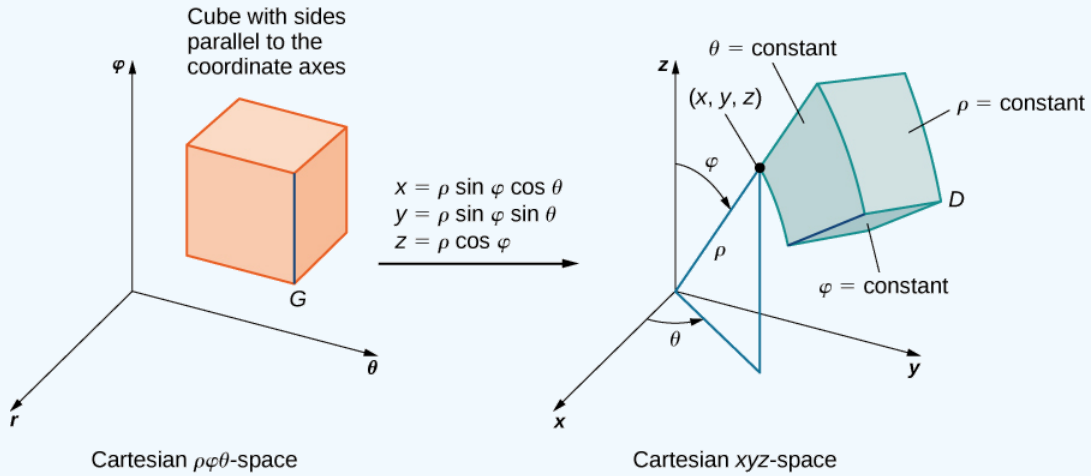

Figure 15.8.12: The transformation from rectangular coordinates to spherical coordinates can be treated as a change of variables from region $G$ in $\rho\theta\varphi$-space to region $D$ in $xyz$-space.

Then the triple integral becomes

$$\iiint_D f(x,y,z)dV = \iiint_G f(\rho\sin\varphi\cos\theta,\ \rho\sin\varphi\sin\theta,\rho\cos\varphi)\rho^2\sin\varphi\,d\rho\,d\varphi\,d\theta.$$

Let's try another example with a different substitution.

### Example 15.8.6B: Evaluating a Triple Integral with a Change of Variables

Evaluate the triple integral

$$\int_0^3\int_0^4\int_{y/2}^{(y/2)+1}\left(x+\frac{z}{3}\right)dx\,dy\,dz$$

In $xyz$-space by using the transformation

$u = (2x-y)/2$, $v = y/2$, and $w = z/3$.

Then integrate over an appropriate region in $uvw$-space.

#### Solution

As before, some kind of sketch of the region $G$ in $xyz$-space over which we have to perform the integration can help identify the region $D$ in $uvw$-space (Figure 15.8.13). Clearly $G$ in $xyz$-space is bounded by the planes $x = y/2$, $x = (y/2)+1$, $y = 0$, $y = 4$, $z = 0$, and $z = 4$. We also know that we have to use $u = (2x-y)/2$, $v = y/2$, and $w = z/3$ for the transformations. We need to solve for $x, y$ and $z$. Here we find that $x = u+v$, $y = 2v$, and $z = 3w$.

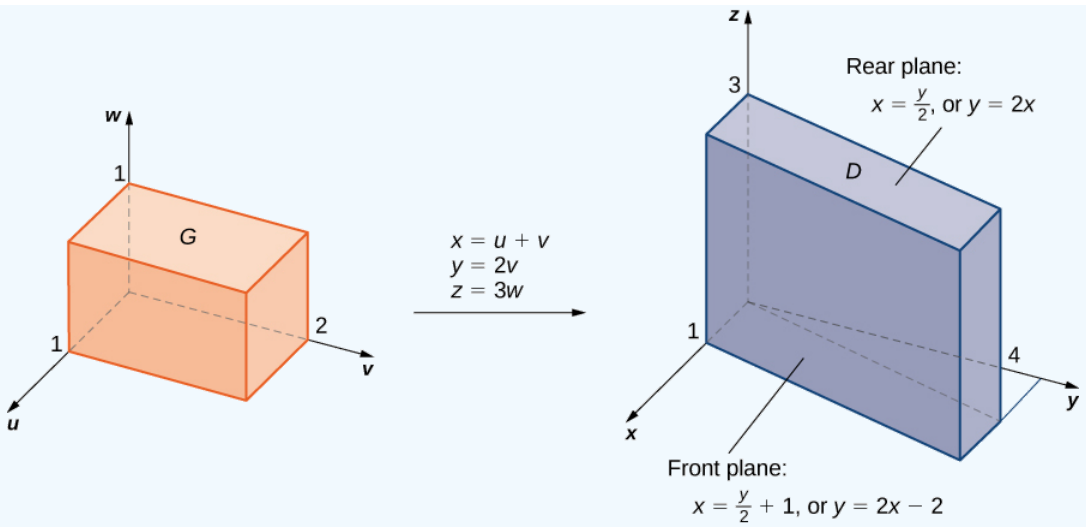

Figure 15.8.13: The region $G$ in $uvw$-space is transformed to region $D$ in $xyz$-space.

Using elementary algebra, we can find the corresponding surfaces for the region $G$ and the limits of integration in $uvw$-space. It is convenient to list these equations in a table.

| Equations in $xyz$ for the region $D$ | Corresponding equations in $uvw$ for the region $G$ | Limits for the integration in $uvw$ |
|---|---|---|
| $x = y/2$ | $u + v = 2v/2 = v$ | $u = 0$ |
| $x = y/2$ | $u + v = (2v/2) + 1 = v + 1$ | $u = 1$ |
| $y = 0$ | $2v = 0$ | $v = 0$ |
| $y = 4$ | $2v = 4$ | $v = 2$ |
| $z = 0$ | $3w = 0$ | $w = 0$ |
| $z = 3$ | $3w = 3$ | $w = 1$ |

Now we can calculate the Jacobian for the transformation:

$$J(u,v,w) = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} & \frac{\partial x}{\partial w} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} & \frac{\partial y}{\partial w} \\ \frac{\partial z}{\partial u} & \frac{\partial z}{\partial v} & \frac{\partial z}{\partial w} \end{vmatrix} = \begin{vmatrix} 1 & 1 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 3 \end{vmatrix} = 6.$$

The function to be integrated becomes

$$f(x,y,z) = x + \frac{z}{3} = u + v + \frac{3w}{3} = u + v + w.$$

We are now ready to put everything together and complete the problem.

$$\int_0^3 \int_0^4 \int_{y/2}^{(y/2)+1} \left(x + \frac{z}{3}\right) dx\, dy\, dz = \int_0^1 \int_0^2 \int_0^1 (u+v+w)|J(u,v,w)|\, du\, dv\, dw$$
$$= \int_0^1 \int_0^2 \int_0^1 (u+v+w)|6|\, du\, dv\, dw$$
$$= 6\int_0^1 \int_0^2 \int_0^1 (u+v+w)\, du\, dv\, dw$$
$$= 6\int_0^1 \int_0^2 \left[\frac{u^2}{2} + vu + wu\right]_0^1 dv\, dw$$
$$= 6\int_0^1 \int_0^2 \left(\frac{1}{2} + v + u\right) dv\, dw$$
$$= 6\int_0^1 \left[\frac{1}{2}v + \frac{v^2}{2} + wv\right]_0^2 dw$$
$$= 6\int_0^1 (3+2w)\, dw = 6\left[3w + w^2\right]_0^1 = 24.$$

**? Exercise 15.8.6**

Let $D$ be the region in $xyz$-space defined by $1 \le x \le 2,\ 0 \le xy \le 2$, and $0 \le z \le 1$.

Evaluate $\iiint_D (x^2y + 3xyz)\, dx\, dy\, dz$ by using the transformation $u = x,\ v = xy$, and $w = 3z$.

**Hint**

Make a table for each surface of the regions and decide on the limits, as shown in the example.

**Answer**

$$\int_0^3 \int_0^2 \int_1^2 \left(\frac{v}{3} + \frac{vw}{3u}\right) du\, dv\, dw = 2 + \ln 8$$

## Key Concepts

- A transformation $T$ is a function that transforms a region $G$ in one plane (space) into a region $R$. in another plane (space) by a change of variables.
- A transformation $T : G \to R$ defined as $T(u,v) = (x,y)$ (or $T(u,v,w) = (x,y,z)$)is said to be a one-to-one transformation if no two points map to the same image point.
- If $f$ is continuous on $R$, then

$$\iint_R f(x,y)dA = \iint_S f(g(u,v),\ h(u,v)) \left|\frac{\partial(x,y)}{\partial(u,v)}\right| du\, dv.$$

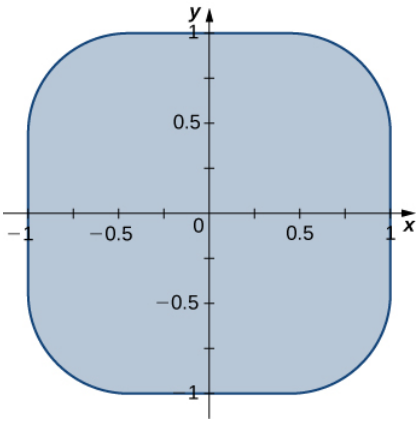
- If $F$ is continuous on $R$, then

$$\iiint_R F(x,y,z)\, dV = \iiint_G F(g(u,v,w),\ h(u,v,w),\ k(u,v,w)) \left|\frac{\partial(x,y,z)}{\partial(u,v,w)}\right| du\, dv\, dw$$
$$= \iiint_G H(u,v,w)|J(u,v,w)|\, du\, dv\, dw.$$

[T] Lamé ovals (or superellipses) are plane curves of equations $\left(\frac{x}{a}\right)^n + \left(\frac{y}{b}\right)^n = 1$, where $a$, $b$, and $n$ are positive real numbers.

a. Use a CAS to graph the regions $R$ bounded by Lamé ovals for $a = 1,\ b = 2,\ n = 4$ and $n = 6$ respectively.

b. Find the transformations that map the region $R$ bounded by the Lamé oval $x^4 + y^4 = 1$ also called a squircle and graphed in the following figure, into the unit disk.



c. Use a CAS to find an approximation of the area $A(R)$ of the region $R$ bounded by $x^4 + y^4 = 1$. Round your answer to two decimal places.

[T] Lamé ovals have been consistently used by designers and architects. For instance, Gerald Robinson, a Canadian architect, has designed a parking garage in a shopping center in Peterborough, Ontario, in the shape of a superellipse of the equation $(\frac{x}{a})^n + (\frac{y}{b})^n = 1$ with $\frac{a}{b} = \frac{9}{7}$ and $n = e$. Use a CAS to find an approximation of the area of the parking garage in the case $a = 900$ yards, $b = 700$ yards, and $n = 2.72$ yards.

[Hide Solution]

$A(R) \simeq 83,999.2$

## Chapter Review Exercises

*True or False?* Justify your answer with a proof or a counterexample.

$$\int_a^b \int_c^d f(x,y)\,dy\,dx = \int_c^d \int_a^b f(x,y)\,dy\,dx$$

Fubini's theorem can be extended to three dimensions, as long as $f$ is continuous in all variables.

[Hide solution]

True.

The integral

$$\int_0^{2\pi} \int_0^1 \int_0^1 dz\,dr\,d\theta$$

represents the volume of a right cone.

The Jacobian of the transformation for $x = u^2 - 2v$, $y = 3v - 2uv$ is given by $-4u^2 + 6u + 4v$.

[Hide Solution]

False.

Evaluate the following integrals.

$$\iint_R (5x^3y^2 - y^2)\,dA,\ R = \{(x,y) | 0 \le x \le 2,\ 1 \le y \le 4\}$$

$$\iint_D \frac{y}{3x^2 + 1} dA,\ D = \{(x,y) | 0 \le x \le 1,\ -x \le y \le x\}$$

[Hide Solution]

0

$$\iint_D \sin(x^2+y^2)dA$$

where $D$ is a disk of radius $2$ centered at the origin

$$\int_0^1 \int_0^1 xye^{x^2}\,dx\,dy$$

[Hide Solution]

$\frac{1}{4}$

$$\int_{-1}^1 \int_0^z \int_0^{x-z} 6dy\,dx\,dz$$

$$\iiint_R 3y\,dV,$$

where $R = \{(x,y,z)|0 \le x \le 1,\ 0 \le y \le x,\ 0 \le z \le \sqrt{9-y^2}\}$

[Hide Solution]

$1.475$

$$\int_0^2 \int_0^{2\pi} \int_r^1 r\,dz\,d\theta\,dr$$

$$\int_0^{2\pi} \int_0^{\pi/2} \int_1^3 \rho^2\,\sin(\varphi)d\rho\,d\varphi,\ d\theta$$

[Hide Solution]

$\frac{52}{3}\pi$

$$\int_0^1 \int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} \int_{-\sqrt{1-x^2-y^2}}^{\sqrt{1-x^2-y^2}} dz\,dy\,sx$$

For the following problems, find the specified area or volume.

The area of region enclosed by one petal of $r = \cos(4\theta)$.

[Hide Solution]

$\frac{\pi}{16}$

The volume of the solid that lies between the paraboloid $z = 2x^2 + 2y^2$ and the plane $z = 8$.

The volume of the solid bounded by the cylinder $x^2 + y^2 = 16$ and from $z = 1$ to $z + x = 2$.

[Hide Solution]

$93.291$

The volume of the intersection between two spheres of radius 1, the top whose center is $(0, 0, 0.25)$ and the bottom, which is centered at $(0, 0, 0)$.

For the following problems, find the center of mass of the region.

$\rho(x, y) = xy$ on the circle with radius $1$ in the first quadrant only.

[Hide Solution]

$(\frac{8}{15}, \frac{8}{15})$

$\rho(x, y) = (y + 1)\sqrt{x}$ in the region bounded by $y = e^x$, $y = 0$, and $x = 1$.

$\rho(x, y, z) = z$ on the inverted cone with radius $2$ and height $2$.

$(0, 0, \frac{8}{5})$

The volume an ice cream cone that is given by the solid above $z = \sqrt{(x^2 + y^2)}$ and below $z^2 + x^2 + y^2 = z$.

The following problems examine Mount Holly in the state of Michigan. Mount Holly is a landfill that was converted into a ski resort. The shape of Mount Holly can be approximated by a right circular cone of height 1100 ft and radius 6000 ft.

If the compacted trash used to build Mount Holly on average has a density $400\ lb/ft^3$, find the amount of work required to build the mountain.

[Hide Solution]

$1.452\pi \times 10^{15}$ ft-lb

In reality, it is very likely that the trash at the bottom of Mount Holly has become more compacted with all the weight of the above trash. Consider a density function with respect to height: the density at the top of the mountain is still density $400\ lb/ft^3$ and the density increases. Every 100 feet deeper, the density doubles. What is the total weight of Mount Holly?

The following problems consider the temperature and density of Earth's layers.

[T] The temperature of Earth's layers is exhibited in the table below. Use your calculator to fit a polynomial of degree 3 to the temperature along the radius of the Earth. Then find the average temperature of Earth. (*Hint*: begin at 0 in the inner core and increase outward toward the surface)

| Layer | Depth from center (km) | Temperature $°C$ |
|---|---|---|
| Rocky Crust | 0 to 40 | 0 |
| Upper Mantle | 40 to 150 | 870 |
| Mantle | 400 to 650 | 870 |
| Inner Mantel | 650 to 2700 | 870 |
| Molten Outer Core | 2890 to 5150 | 4300 |
| Inner Core | 5150 to 6378 | 7200 |

Source: http://www.enchantedlearning.com/sub...h/Inside.shtml

[Hide Solution]

$y = -1.238 \times 10^{-7}x^3 + 0.001196x^2 - 3.666x + 7208$; average temperature approximately $2800°C$

[T] The density of Earth's layers is displayed in the table below. Using your calculator or a computer program, find the best-fit quadratic equation to the density. Using this equation, find the total mass of Earth.

| Layer | Depth from center (km) | Density $(g/cm^3)$ |
|---|---|---|
| Inner Core | 0 | 12.95 |
| Outer Core | 1228 | 11.05 |
| Mantle | 3488 | 5.00 |
| Upper Mantle | 6338 | 3.90 |
| Crust | 6378 | 2.55 |

Source: http://hyperphysics.phy-astr.gsu.edu...rthstruct.html

The following problems concern the Theorem of Pappus (see Moments and Centers of Mass for a refresher), a method for calculating volume using centroids. Assuming a region $R$, when you revolve around the $x$-axis the volume is given by $V_x$

$= 2\pi A\bar{y}$, and when you revolve around the $y$-axis the volume is given by $V_y = 2\pi A\bar{x}$, where $A$ is the area of $R$. Consider the region bounded by $x^2 + y^2 = 1$ and above $y = x + 1$.

Find the volume when you revolve the region around the $x$-axis.

[Hide Solution]

$\frac{\pi}{3}$

Find the volume when you revolve the region around the $y$-axis.

## Glossary

**Jacobian**

the Jacobian $J(u, v)$ in two variables is a $2 \times 2$ determinant:

$$J(u, v) = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial y}{\partial u} \\ \frac{\partial x}{\partial v} & \frac{\partial y}{\partial v} \end{vmatrix};$$

the Jacobian $J(u, v, w)$ in three variables is a $3 \times 3$ determinant:

$$J(u, v, w) = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial y}{\partial u} & \frac{\partial z}{\partial u} \\ \frac{\partial x}{\partial v} & \frac{\partial y}{\partial v} & \frac{\partial z}{\partial v} \\ \frac{\partial x}{\partial w} & \frac{\partial y}{\partial w} & \frac{\partial z}{\partial w} \end{vmatrix}$$

**one-to-one transformation**

a transformation $T : G \to R$ defined as $T(u, v) = (x, y)$ is said to be one-to-one if no two points map to the same image point

**planar transformation**

a function $T$ that transforms a region $G$ in one plane into a region $R$ in another plane by a change of variables

**transformation**

a function that transforms a region GG in one plane into a region RR in another plane by a change of variables

---

# 15.8E: EXERCISES FOR SECTION 15.7

**In exercises 1 - 6, the function $T: S \to R,\ T(u,v) = (x,y)$ on the region $S = \{(u,v) \mid 0 \le u \le 1,\ 0 \le v \le 1\}$ bounded by the unit square is given, where $R \in R^2$ is the image of $S$ under $T$.**

**a. Justify that the function $T$ is a $C^1$ transformation.**

**b. Find the images of the vertices of the unit square $S$ through the function $T$.**

**c. Determine the image $R$ of the unit square $S$ and graph it.**

1. $x = 2u,\ y = 3v$

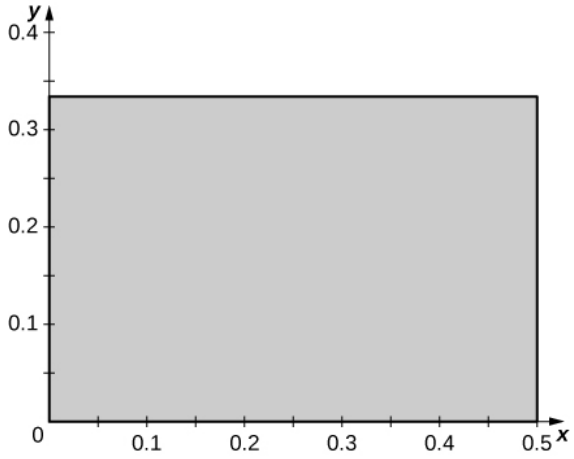
2. $x = \frac{u}{2},\ y = \frac{v}{3}$

**Answer**

a. $T(u,v) = (g(u,v),\ h(u,v),\ x = g(u,v) = \frac{u}{2}$ and $y = h(u,v) = \frac{v}{3}$. The functions $g$ and $h$ are continuous and differentiable, and the partial derivatives $g_u(u,v) = \frac{1}{2},\ g_v(u,v) = 0,\ h_u(u,v) = 0$ and $h_v(u,v) = \frac{1}{3}$ are continuous on $S$;

b. $T(0,0) = (0,0),\ T(1,0) = \left(\frac{1}{2}, 0\right),\ T(0,1) = \left(0, \frac{1}{3}\right)$, and $T(1,1) = \left(\frac{1}{2}, \frac{1}{3}\right)$;

c. $R$ is the rectangle of vertices $(0,0),\ \left(0, \frac{1}{3}\right),\ \left(\frac{1}{2}, \frac{1}{3}\right)$, and $\left(0, \frac{1}{3}\right)$ in the $xy$-plane; the following figure.



3. $x = u - v,\ y = u + v$

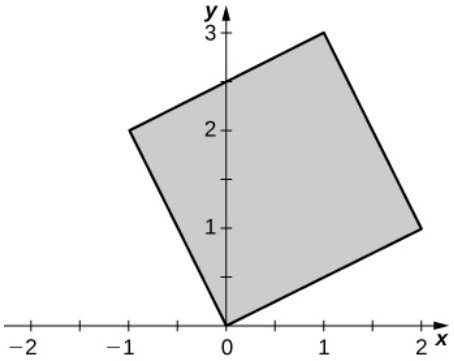
4. $x = 2u - v,\ y = u + 2v$

**Answer**

a. $T(u,v) = (g(u,v),\ h(u,v),\ x = g(u,v) = 2u - v$ and $y = h(u,v) = u + 2v$. The functions $g$ and $h$ are continuous and differentiable, and the partial derivatives $g_u(u,v) = 2,\ g_v(u,v) = -1,\ h_u(u,v) = 1$ and $h_v(u,v) = 2$ are continuous on $S$;

b. $T(0,0) = (0,0),\ T(1,0) = (2,1),\ T(0,1) = (-1,2)$, and $T(1,1) = (1,3)$;

c. $R$ is the parallelogram of vertices $(0,0),\ (2,1)\ (1,3)$, and $(-1,2)$ in the $xy$-plane; the following figure.



5. $x = u^2,\ y = v^2$

https://math.libretexts.org/@go/page/175781

6. $x = u^3,\ y = v^3$

**Answer**

a. $T(u,v) = (g(u,v),\ h(u,v),\ x = g(u,v) = u^3$ and $y = h(u,v) = v^3$. The functions $g$ and $h$ are continuous and differentiable, and the partial derivatives $g_u(u,v) = 3u^2,\ g_v(u,v) = 0,\ h_u(u,v) = 0$ and $h_v(u,v) = 3v^2$ are continuous on $S$;

b. $T(0,0) = (0,0),\ T(1,0) = (1,0),\ T(0,1) = (0,1)$, and $T(1,1) = (1,1)$;

c. $R$ is the unit square in the $xy$-plane see the figure in the answer to the previous exercise.

**In exercises 7 - 12, determine whether the transformations $T : S \to R$ are one-to-one or not.**

7. $x = u^2,\ y = v^2$, where $S$ is the rectangle of vertices $(-1,0),\ (1,0),\ (1,1)$, and $(-1,1)$.

8. $x = u^4,\ y = u^2 + v$, where $S$ is the triangle of vertices $(-2,0),\ (2,0)$, and $(0,2)$.

**Answer**

$T$ is not one-to-one: two points of $S$ have the same image. Indeed, $T(-2,0) = T(2,0) = (16,4)$.

9. $x = 2u,\ y = 3v$, where $S$ is the square of vertices $(-1,1),\ (-1,-1),\ (1,-1)$, and $(1,1)$.

10. $T(u,v) = (2u - v, u)$, where $S$ is the triangle with vertices $(-1,1),\ (-1,-1)$, and $(1,-1)$.

**Answer**

$T$ is one-to-one: We argue by contradiction. $T(u_1,v_1) = T(u_2,v_2)$ implies $2u_1 - v_1 = 2u_2 - v_2$ and $u_1 = u_2$. Thus, $u_1 = u + 2$ and $v_1 = v_2$.

11. $x = u + v + w,\ y = u + v,\ z = w$, where $S = R = R^3$.

12. $x = u^2 + v + w,\ y = u^2 + v,\ z = w$, where $S = R = R^3$.

**Answer**

$T$ is not one-to-one: $T(1,v,w) = (-1,v,w)$

**In exercises 13 - 18, the transformations $T : R \to S$ are one-to-one. Find their related inverse transformations $T^{-1} : R \to S$.**

13. $x = 4u,\ y = 5v$, where $S = R = R^2$.

14. $x = u + 2v,\ y = -u + v$, where $S = R = R^2$.

**Answer**

$u = \frac{x-2y}{3},\ v = \frac{x+y}{3}$

15. $x = e^{2u+v},\ y = e^{u-v}$, where $S = R^2$ and $R = \{(x,y) \mid x > 0,\ y > 0\}$

16. $x = \ln u,\ y = \ln(uv)$, where $S = \{(u,v) \mid u > 0,\ v > 0\}$ and $R = R^2$.

**Answer**

$u = e^x,\ v = e^{-x+y}$

17. $x = u + v + w,\ y = 3v,\ z = 2w$, where $S = R = R^3$.

18. $x = u + v,\ y = v + w,\ z = u + w$, where $S = R = R^3$.

**Answer**

$u = \frac{x-y+z}{2},\ v = \frac{x+y-z}{2},\ w = \frac{-x+y+z}{2}$

**In exercises 19 - 22, the transformation $T : S \to R,\ T(u,v) = (x,y)$ and the region $R \subset R^2$ are given. Find the region $S \subset R^2$.**

19. $x = au,\ y = bv,\ R = \{(x,y) \mid x^2 + y^2 \le a^2b^2\}$ where $a,b > 0$

20. $x = au,\ y = bc,\ R = \{(x,y) \mid \frac{x^2}{a^2} + \frac{y^2}{b^2} \le 1\}$, where $a,b > 0$

**Answer**

$S = \{(u,v) \mid u^2 + v^2 \le 1\}$

21. $x = \frac{u}{a},\ y = \frac{v}{b},\ z = \frac{w}{c},\ R = \{(x,y) \mid x^2 + y^2 + z^2 \le 1\}$, where $a,b,c > 0$

22. $x = au,\ y = bv,\ z = cw,\ R = \left\{(x,y)\,|\,\frac{x^2}{a^2} - \frac{y^2}{b^2} - \frac{z^2}{c^2} \le 1,\ z > 0\right\}$, where $a, b, c > 0$

**Answer**

$R = \left\{(u,v,w)\,|\,u^2 - v^2 - w^2 \le 1,\ w > 0\right\}$

**In exercises 23 - 32, find the Jacobian $J$ of the transformation.**

23. $x = u + 2v,\ y = -u + v$

24. $x = \frac{u^3}{2},\ y = \frac{v}{u^2}$

**Answer**

$\frac{3}{2}$

25. $x = e^{2u-v},\ y = e^{u+v}$

26. $x = ue^v,\ y = e^{-v}$

**Answer**

$-1$

27. $x = u\ \cos(e^v),\ y = u\ \sin(e^v)$

28. $x = v\ \sin(u^2),\ y = v\ \cos(u^2)$

**Answer**

$2uv$

29. $x = u\ \cosh v,\ y = u\ \sinh v,\ z = w$

30. $x = v\ \cosh\left(\frac{1}{u}\right),\ y = v\ \sinh\left(\frac{1}{u}\right),\ z = u + w^2$

**Answer**

$\frac{v}{u^2}$

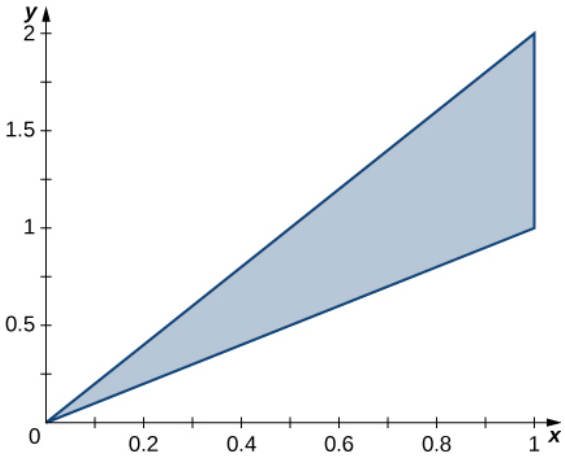
31. $x = u + v,\ y = v + w,\ z = u$

32. $x = u - v,\ y = u + v,\ z = u + v + w$

**Answer**

$2$

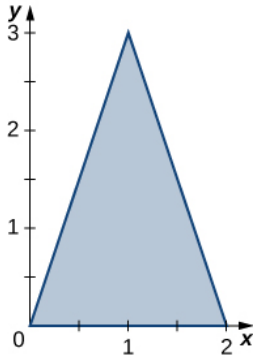
33. The triangular region $R$ with the vertices $(0,0),\ (1,1)$, and $(1,2)$ is shown in the following figure.



a. Find a transformation $T : S \to R,\ T(u,v) = (x,y) = (au + bv + dv)$, where $a, b, c$, and $d$ are real numbers with $ad - bc \neq 0$ such that $T^{-1}(0,0) = (0,0),\ T^{-1}(1,1) = (1,0)$, and $T^{-1}(1,2) = (0,1)$.

b. Use the transformation $T$ to find the area $A(R)$ of the region $R$.

34. The triangular region $R$ with the vertices $(0,0),\ (2,0)$, and $(1,3)$ is shown in the following figure.



a. Find a transformation $T: S \to R,\ T(u,v) = (x,y) = (au + bv + dv)$, where $a, b, c$, and $d$ are real numbers with $ad - bc \neq 0$ such that $T^{-1}(0,0) = (0,0),\ T^{-1}(2,0) = (1,0)$, and $T^{-1}(1,3) = (0,1)$.

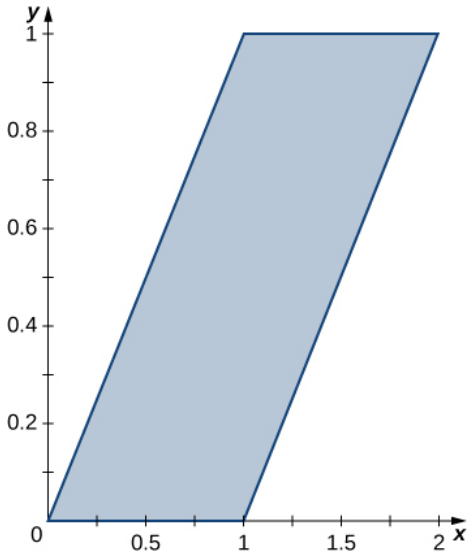
b. Use the transformation $T$ to find the area $A(R)$ of the region $R$.

**Answer**

a. $T(u,v) = (2u + v,\ 3v)$

b. The area of $R$ is $A(R) = \int_0^3 \int_{y/3}^{(6-y)/3} dx\, dy = \int_0^1 \int_0^{1-u} \left| \frac{\partial(x,y)}{\partial(u,v)} \right| dv\, du = \int_0^1 \int_0^{1-u} 6\, dv\, du = 3.$

**In exercises 35 - 36, use the transformation $u = y - x,\ v = y$, to evaluate the integrals on the parallelogram $R$ of vertices $(0,0)$, $(1,0)$, $(2,1)$, and $(1,1)$ shown in the following figure.**



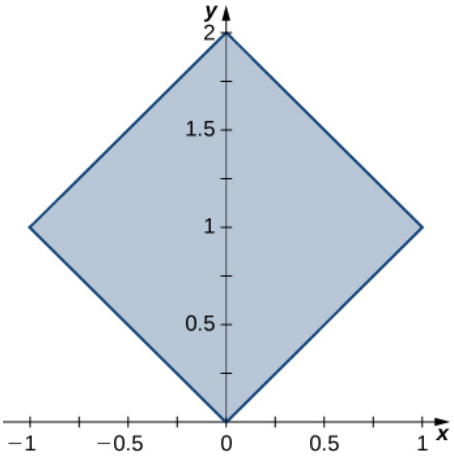
35. $\iint_R (y - x)\, dA$

36. $\iint_R (y^2 - xy)\, dA$

**Answer**

$-\frac{1}{4}$

**In exercises 37 - 38, use the transformation $y = x = u,\ x + y = v$ to evaluate the integrals on the square $R$ determined by the lines $y = x,\ y = -x + 2,\ y = x + 2$, and $y = -x$ shown in the following figure.**



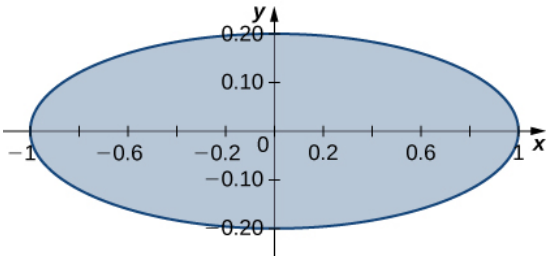
37. $\iint_R e^{x+y}\,dA$

38. $\iint_R \sin(x-y)\,dA$

**Answer**

$-1+\cos 2$

**In exercises 39 - 40, use the transformation $x=u$, $5y=v$ to evaluate the integrals on the region $R$ bounded by the ellipse $x^2+25y^2=1$ shown in the following figure.**



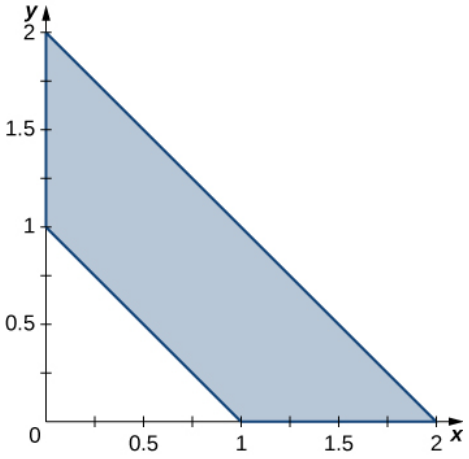
39. $\iint_R \sqrt{x^2+25y^2}\,dA$

40. $\iint_R (x^2+25y^2)^2\,dA$

**Answer**

$\frac{\pi}{15}$

**In exercises 41 - 42, use the transformation $u=x+y$, $v=x-y$ to evaluate the integrals on the trapezoidal region $R$ determined by the points $(1,0)$, $(2,0)$, $(0,2)$, and $(0,1)$ shown in the following figure.**



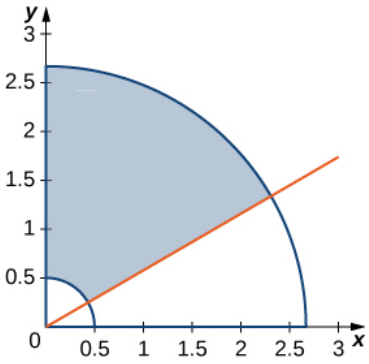
41. $\iint_R (x^2 - 2xy + y^2)\, e^{x+y}\, dA$

42. $\iint_R (x^3 + 3x^2y + 3xy^2 + y^3)\, dA$

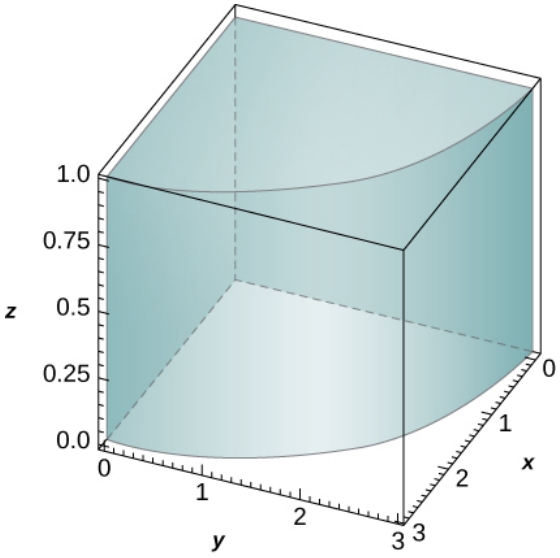
**Answer**

$\frac{31}{5}$

43. The circular annulus sector $R$ bounded by the circles $4x^2 + 4y^2 = 1$ and $9x^2 + 9y^2 = 64$, the line $x = y\sqrt{3}$, and the $y$-axis is shown in the following figure. Find a transformation $T$ from a rectangular region $S$ in the $r\theta$-plane to the region $R$ in the $xy$-plane. Graph $S$.



44. The solid $R$ bounded by the circular cylinder $x^2 + y^2 = 9$ and the planes $z = 0,\ z = 1,\ x = 0$, and $y = 0$ is shown in the following figure. Find a transformation $T$ from a cylindrical box $S$ in $r\theta z$-space to the solid $R$ in $xyz$-space.



https://math.libretexts.org/@go/page/175781

**Answer**

$T(r,\theta,z) = (r\ \cos\theta,\ r\ \sin\theta,\ z);\ S = [0,3] \times [0,\frac{\pi}{2}] \times [0,1]$ in the $r\theta z$-space

45. Show that

$$\iint_R f\left(\sqrt{\frac{x^2}{3} + \frac{y^2}{3}}\right) dA = 2\pi\sqrt{15}\int_0^1 f(\rho)\rho\ d\rho,$$

where $f$ is a continuous function on $[0,1]$ and $R$ is the region bounded by the ellipse $5x^2 + 3y^2 = 15$.

46. Show that

$$\iiint_R f\left(\sqrt{16x^2 + 4y^2 + z^2}\right) dV = \frac{\pi}{2}\int_0^1 f(\rho)\rho^2 d\rho,$$

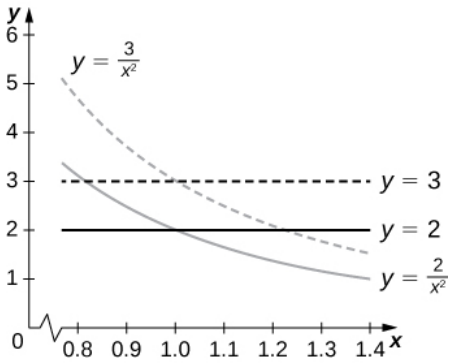
where $f$ is a continuous function on $[0,1]$ and $R$ is the region bounded by the ellipsoid $16x^2 + 4y^2 + z^2 = 1$.

47. [T] Find the area of the region bounded by the curves $xy = 1,\ xy = 3,\ y = 2x$, and $y = 3x$ by using the transformation $u = xy$ and $v = \frac{y}{x}$. Use a computer algebra system (CAS) to graph the boundary curves of the region $R$.

48. [T] Find the area of the region bounded by the curves $x^2y = 2,\ x^2y = 3,\ y = x$, and $y = 2x$ by using the transformation $u = x^2y$ and $v = \frac{y}{x}$. Use a CAS to graph the boundary curves of the region $R$.

**Answer**

The area of $R$ is $10 - 4\sqrt{6}$; the boundary curves of $R$ are graphed in the following figure.



49. Evaluate the triple integral

$$\int_0^1 \int_1^2 \int_z^{z+1} (y+1)\ dx\ dy\ dz$$

by using the transformation $u = x - z,\ v = 3y$, and $w = \frac{z}{2}$.

50. Evaluate the triple integral

$$\int_0^2 \int_4^6 \int_{3z}^{3z+2} (5 - 4y)\ dx\ dy\ dz$$

by using the transformation $u = x - 3z,\ v = 4y$, and $w = z$.

**Answer**

8

51. A transformation $T : R^2 \to R^2,\ T(u,v) = (x,y)$ of the form $x = au + bv,\ y = cu + dv$, where $a, b, c$, and $d$ are real numbers, is called linear. Show that a linear transformation for which $ad - bc \neq 0$ maps parallelograms to parallelograms.

52. A transformation $T_\theta : R^2 \to R^2,\ T_\theta(u,v) = (x,y)$ of the form $x = u\ \cos\theta - v\ \sin\theta,\ y = u\ \sin\theta + v\ \cos\theta$, is called a rotation angle $\theta$. Show that the inverse transformation of $T_\theta$ satisfies $T_\theta^{-1} = T_{-\theta}$ where $T_{-\theta}$ is the rotation of angle $-\theta$.

53. [T] Find the region $S$ in the $uv$-plane whose image through a rotation of angle $\frac{\pi}{4}$ is the region $R$ enclosed by the ellipse $x^2 + 4y^2 = 1$. Use a CAS to answer the following questions.

a. Graph the region $S$.

b. Evaluate the integral $\iint_S e^{-2uv}\,du\,dv$. Round your answer to two decimal places.

54. [T] The transformations $T_i : \mathbb{R}^2 \to \mathbb{R}^2$, $i = 1, ..., 4$, defined by $T_1(u,v) = (u,-v)$, $T_2(u,v) = (-u,v)$, $T_3(u,v) = (-u,-v)$, and $T_4(u,v) = (v,u)$ are called reflections about the $x$-axis, $y$-axis origin, and the line $y = x$, respectively.

a. Find the image of the region $S = \{(u,v) \mid u^2 + v^2 - 2u - 4v + 1 \le 0\}$ in the $xy$-plane through the transformation $T_1 \circ T_2 \circ T_3 \circ T_4$.

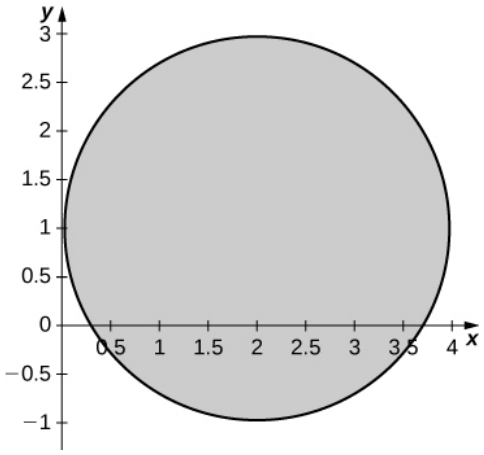
b. Use a CAS to graph $R$.

c. Evaluate the integral $\iint_S \sin(u^2)\,du\,dv$ by using a CAS. Round your answer to two decimal places.

**Answer**

a. $R = \{(x,y) \mid y^2 + x^2 - 2y - 4x + 1 \le 0\}$;

b. $R$ is graphed in the following figure;



c. **3.16**

55. [T] The transformations $T_{k,1,1} : \mathbb{R}^3 \to \mathbb{R}^3$, $T_{k,1,1}(u,v,w) = (x,y,z)$ of the form $x = ku$, $y = v$, $z = w$, where $k \neq 1$ is a positive real number, is called a stretch if $k > 1$ and a compression if $0 < k < 1$ in the $x$-direction. Use a CAS to evaluate the integral $\iiint_S e^{-(4x^2+9y^2+25z^2)}\,dx\,dy\,dz$ on the solid $S = \{(x,y,z) \mid 4x^2 + 9y^2 + 25z^2 \le 1\}$ by considering the compression $T_{2,3,5}(u,v,w) = (x,y,z)$ defined by $x = \frac{u}{2}$, $y = \frac{v}{3}$, and $z = \frac{w}{5}$. Round your answer to four decimal places.

56. [T] The transformation $T_{a,0} : \mathbb{R}^2 \to \mathbb{R}^2$, $T_{a,0}(u,v) = (u + av, v)$, where $a \neq 0$ is a real number, is called a shear in the $x$-direction. The transformation, $T_{b,0} : R^2 \to R^2$, $T_{o,b}(u,v) = (u, bu + v)$, where $b \neq 0$ is a real number, is called a shear in the $y$-direction.

a. Find transformations $T_{0,2} \circ T_{3,0}$.

b. Find the image $R$ of the trapezoidal region $S$ bounded by $u = 0$, $v = 0$, $v = 1$, and $v = 2 - u$ through the transformation $T_{0,2} \circ T_{3,0}$.

c. Use a CAS to graph the image $R$ in the $xy$-plane.

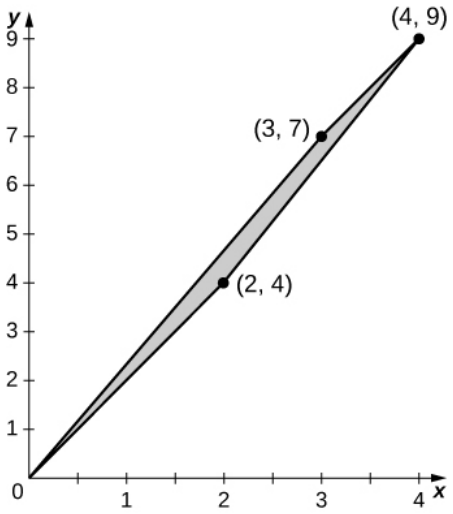
d. Find the area of the region $R$ by using the area of region $S$.

**Answer**

a. $T_{0,2} \circ T_{3,0}(u,v) = (u + 3v, 2u + 7v)$;

b. The image $S$ is the quadrilateral of vertices $(0,0)$, $(3,7)$, $(2,4)$, and $(4,9)$;

c. $S$ is graphed in the following figure;



d. $\frac{3}{2}$

57. Use the transformation, $x = au,\ y = av,\ z = cw$ and spherical coordinates to show that the volume of a region bounded by the spheroid $\frac{x^2+y^2}{a^2} + \frac{z^2}{c^2} = 1$ is $\frac{4\pi a^2 c}{3}$.

58. Find the volume of a football whose shape is a spheroid $\frac{x^2+y^2}{a^2} + \frac{z^2}{c^2} = 1$ whose length from tip to tip is $11$ inches and circumference at the center is $22$ inches. Round your answer to two decimal places.

**Answer**

$\frac{2662}{3\pi} \approx 282.45\ in^3$

# 15.R: CHAPTER 15 REVIEW EXERCISES

***True or False?*** **Justify your answer with a proof or a counterexample.**

1. $\int_a^b \int_c^d f(x,y)\,dy\,dx = \int_c^d \int_a^b f(x,y)\,dy\,dx$

2. Fubini's theorem can be extended to three dimensions, as long as $f$ is continuous in all variables.

**Answer**

True

3. The integral $\int_0^{2\pi} \int_0^1 \int_r^1 dz\,dr\,d\theta$ represents the volume of a right cone.

4. The Jacobian of the transformation for $x = u^2 - 2v$, $y = 3v - 2uv$ is given by $-4u^2 + 6u + 4v$.

**Answer**

False

**Evaluate the following integrals.**

5. $\iint_R (5x^3y^2 - y^2)\,dA$, where $R = \{(x,y) \mid 0 \le x \le 2,\ 1 \le y \le 4\}$

6. $\iint_D \dfrac{y}{3x^2+1}\,dA$, where $D = \{(x,y) \mid 0 \le x \le 1,\ -x \le y \le x\}$

**Answer**

$0$

7. $\iint_D \sin(x^2+y^2)\,dA$ where $D$ is a disk of radius $2$ centered at the origin.

8. $\int_0^1 \int_y^1 xye^{x^2}\,dx\,dy$

**Answer**

$\frac{1}{4}$

9. $\int_{-1}^1 \int_0^z \int_0^{x-z} 6\,dy\,dx\,dz$

10. $\iiint_R 3y\,dV$, where $R = \{(x,y,z) \mid 0 \le x \le 1,\ 0 \le y \le x,\ 0 \le z \le 9 - y^2\}$

**Answer**

$1.475$

11. $\int_0^2 \int_0^{2\pi} \int_r^1 r\,dz\,d\theta\,dr$

12. $\int_0^{2\pi} \int_0^{\pi/2} \int_1^3 \rho^2 \sin(\varphi)\,d\rho\,d\varphi\,d\theta$

**Answer**

$\frac{52\pi}{3}$

13. $\int_0^1 \int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} \int_{-\sqrt{1-x^2-y^2}}^{\sqrt{1-x^2-y^2}} dz\,dy\,dx$

**For the following problems, find the specified area or volume.**

14. The area of region enclosed by one petal of $r = \cos(4\theta)$.

**Answer**

$\frac{\pi}{16}$ units$^3$

15. The volume of the solid that lies between the paraboloid $z = 2x^2 + 2y^2$ and the plane $z = 8$.

16. The volume of the solid bounded by the cylinder $x^2 + y^2 = 16$ and from $z = 1$ to $z + x = 2$.

**Answer**

$93.291 \text{ units}^3$

17. The volume of the intersection between two spheres of radius $1$, the top whose center is $(0, 0, 0.25)$ and the bottom, which is centered at $(0, 0, 0)$.

**For the following problems, find the center of mass of the region.**

18. $\rho(x, y) = xy$ on the circle with radius $1$ in the first quadrant only.

**Answer**

$\left(\frac{8}{15}, \frac{8}{15}\right)$

19. $\rho(x, y) = (y + 1)\sqrt{x}$ in the region bounded by $y = e^x$, $y = 0$, and $x = 1$.

20. $\rho(x, y, z) = z$ on the inverted cone with radius $2$ and height $2$.

**Answer**

$\left(0, 0, \frac{8}{5}\right)$

21. The volume an ice cream cone that is given by the solid above $z = \sqrt{x^2 + y^2}$ and below $z^2 + x^2 + y^2 = z$.

**The following problems examine Mount Holly in the state of Michigan. Mount Holly is a landfill that was converted into a ski resort. The shape of Mount Holly can be approximated by a right circular cone of height 1100 ft and radius 6000 ft.**

22. If the compacted trash used to build Mount Holly on average has a density $400 \text{ lb/ft}^3$, find the amount of work required to build the mountain.

**Answer**

$1.452\pi \times 10^{15}$ ft-lb

23. In reality, it is very likely that the trash at the bottom of Mount Holly has become more compacted with all the weight of the above trash. Consider a density function with respect to height: the density at the top of the mountain is still density $400 \text{ lb/ft}^3$, and the density increases. Every 100 feet deeper, the density doubles. What is the total weight of Mount Holly?

**The following problems consider the temperature and density of Earth's layers.**

24. **[T]** The temperature of Earth's layers is exhibited in the table below. Use your calculator to fit a polynomial of degree 3 to the temperature along the radius of the Earth. Then find the average temperature of Earth. (*Hint*: begin at 0 in the inner core and increase outward toward the surface)

Source: http://www.enchantedlearning.com/sub...h/Inside.shtml

| Layer | Depth from center (km) | Temperature °C |
|---|---|---|
| Rocky Crust | 0 to 40 | 0 |
| Upper Mantle | 40 to 150 | 870 |
| Mantle | 400 to 650 | 870 |
| Inner Mantel | 650 to 2700 | 870 |
| Molten Outer Core | 2890 to 5150 | 4300 |
| Inner Core | 5150 to 6378 | 7200 |

**Answer**

$y = -1.238 \times 10^{-7}x^3 + 0.001196x^2 - 3.666x + 7208$;
The average temperature is approximately 2800 °C.

25. **[T]** The density of Earth's layers is displayed in the table below. Using your calculator or a computer program, find the best-fit quadratic equation to the density. Using this equation, find the total mass of Earth.

| Layer | Depth from center (km) | Density ($\mathrm{g/cm^3}$) |
|---|---|---|
| Inner Core | 0 | 12.95 |
| Outer Core | 1228 | 11.05 |
| Mantle | 3488 | 5.00 |
| Upper Mantle | 6338 | 3.90 |
| Crust | 6378 | 2.55 |

**The following problems concern the Theorem of Pappus (see Moments and Centers of Mass for a refresher), a method for calculating volume using centroids. Assuming a region $R$, when you revolve around the $x$-axis the volume is given by $V_x = 2\pi A\bar{y}$, and when you revolve around the $y$-axis the volume is given by $V_y = 2\pi A\bar{x}$, where $A$ is the area of $R$. Consider the region bounded by $x^2 + y^2 = 1$ and above $y = x + 1$.**

26. Find the volume when you revolve the region around the $x$-axis.

**Answer**

$\frac{\pi}{3}$ $\mathrm{units}^3$

27. Find the volume when you revolve the region around the $y$-axis.

# CHAPTER OVERVIEW

## 16: Vector Calculus

In this chapter, we learn to model new kinds of integrals over fields such as magnetic fields, gravitational fields, or velocity fields. We also learn how to calculate the work done on a charged particle traveling through a magnetic field, the work done on a particle with mass traveling through a gravitational field, and the volume per unit time of water flowing through a net dropped in a river. All these applications are based on the concept of a vector field.

# 16.1: Prelude to Vector Calculus

Hurricanes are huge storms that can produce tremendous amounts of damage to life and property, especially when they reach land. Predicting where and when they will strike and how strong the winds will be is of great importance for preparing for protection or evacuation. Scientists rely on studies of rotational vector fields for their forecasts.

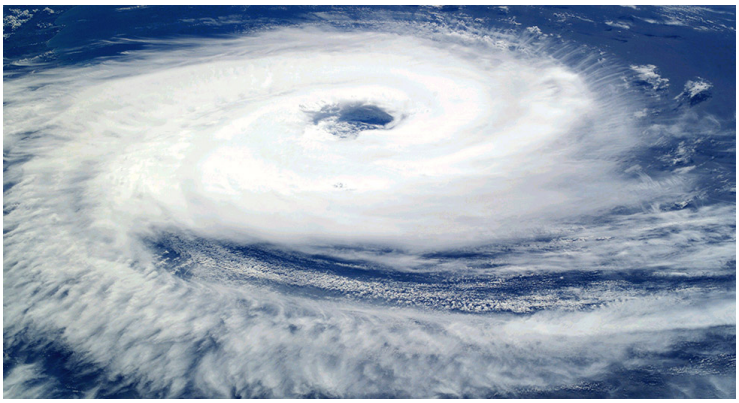

Figure **16.1.1**: Hurricanes form from rotating winds driven by warm temperatures over the ocean. Meteorologists forecast the motion of hurricanes by studying the rotating vector fields of their wind velocity. Shown is Cyclone Catarina in the South Atlantic Ocean in 2004, as seen from the International Space Station. (credit: modification of work by NASA)

In this chapter, we learn to model new kinds of integrals over fields such as magnetic fields, gravitational fields, or velocity fields. We also learn how to calculate the work done on a charged particle traveling through a magnetic field, the work done on a particle with mass traveling through a gravitational field, and the volume per unit time of water flowing through a net dropped in a river.

All these applications are based on the concept of a vector field, which we explore in this chapter. Vector fields have many applications because they can be used to model real fields such as electromagnetic or gravitational fields. A deep understanding of physics or engineering is impossible without an understanding of vector fields. Furthermore, vector fields have mathematical properties that are worthy of study in their own right. In particular, vector fields can be used to develop several higher-dimensional versions of the Fundamental Theorem of Calculus.

# 16.2: Vector Fields

**Learning Objectives**

- Recognize a vector field in a plane or in space.
- Sketch a vector field from a given equation.
- Identify a conservative field and its associated potential function.

Vector fields are an important tool for describing many physical concepts, such as gravitation and electromagnetism, which affect the behavior of objects over a large region of a plane or of space. They are also useful for dealing with large-scale behavior such as atmospheric storms or deep-sea ocean currents. In this section, we examine the basic definitions and graphs of vector fields so we can study them in more detail in the rest of this chapter.

## Examples of Vector Fields

How can we model the gravitational force exerted by multiple astronomical objects? How can we model the velocity of water particles on the surface of a river? Figure **16.2.1** gives visual representations of such phenomena.

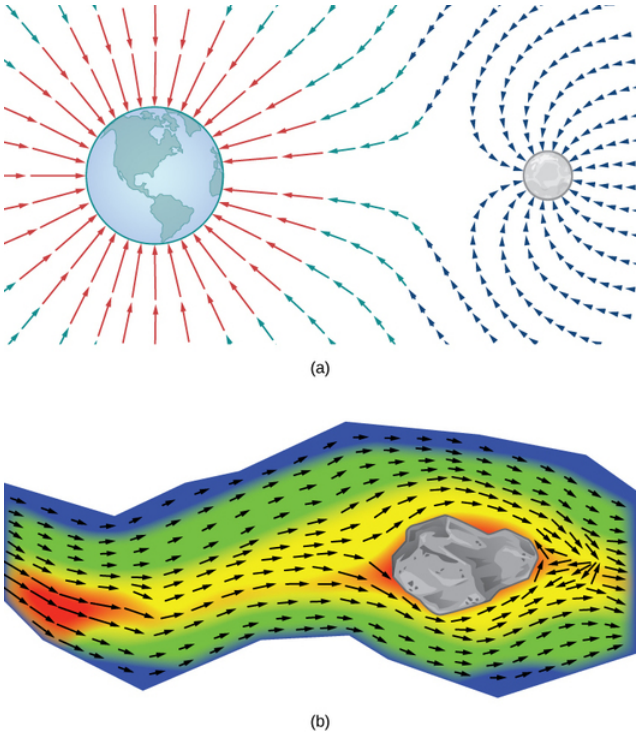

Figure **16.2.1** (a) The gravitational field exerted by two astronomical bodies on a small object. (b) The vector velocity field of water on the surface of a river shows the varied speeds of water. Red indicates that the magnitude of the vector is greater, so the water flows more quickly; blue indicates a lesser magnitude and a slower speed of water flow.

Figure **16.2.1***a* shows a gravitational field exerted by two astronomical objects, such as a star and a planet or a planet and a moon. At any point in the figure, the vector associated with a point gives the net gravitational force exerted by the two objects on an object of unit mass. The vectors of largest magnitude in the figure are the vectors closest to the larger object. The larger object has greater mass, so it exerts a gravitational force of greater magnitude than the smaller object.

Figure **16.2.1***b* shows the velocity of a river at points on its surface. The vector associated with a given point on the river's surface gives the velocity of the water at that point. Since the vectors to the left of the figure are small in magnitude, the water is flowing slowly on that part of the surface. As the water moves from left to right, it encounters some rapids around a rock. The speed of the water increases, and a whirlpool occurs in part of the rapids.

Each figure illustrates an example of a vector field. Intuitively, a vector field is a map of vectors. In this section, we study vector fields in $\mathbb{R}^2$ and $\mathbb{R}^3$.

**DEFINITION: Vector Field**

- A vector field $\vec{\mathbf{F}}$ in $\mathbb{R}^2$ is an assignment of a two-dimensional vector $\vec{\mathbf{F}}(x,y)$ to each point $(x,y)$ of a subset $D$ of $\mathbb{R}^2$. The subset $D$ is the domain of the vector field.
- A vector field $\vec{\mathbf{F}}$ in $\mathbb{R}^3$ is an assignment of a three-dimensional vector $\vec{\mathbf{F}}(x,y,z)$ to each point $(x,y,z)$ of a subset $D$ of $\mathbb{R}^3$. The subset $D$ is the domain of the vector field.

## Vector Fields in $\mathbb{R}^2$

A vector field in $\mathbb{R}^2$ can be represented in either of two equivalent ways. The first way is to use a vector with components that are two-variable functions:

$$\vec{\mathbf{F}}(x,y) = \langle P(x,y), Q(x,y) \rangle$$

The second way is to use the standard unit vectors:

$$\vec{\mathbf{F}}(x,y) = P(x,y)\,\hat{\mathbf{i}} + Q(x,y)\,\hat{\mathbf{j}}.$$

A vector field is said to be *continuous* if its component functions are continuous.

**Example 16.2.1: Finding a Vector Associated with a Given Point**

Let $\vec{\mathbf{F}}(x,y) = (2y^2 + x - 4)\,\hat{\mathbf{i}} + \cos(x)\,\hat{\mathbf{j}}$ be a vector field in $\mathbb{R}^2$. Note that this is an example of a continuous vector field since both component functions are continuous. What vector is associated with point $(0,-1)$?

**Solution**

Substitute the point values for $x$ and $y$:

$$\begin{aligned}\vec{\mathbf{F}}(0,-1) &= (2(-1)^2 + 0 - 4)\,\hat{\mathbf{i}} + \cos(0)\,\hat{\mathbf{j}} \\ &= -2\,\hat{\mathbf{i}} + \hat{\mathbf{j}}.\end{aligned}$$

**Exercise 16.2.1**

Let $\vec{\mathbf{G}}(x,y) = x^2 y\,\hat{\mathbf{i}} - (x+y)\,\hat{\mathbf{j}}$ be a vector field in $\mathbb{R}^2$. What vector is associated with the point $(-2,3)$?

**Hint**

Substitute the point values into the vector function.

**Answer**

$\vec{\mathbf{G}}(-2,3) = 12\hat{\mathbf{i}} - \hat{\mathbf{j}}$

### Drawing a Vector Field

We can now represent a vector field in terms of its components of functions or unit vectors, but representing it visually by sketching it is more complex because the domain of a vector field is in $\mathbb{R}^2$, as is the range. Therefore the "graph" of a vector field in $\mathbb{R}^2$ lives in four-dimensional space. Since we cannot represent four-dimensional space visually, we instead draw vector fields in $\mathbb{R}^2$ in a plane itself. To do this, draw the vector associated with a given point at the point in a plane. For example, suppose the vector associated with point $(4,-1)$ is $\langle 3,1 \rangle$. Then, we would draw vector $\langle 3,1 \rangle$ at point $(4,-1)$.

We should plot enough vectors to see the general shape, but not so many that the sketch becomes a jumbled mess. If we were to plot the image vector at each point in the region, it would fill the region completely and is useless. Instead, we can choose points at the intersections of grid lines and plot a sample of several vectors from each quadrant of a rectangular coordinate system in $\mathbb{R}^2$.

There are two types of vector fields in $\mathbb{R}^2$ on which this chapter focuses: radial fields and rotational fields. Radial fields model certain gravitational fields and energy source fields, and rotational fields model the movement of a fluid in a vortex. In a radial field, all vectors either point directly toward or directly away from the origin. Furthermore, the magnitude of any vector depends only on its distance from the origin. In a radial field, the vector located at point $(x, y)$ is perpendicular to the circle centered at the origin that contains point $(x, y)$, and all other vectors on this circle have the same magnitude.

### Example 16.2.2: Drawing a Radial Vector Field

Sketch the vector field $\vec{\mathbf{F}}(x, y) = \frac{x}{2}\hat{\mathbf{i}} + \frac{y}{2}\hat{\mathbf{j}}$.

#### Solution

To sketch this vector field, choose a sample of points from each quadrant and compute the corresponding vector. The following table gives a representative sample of points in a plane and the corresponding vectors.

Table 16.2.1

| $(x, y)$ | $\vec{\mathbf{F}}(x, y)$ | $(x, y)$ | $\vec{\mathbf{F}}(x, y)$ | $(x, y)$ | $\vec{\mathbf{F}}(x, y)$ |
|---|---|---|---|---|---|
| $(1, 0)$ | $\langle \frac{1}{2}, 0 \rangle$ | $(2, 0)$ | $\langle 1, 0 \rangle$ | $(1, 1)$ | $\langle \frac{1}{2}, \frac{1}{2} \rangle$ |
| $(0, 1)$ | $\langle 0, \frac{1}{2} \rangle$ | $(0, 2)$ | $\langle 0, 1 \rangle$ | $(-1, 1)$ | $\langle -\frac{1}{2}, \frac{1}{2} \rangle$ |
| $(-1, 0)$ | $\langle -\frac{1}{2}, 0 \rangle$ | $(-2, 0)$ | $\langle -1, 0 \rangle$ | $(-1, -1)$ | $\langle -\frac{1}{2}, -\frac{1}{2} \rangle$ |
| $(0, -1)$ | $\langle 0, -\frac{1}{2} \rangle$ | $(0, -2)$ | $\langle 0, -1 \rangle$ | $(1, -1)$ | $\langle \frac{1}{2}, -\frac{1}{2} \rangle$ |

Figure 16.2.2*a* shows the vector field. To see that each vector is perpendicular to the corresponding circle, Figure 16.2.2*b* shows circles overlain on the vector field.

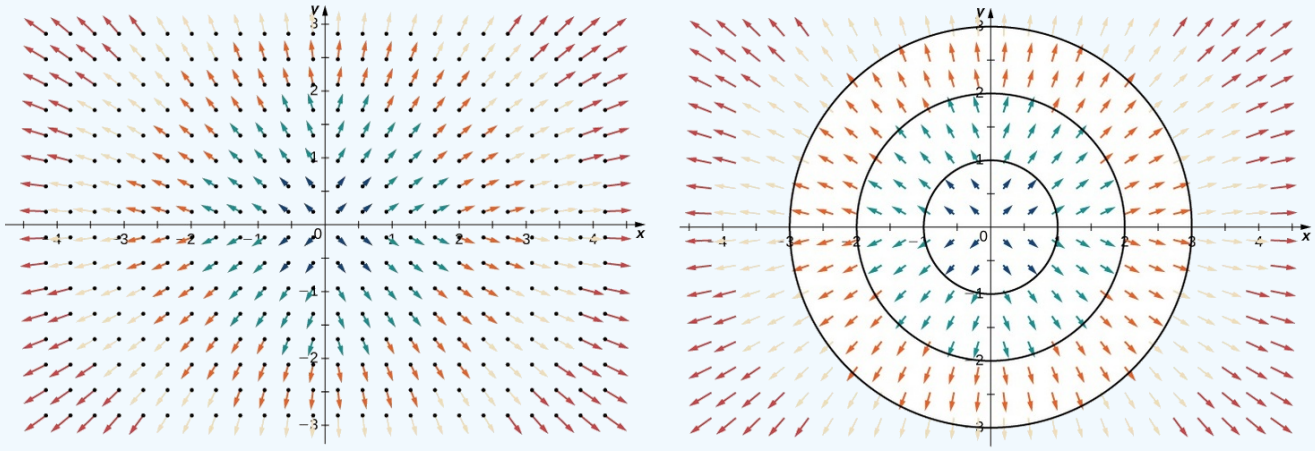

Figure 16.2.2: (a) A visual representation of the radial vector field $\vec{\mathbf{F}}(x, y) = \frac{x}{2}\hat{\mathbf{i}} + \frac{y}{2}\hat{\mathbf{j}}$. (b) The radial vector field $\vec{F}(x, y) = \frac{x}{2}\hat{\mathbf{i}} + \frac{y}{2}\hat{\mathbf{j}}$ with overlaid circles. Notice that each vector is perpendicular to the circle on which it is located.

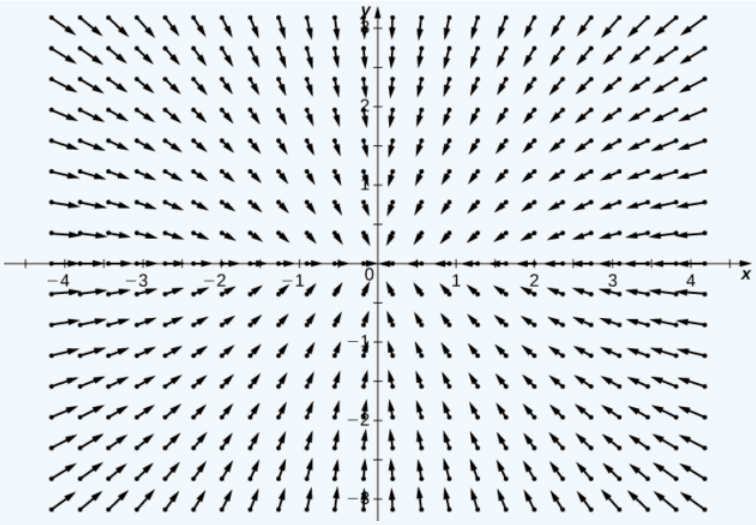
### Exercise 16.2.2

Draw the radial field $\vec{\mathbf{F}}(x, y) = -\frac{x}{3}\hat{\mathbf{i}} - \frac{y}{3}\hat{\mathbf{j}}$.

**Hint**

Sketch enough vectors to get an idea of the shape.

**Answer**



In contrast to radial fields, in a *rotational field*, the vector at point $(x, y)$ is tangent (not perpendicular) to a circle with radius $r = \sqrt{x^2 + y^2}$. In a standard rotational field, all vectors point either in a clockwise direction or in a counterclockwise direction, and the magnitude of a vector depends only on its distance from the origin. Both of the following examples are clockwise rotational fields, and we see from their visual representations that the vectors appear to rotate around the origin.

### Example 16.2.3: Drawing a Rotational Vector Field

Sketch the vector field $\vec{\mathbf{F}}(x, y) = \langle y, -x \rangle$.

#### Solution

Create a table (see the one that follows) using a representative sample of points in a plane and their corresponding vectors. Figure 16.2.3 shows the resulting vector field.

Table 16.2.2

| $(x, y)$ | $\vec{\mathbf{F}}(x, y)$ | $(x, y)$ | $\vec{\mathbf{F}}(x, y)$ | $(x, y)$ | $\vec{\mathbf{F}}(x, y)$ |
|---|---|---|---|---|---|
| $(1, 0)$ | $\langle 0, -1 \rangle$ | $(2, 0)$ | $\langle 0, -2 \rangle$ | $(1, 1)$ | $\langle 1, -1 \rangle$ |
| $(0, 1)$ | $\langle 1, 0 \rangle$ | $(0, 2)$ | $\langle 2, 0 \rangle$ | $(-1, 1)$ | $\langle 1, 1 \rangle$ |
| $(-1, 0)$ | $\langle 0, 1 \rangle$ | $(-2, 0)$ | $\langle 0, 2 \rangle$ | $(-1, -1)$ | $\langle -1, 1 \rangle$ |
| $(0, -1)$ | $\langle -1, 0 \rangle$ | $(0, -2)$ | $\langle -2, 0 \rangle$ | $(1, -1)$ | $\langle -1, -1 \rangle$ |

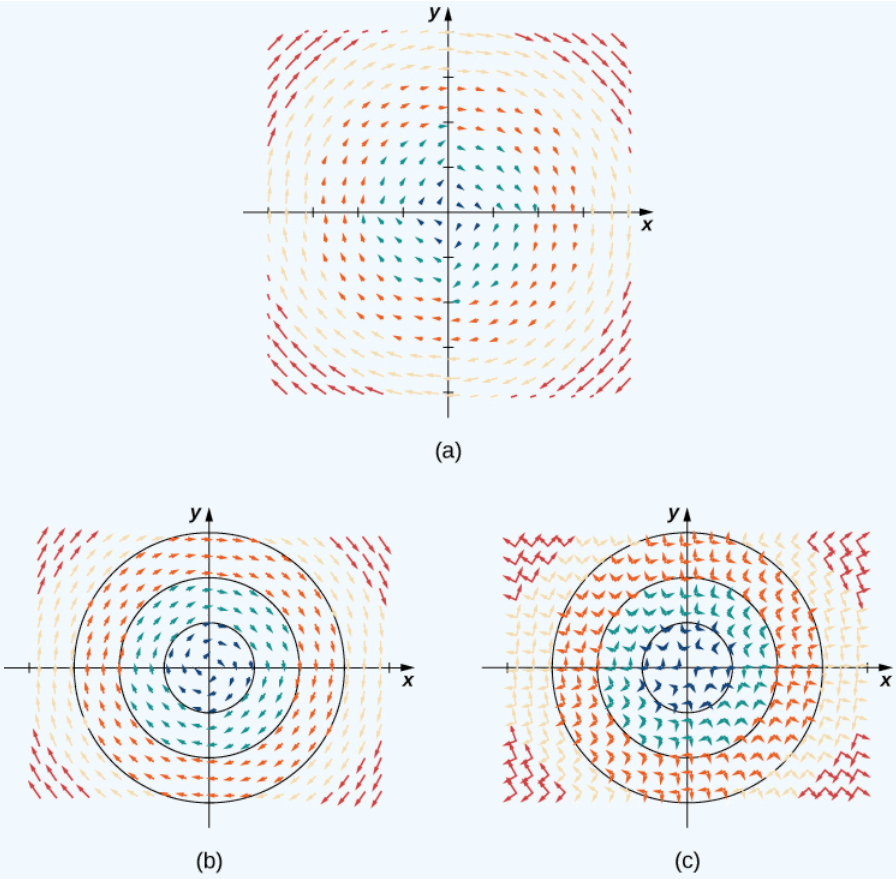


Figure **16.2.3**: (a) A visual representation of vector field $\vec{\mathbf{F}}(x,y) = \langle y, -x \rangle$. (b) Vector field $\vec{\mathbf{F}}(x,y) = \langle y, -x \rangle$ with circles centered at the origin. (c) Vector $\vec{\mathbf{F}}(a,b)$ is perpendicular to radial vector $\langle a, b \rangle$ at point $(a,b)$.

### Analysis

Note that vector $\vec{\mathbf{F}}(a,b) = \langle b, -a \rangle$ points clockwise and is perpendicular to radial vector $\langle a, b \rangle$. (We can verify this assertion by computing the dot product of the two vectors: $\langle a, b \rangle \cdot \langle -b, a \rangle = -ab + ab = 0$.) Furthermore, vector $\langle b, -a \rangle$ has length $r = \sqrt{a^2 + b^2}$. Thus, we have a complete description of this rotational vector field: the vector associated with point $(a,b)$ is the vector with length $r$ tangent to the circle with radius $r$, and it points in the clockwise direction.

Sketches such as that in Figure **16.2.3** are often used to analyze major storm systems, including hurricanes and cyclones. In the northern hemisphere, storms rotate counterclockwise; in the southern hemisphere, storms rotate clockwise. (This is an effect caused by Earth's rotation about its axis and is called the Coriolis Effect.)

Figure **16.2.4**: (credit: modification of work by NASA)

### Example 16.2.4: Sketching a Vector Field

Sketch vector field $\vec{\mathbf{F}}(x,y) = \frac{y}{x^2+y^2}\hat{\mathbf{i}}, -\frac{x}{x^2+y^2}\hat{\mathbf{j}}$.

**Solution**

To visualize this vector field, first note that the dot product $\vec{\mathbf{F}}(a,b) \cdot (a\,\hat{\mathbf{i}} + b\,\hat{\mathbf{j}})$ is zero for any point $(a,b)$. Therefore, each vector is tangent to the circle on which it is located. Also, as $(a,b) \to (0,0)$, the magnitude of $\vec{\mathbf{F}}(a,b)$ goes to infinity. To see this, note that

$$||\vec{\mathbf{F}}(a,b)|| = \sqrt{\frac{a^2+b^2}{(a^2+b^2)^2}} = \sqrt{\frac{1}{a^2+b^2}}.$$

Since $\dfrac{1}{a^2+b^2} \to \infty$ as $(a,b) \to (0,0)$, then $||\vec{\mathbf{F}}(a,b)|| \to \infty$ as $(a,b) \to (0,0)$. This vector field looks similar to the vector field in Example **16.2.3**, but in this case the magnitudes of the vectors close to the origin are large. Table **16.2.3** shows a sample of points and the corresponding vectors, and Figure **16.2.5** shows the vector field. Note that this vector field models the whirlpool motion of the river in Figure **16.2.5**(b). The domain of this vector field is all of $\mathbb{R}^2$ except for point $(0,0)$.

Table **16.2.3**

| $(x,y)$ | $\vec{\mathbf{F}}(x,y)$ | $(x,y)$ | $\vec{\mathbf{F}}(x,y)$ | $(x,y)$ | $\vec{\mathbf{F}}(x,y)$ |
|---|---|---|---|---|---|
| $(1,0)$ | $\langle 0,-1\rangle$ | $(2,0)$ | $\langle 0,-\frac{1}{2}\rangle$ | $(1,1)$ | $\langle \frac{1}{2},-\frac{1}{2}\rangle$ |
| $(0,1)$ | $\langle 1,0\rangle$ | $(0,2)$ | $\langle \frac{1}{2},0\rangle$ | $(-1,1)$ | $\langle \frac{1}{2},\frac{1}{2}\rangle$ |
| $(-1,0)$ | $\langle 0,1\rangle$ | $(-2,0)$ | $\langle 0,\frac{1}{2}\rangle$ | $(-1,-1)$ | $\langle -\frac{1}{2},\frac{1}{2}\rangle$ |
| $(0,-1)$ | $\langle -1,0\rangle$ | $(0,-2)$ | $\langle -\frac{1}{2},0\rangle$ | $(1,-1)$ | $\langle -\frac{1}{2},-\frac{1}{2}\rangle$ |

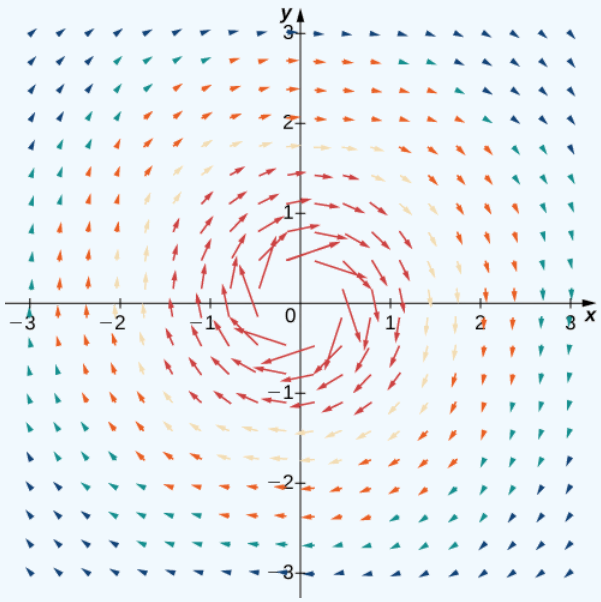

Figure **16.2.5**: A visual representation of vector field $\vec{\mathbf{F}}(x,y) = \dfrac{y}{x^2+y^2}\hat{\mathbf{i}} - \dfrac{x}{x^2+y^2}\hat{\mathbf{j}}$. *This vector field could be used to model whirlpool motion of a fluid.*

**? Exercise 16.2.4**

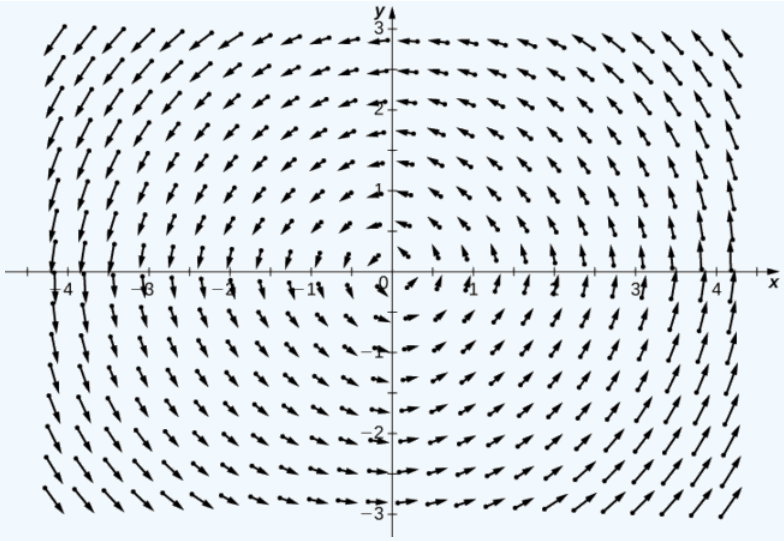
Sketch vector field $\vec{\mathbf{F}}(x,y) = \langle -2y, 2x\rangle$. Is the vector field radial, rotational, or neither?

**Hint**

Substitute enough points into $\vec{\mathbf{F}}$ to get an idea of the shape.

**Answer**

Rotational



### Example 16.2.5: Velocity Field of a Fluid

Suppose that $\vec{\mathbf{v}}(x,y) = -\frac{2y}{x^2+y^2}\hat{\mathbf{i}} + \frac{2x}{x^2+y^2}\hat{\mathbf{j}}$ is the velocity field of a fluid. How fast is the fluid moving at point $(1,-1)$? (Assume the units of speed are meters per second.)

**Solution**

To find the velocity of the fluid at point $(1,-1)$, substitute the point into $\vec{\mathbf{v}}$:

$$\vec{\mathbf{v}}(1,-1) = \frac{-2(-1)}{1+1}\hat{\mathbf{i}} + \frac{2(1)}{1+1}\hat{\mathbf{j}} = \hat{\mathbf{i}} + \hat{\mathbf{j}}.$$

The speed of the fluid at $(1,-1)$ is the magnitude of this vector. Therefore, the speed is $||\hat{\mathbf{i}} + \hat{\mathbf{j}}|| = \sqrt{2}$ m/sec.

### Exercise 16.2.5

Vector field $\vec{\mathbf{v}}(x,y) = \langle 4|x|,\ 1\rangle$ models the velocity of water on the surface of a river. What is the speed of the water at point $(2,3)$? Use meters per second as the units.

**Hint**

Remember, speed is the magnitude of velocity.

**Answer**

$\sqrt{65}$ m/sec

We have examined vector fields that contain vectors of various magnitudes, but just as we have unit vectors, we can also have a unit vector field. A vector field $\vec{\mathbf{F}}$ is a **unit vector field** if the magnitude of each vector in the field is 1. In a unit vector field, the only relevant information is the direction of each vector.

### Example 16.2.6: A Unit Vector Field

Show that vector field $\vec{\mathbf{F}}(x,y) = \left\langle \frac{y}{\sqrt{x^2+y^2}}, -\frac{x}{\sqrt{x^2+y^2}} \right\rangle$ is a unit vector field.

**Solution**

To show that $\vec{\mathbf{F}}$ is a unit field, we must show that the magnitude of each vector is $1$. Note that

$$\sqrt{\left(\frac{y}{\sqrt{x^2+y^2}}\right)^2+\left(-\frac{x}{\sqrt{x^2+y^2}}\right)^2}=\sqrt{\frac{y^2}{x^2+y^2}+\frac{x^2}{x^2+y^2}}$$
$$=\sqrt{\frac{x^2+y^2}{x^2+y^2}}$$
$$=1$$

Therefore, $\vec{\mathbf{F}}$ is a unit vector field.

**? Exercise 16.2.6**

Is vector field $\vec{\mathbf{F}}(x,y)=\langle -y,\, x\rangle$ a unit vector field?

**Hint**

Calculate the magnitude of $\vec{\mathbf{F}}$ at an arbitrary point $(x,y)$.

**Answer**

No.

Why are unit vector fields important? Suppose we are studying the flow of a fluid, and we care only about the direction in which the fluid is flowing at a given point. In this case, the speed of the fluid (which is the magnitude of the corresponding velocity vector) is irrelevant, because all we care about is the direction of each vector. Therefore, the unit vector field associated with velocity is the field we would study.

If $\vec{\mathbf{F}}=\langle P,Q,R\rangle$ is a vector field, then the corresponding unit vector field is $\left\langle \frac{P}{||\vec{\mathbf{F}}||}, \frac{Q}{||\vec{\mathbf{F}}||}, \frac{R}{||\vec{\mathbf{F}}||}\right\rangle$. Notice that if $\vec{\mathbf{F}}(x,y)=\langle y,\, -x\rangle$ is the vector field from Example 16.2.6, then the magnitude of $\vec{\mathbf{F}}$ is $\sqrt{x^2+y^2}$, and therefore the corresponding unit vector field is the field $\vec{\mathbf{G}}$ from the previous example.

If $\vec{\mathbf{F}}$ is a vector field, then the process of dividing $\vec{\mathbf{F}}$ by its magnitude to form unit vector field $\vec{\mathbf{F}}/||\vec{\mathbf{F}}||$ is called normalizing the field $\vec{\mathbf{F}}$.

## Vector Fields in $\mathbb{R}^3$

We have seen several examples of vector fields in $\mathbb{R}^2$; let's now turn our attention to vector fields in $\mathbb{R}^3$. These vector fields can be used to model gravitational or electromagnetic fields, and they can also be used to model fluid flow or heat flow in three dimensions. A two-dimensional vector field can really only model the movement of water on a two-dimensional slice of a river (such as the river's surface). Since a river flows through three spatial dimensions, to model the flow of the entire depth of the river, we need a vector field in three dimensions.

The extra dimension of a three-dimensional field can make vector fields in $\mathbb{R}^3$ more difficult to visualize, but the idea is the same. To visualize a vector field in $\mathbb{R}^3$, plot enough vectors to show the overall shape. We can use a similar method to visualizing a vector field in $\mathbb{R}^2$ by choosing points in each octant.

Just as with vector fields in $\mathbb{R}^2$, we can represent vector fields in $\mathbb{R}^3$ with component functions. We simply need an extra component function for the extra dimension. We write either

$$\vec{\mathbf{F}}(x,y,z)=\langle P(x,y,z),Q(x,y,z),R(x,y,z)\rangle$$

or

$$\vec{\mathbf{F}}(x,y,z)=P(x,y,z)\hat{\mathbf{i}}+Q(x,y,z)\hat{\mathbf{j}}+R(x,y,z)\hat{\mathbf{k}}.$$

## Example 16.2.7: Sketching a Vector Field in Three Dimensions

Describe vector field $\vec{\mathbf{F}}(x, y, z) = \langle 1, 1, z \rangle$.

### Solution

For this vector field, the $x$- and $y$-components are constant, so every point in $\mathbb{R}^3$ has an associated vector with $x$- and $y$-components equal to one. To visualize $\vec{\mathbf{F}}$, we first consider what the field looks like in the $xy$-plane. In the $xy$-plane, $z = 0$. Hence, each point of the form $(a, b, 0)$ has vector $\langle 1, 1, 0 \rangle$ associated with it. For points not in the $xy$-plane but slightly above it, the associated vector has a small but positive $z$-component, and therefore the associated vector points slightly upward. For points that are far above the $xy$-plane, the $z$-component is large, so the vector is almost vertical. Figure 16.2.6 shows this vector field.

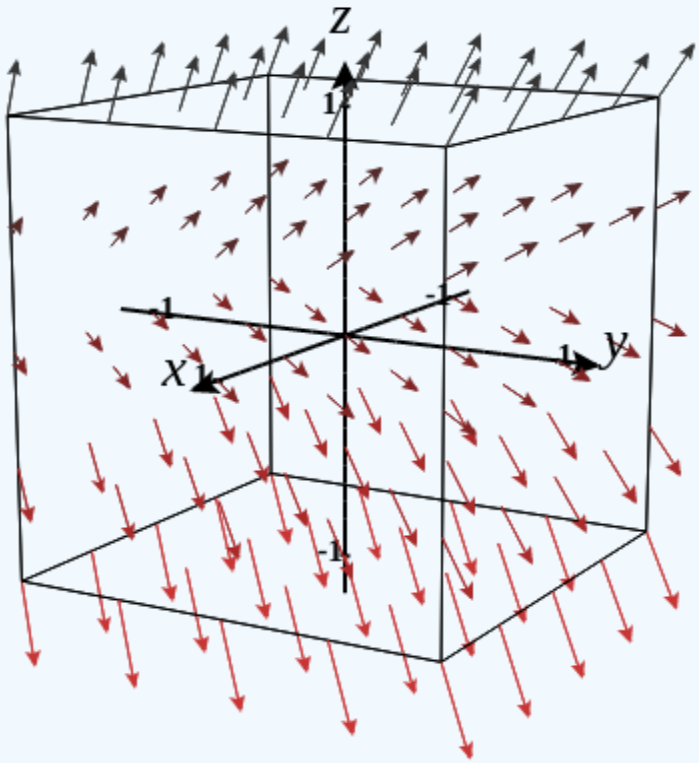


Figure 16.2.6: A visual representation of vector field $\vec{\mathbf{F}}(x, y, z) = \langle 1, 1, z \rangle$.

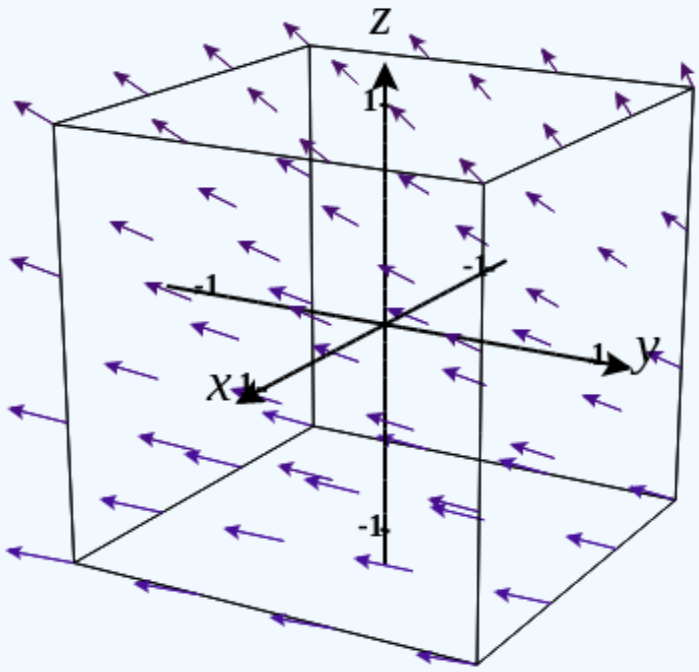
## Exercise 16.2.7

Sketch vector field $\vec{\mathbf{G}}(x, y, z) = \langle 2, \frac{z}{2}, 1 \rangle$.

**Hint**

Substitute enough points into the vector field to get an idea of the general shape.

**Answer**



In the next example, we explore one of the classic cases of a three-dimensional vector field: a gravitational field.

### Example 16.2.8: Describing a Gravitational Vector Field

Newton's law of gravitation states that $\vec{\mathbf{F}} = -G\frac{m_1 m_2}{r^2}\hat{\mathbf{r}}$, where $G$ is the universal gravitational constant. It describes the gravitational field exerted by an object (object 1) of mass $m_1$ located at the origin on another object (object 2) of mass $m_2$ located at point $(x, y, z)$. Field $\vec{\mathbf{F}}$ denotes the gravitational force that object 1 exerts on object 2, $r$ is the distance between the two objects, and $\hat{\mathbf{r}}$ indicates the unit vector from the first object to the second. The minus sign shows that the gravitational force attracts toward the origin; that is, the force of object 1 is attractive. Sketch the vector field associated with this equation.

**Solution**

Since object 1 is located at the origin, the distance between the objects is given by $r = \sqrt{x^2 + y^2 + z^2}$. The unit vector from object 1 to object 2 is $\hat{\mathbf{r}} = \frac{\langle x, y, z\rangle}{||\langle x, y, z\rangle||}$, and hence $\hat{\mathbf{r}} = \langle \frac{x}{r}, \frac{y}{r}, \frac{z}{r}\rangle$. Therefore, gravitational vector field $\vec{\mathbf{F}}$ exerted by object 1 on object 2 is

$$\vec{\mathbf{F}} = -Gm_1 m_2 \langle \frac{x}{r^3}, \frac{y}{r^3}, \frac{z}{r^3}\rangle.$$

This is an example of a radial vector field in $\mathbb{R}^3$.

Figure 16.2.7 shows what this gravitational field looks like for a large mass at the origin. Note that the magnitudes of the vectors increase as the vectors get closer to the origin.

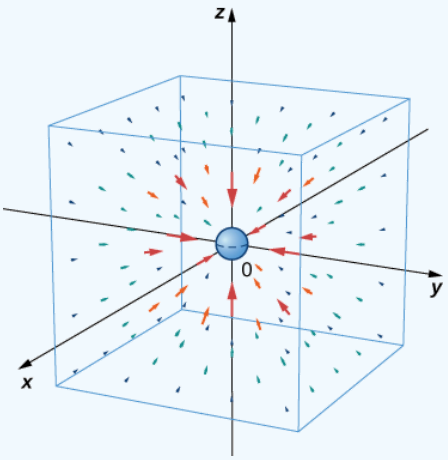


Figure 16.2.7: A visual representation of gravitational vector field $\vec{\mathbf{F}} = -Gm_1m_2\langle \frac{x}{r^3}, \frac{y}{r^3}, \frac{z}{r^3} \rangle$ for a large mass at the origin.

### ? Exercise 16.2.8

The mass of asteroid 1 is 750,000 kg and the mass of asteroid 2 is 130,000 kg. Assume asteroid 1 is located at the origin, and asteroid 2 is located at $(15, -5, 10)$, measured in units of 10 to the eighth power kilometers. Given that the universal gravitational constant is $G = 6.67384 \times 10^{-11} m^3 kg^{-1} s^{-2}$, find the gravitational force vector that asteroid 1 exerts on asteroid 2.

**Hint**

Follow Example 16.2.8 and first compute the distance between the asteroids.

**Answer**

$1.49063 \times 10^{-18}$, $4.96876 \times 10^{-19}$, $9.93752 \times 10^{-19}$ N

## Gradient Fields (Conservative Fields)

In this section, we study a special kind of vector field called a gradient field or a **conservative field**. These vector fields are extremely important in physics because they can be used to model physical systems in which energy is conserved. Gravitational fields and electric fields associated with a static charge are examples of gradient fields.

Recall that if $f$ is a (scalar) function of $x$ and $y$, then the gradient of $f$ is

$$\text{grad } f = \vec{\nabla} f(x, y) = f_x(x, y)\hat{\mathbf{i}} + f_y(x, y)\hat{\mathbf{j}}.$$

We can see from the form in which the gradient is written that $\vec{\nabla} f$ is a vector field in $\mathbb{R}^2$. Similarly, if $f$ is a function of $x$, $y$, and $z$, then the gradient of $f$ is

$$\text{grad } f = \vec{\nabla} f(x, y, z) = f_x(x, y, z)\hat{\mathbf{i}} + f_y(x, y, z)\hat{\mathbf{j}} + f_z(x, y, z)\hat{\mathbf{k}}.$$

The gradient of a three-variable function is a vector field in $\mathbb{R}^3$. A gradient field is a vector field that can be written as the gradient of a function, and we have the following definition.

### DEFINITION: Gradient Field

A vector field $\vec{\mathbf{F}}$ in $\mathbb{R}^2$ or in $\mathbb{R}^3$ is a gradient field if there exists a scalar function $f$ such that $\vec{\nabla} f = \vec{\mathbf{F}}$.

### ✓ Example 16.2.9: Sketching a Gradient Vector Field

Use technology to plot the gradient vector field of $f(x, y) = x^2 y^2$.

**Solution**

The gradient of $f$ is $\vec{\nabla} f(x,y) = \langle 2xy^2,\ 2x^2y \rangle$. To sketch the vector field, use a computer algebra system such as Mathematica. Figure 16.2.8 shows $\vec{\nabla} f$.

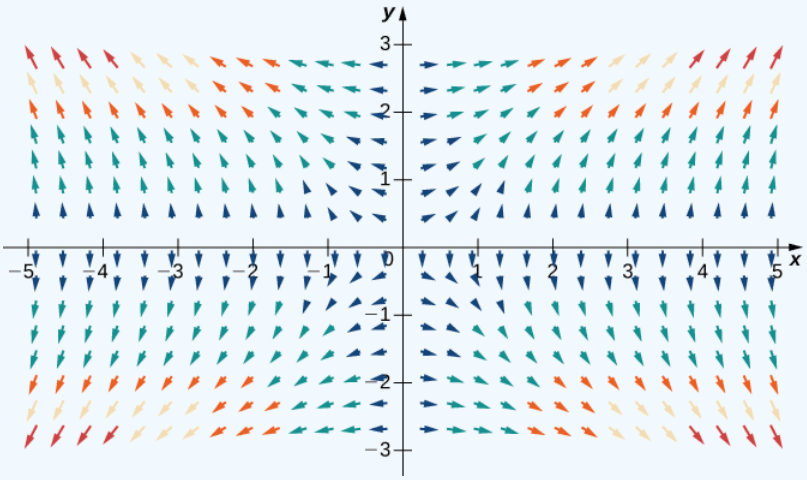

Figure 16.2.8: The gradient vector field is $\vec{\nabla} f$, where $f(x,y) = x^2y^2$.

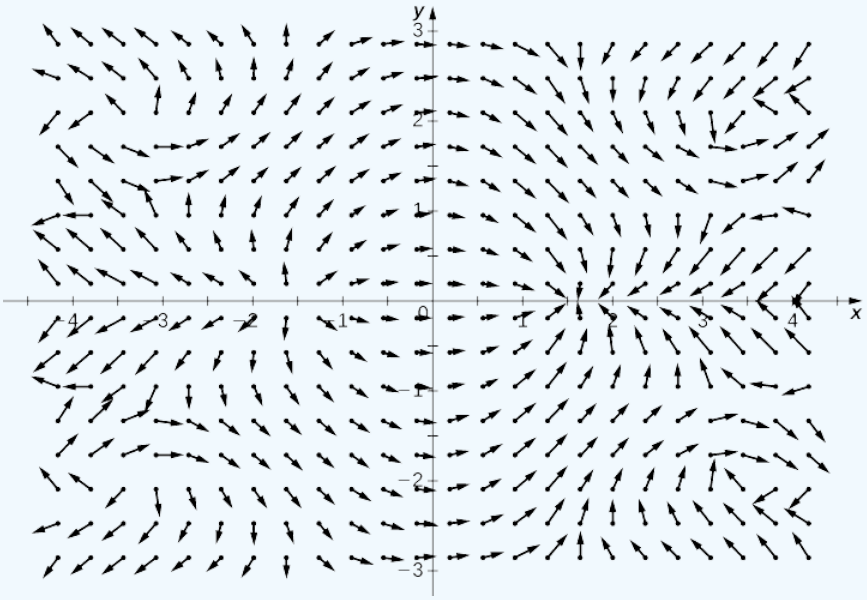
**? Exercise 16.2.9**

Use technology to plot the gradient vector field of $f(x,y) = \sin x \cos y$.

**Hint**

Find the gradient of $f$.

**Answer**



Consider the function $f(x,y) = x^2y^2$ from Example 16.2.9. Figure 16.2.9 shows the level curves of this function overlaid on the function's gradient vector field. The gradient vectors are perpendicular to the level curves, and the magnitudes of the vectors get larger as the level curves get closer together, because closely grouped level curves indicate the graph is steep, and the magnitude of the gradient vector is the largest value of the directional derivative. Therefore, you can see the local steepness of a graph by investigating the corresponding function's gradient field.

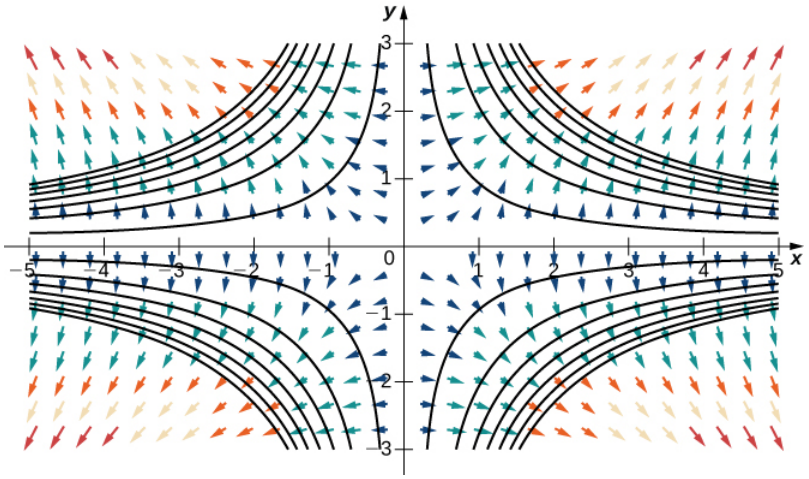


Figure 16.2.9: The gradient field of $f(x,y) = x^2y^2$ and several level curves of $f$. Notice that as the level curves get closer together, the magnitude of the gradient vectors increases.

As we learned earlier, a vector field $\vec{\mathbf{F}}$ is a conservative vector field, or a gradient field if there exists a scalar function $f$ such that $\vec{\nabla} f = \vec{\mathbf{F}}$. In this situation, $f$ is called a **potential function** for $\vec{\mathbf{F}}$. Conservative vector fields arise in many applications, particularly in physics. The reason such fields are called *conservative* is that they model forces of physical systems in which energy is conserved. We study conservative vector fields in more detail later in this chapter.

You might notice that, in some applications, a potential function $f$ for $\vec{\mathbf{F}}$ is defined instead as a function such that $-\vec{\nabla} f = \vec{\mathbf{F}}$. This is the case for certain contexts in physics, for example.

### Example 16.2.10: Verifying a Potential Function

Is $f(x,y,z) = x^2yz - \sin(xy)$ a potential function for vector field

$$\vec{\mathbf{F}}(x,y,z) = \langle 2xyz - y\cos(xy), x^2z - x\cos(xy), x^2y\rangle?$$

**Solution**

We need to confirm whether $\vec{\nabla} f = \vec{\mathbf{F}}$. We have

$$f_x(x,y) = 2xyz - y\cos(xy)$$
$$f_y(x,y) = x^2z - x\cos(xy).$$
$$f_z(x,y) = x^2y$$

Therefore, $\vec{\nabla} f = \vec{\mathbf{F}}$ and $f$ is a potential function for $\vec{\mathbf{F}}$.

### Exercise 16.2.10

Is $f(x,y,z) = x^2\cos(yz) + y^2z^2$ a potential function for $\vec{\mathbf{F}}(x,y,z) = \langle 2x\cos(yz), -x^2z\sin(yz) + 2yz^2, y^2\rangle$?

**Hint**

Compute the gradient of $f$.

**Answer**

No

### Example 16.2.11: Verifying a Potential Function

The velocity of a fluid is modeled by field $\vec{\mathbf{v}}(x,y) = \langle xy, \frac{x^2}{2} - y\rangle$. Verify that $f(x,y) = \frac{x^2y}{2} - \frac{y^2}{2}$ is a potential function for $\vec{\mathbf{v}}$.

**Solution**

To show that $f$ is a potential function, we must show that $\vec{\nabla} f = \vec{v}$. Note that $f_x(x,y) = xy$ and $f_y(x,y) = \frac{x^2}{2} - y$. Therefore, $\vec{\nabla} f(x,y) = \langle xy, \frac{x^2}{2} - y \rangle$ and $f$ is a potential function for $\vec{v}$ (Figure 16.2.10).

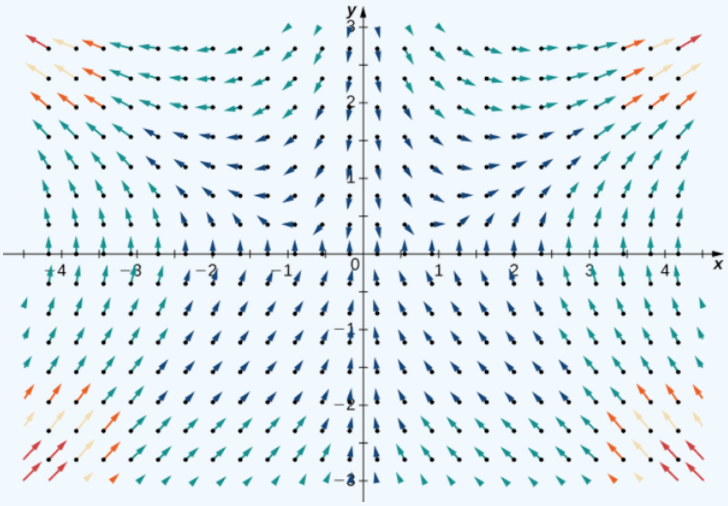

Figure 16.2.10: Velocity field $\vec{v}(x,y)$ has a potential function and is a conservative field.

**? Exercise 16.2.11**

Verify that $f(x,y) = x^3y^2 + x$ is a potential function for velocity field $\vec{v}(x,y) = \langle 3x^2y^2 + 1, 2x^3y \rangle$.

**Hint**

Calculate the gradient.

**Answer**

$\vec{\nabla} f(x,y) = \vec{v}(x,y)$

If $\vec{F}$ is a conservative vector field, then there is at least one potential function $f$ such that $\vec{\nabla} f = \vec{F}$. But, could there be more than one potential function? If so, is there any relationship between two potential functions for the same vector field? Before answering these questions, let's recall some facts from single-variable calculus to guide our intuition. Recall that if $k(x)$ is an integrable function, then $k$ has infinitely many antiderivatives. Furthermore, if $\vec{F}$ and $\vec{G}$ are both antiderivatives of $k$, then $\vec{F}$ and $\vec{G}$ **differ only by a constant**. That is, there is some number $C$ such that $\vec{F}(x) = \vec{G}(x) + C$.

Now let $\vec{F}$ be a conservative vector field and let $f$ and $g$ be potential functions for $\vec{F}$. Since the gradient is like a derivative, $\vec{F}$ being conservative means that $\vec{F}$ is "integrable" with "antiderivatives" $f$ and $g$. Therefore, if the analogy with single-variable calculus is valid, we expect there is some constant $C$ such that $f(x) = g(x) + C$. The next theorem says that this is indeed the case.

To state the next theorem with precision, we need to assume the domain of the vector field is connected and open. To be connected means if $P_1$ and $P_2$ are any two points in the domain, then you can walk from $P_1$ to $P_2$ along a path that stays entirely inside the domain.

**UNIQUENESS OF POTENTIAL FUNCTIONS**

Let $\vec{F}$ be a conservative vector field on an open and connected domain and let $f$ and $g$ be functions such that $\vec{\nabla} f = \vec{F}$ and $\vec{\nabla} g = \vec{F}$. Then, there is a constant $C$ such that $f = g + C$.

**Proof**

Since $f$ and $g$ are both potential functions for $\vec{\mathbf{F}}$, then $\vec{\nabla}(f-g) = \vec{\nabla}f - \vec{\nabla}g = \vec{\mathbf{F}} - \vec{\mathbf{F}} = \vec{\mathbf{0}}$. Let $h = f - g$, then we have $\vec{\nabla}h = \vec{\mathbf{0}}$.We would like to show that $h$ is a constant function.

Assume $h$ is a function of $x$ and $y$ (the logic of this proof extends to any number of independent variables). Since $\vec{\nabla}h = \vec{\mathbf{0}}$, we have $h_x(x,y) = 0$ and $h_y(x,y) = 0$. The expression $h_x(x,y) = 0$ implies that $h$ is a constant function with respect to $x$—that is, $h(x,y) = k_1(y)$ for some function $k_1$. Similarly, $h_y(x,y) = 0$ implies $h(x,y) = k_2(x)$ for some function $k_2$. Therefore, function $h$ depends only on $y$ and also depends only on $x$. Thus, $h(x,y) = C$ for some constant $C$ on the connected domain of $\vec{\mathbf{F}}$. Note that we really do need connectedness at this point; if the domain of $\vec{\mathbf{F}}$ came in two separate pieces, then $k$ could be a constant $C_1$ on one piece but could be a different constant $C_2$ on the other piece. Since $f - g = h = C$, we have that $f = g + C$, as desired.

□

Conservative vector fields also have a special property called the ***cross-partial property***. This property helps test whether a given vector field is conservative.

**THE CROSS-PARTIAL PROPERTY OF CONSERVATIVE VECTOR FIELDS**

Let $\vec{\mathbf{F}}$ be a vector field in two or three dimensions such that the component functions of $\vec{\mathbf{F}}$ have continuous second-order mixed-partial derivatives on the domain of $\vec{\mathbf{F}}$.

If $\vec{\mathbf{F}}(x,y) = \langle P(x,y), Q(x,y)\rangle$ is a conservative vector field in $\mathbb{R}^2$, then

$$\frac{\partial P}{\partial y} = \frac{\partial Q}{\partial x}.$$

If $\vec{\mathbf{F}}(x,y,z) = \langle P(x,y,z), Q(x,y,z), R(x,y,z)\rangle$ is a conservative vector field in $\mathbb{R}^3$, then

$$\frac{\partial P}{\partial y} = \frac{\partial Q}{\partial x}$$
$$\frac{\partial Q}{\partial z} = \frac{\partial R}{\partial y}$$
$$\frac{\partial R}{\partial x} = \frac{\partial P}{\partial z}.$$

**Proof**

Since $\vec{\mathbf{F}}$ is conservative, there is a function $f(x,y)$ such that $\vec{\nabla}f = \vec{\mathbf{F}}$. Therefore, by the definition of the gradient, $f_x = P$ and $f_y = Q$. By Clairaut's theorem, $f_{xy} = f_{yx}$, But, $f_{xy} = P_y$ and $f_{yx} = Q_x$, and thus $P_y = Q_x$.

□

Clairaut's theorem gives a fast proof of the cross-partial property of conservative vector fields in $\mathbb{R}^3$, just as it did for vector fields in $\mathbb{R}^2$.

The Cross-Partial Property of Conservative Vector Fields shows that most vector fields are not conservative. The cross-partial property is difficult to satisfy in general, so most vector fields won't have equal cross-partials.

Show that rotational vector field $\vec{\mathbf{F}}(x,y) = \langle y, -x\rangle$ is not conservative.

**Solution**

Let $P(x,y) = y$ and $Q(x,y) = -x$. If $\vec{\mathbf{F}}$ is conservative, then the cross-partials would be equal—that is, $P_y$ would equal $Q_x$.Therefore, to show that $\vec{\mathbf{F}}$ is not conservative, check that $P_y \neq Q_x$. Since $P_y = 1$ and $Q_x = -1$, the vector field is not conservative.

**? Exercise 16.2.12**

Show that vector field $\vec{\mathbf{F}}(x,y) = xy\,\hat{\mathbf{i}} - x^2y\,\hat{\mathbf{j}}$ is not conservative.

**Hint**

Check the cross-partials.

**Answer**

$P_y(x,y) = x$ and $Q_x(x,y) = -2xy$. Since $P_y(x,y) \neq Q_x(x,y)$, $\vec{\mathbf{F}}$ is not conservative.

**✓ Example 16.2.13: Showing a Vector Field Is Not Conservative**

Is vector field $\vec{\mathbf{F}}(x,y,z) = \langle 7, -2, x^3 \rangle$ conservative?

**Solution**

Let $P(x,y,z) = 7$, $Q(x,y,z) = -2$, and $R(x,y,z) = x^3$. If $\vec{\mathbf{F}}$ is conservative, then all three cross-partial equations will be satisfied —that is, if $\vec{\mathbf{F}}$ is conservative, then $P_y$ would equal $Q_x$, $Q_z$ would equal $R_y$, and $R_x$ would equal $P_z$. Note that

$$P_y = Q_x = R_y = Q_z = 0$$

so the first two necessary equalities hold. However, $R_x(x,y,z) = x^3$ and $P_z(x,y,z) = 0$ so $R_x \neq P_z$. Therefore, $\vec{\mathbf{F}}$ is not conservative.

**? Exercise 16.2.13**

Is vector field $\vec{\mathbf{G}}(x,y,z) = \langle y, x, xyz \rangle$ conservative?

**Hint**

Check the cross-partials.

**Answer**

No

We conclude this section with a word of warning: The Cross-Partial Property of Conservative Vector Fields says that if $\vec{\mathbf{F}}$ is conservative, then $\vec{\mathbf{F}}$ has the cross-partial property. The theorem does *not* say that, if $\vec{\mathbf{F}}$ has the cross-partial property, then $\vec{\mathbf{F}}$ is conservative (the converse of an implication is not logically equivalent to the original implication). In other words, The Cross-Partial Property of Conservative Vector Fields can only help determine that a field is not conservative; it does not let you conclude that a vector field is conservative.

For example, consider vector field $\vec{\mathbf{F}}(x,y) = \langle x^2y, \frac{x^3}{3} \rangle$. This field has the cross-partial property, so it is natural to try to use The Cross-Partial Property of Conservative Vector Fields to conclude this vector field is conservative. However, this is a misapplication of the theorem. We learn later how to conclude that $\vec{\mathbf{F}}$ is conservative.

## Key Concepts

- A vector field assigns a vector $\vec{\mathbf{F}}(x,y)$ to each point $(x,y)$ in a subset $D$ of $\mathbb{R}^2$ or $\mathbb{R}^3$. $\vec{\mathbf{F}}(x,y,z)$ to each point $(x,y,z)$ in a subset $D$ of $\mathbb{R}^3$.
- Vector fields can describe the distribution of vector quantities such as forces or velocities over a region of the plane or of space. They are in common use in such areas as physics, engineering, meteorology, oceanography.
- We can sketch a vector field by examining its defining equation to determine relative magnitudes in various locations and then drawing enough vectors to determine a pattern.
- A vector field $\vec{\mathbf{F}}$ is called conservative if there exists a scalar function $f$ such that $\vec{\nabla} f = \vec{\mathbf{F}}$.

## Key Equations

- **Vector field in $\mathbb{R}^2$**
  $\vec{\mathbf{F}}(x, y) = \langle P(x, y), Q(x, y) \rangle$
  or
  $\vec{\mathbf{F}}(x, y) = P(x, y)\,\hat{\mathbf{i}} + Q(x, y)\,\hat{\mathbf{j}}$
- **Vector field in $\mathbb{R}^3$**
  $\vec{\mathbf{F}}(x, y, z) = \langle P(x, y, z), Q(x, y, z), R(x, y, z) \rangle$
  or
  $\vec{\mathbf{F}}(x, y, z) = P(x, y, z)\,\hat{\mathbf{i}} + Q(x, y, z)\,\hat{\mathbf{j}} + R(x, y, z)\,\hat{\mathbf{k}}$

## Glossary

**conservative field**

a vector field for which there exists a scalar function $f$ such that $\vec{\nabla} f = \vec{\mathbf{F}}$

**gradient field**

a vector field $\vec{\mathbf{F}}$ for which there exists a scalar function $f$ such that $\vec{\nabla} f = \vec{\mathbf{F}}$; in other words, a vector field that is the gradient of a function; such vector fields are also called *conservative*

**potential function**

a scalar function $f$ such that $\vec{\nabla} f = \vec{\mathbf{F}}$

**radial field**

a vector field in which all vectors either point directly toward or directly away from the origin; the magnitude of any vector depends only on its distance from the origin

**rotational field**

a vector field in which the vector at point $(x, y)$ is tangent to a circle with radius $r = \sqrt{x^2 + y^2}$; in a rotational field, all vectors flow either clockwise or counterclockwise, and the magnitude of a vector depends only on its distance from the origin

**unit vector field**

a vector field in which the magnitude of every vector is 1

**vector field**

measured in $\mathbb{R}^2$, an assignment of a vector $\vec{\mathbf{F}}(x, y)$ to each point $(x, y)$ of a subset $D$ of $\mathbb{R}^2$; in $\mathbb{R}^3$, an assignment of a vector $\vec{\mathbf{F}}(x, y, z)$ to each point $(x, y, z)$ of a subset $D$ of $\mathbb{R}^3$

# 16.2E: Exercises for Section 16.1

**1.** The domain of vector field $\vec{\mathbf{F}} = \vec{\mathbf{F}}(x, y)$ is a set of points $(x, y)$ in a plane, and the range of $\vec{\mathbf{F}}$ is a set of *what* in the plane?

**For exercises 2 - 4, determine whether the statement is *true or false*.**

**2.** Vector field $\vec{\mathbf{F}} = \langle 3x^2, 1 \rangle$ is a gradient field for both $\phi_1(x, y) = x^3 + y$ and $\phi_2(x, y) = y + x^3 + 100$.

**3.** Vector field $\vec{\mathbf{F}} = \dfrac{\langle y, x \rangle}{\sqrt{x^2 + y^2}}$ is constant in direction and magnitude on a unit circle.

**4.** Vector field $\vec{\mathbf{F}} = \dfrac{\langle y, x \rangle}{\sqrt{x^2 + y^2}}$ is neither a radial field nor a rotation field.

**For exercises 5 - 13, describe each vector field by drawing some of its vectors.**

**5.** [T] $\vec{\mathbf{F}}(x, y) = x\,\hat{\mathbf{i}} + y\,\hat{\mathbf{j}}$

**6.** [T] $\vec{\mathbf{F}}(x, y) = -y\,\hat{\mathbf{i}} + x\,\hat{\mathbf{j}}$

**7.** [T] $\vec{\mathbf{F}}(x, y) = x\,\hat{\mathbf{i}} - y\,\hat{\mathbf{j}}$

**8.** [T] $\vec{\mathbf{F}}(x, y) = \hat{\mathbf{i}} + \hat{\mathbf{j}}$

**9.** [T] $\vec{\mathbf{F}}(x, y) = 2x\,\hat{\mathbf{i}} + 3y\,\hat{\mathbf{j}}$

**10.** [T] $\vec{\mathbf{F}}(x, y) = 3\,\hat{\mathbf{i}} + x\,\hat{\mathbf{j}}$

**11.** [T] $\vec{\mathbf{F}}(x, y) = y\,\hat{\mathbf{i}} + \sin x\,\hat{\mathbf{j}}$

**12.** [T] $\vec{\mathbf{F}}(x, y, z) = x\,\hat{\mathbf{i}} + y\,\hat{\mathbf{j}} + z\,\hat{\mathbf{k}}$

**13.** [T] $\vec{\mathbf{F}}(x, y, z) = 2x\,\hat{\mathbf{i}} - 2y\,\hat{\mathbf{j}} - 2z\,\hat{\mathbf{k}}$

**14.** [T] $\vec{\mathbf{F}}(x, y, z) = yz\,\hat{\mathbf{i}} - xz\,\hat{\mathbf{j}}$

**For exercises 15 - 20, find the gradient vector field of each function $f$.**

**15.** $f(x, y) = x \sin y + \cos y$

**16.** $f(x, y, z) = ze^{-xy}$

**17.** $f(x, y, z) = x^2y + xy + y^2z$

**18.** $f(x, y) = x^2 \sin(5y)$

**19.** $f(x, y) = \ln(1 + x^2 + 2y^2)$

**20.** $f(x, y, z) = x \cos\left(\frac{y}{z}\right)$

**21.** What is vector field $\vec{\mathbf{F}}(x, y)$ with a value at $(x, y)$ that is of unit length and points toward $(1, 0)$?

**For exercises 22 - 24, write formulas for the vector fields with the given properties.**

**22.** All vectors are parallel to the $x$-axis and all vectors on a vertical line have the same magnitude.

**23.** All vectors point toward the origin and have constant length.

**24.** All vectors are of unit length and are perpendicular to the position vector at that point.

**25.** Give a formula $\vec{\mathbf{F}}(x, y) = M(x, y)\,\hat{\mathbf{i}} + N(x, y)\,\hat{\mathbf{j}}$ for the vector field in a plane that has the properties that $\vec{\mathbf{F}} = \vec{\mathbf{0}}$ at $(0, 0)$ and that at any other point $(a, b)$, $\vec{\mathbf{F}}$ is tangent to circle $x^2 + y^2 = a^2 + b^2$ and points in the clockwise direction with magnitude $\|\vec{\mathbf{F}}\| = \sqrt{a^2 + b^2}$.

**26.** Is vector field $\vec{\mathbf{F}}(x, y) = (P(x, y), Q(x, y)) = (\sin x + y)\,\hat{\mathbf{i}} + (\cos y + x)\,\hat{\mathbf{j}}$ a gradient field?

**27.** Find a formula for vector field $\vec{\mathbf{F}}(x, y) = M(x, y)\,\hat{\mathbf{i}} + N(x, y)\,\hat{\mathbf{j}}$ given the fact that for all points $(x, y)$, $\vec{\mathbf{F}}$ points toward the origin and $\|\vec{\mathbf{F}}\| = \dfrac{10}{x^2 + y^2}$.

**For exercises 28 - 29, assume that an electric field in the $xy$-plane caused by an infinite line of charge along the $x$-axis is a gradient field with potential function $V(x,y) = c\ln\left(\frac{r_0}{\sqrt{x^2+y^2}}\right)$, where $c > 0$ is a constant and $r_0$ is a reference distance at which the potential is assumed to be zero.**

**28.** Find the components of the electric field in the $x$- and $y$-directions, where $\vec{\mathbf{E}}(x,y) = -\vec{\nabla}V(x,y)$.

**29.** Show that the electric field at a point in the $xy$-plane is directed outward from the origin and has magnitude $\|\vec{\mathbf{E}}\| = \frac{c}{r}$, where $r = \sqrt{x^2+y^2}$.

A ***flow line*** (or *streamline*) of a vector field $\vec{\mathbf{F}}$ is a curve $\vec{\mathbf{r}}(t)$ such that $d\vec{\mathbf{r}}/dt = \vec{\mathbf{F}}(\vec{\mathbf{r}}(t))$. If $\vec{\mathbf{F}}$ represents the velocity field of a moving particle, then the flow lines are paths taken by the particle. Therefore, flow lines are tangent to the vector field.

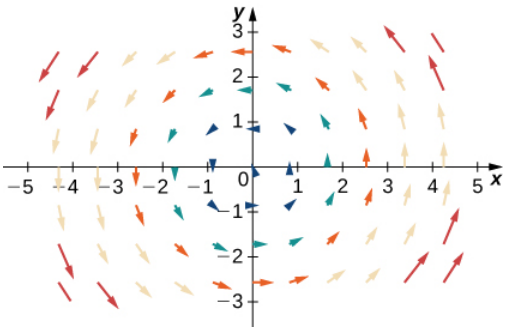
**For exercises 30 and 31, show that the given curve $\vec{\mathbf{c}}(t)$ is a flow line of the given velocity vector field $\vec{\mathbf{F}}(x,y,z)$.**

**30.** $\vec{\mathbf{c}}(t) = \langle e^{2t}, \ln|t|, \frac{1}{t}\rangle$, $t \neq 0$; $\quad \vec{\mathbf{F}}(x,y,z) = \langle 2x, z, -z^2\rangle$

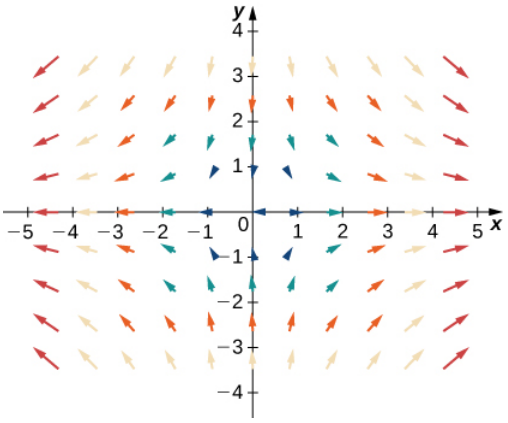
**31.** $\vec{\mathbf{c}}(t) = \langle \sin t, \cos t, e^t\rangle$; $\quad \vec{\mathbf{F}}(x,y,z) = \langle y, -x, z\rangle$

**For exercises 32 - 34, let $\vec{\mathbf{F}} = x\,\hat{\mathbf{i}} + y\,\hat{\mathbf{j}}$, $\vec{\mathbf{G}} = -y\,\hat{\mathbf{i}} + x\,\hat{\mathbf{j}}$, and $\vec{\mathbf{H}} = x\,\hat{\mathbf{i}} - y\,\hat{\mathbf{j}}$. Match $\vec{\mathbf{F}}$, $\vec{\mathbf{G}}$, and $\vec{\mathbf{H}}$ with their graphs.**

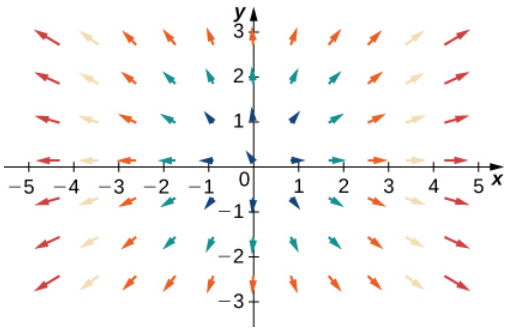
**32.**



**33.**



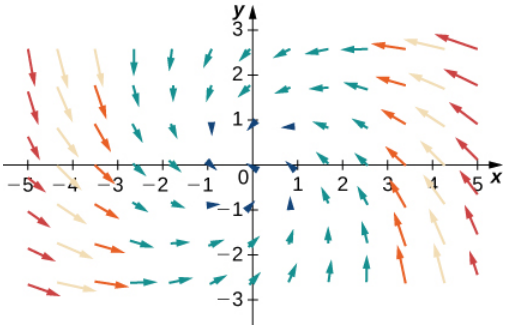
**34.**



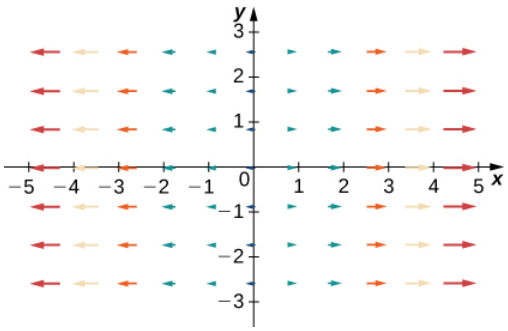
**For exercises 35 - 38, let $\vec{\mathbf{F}} = x\,\hat{\mathbf{i}} + y\,\hat{\mathbf{j}}$, $\vec{\mathbf{G}} = -y\,\hat{\mathbf{i}} + x\,\hat{\mathbf{j}}$, and $\vec{\mathbf{H}} = -x\,\hat{\mathbf{i}} + y\,\hat{\mathbf{j}}$. Match the vector fields with their graphs in (I)−(IV).**

a. $\vec{\mathbf{F}} + \vec{\mathbf{G}}$
b. $\vec{\mathbf{F}} + \vec{\mathbf{H}}$
c. $\vec{\mathbf{G}} + \vec{\mathbf{H}}$
d. $-\vec{\mathbf{F}} + \vec{\mathbf{G}}$

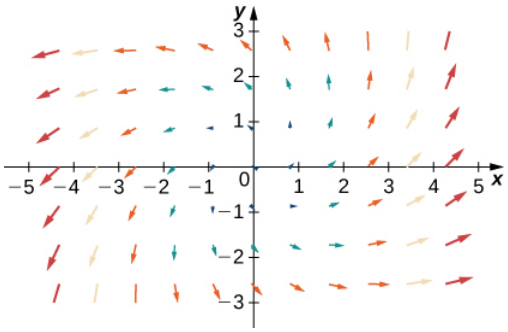
**35.**



**36.**



**37.**



**38.**

# 16.3: Line Integrals

**Learning Objectives**

- Calculate a scalar line integral along a curve.
- Calculate a vector line integral along an oriented curve in space.
- Use a line integral to compute the work done in moving an object along a curve in a vector field.
- Describe the flux and circulation of a vector field.

We are familiar with single-variable integrals of the form $\int_a^b f(x)\,dx$, where the domain of integration is an interval $[a, b]$. Such an interval can be thought of as a curve in the $xy$-plane, since the interval defines a line segment with endpoints $(a, 0)$ and $(b, 0)$—in other words, a line segment located on the $x$-axis. Suppose we want to integrate over *any* curve in the plane, not just over a line segment on the $x$-axis. Such a task requires a new kind of integral, called a *line integral.*

Line integrals have many applications to engineering and physics. They also allow us to make several useful generalizations of the Fundamental Theorem of Calculus. And, they are closely connected to the properties of vector fields, as we shall see.

## Scalar Line Integrals

A line integral gives us the ability to integrate multivariable functions and vector fields over arbitrary curves in a plane or in space. There are two types of line integrals: scalar line integrals and vector line integrals. Scalar line integrals are integrals of a scalar function over a curve in a plane or in space. Vector line integrals are integrals of a vector field over a curve in a plane or in space. Let's look at scalar line integrals first.

A scalar line integral is defined just as a single-variable integral is defined, except that for a scalar line integral, the integrand is a function of more than one variable and the domain of integration is a curve in a plane or in space, as opposed to a curve on the $x$-axis.

For a scalar line integral, we let $C$ be a smooth curve in a plane or in space and let $f$ be a function with a domain that includes $C$. We chop the curve into small pieces. For each piece, we choose point $P$ in that piece and evaluate $f$ at $P$. (We can do this because all the points in the curve are in the domain of $f$.) We multiply $f(P)$ by the arc length of the piece $\Delta s$, add the product $f(P)\Delta s$ over all the pieces, and then let the arc length of the pieces shrink to zero by taking a limit. The result is the scalar line integral of the function over the curve.

For a formal description of a scalar line integral, let $C$ be a smooth curve in space given by the parameterization $\vec{\mathbf{r}}(t) = \langle x(t), y(t), z(t)\rangle$, $a \le t \le b$. Let $f(x, y, z)$ be a function with a domain that includes curve $C$. To define the line integral of the function $f$ over $C$, we begin as most definitions of an integral begin: we chop the curve into small pieces. Partition the parameter interval $[a, b]$ into $n$ subintervals $[t_{i-1}, t_i]$ of equal width for $1 \le i \le n$, where $t_0 = a$ and $t_n = b$ (Figure 16.3.1). Let $t_i^*$ be a value in the $i^{th}$ interval $[t_{i-1}, t_i]$. Denote the endpoints of $\vec{\mathbf{r}}(t_0)$, $\vec{\mathbf{r}}(t_1)$,…, $\vec{\mathbf{r}}(t_n)$ by $P_0$,…, $P_n$. Points $P_i$ divide curve $C$ into $n$ pieces $C_1$, $C_2$,…, $C_n$,with lengths $\Delta s_1$, $\Delta s_2$,…, $\Delta s_n$, respectively. Let $P_i^*$ denote the endpoint of $\vec{\mathbf{r}}(t_i^*)$ for $1 \le i \le n$. Now, we evaluate the function $f$ at point $P_i^*$ for $1 \le i \le n$. Note that $P_i^*$ is in piece $C_1$, and therefore $P_i^*$ is in the domain of $f$. Multiply $f(P_i^*)$ by the length $\Delta s_1$ of $C_1$, which gives the area of the "sheet" with base $C_1$, and height $f(P_i^*)$. This is analogous to using rectangles to approximate area in a single-variable integral. Now, we form the sum $\sum_{i=1}^{n} f(P_i^*)\,\Delta s_i$.

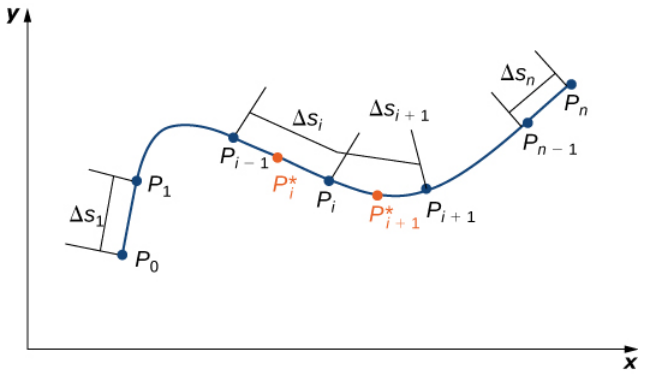

Figure 16.3.1: Curve $C$ has been divided into n pieces, and a point inside each piece has been chosen.

Note the similarity of this sum versus a Riemann sum; in fact, this definition is a generalization of a Riemann sum to arbitrary curves in space. Just as with Riemann sums and integrals of form $\int_a^b g(x)\,dx$, we define an integral by letting the width of the pieces of the curve shrink to zero by taking a limit. The result is the scalar line integral of $f$ along $C$.

You may have noticed a difference between this definition of a scalar line integral and a single-variable integral. In this definition, the arc lengths $\Delta s_1$, $\Delta s_2$,…, $\Delta s_n$ aren't necessarily the same; in the definition of a single-variable integral, the curve in the $x$-axis is partitioned into pieces of equal length. This difference does not have any effect in the limit. As we shrink the arc lengths to zero, their values become close enough that any small difference becomes irrelevant.

**DEFINITION: Scalar Line Integral**

Let $f$ be a function with a domain that includes the smooth curve $C$ that is parameterized by $\vec{\mathbf{r}}(t) = \langle x(t), y(t), z(t)\rangle$, $a \le t \le b$. The *scalar line integral* of $f$ along $C$ is

$$\int_C f(x,y,z)\,ds = \lim_{n\to\infty} \sum_{i=1}^{n} f(P_i^*)\,\Delta s_i \tag{16.3.1}$$

if this limit exists ($t_i^*$ and $\Delta s_i$ are defined as in the previous paragraphs). If $C$ is a planar curve, then $C$ can be represented by the parametric equations $x = x(t)$, $y = y(t)$, and $a \le t \le b$. If $C$ is smooth and $f(x,y)$ is a function of two variables, then the scalar line integral of $f$ along $C$ is defined similarly as

$$\int_C f(x,y)\,ds = \lim_{n\to\infty} \sum_{i=1}^{n} f(P_i^*)\,\Delta s_i, \tag{16.3.2}$$

if this limit exists.

If $f$ is a continuous function on a smooth curve $C$, then $\int_C f\,ds$ always exists. Since $\int_C f\,ds$ is defined as a limit of Riemann sums, the continuity of $f$ is enough to guarantee the existence of the limit, just as the integral $\int_a^b g(x)\,dx$ exists if $g$ is continuous over $[a,b]$.

Before looking at how to compute a line integral, we need to examine the geometry captured by these integrals. Suppose that $f(x,y) \ge 0$ for all points $(x,y)$ on a smooth planar curve $C$. Imagine taking curve $C$ and projecting it "up" to the surface defined by $f(x,y)$, thereby creating a new curve $C'$ that lies in the graph of $f(x,y)$ (Figure 16.3.2). Now we drop a "sheet" from $C'$ down to the $xy$-plane. The area of this sheet is $\int_C f(x,y)ds$. If $f(x,y) \le 0$ for some points in $C$, then the value of $\int_C f(x,y)\,ds$ is the area above the $xy$-plane less the area below the $xy$-plane. (Note the similarity with integrals of the form $\int_a^b g(x)\,dx$.)

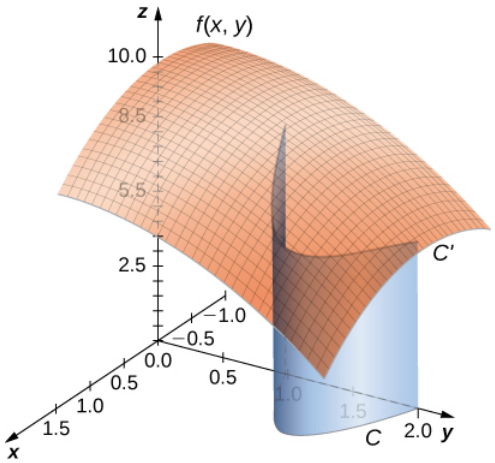

Figure **16.3.2**: The area of the blue sheet is $\int_C f(x,y)\,ds$.

From this geometry, we can see that line integral $\int_C f(x,y)\,ds$ does not depend on the parameterization $\vec{\mathbf{r}}(t)$ of $C$. As long as the curve is traversed exactly once by the parameterization, the area of the sheet formed by the function and the curve is the same. This same kind of geometric argument can be extended to show that the line integral of a three-variable function over a curve in space does not depend on the parameterization of the curve.

### Example 16.3.1: Finding the Value of a Line Integral

Find the value of integral $\int_C 2\,ds$, where $C$ is the upper half of the unit circle.

**Solution**

The integrand is $f(x,y) = 2$. Figure **16.3.3** shows the graph of $f(x,y) = 2$, curve $C$, and the sheet formed by them. Notice that this sheet has the same area as a rectangle with width $\pi$ and length $2$. Therefore, $\int_C 2\,ds = 2\pi$ units$^2$.

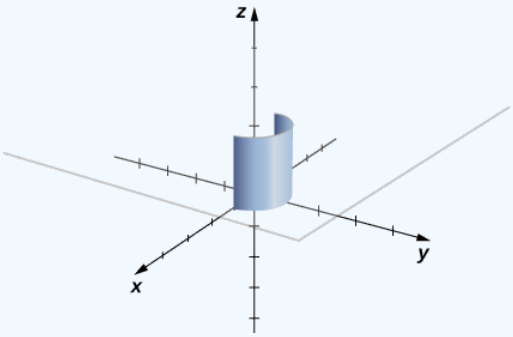

Figure **16.3.3**: The sheet that is formed by the upper half of the unit circle in a plane and the graph of $f(x,y) = 2$.

To see that $\int_C 2\,ds = 2\pi$ using the definition of line integral, we let $\vec{\mathbf{r}}(t)$ be a parameterization of $C$. Then, $f(\vec{\mathbf{r}}(t_i)) = 2$ for any number $t_i$ in the domain of $\vec{\mathbf{r}}$. Therefore,

$$\begin{aligned}\int_C f\,ds &= \lim_{n\to\infty}\sum_{i=1}^{n} f(\vec{\mathbf{r}}(t_i^*))\,\Delta s_i \\ &= \lim_{n\to\infty}\sum_{i=1}^{n} 2\,\Delta s_i \\ &= 2\lim_{n\to\infty}\sum_{i=1}^{n} \Delta s_i \\ &= 2(\text{length of } C) \\ &= 2\pi \text{ units}^2.\end{aligned}$$

**? Exercise 16.3.1**

Find the value of $\int_C (x+y)\,ds$, where $C$ is the curve parameterized by $x=t$, $y=t$, $0 \le t \le 1$.

**Hint**

Find the shape formed by $C$ and the graph of function $f(x,y)=x+y$.

**Answer**

$\sqrt{2}$

Note that in a scalar line integral, the integration is done with respect to arc length $s$, which can make a scalar line integral difficult to calculate. To make the calculations easier, we can translate $\int_C f\,ds$ to an integral with a variable of integration that is $t$.

Let $\vec{\mathbf{r}}(t)=\langle x(t),y(t),z(t)\rangle$ for $a \le t \le b$ be a parameterization of $C$. Since we are assuming that $C$ is smooth, $\vec{\mathbf{r}}\,'(t)=\langle x'(t),y'(t),z'(t)\rangle$ is continuous for all $t$ in $[a,b]$. In particular, $x'(t)$, $y'(t)$, and $z'(t)$ exist for all $t$ in $[a,b]$. According to the arc length formula, we have

$$\text{length}(C_i)=\Delta s_i=\int_{t_{i-1}}^{t_i}\|\vec{\mathbf{r}}\,'(t)\|\,dt.$$

If width $\Delta t_i=t_i-t_{i-1}$ is small, then function $\int_{t_{i-1}}^{t_i}\|\vec{\mathbf{r}}\,'(t)\|\,dt \approx \|\vec{\mathbf{r}}\,'(t_i^*)\|\,\Delta t_i$, $\|\vec{\mathbf{r}}\,'(t)\|$ is almost constant over the interval $[t_{i-1},t_i]$.Therefore,

$$\int_{t_{i-1}}^{t_i}\|\vec{\mathbf{r}}\,'(t)\|\,dt \approx \|\vec{\mathbf{r}}\,'(t_i^*)\|\,\Delta t_i, \tag{16.3.3}$$

and we have

$$\sum_{i=1}^{n} f(\vec{\mathbf{r}}(t_i^*))\,\Delta s_i \approx \sum_{i=1}^{n} f(\vec{\mathbf{r}}(t_i^*))\|\vec{\mathbf{r}}\,'(t_i^*)\|\,\Delta t_i.$$

See Figure 16.3.4.

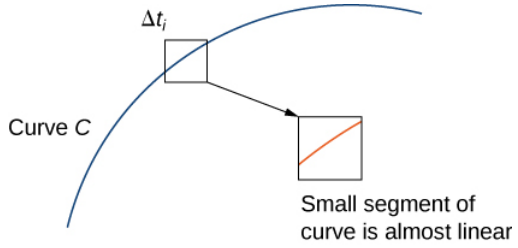

Figure 16.3.4: If we zoom in on the curve enough by making $\Delta t_i$ very small, then the corresponding piece of the curve is approximately linear.

Note that

$$\lim_{n\to\infty}\sum_{i=1}^{n} f(\vec{\mathbf{r}}(t_i^*))\|\vec{\mathbf{r}}\,'(t_i^*)\|\,\Delta t_i=\int_a^b f(\vec{\mathbf{r}}(t))\|\vec{\mathbf{r}}\,'(t)\|\,dt.$$

In other words, as the widths of intervals $[t_{i-1},t_i]$ shrink to zero, the sum $\sum_{i=1}^{n} f(\vec{\mathbf{r}}(t_i^*))\|\vec{\mathbf{r}}\,'(t_i^*)\|\,\Delta t_i$ converges to the integral $\int_a^b f(\vec{\mathbf{r}}(t))\|\vec{\mathbf{r}}\,'(t)\|\,dt$. Therefore, we have the following theorem.

**Theorem: Evaluating a Scalar Line Integral**

Let $f$ be a continuous function with a domain that includes the smooth curve $C$ with parameterization $\vec{\mathbf{r}}(t)$, $a \le t \le b$. Then

$$\int_C f\,ds = \int_a^b f(\vec{\mathbf{r}}(t))\|\vec{\mathbf{r}}'(t)\|\,dt. \tag{16.3.4}$$

Although we have labeled Equation 16.3.3 as an equation, it is more accurately considered an approximation because we can show that the left-hand side of Equation 16.3.3 approaches the right-hand side as $n \to \infty$. In other words, letting the widths of the pieces shrink to zero makes the right-hand sum arbitrarily close to the left-hand sum. Since

$$\|\vec{\mathbf{r}}'(t)\| = \sqrt{(x'(t))^2 + (y'(t))^2 + (z'(t))^2},$$

we obtain the following theorem, which we use to compute scalar line integrals.

**Theorem: Scalar Line Integral Calculation**

Let $f$ be a continuous function with a domain that includes the smooth curve $C$ with parameterization $\vec{\mathbf{r}}(t) = \langle x(t), y(t), z(t)\rangle$, $a \le t \le b$. Then

$$\int_C f(x,y,z)\,ds = \int_a^b f(\vec{\mathbf{r}}(t))\sqrt{(x'(t))^2 + (y'(t))^2 + (z'(t))^2}\,dt.$$

Similarly,

$$\int_C f(x,y)\,ds = \int_a^b f(\vec{\mathbf{r}}(t))\sqrt{(x'(t))^2 + (y'(t))^2}\,dt$$

if $C$ is a planar curve and $f$ is a function of two variables.

Note that a consequence of this theorem is the equation $ds = \|\vec{\mathbf{r}}'(t)\|\,dt$. In other words, the change in arc length can be viewed as a change in the $t$-domain, scaled by the magnitude of vector $\vec{\mathbf{r}}'(t)$.

**Example 16.3.2: Evaluating a Line Integral**

Find the value of integral $\int_C (x^2 + y^2 + z)\,ds$, where $C$ is part of the helix parameterized by $\vec{\mathbf{r}}(t) = \langle \cos t, \sin t, t\rangle$, $0 \le t \le 2\pi$.

**Solution**

To compute a scalar line integral, we start by converting the variable of integration from arc length $s$ to $t$. Then, we can use Equation 16.3.1 to compute the integral with respect to $t$. Note that

$$f(\vec{\mathbf{r}}(t)) = \cos^2 t + \sin^2 t + t = 1 + t$$

and

$$\sqrt{(x'(t))^2 + (y'(t))^2 + (z'(t))^2} = \sqrt{(-\sin(t))^2 + \cos^2(t) + 1} = \sqrt{2}.$$

Therefore,

$$\int_C (x^2 + y^2 + z)\,ds = \int_0^{2\pi} (1 + t)\sqrt{2}\,dt.$$

Notice that Equation 16.3.1 translated the original difficult line integral into a manageable single-variable integral. Since

$$\begin{aligned}\int_0^{2\pi} (1 + t)\sqrt{2}\,dt &= \left[\sqrt{2}t + \frac{\sqrt{2}t^2}{2}\right]_0^{2\pi} \\ &= 2\sqrt{2}\pi + 2\sqrt{2}\pi^2,\end{aligned}$$

we have

$$\int_C (x^2+y^2+z)\,ds = 2\sqrt{2}\pi + 2\sqrt{2}\pi^2.$$

**? Exercise 16.3.2**

Evaluate $\int_C (x^2+y^2+z)ds$, where $C$ is the curve with parameterization $\vec{\mathbf{r}}(t) = \langle \sin(3t), \cos(3t)\rangle$, $0 \le t \le \frac{\pi}{4}$.

**Hint**

Use the two-variable version of scalar line integral definition (Equation 16.3.2).

**Answer**

$$\frac{1}{3} + \frac{\sqrt{2}}{6} + \frac{3\pi}{4}$$

**✓ Example 16.3.3: Independence of Parameterization**

Find the value of integral $\int_C (x^2+y^2+z)\,ds$, where $C$ is part of the helix parameterized by $\vec{\mathbf{r}}(t) = \langle \cos(2t), \sin(2t), 2t\rangle$, $0 \le t \le \pi$. Notice that this function and curve are the same as in the previous example; the only difference is that the curve has been reparameterized so that time runs twice as fast.

**Solution**

As with the previous example, we use Equation 16.3.1 to compute the integral with respect to $t$. Note that $f(\vec{\mathbf{r}}(t)) = \cos^2(2t) + \sin^2(2t) + 2t = 2t + 1$ and

$$\begin{aligned}\sqrt{(x'(t))^2 + (y'(t))^2 + (z'(t))^2} &= \sqrt{(-\sin t + \cos t + 4)} \\ &= 22\end{aligned}$$

so we have

$$\begin{aligned}\int_C (x^2+y^2+z)ds &= 2\sqrt{2}\int_0^{\pi} (1+2t)dt \\ &= 2\sqrt{2}\left[t+t^2\right]_0^{\pi} \\ &= 2\sqrt{2}(\pi+\pi^2).\end{aligned}$$

Notice that this agrees with the answer in the previous example. Changing the parameterization did not change the value of the line integral. Scalar line integrals are independent of parameterization, as long as the curve is traversed exactly once by the parameterization.

**? Exercise 16.3.3**

Evaluate line integral $\int_C (x^2+yz)\,ds$, where $C$ is the line with parameterization $\vec{\mathbf{r}}(t) = \langle 2t, 5t, -t\rangle$, $0 \le t \le 10$. Reparameterize $C$ with parameterization $s(t) = \langle 4t, 10t, -2t\rangle$, $0 \le t \le 5$, recalculate line integral $\int_C (x^2+yz)\,ds$, and notice that the change of parameterization had no effect on the value of the integral.

**Hint**

Use Equation 16.3.1.

**Answer**

Both line integrals equal $-\frac{1000\sqrt{30}}{3}$.

Now that we can evaluate line integrals, we can use them to calculate arc length. If $f(x,y,z)=1$, then

$$\begin{aligned}\int_C f(x,y,z)\,ds &= \lim_{n\to\infty}\sum_{i=1}^{n} f(t_i^*)\,\Delta s_i \\ &= \lim_{n\to\infty}\sum_{i=1}^{n}\Delta s_i \\ &= \lim_{n\to\infty}\text{length}(C) \\ &= \text{length}(C).\end{aligned}$$

Therefore, $\int_C 1\,ds$ is the arc length of $C$.

**Example 16.3.4: Calculating Arc Length**

A wire has a shape that can be modeled with the parameterization $\vec{\mathbf{r}}(t)=\langle\cos t,\sin t,\frac{2}{3}t^{3/2}\rangle$, $0\le t\le 4\pi$. Find the length of the wire.

**Solution**

The length of the wire is given by $\int_C 1\,ds$, where $C$ is the curve with parameterization $\vec{\mathbf{r}}$. Therefore,

$$\begin{aligned}\text{The length of the wire} &= \int_C 1\,ds \\ &= \int_0^{4\pi}||\vec{\mathbf{r}}'(t)||\,dt \\ &= \int_0^{4\pi}\sqrt{(-\sin t)^2+\cos^2 t+t}dt \\ &= \int_0^{4\pi}\sqrt{1+t}dt \\ &= \frac{2(1+t)^{\frac{3}{2}}}{3}\Bigg|_0^{4\pi} \\ &= \frac{2}{3}\left((1+4\pi)^{3/2}-1\right).\end{aligned}$$

**Exercise 16.3.4**

Find the length of a wire with parameterization $\vec{\mathbf{r}}(t)=\langle 3t+1,4-2t,5+2t\rangle$, $0\le t\le 4$.

**Hint**

Find the line integral of one over the corresponding curve.

**Answer**

$4\sqrt{17}$

## Vector Line Integrals

The second type of line integrals are vector line integrals, in which we integrate along a curve through a vector field. For example, let

$$\vec{\mathbf{F}}(x,y,z)=P(x,y,z)\,\hat{\mathbf{i}}+Q(x,y,z)\,\hat{\mathbf{j}}+R(x,y,z)\,\hat{\mathbf{k}}$$

be a continuous vector field in $\mathbb{R}^3$ that represents a force on a particle, and let $C$ be a smooth curve in $\mathbb{R}^3$ contained in the domain of $\vec{\mathbf{F}}$. How would we compute the work done by $\vec{\mathbf{F}}$ in moving a particle along $C$?

To answer this question, first note that a particle could travel in two directions along a curve: a forward direction and a backward direction. The work done by the vector field depends on the direction in which the particle is moving. Therefore, we must specify a direction along curve $C$; such a specified direction is called an orientation of a curve. The specified direction is the positive direction along $C$; the opposite direction is the negative direction along $C$. When $C$ has been given an orientation, $C$ is called an oriented curve (Figure 16.3.5). The work done on the particle depends on the direction along the curve in which the particle is moving.

A closed curve is one for which there exists a parameterization $\vec{\mathbf{r}}(t)$, $a \le t \le b$, such that $\vec{\mathbf{r}}(a) = \vec{\mathbf{r}}(b)$, and the curve is traversed exactly once. In other words, the parameterization is one-to-one on the domain $(a, b)$.

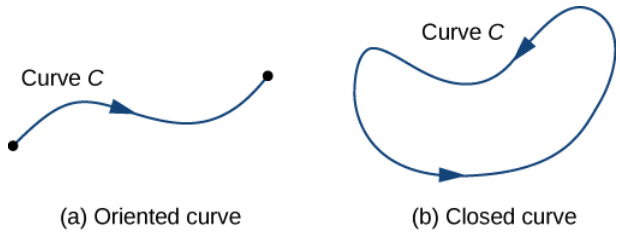

Figure 16.3.5: (a) An oriented curve between two points. (b) A closed oriented curve.

Let $\vec{\mathbf{r}}(t)$ be a parameterization of $C$ for $a \le t \le b$ such that the curve is traversed exactly once by the particle and the particle moves in the positive direction along $C$. Divide the parameter interval $[a, b]$ into n subintervals $[t_{i-1}, t_i]$, $0 \le i \le n$, of equal width. Denote the endpoints of $r(t_0)$, $r(t_1)$,…, $r(t_n)$ by $P_0$,…,$P_n$. Points $P_i$ divide $C$ into n pieces. Denote the length of the piece from $P_{i-1}$ to $P_i$ by $\Delta s_i$. For each $i$, choose a value $t_i^*$ in the subinterval $[t_{i-1}, t_i]$. Then, the endpoint of $\vec{\mathbf{r}}(t_i^*)$ is a point in the piece of $C$ between $P_{i-1}$ and $P_i$ (Figure 16.3.6). If $\Delta s_i$ is small, then as the particle moves from $P_{i-1}$ to $P_i$ along $C$, it moves approximately in the direction of $\vec{\mathbf{T}}(P_i)$, the unit tangent vector at the endpoint of $\vec{\mathbf{r}}(t_i^*)$. Let $P_i^*$ denote the endpoint of $\vec{\mathbf{r}}(t_i^*)$. Then, the work done by the force vector field in moving the particle from $P_{i-1}$ to $P_i$ is $\vec{\mathbf{F}}(P_i^*) \cdot (\Delta s_i \vec{\mathbf{T}}(P_i^*))$, so the total work done along $C$ is

$$\sum_{i=1}^{n} \vec{\mathbf{F}}(P_i^*) \cdot (\Delta s_i \vec{\mathbf{T}}(P_i^*)) = \sum_{i=1}^{n} \vec{\mathbf{F}}(P_i^*) \cdot \vec{\mathbf{T}}(P_i^*)\, \Delta s_i.$$

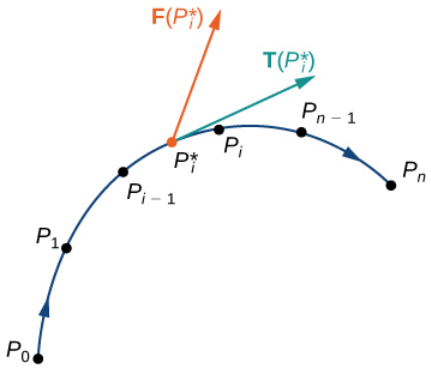

Figure 16.3.6: Curve $C$ is divided into n pieces, and a point inside each piece is chosen. The dot product of any tangent vector in the ith piece with the corresponding vector $\vec{\mathbf{F}}$ is approximated by $\vec{\mathbf{F}}(P_i^*) \cdot \vec{\mathbf{T}}(P_i^*)$.

Letting the arc length of the pieces of $C$ get arbitrarily small by taking a limit as $n \to \infty$ gives us the work done by the field in moving the particle along $C$. Therefore, the work done by $\vec{\mathbf{F}}$ in moving the particle in the positive direction along $C$ is defined as

$$W = \int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, ds,$$

which gives us the concept of a vector line integral.

**DEFINITION: Line Integral of a Vector Field**

The vector line integral of vector field $\vec{\mathbf{F}}$ along oriented smooth curve $C$ is

$$\int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, ds = \lim_{n \to \infty} \sum_{i=1}^{n} \vec{\mathbf{F}}(P_i^*) \cdot \vec{\mathbf{T}}(P_i^*) \Delta s_i$$

if that limit exists.

With scalar line integrals, neither the orientation nor the parameterization of the curve matters. As long as the curve is traversed exactly once by the parameterization, the value of the line integral is unchanged. With vector line integrals, the orientation of the curve does matter. If we think of the line integral as computing work, then this makes sense: if you hike up a mountain, then the gravitational force of Earth does negative work on you. If you walk down the mountain by the exact same path, then Earth's gravitational force does positive work on you. In other words, reversing the path changes the work value from negative to positive in this case. Note that if $C$ is an oriented curve, then we let $-C$ represent the same curve but with opposite orientation.

As with scalar line integrals, it is easier to compute a vector line integral if we express it in terms of the parameterization function $\vec{\mathbf{r}}$ and the variable $t$. To translate the integral $\int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{T}} ds$ in terms of $t$, note that unit tangent vector $\vec{\mathbf{T}}$ along $C$ is given by $\vec{\mathbf{T}} = \dfrac{\vec{\mathbf{r}}'(t)}{\|\vec{\mathbf{r}}'(t)\|}$ (assuming $\|\vec{\mathbf{r}}'(t)\| \neq 0$). Since $ds = \|\vec{\mathbf{r}}'(t)\|\, dt$, as we saw when discussing scalar line integrals, we have

$$\vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, ds = \vec{\mathbf{F}}(\vec{\mathbf{r}}(t)) \cdot \frac{\vec{\mathbf{r}}'(t)}{\|\vec{\mathbf{r}}'(t)\|} \|\vec{\mathbf{r}}'(t)\| dt = \vec{\mathbf{F}}(\vec{\mathbf{r}}(t)) \cdot \vec{\mathbf{r}}'(t)\, dt.$$

Thus, we have the following formula for computing vector line integrals:

$$\int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, ds = \int_a^b \vec{\mathbf{F}}(\vec{\mathbf{r}}(t)) \cdot \vec{\mathbf{r}}'(t)\, dt. \tag{16.3.5}$$

Because of Equation 16.3.5, we often use the notation $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$ for the line integral $\int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, ds$.

If $\vec{\mathbf{r}}(t) = \langle x(t), y(t), z(t) \rangle$, then $\dfrac{d\vec{\mathbf{r}}}{dt}$ denotes vector $\langle x'(t), y'(t), z'(t) \rangle$, and $d\vec{\mathbf{r}} = \vec{\mathbf{r}}'(t)\, dt$.

### Example 16.3.5: Evaluating a Vector Line Integral

Find the value of integral $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$, where $C$ is the semicircle parameterized by $\vec{\mathbf{r}}(t) = \langle \cos t, \sin t \rangle$, $0 \leq t \leq \pi$ and $\vec{\mathbf{F}} = \langle -y, x \rangle$.

**Solution**

We can use Equation 16.3.5 to convert the variable of integration from $s$ to $t$. We then have

$$\vec{\mathbf{F}}(\vec{\mathbf{r}}(t)) = \langle -\sin t, \cos t \rangle \text{ and } \vec{\mathbf{r}}'(t) = \langle -\sin t, \cos t \rangle.$$

Therefore,

$$\begin{aligned} \int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} &= \int_0^\pi \langle -\sin t, \cos t \rangle \cdot \langle -\sin t, \cos t \rangle\, dt \\ &= \int_0^\pi \sin^2 t + \cos^2 t\, dt \\ &= \int_0^\pi 1\, dt = \pi. \end{aligned}$$

See Figure 16.3.7.

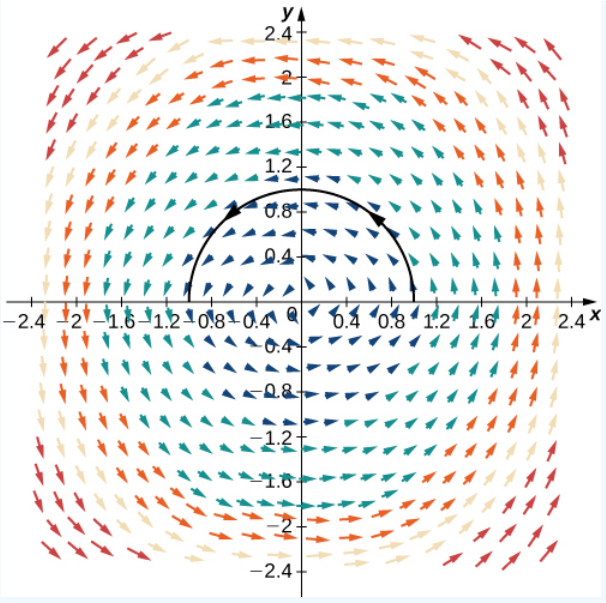

Figure 16.3.7: This figure shows curve $\vec{\mathbf{r}}(t) = \langle \cos t, \sin t \rangle$, $0 \le t \le \pi$ in vector field $\vec{\mathbf{F}} = \langle -y, x \rangle$.

### Example 16.3.6: Reversing Orientation

Find the value of integral $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$, where $C$ is the semicircle parameterized by $\vec{\mathbf{r}}(t) = \langle \cos(t + \pi), \sin t \rangle$, $0 \le t \le \pi$ and $\vec{\mathbf{F}} = \langle -y, x \rangle$.

**Solution**

Notice that this is the same problem as Example 16.3.5, except the orientation of the curve has been traversed. In this example, the parameterization starts at $\vec{\mathbf{r}}(0) = \langle -1, 0 \rangle$ and ends at $\vec{\mathbf{r}}(\pi) = \langle 1, 0 \rangle$. By Equation 16.3.5,

$$\begin{aligned} \int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} &= \int_0^\pi \langle -\sin t, \cos(t+\pi) \rangle \cdot \langle -\sin(t+\pi), \cos t \rangle dt \\ &= \int_0^\pi \langle -\sin t, -\cos t \rangle \cdot \langle \sin t, \cos t \rangle dt \\ &= \int_0^\pi (-\sin^2 t - \cos^2 t) dt \\ &= \int_0^\pi -1 dt \\ &= -\pi. \end{aligned}$$

Notice that this is the negative of the answer in Example 16.3.5. It makes sense that this answer is negative because the orientation of the curve goes against the "flow" of the vector field.

Let $C$ be an oriented curve and let $-C$ denote the same curve but with the orientation reversed. Then, the previous two examples illustrate the following fact:

$$\int_{-C} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = -\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}.$$

That is, reversing the orientation of a curve changes the sign of a line integral.

### Exercise 16.3.6

Let $\vec{\mathbf{F}} = x\,\hat{\mathbf{i}} + y\,\hat{\mathbf{j}}$ be a vector field and let $C$ be the curve with parameterization $\langle t, t^2 \rangle$ for $0 \le t \le 2$. Which is greater: $\int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, ds$ or $\int_{-C} \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, ds$?

**Hint**

Imagine moving along the path and computing the dot product $\vec{\mathbf{F}} \cdot \vec{\mathbf{T}}$ as you go.

**Answer**

$$\int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, ds$$

Another standard notation for integral $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$ is $\int_C P\, dx + Q\, dy + R\, dz$. In this notation, $P$, $Q$, and $R$ are functions, and we think of $d\vec{\mathbf{r}}$ as vector $\langle dx, dy, dz \rangle$. To justify this convention, recall that $d\vec{\mathbf{r}} = \vec{\mathbf{T}}\, ds = \vec{\mathbf{r}}'(t)\, dt = \left\langle \frac{dx}{dt}, \frac{dy}{dt}, \frac{dz}{dt} \right\rangle dt$. Therefore,

$$\vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \langle P, Q, R \rangle \cdot \langle dx, dy, dz \rangle = P\, dx + Q\, dy + R\, dz.$$

If $d\vec{\mathbf{r}} = \langle dx, dy, dz \rangle$, then $\frac{d\mathbf{r}}{dt} = \left\langle \frac{dx}{dt}, \frac{dy}{dt}, \frac{dz}{dt} \right\rangle$, which implies that $d\vec{\mathbf{r}} = \left\langle \frac{dx}{dt}, \frac{dy}{dt}, \frac{dz}{dt} \right\rangle dt$. Therefore

$$\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \int_C P\, dx + Q\, dy + R\, dz \tag{16.3.6}$$

$$= \int_a^b \left( P\big(\vec{\mathbf{r}}(t)\big) \frac{dx}{dt} + Q\big(\vec{\mathbf{r}}(t)\big) \frac{dy}{dt} + R\big(\vec{\mathbf{r}}(t)\big) \frac{dz}{dt} \right) dt. \tag{16.3.7}$$

### Example 16.3.7: Finding the Value of an Integral of the Form $\int_C P\, dx + Q\, dy + R\, dz$

Find the value of integral $\int_C z\, dx + x\, dy + y\, dz$, where $C$ is the curve parameterized by $\vec{\mathbf{r}}(t) = \langle t^2, \sqrt{t}, t \rangle$, $1 \le t \le 4$.

**Solution**

As with our previous examples, to compute this line integral we should perform a change of variables to write everything in terms of $t$. In this case, Equation 16.3.7 allows us to make this change:

$$\begin{aligned} \int_C z\, dx + x\, dy + y\, dz &= \int_1^4 \left( t(2t) + t^2 \left( \frac{1}{2\sqrt{t}} \right) + \sqrt{t} \right) dt \\ &= \int_1^4 \left( 2t^2 + \frac{t^{3/2}}{2} + \sqrt{t} \right) dt \\ &= \left[ \frac{2t^3}{3} + \frac{t^{5/2}}{5} + \frac{2t^{3/2}}{3} \right]_{t=1}^{t=4} \\ &= \frac{793}{15}. \end{aligned}$$

### Exercise 16.3.7

Find the value of $\int_C 4x\, dx + z\, dy + 4y^2\, dz$, where $C$ is the curve parameterized by $\vec{\mathbf{r}}(t) = \langle 4\cos(2t), 2\sin(2t), 3 \rangle$, $0 \le t \le \frac{\pi}{4}$.

**Hint**

Write the integral in terms of $t$ using Equation 16.3.7.

**Answer**

$-26$

We have learned how to integrate smooth oriented curves. Now, suppose that $C$ is an oriented curve that is not smooth, but can be written as the union of finitely many smooth curves. In this case, we say that $C$ is a piecewise smooth curve. To be precise, curve $C$ is piecewise smooth if $C$ can be written as a union of n smooth curves $C_1$, $C_2$,…, $C_n$ such that the endpoint of $C_i$ is the starting point of $C_{i+1}$ (Figure 16.3.8). When curves $C_i$ satisfy the condition that the endpoint of $C_i$ is the starting point of $C_{i+1}$, we write their union as $C_1 + C_2 + \cdots + C_n$.

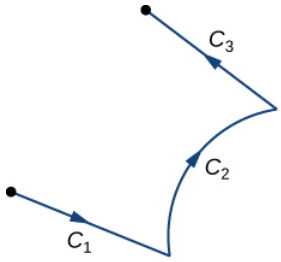

Figure **16.3.8**: The union of $C_1$, $C_2$, $C_3$ is a piecewise smooth curve.

The next theorem summarizes several key properties of vector line integrals.

**Theorem: Properties of Vector Line Integrals**

Let $\vec{\mathbf{F}}$ and $\vec{\mathbf{G}}$ be continuous vector fields with domains that include the oriented smooth curve $C$. Then

1. $\displaystyle\int_C (\vec{\mathbf{F}} + \vec{\mathbf{G}}) \cdot d\vec{\mathbf{r}} = \int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} + \int_C \vec{\mathbf{G}} \cdot d\vec{\mathbf{r}}$
2. $\displaystyle\int_C k\vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = k\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$, where $k$ is a constant
3. $\displaystyle\int_{-C} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = -\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$
4. Suppose instead that $C$ is a piecewise smooth curve in the domains of $\vec{\mathbf{F}}$ and $\vec{\mathbf{G}}$, where $C = C_1 + C_2 + \cdots + C_n$ and $C_1, C_2, \ldots, C_n$ are smooth curves such that the endpoint of $C_i$ is the starting point of $C_{i+1}$. Then

$$\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \int_{C_1} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} + \int_{C_2} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} + \cdots + \int_{C_n} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}.$$

Notice the similarities between these items and the properties of single-variable integrals. Properties i. and ii. say that line integrals are linear, which is true of single-variable integrals as well. Property iii. says that reversing the orientation of a curve changes the sign of the integral. If we think of the integral as computing the work done on a particle traveling along $C$, then this makes sense. If the particle moves backward rather than forward, then the value of the work done has the opposite sign. This is analogous to the equation $\displaystyle\int_a^b f(x)\,dx = -\int_b^a f(x)\,dx$. Finally, if $[a_1, a_2]$, $[a_2, a_3]$,…, $[a_{n-1}, a_n]$ are intervals, then

$$\int_{a_1}^{a_n} f(x)\,dx = \int_{a_1}^{a_2} f(x)\,dx + \int_{a_1}^{a_3} f(x)\,dx + \cdots + \int_{a_{n-1}}^{a_n} f(x)\,dx,$$

which is analogous to property iv.

**Example 16.3.8: Using Properties to Compute a Vector Line Integral**

Find the value of integral $\displaystyle\int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\,ds$, where $C$ is the rectangle (oriented counterclockwise) in a plane with vertices $(0,0)$, $(2,0)$, $(2,1)$, and $(0,1)$, and where $\vec{\mathbf{F}} = \langle x - 2y, y - x\rangle$ (Figure 16.3.9).

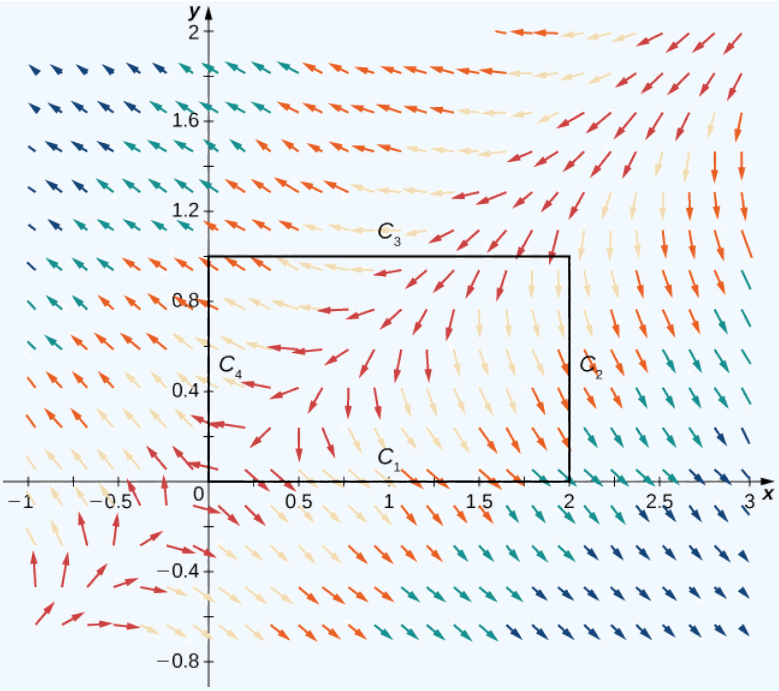

Figure **16.3.9**: Rectangle and vector field for Example **16.3.8**.

### Solution

Note that curve $C$ is the union of its four sides, and each side is smooth. Therefore $C$ is piecewise smooth. Let $C_1$ represent the side from $(0,0)$ to $(2,0)$, let $C_2$ represent the side from $(2,0)$ to $(2,1)$, let $C_3$ represent the side from $(2,1)$ to $(0,1)$, and let $C_4$ represent the side from $(0,1)$ to $(0,0)$ (Figure **16.3.9**). Then,

$$\int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, dr = \int_{C_1} \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, dr + \int_{C_2} \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, dr + \int_{C_3} \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, dr + \int_{C_4} \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, dr.$$

We want to compute each of the four integrals on the right-hand side using Equation **16.3.1**. Before doing this, we need a parameterization of each side of the rectangle. Here are four parameterizations (note that they traverse $C$ counterclockwise):

$$\begin{aligned} C_1 &: \langle t, 0\rangle, 0 \le t \le 2 \\ C_2 &: \langle 2, t\rangle, 0 \le t \le 1 \\ C_3 &: \langle 2-t, 1\rangle, 0 \le t \le 2 \\ C_4 &: \langle 0, 1-t\rangle, 0 \le t \le 1. \end{aligned}$$

Therefore,

$$\begin{aligned} \int_{C_1} \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, dr &= \int_0^2 \vec{\mathbf{F}}(\vec{\mathbf{r}}(t)) \cdot \vec{\mathbf{r}}'(t)\, dt \\ &= \int_0^2 \langle t - 2(0), 0 - t\rangle \cdot \langle 1, 0\rangle\, dt = \int_0^2 t\, dt \\ &= \left[\tfrac{t^2}{2}\right]_0^2 = 2. \end{aligned}$$

Notice that the value of this integral is positive, which should not be surprising. As we move along curve $C_1$ from left to right, our movement flows in the general direction of the vector field itself. At any point along $C_1$, the tangent vector to the curve and the corresponding vector in the field form an angle that is less than 90°. Therefore, the tangent vector and the force vector have a positive dot product all along $C_1$, and the line integral will have positive value.

The calculations for the three other line integrals are done similarly:

$$\int_{C_2} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \int_0^1 \langle 2-2t, t-2\rangle \cdot \langle 0,1\rangle \, dt$$
$$= \int_0^1 (t-2)\, dt$$
$$= \left[\tfrac{t^2}{2} - 2t\right]_0^1 = -\frac{3}{2},$$

$$\int_{C_3} \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, ds = \int_0^2 \langle (2-t)-2, 1-(2-t)\rangle \cdot \langle -1,0\rangle \, dt$$
$$= \int_0^2 t\, dt = 2,$$

and

$$\int_{C_4} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \int_0^1 \langle -2(1-t), 1-t\rangle \cdot \langle 0,-1\rangle \, dt$$
$$= \int_0^1 (t-1)\, dt$$
$$= \left[\tfrac{t^2}{2} - t\right]_0^1 = -\frac{1}{2}.$$

Thus, we have $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = 2$.

**? Exercise 16.3.8**

Calculate line integral $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$, where $\vec{\mathbf{F}}$ is vector field $\langle y^2, 2xy+1\rangle$ and $C$ is a triangle with vertices $(0,0)$, $(4,0)$, and $(0,5)$, oriented counterclockwise.

**Hint**

Write the triangle as a union of its three sides, then calculate three separate line integrals.

**Answer**

0

## Applications of Line Integrals

Scalar line integrals have many applications. They can be used to calculate the length or mass of a wire, the surface area of a sheet of a given height, or the electric potential of a charged wire given a linear charge density. Vector line integrals are extremely useful in physics. They can be used to calculate the work done on a particle as it moves through a force field, or the flow rate of a fluid across a curve. Here, we calculate the mass of a wire using a scalar line integral and the work done by a force using a vector line integral.

Suppose that a piece of wire is modeled by curve $C$ in space. The mass per unit length (the linear density) of the wire is a continuous function $\rho(x,y,z)$. We can calculate the total mass of the wire using the scalar line integral $\int_C \rho(x,y,z)\, ds$. The reason is that mass is density multiplied by length, and therefore the density of a small piece of the wire can be approximated by $\rho(x^*,y^*,z^*)\, \Delta s$ for some point $(x^*,y^*,z^*)$ in the piece. Letting the length of the pieces shrink to zero with a limit yields the line integral $\int_C \rho(x,y,z)\, ds$.

**✓ Example 16.3.9: Calculating the Mass of a Wire**

Calculate the mass of a spring in the shape of a curve parameterized by $\langle t, 2\cos t, 2\sin t\rangle$, $0 \le t \le \frac{\pi}{2}$, with a density function given by $\rho(x,y,z) = e^x + yz$ kg/m (Figure 16.3.10).

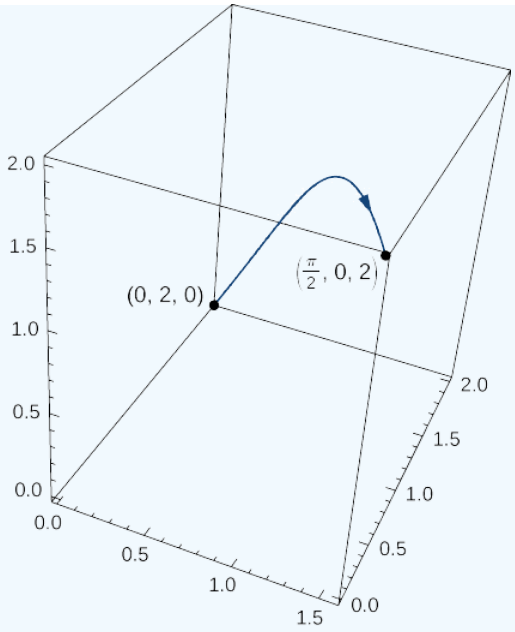

Figure **16.3.10**: The wire from Example **16.3.9**.

### Solution

To calculate the mass of the spring, we must find the value of the scalar line integral $\int_C (e^x + yz)\, ds$, where $C$ is the given helix. To calculate this integral, we write it in terms of $t$ using Equation 16.3.1:

$$\begin{aligned}\int_C (e^x + yz)\, ds &= \int_0^{\frac{\pi}{2}} \left((e^t + 4\cos t \sin t)\sqrt{1 + (-2\cos t)^2 + (2\sin t)^2}\right) dt \\ &= \int_0^{\frac{\pi}{2}} \left((e^t + 4\cos t \sin t)\sqrt{5}\right) dt \\ &= \sqrt{5}\left[e^t + 2\sin^2 t\right]_{t=0}^{t=\pi/2} \\ &= \sqrt{5}(e^{\pi/2} + 1).\end{aligned}$$

Therefore, the mass is $\sqrt{5}(e^{\pi/2} + 1)$ kg.

## Exercise 16.3.9

Calculate the mass of a spring in the shape of a helix parameterized by $\vec{\mathbf{r}}(t) = \langle \cos t, \sin t, t\rangle$, $0 \le t \le 6\pi$, with a density function given by $\rho(x, y, z) = x + y + z$ kg/m.

**Hint**

Calculate the line integral of $\rho$ over the curve with parameterization $\vec{\mathbf{r}}$.

**Answer**

$18\sqrt{2}\pi^2$ kg

When we first defined vector line integrals, we used the concept of work to motivate the definition. Therefore, it is not surprising that calculating the **work done by a vector field** representing a force is a standard use of vector line integrals. Recall that if an object moves along curve $C$ in force field $\vec{\mathbf{F}}$, then the work required to move the object is given by $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$.

### Example 16.3.10: Calculating Work

How much work is required to move an object in vector force field $\vec{\mathbf{F}} = \langle yz, xy, xz \rangle$ along path $\vec{\mathbf{r}}(t) = \langle t^2, t, t^4 \rangle$, $0 \le t \le 1$? See Figure 16.3.11.

**Solution**

Let $C$ denote the given path. We need to find the value of $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$. To do this, we use Equation 16.3.5 :

$$\begin{aligned} \int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} &= \int_0^1 (\langle t^5, t^3, t^6 \rangle \cdot \langle 2t, 1, 4t^3 \rangle)\, dt \\ &= \int_0^1 (2t^6 + t^3 + 4t^9)\, dt \\ &= \left[ \frac{2t^7}{7} + \frac{t^4}{4} + \frac{2t^{10}}{5} \right]_{t=0}^{t=1} = \frac{131}{140} \text{ units of work.} \end{aligned}$$

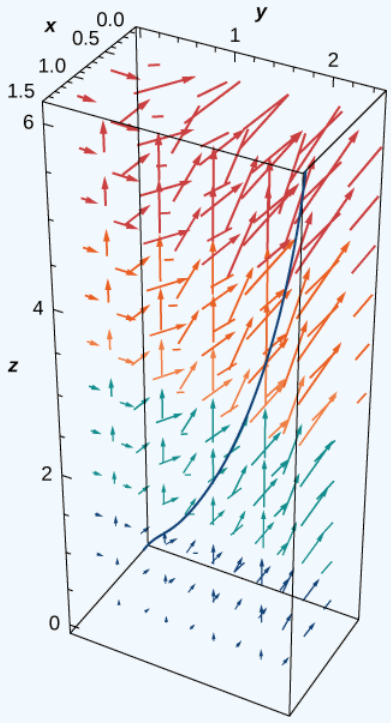

Figure 16.3.11: The curve and vector field for Example 16.3.10.

## Flux

We close this section by discussing two key concepts related to line integrals: flux across a plane curve and circulation along a plane curve. Flux is used in applications to calculate fluid flow across a curve, and the concept of circulation is important for characterizing conservative gradient fields in terms of line integrals. Both these concepts are used heavily throughout the rest of this chapter. The idea of flux is especially important for Green's theorem, and in higher dimensions for Stokes' theorem and the divergence theorem.

Let $C$ be a plane curve and let $\vec{\mathbf{F}}$ be a vector field in the plane. Imagine $C$ is a membrane across which fluid flows, but $C$ does not impede the flow of the fluid. In other words, $C$ is an idealized membrane invisible to the fluid. Suppose $\vec{\mathbf{F}}$ represents the velocity field of the fluid. How could we quantify the rate at which the fluid is crossing $C$?

Recall that the line integral of $\vec{\mathbf{F}}$ along $C$ is $\int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, ds$—in other words, the line integral is the dot product of the vector field with the unit tangential vector with respect to arc length. If we replace the unit tangential vector with unit normal vector $\vec{\mathbf{N}}(t)$ and instead

compute integral $\int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, ds$, we determine the flux across $C$. To be precise, the definition of integral $\int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, ds$ is the same as integral $\int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, ds$, except the $\vec{\mathbf{T}}$ in the Riemann sum is replaced with $\vec{\mathbf{N}}$. Therefore, the flux across $C$ is defined as

$$\int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, ds = \lim_{n\to\infty} \sum_{i=1}^{n} \vec{\mathbf{F}}(P_i^*) \cdot \vec{\mathbf{N}}(P_i^*)\, \Delta s_i,$$

where $P_i^*$ and $\Delta s_i$ are defined as they were for integral $\int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, ds$. Therefore, a flux integral is an integral that is *perpendicular* to a vector line integral, because $\vec{\mathbf{N}}$ and $\vec{\mathbf{T}}$ are perpendicular vectors.

If $\vec{\mathbf{F}}$ is a velocity field of a fluid and $C$ is a curve that represents a membrane, then the flux of $\vec{\mathbf{F}}$ across $C$ is the quantity of fluid flowing across $C$ per unit time, or the rate of flow.

More formally, let $C$ be a plane curve parameterized by $\vec{\mathbf{r}}(t) = \langle x(t), y(t)\rangle$, $a \le t \le b$. Let $\vec{\mathbf{n}}(t) = \langle y'(t), -x'(t)\rangle$ be the vector that is normal to $C$ at the endpoint of $\vec{\mathbf{r}}(t)$ and points to the right as we traverse $C$ in the positive direction (Figure 16.3.12). Then, $\vec{\mathbf{N}}(t) = \dfrac{\vec{\mathbf{n}}(t)}{\|\vec{\mathbf{n}}(t)\|}$ is the unit normal vector to $C$ at the endpoint of $\vec{\mathbf{r}}(t)$ that points to the right as we traverse $C$.

**DEFINITION: Flux**

The *flux* of $\vec{\mathbf{F}}$ across $C$ is line integral

$$\int_C \vec{\mathbf{F}} \cdot \frac{\vec{\mathbf{n}}(t)}{\|\vec{\mathbf{n}}(t)\|}\, ds.$$

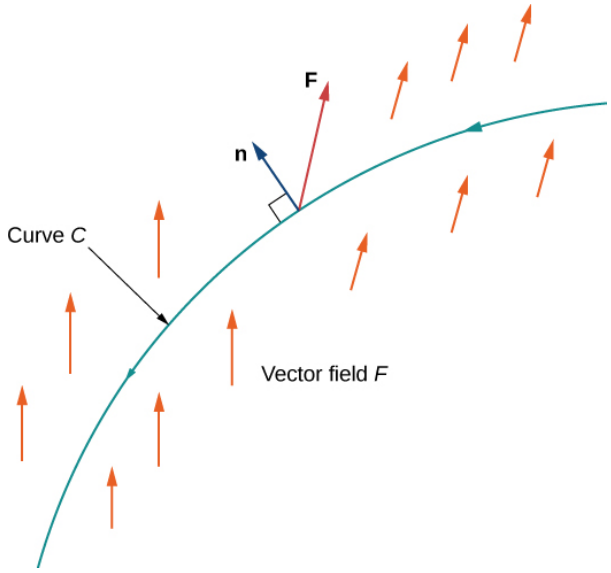

Figure 16.3.12: The flux of vector field $\vec{\mathbf{F}}$ *across curve* $C$ *is computed by an integral similar to a vector line integral.*

We now give a formula for calculating the flux across a curve. This formula is analogous to the formula used to calculate a vector line integral (see Equation 16.3.5).

**Theorem: Calculating Flux Across a Curve**

Let $\vec{\mathbf{F}}$ be a vector field and let $C$ be a smooth curve with parameterization $r(t) = \langle x(t), y(t)\rangle$, $a \le t \le b$.Let $\vec{\mathbf{n}}(t) = \langle y'(t), -x'(t)\rangle$. The flux of $\vec{\mathbf{F}}$ across $C$ is

$$\int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, ds = \int_a^b \vec{\mathbf{F}}(\vec{\mathbf{r}}(t)) \cdot \vec{\mathbf{n}}(t)\, dt. \tag{16.3.8}$$

**Proof**

Before deriving the formula, note that

$$\|\vec{\mathbf{n}}(t)\| = \|\langle y'(t), -x'(t)\rangle\| = \sqrt{(y'(t))^2 + (x'(t))^2} = \|\vec{\mathbf{r}}'(t)\|.$$

Therefore,

$$\begin{aligned}\int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, ds &= \int_C \vec{\mathbf{F}} \cdot \frac{\vec{\mathbf{n}}(t)}{\|\vec{\mathbf{n}}(t)\|}\, ds \\ &= \int_a^b \vec{\mathbf{F}} \cdot \frac{\vec{\mathbf{n}}(t)}{\|\vec{\mathbf{n}}(t)\|} \|\vec{\mathbf{r}}'(t)\|\, dt \\ &= \int_a^b \vec{\mathbf{F}}(\vec{\mathbf{r}}(t)) \cdot \vec{\mathbf{n}}(t)\, dt.\end{aligned}$$

□

**Example 16.3.11: Flux across a Curve**

Calculate the flux of $\vec{\mathbf{F}} = \langle 2x, 2y\rangle$ across a unit circle oriented counterclockwise (Figure 16.3.13).

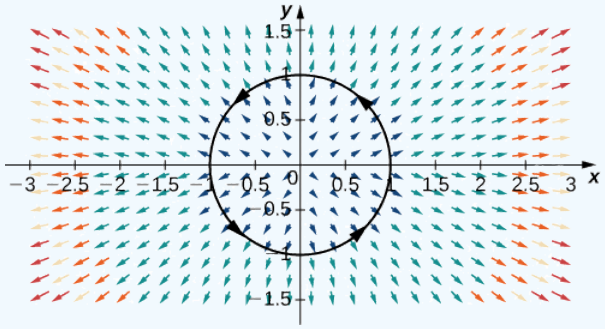

Figure 16.3.13: A unit circle in vector field $\vec{\mathbf{F}} = \langle 2x, 2y\rangle$.

**Solution**

To compute the flux, we first need a parameterization of the unit circle. We can use the standard parameterization $\vec{\mathbf{r}}(t) = \langle \cos t, \sin t\rangle$, $0 \le t \le 2\pi$. The normal vector to a unit circle is $\langle \cos t, \sin t\rangle$. Therefore, the flux is

$$\begin{aligned}\int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, ds &= \int_0^{2\pi} \langle 2\cos t, 2\sin t\rangle \cdot \langle \cos t, \sin t\rangle\, dt \\ &= \int_0^{2\pi} (2\cos^2 t + 2\sin^2 t)\, dt \\ &= 2\int_0^{2\pi} (\cos^2 t + \sin^2 t)\, dt \\ &= 2\int_0^{2\pi} dt = 4\pi.\end{aligned}$$

**Exercise 16.3.11**

Calculate the flux of $\vec{\mathbf{F}} = \langle x + y, 2y\rangle$ across the line segment from $(0, 0)$ to $(2, 3)$, where the curve is oriented from left to right.

**Hint**

Use Equation 16.3.8.

**Answer**

3/2

Let $\vec{\mathbf{F}}(x,y) = \langle P(x,y), Q(x,y)\rangle$ be a two-dimensional vector field. Recall that integral $\int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, ds$ is sometimes written as $\int_C P\, dx + Q\, dy$. Analogously, flux $\int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, ds$ is sometimes written in the notation $\int_C -Q\, dx + P\, dy$, because the unit normal vector $\vec{\mathbf{N}}$ is perpendicular to the unit tangent $\vec{\mathbf{T}}$. Rotating the vector $d\vec{\mathbf{r}} = \langle dx, dy\rangle$ by 90° results in vector $\langle dy, -dx\rangle$. Therefore, the line integral in Example 16.3.8 can be written as $\int_C -2y\, dx + 2x\, dy$.

## Circulation

Now that we have defined flux, we can turn our attention to circulation. The line integral of vector field $\vec{\mathbf{F}}$ along an oriented closed curve is called the circulation of $\vec{\mathbf{F}}$ along $C$. Circulation line integrals have their own notation: $\oint_C \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, ds$. The circle on the integral symbol denotes that $C$ is "circular" in that it has no endpoints. Example 16.3.5 shows a calculation of circulation.

To see where the term *circulation* comes from and what it measures, let $\vec{\mathbf{v}}$ represent the velocity field of a fluid and let $C$ be an oriented closed curve. At a particular point $P$, the closer the direction of $\vec{\mathbf{v}}(P)$ is to the direction of $\vec{\mathbf{T}}(P)$, the larger the value of the dot product $\vec{\mathbf{v}}(P) \cdot \vec{\mathbf{T}}(P)$. The maximum value of $\vec{\mathbf{v}}(P) \cdot \vec{\mathbf{T}}(P)$ occurs when the two vectors are pointing in the exact same direction; the minimum value of $\vec{\mathbf{v}}(P) \cdot \vec{\mathbf{T}}(P)$ occurs when the two vectors are pointing in opposite directions. Thus, the value of the circulation $\oint_C \vec{\mathbf{v}} \cdot \vec{\mathbf{T}}\, ds$ measures the tendency of the fluid to move in the direction of $C$.

### Example 16.3.12: Calculating Circulation

Let $\vec{\mathbf{F}} = \langle -y, x\rangle$ be the vector field from Example 16.3.3 and let $C$ represent the unit circle oriented counterclockwise. Calculate the circulation of $\vec{\mathbf{F}}$ along $C$.

**Solution**

We use the standard parameterization of the unit circle: $\vec{\mathbf{r}}(t) = \langle \cos t, \sin t\rangle$, $0 \le t \le 2\pi$. Then, $\vec{\mathbf{F}}(\vec{\mathbf{r}}(t)) = \langle -\sin t, \cos t\rangle$ and $\vec{\mathbf{r}}\,'(t) = \langle -\sin t, \cos t\rangle$. Therefore, the circulation of $\vec{\mathbf{F}}$ along $C$ is

$$\begin{aligned}\oint_C \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, ds &= \int_0^{2\pi} \langle -\sin t, \cos t\rangle \cdot \langle -\sin t, \cos t\rangle\, dt \\ &= \int_0^{2\pi} (\sin^2 t + \cos^2 t)\, dt \\ &= \int_0^{2\pi} dt = 2\pi \text{ units of work.}\end{aligned}$$

Notice that the circulation is positive. The reason for this is that the orientation of $C$ "flows" with the direction of $\vec{\mathbf{F}}$. At any point along the circle, the tangent vector and the vector from $\vec{\mathbf{F}}$ form an angle of less than 90°, and therefore the corresponding dot product is positive.

In Example 16.3.12, what if we had oriented the unit circle clockwise? We denote the unit circle oriented clockwise by $-C$. Then

$$\oint_{-C} \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, ds = -\oint_C \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, ds = -2\pi \text{ units of work.}$$

Notice that the circulation is negative in this case. The reason for this is that the orientation of the curve flows against the direction of $\vec{\mathbf{F}}$.

### Exercise 16.3.12

Calculate the circulation of $\vec{\mathbf{F}}(x,y) = \langle -\frac{y}{x^2+y^2}, \frac{x}{x^2+y^2}\rangle$ along a unit circle oriented counterclockwise.

**Hint**

Use Equation 16.3.8.

**Answer**

$2\pi$ units of work

### Example 16.3.13: Calculating Work

Calculate the work done on a particle that traverses circle $C$ of radius 2 centered at the origin, oriented counterclockwise, by field $\vec{\mathbf{F}}(x, y) = \langle -2, y \rangle$. Assume the particle starts its movement at $(1, 0)$.

**Solution**

The work done by $\vec{\mathbf{F}}$ on the particle is the circulation of $\vec{\mathbf{F}}$ along $C$: $\oint_C \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, ds$. We use the parameterization $\vec{\mathbf{r}}(t) = \langle 2\cos t, 2\sin t \rangle$, $0 \le t \le 2\pi$ for $C$. Then, $\vec{\mathbf{r}}'(t) = \langle -2\sin t, 2\cos t \rangle$ and $\vec{\mathbf{F}}(\vec{\mathbf{r}}(t)) = \langle -2, 2\sin t \rangle$. Therefore, the circulation of $\vec{\mathbf{F}}$ along $C$ is

$$\begin{aligned} \oint_C \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, ds &= \int_0^{2\pi} \langle -2, 2\sin t \rangle \cdot \langle -2\sin t, 2\cos t \rangle\, dt \\ &= \int_0^{2\pi} (4\sin t + 4\sin t \cos t)\, dt \\ &= \Big[ -4\cos t + 4\sin^2 t \Big]_0^{2\pi} \\ &= \big(-4\cos(2\pi) + 2\sin^2(2\pi)\big) - \big(-4\cos(0) + 4\sin^2(0)\big) \\ &= -4 + 4 = 0 \text{ units of work.} \end{aligned}$$

The force field does zero work on the particle.

Notice that the circulation of $\vec{\mathbf{F}}$ along $C$ is zero. Furthermore, notice that since $\vec{\mathbf{F}}$ is the gradient of $f(x, y) = -2x + \frac{y^2}{2}$, $\vec{\mathbf{F}}$ is conservative. We prove in a later section that under certain broad conditions, the circulation of a conservative vector field along a closed curve is zero.

### Exercise 16.3.14

Calculate the work done by field $\vec{\mathbf{F}}(x, y) = \langle 2x, 3y \rangle$ on a particle that traverses the unit circle. Assume the particle begins its movement at $(-1, 0)$.

**Hint**

Use Equation 16.3.8.

**Answer**

$0$ units of work

## Key Concepts

- Line integrals generalize the notion of a single-variable integral to higher dimensions. The domain of integration in a single-variable integral is a line segment along the $x$-axis, but the domain of integration in a line integral is a curve in a plane or in space.
- If $C$ is a curve, then the length of $C$ is $\int_C ds$.
- There are two kinds of line integral: scalar line integrals and vector line integrals. Scalar line integrals can be used to calculate the mass of a wire; vector line integrals can be used to calculate the work done on a particle traveling through a field.
- Scalar line integrals can be calculated using Equation 16.3.1; vector line integrals can be calculated using Equation 16.3.5.
- Two key concepts expressed in terms of line integrals are flux and circulation. Flux measures the rate that a field crosses a given line; circulation measures the tendency of a field to move in the same direction as a given closed curve.

## Key Equations

- **Calculating a scalar line integral**

  $$\int_C f(x, y, z)\, ds = \int_a^b f(\vec{\mathbf{r}}(t)) \sqrt{(x'(t))^2 + (y'(t))^2 + (z'(t))^2}\, dt$$

- **Calculating a vector line integral**
  $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, ds = \int_a^b \vec{\mathbf{F}}(\vec{\mathbf{r}}(t)) \cdot \vec{\mathbf{r}}'(t)\, dt$
  or
  $\int_C P\, dx + Q\, dy + R\, dz = \int_a^b \left( P\big(\vec{\mathbf{r}}(t)\big) \frac{dx}{dt} + Q\big(\vec{\mathbf{r}}(t)\big) \frac{dy}{dt} + R\big(\vec{\mathbf{r}}(t)\big) \frac{dz}{dt} \right) dt$
- **Calculating flux**
  $\int_C \vec{\mathbf{F}} \cdot \frac{\vec{\mathbf{n}}(t)}{\|\vec{\mathbf{n}}(t)\|}\, ds = \int_a^b \vec{\mathbf{F}}(\vec{\mathbf{r}}(t)) \cdot \vec{\mathbf{n}}(t)\, dt$

## Glossary

**circulation**

the tendency of a fluid to move in the direction of curve $C$. If $C$ is a closed curve, then the circulation of $\vec{\mathbf{F}}$ along $C$ is line integral $\int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, ds$, which we also denote $\oint_C \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, ds$.

**closed curve**

a curve for which there exists a parameterization $\vec{\mathbf{r}}(t), a \leq t \leq b$, such that $\vec{\mathbf{r}}(a) = \vec{\mathbf{r}}(b)$, and the curve is traversed exactly once

**flux**

the rate of a fluid flowing across a curve in a vector field; the flux of vector field $\vec{\mathbf{F}}$ across plane curve $C$ is line integral $\int_C \vec{\mathbf{F}} \cdot \frac{\vec{\mathbf{n}}(t)}{\|\vec{\mathbf{n}}(t)\|}\, ds$

**line integral**

the integral of a function along a curve in a plane or in space

**orientation of a curve**

the orientation of a curve $C$ is a specified direction of $C$

**piecewise smooth curve**

an oriented curve that is not smooth, but can be written as the union of finitely many smooth curves

**scalar line integral**

the scalar line integral of a function $f$ along a curve $C$ with respect to arc length is the integral $\int_C f\, ds$, it is the integral of a scalar function $f$ along a curve in a plane or in space; such an integral is defined in terms of a Riemann sum, as is a single-variable integral

**vector line integral**

the vector line integral of vector field $\vec{\mathbf{F}}$ along curve $C$ is the integral of the dot product of $\vec{\mathbf{F}}$ with unit tangent vector $\vec{\mathbf{T}}$ of $C$ with respect to arc length, $\int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\, ds$; such an integral is defined in terms of a Riemann sum, similar to a single-variable integral

# 16.3E: Exercises for Section 16.2

**1.** *True or False?* Line integral $\int_C f(x,y)\,ds$ is equal to a definite integral if $C$ is a smooth curve defined on $[a,b]$ and if function $f$ is continuous on some region that contains curve $C$.

**2.** *True or False?* Vector functions $\vec{\mathbf{r}}_1 = t\,\hat{\mathbf{i}} + t^2\,\hat{\mathbf{j}}, \quad 0 \le t \le 1$, and $\vec{\mathbf{r}}_2 = (1-t)\,\hat{\mathbf{i}} + (1-t)^2\,\hat{\mathbf{j}}, \quad 0 \le t \le 1$, define the same oriented curve.

**3.** *True or False?* $\int_{-C}(P\,dx + Q\,dy) = \int_C (P\,dx - Q\,dy)$

**4.** *True or False?* A piecewise smooth curve $C$ consists of a finite number of smooth curves that are joined together end to end.

**5.** *True or False?* If $C$ is given by $x(t) = t, \quad y(t) = t, \quad 0 \le t \le 1$, then $\int_C xy\,ds = \int_0^1 t^2\,dt$.

**For the following exercises, use a computer algebra system (CAS) to evaluate the line integrals over the indicated path.**

**6. [T]** $\int_C (x+y)\,ds$

$C: x = t, y = (1-t), z = 0$ from $(0,1,0)$ to $(1,0,0)$

**7. [T]** $\int_C (x-y)ds$

$C: \vec{\mathbf{r}}(t) = 4t\,\hat{\mathbf{i}} + 3t\,\hat{\mathbf{j}}$ when $0 \le t \le 2$

**8. [T]** $\int_C (x^2+y^2+z^2)\,ds$

$C: \vec{\mathbf{r}}(t) = \sin t\,\hat{\mathbf{i}} + \cos t\,\hat{\mathbf{j}} + 8t\,\hat{\mathbf{k}}$ when $0 \le t \le \frac{\pi}{2}$

**9. [T]** Evaluate $\int_C xy^4\,ds$, where $C$ is the right half of circle $x^2 + y^2 = 16$ and is traversed in the clockwise direction.

**10. [T]** Evaluate $\int_C 4x^3 ds$, where $C$ is the line segment from $(-2,-1)$ to $(1,2)$.

**For the following exercises, find the work done.**

**11.** Find the work done by vector field $\vec{\mathbf{F}}(x,y,z) = x\,\hat{\mathbf{i}} + 3xy\,\hat{\mathbf{j}} - (x+z)\,\hat{\mathbf{k}}$ on a particle moving along a line segment that goes from $(1,4,2)$ to $(0,5,1)$.

**12.** Find the work done by a person weighing 150 lb walking exactly one revolution up a circular, spiral staircase of radius 3 ft if the person rises 10 ft.

**13.** Find the work done by force field $\vec{\mathbf{F}}(x,y,z) = -\frac{1}{2}x\,\hat{\mathbf{i}} - \frac{1}{2}y\,\hat{\mathbf{j}} + \frac{1}{4}\,\hat{\mathbf{k}}$ on a particle as it moves along the helix $\vec{\mathbf{r}}(t) = \cos t\,\hat{\mathbf{i}} + \sin t\,\hat{\mathbf{j}} + t\,\hat{\mathbf{k}}$ from point $(1,0,0)$ to point $(-1,0,3\pi)$.

**14.** Find the work done by vector field $\vec{\mathbf{F}}(x,y) = y\,\hat{\mathbf{i}} + 2x\,\hat{\mathbf{j}}$ in moving an object along path $C$, which joins points $(1,0)$ and $(0,1)$.

**15.** Find the work done by force $\vec{\mathbf{F}}(x,y) = 2y\,\hat{\mathbf{i}} + 3x\,\hat{\mathbf{j}} + (x+y)\,\hat{\mathbf{k}}$ in moving an object along curve $\vec{\mathbf{r}}(t) = \cos(t)\,\hat{\mathbf{i}} + \sin(t)\,\hat{\mathbf{j}} + 16\,\hat{\mathbf{k}}$, where $0 \le t \le 2\pi$.

**16.** Find the mass of a wire in the shape of a circle of radius 2 centered at (3, 4) with linear mass density $\rho(x,y) = y^2$.

**For the following exercises, evaluate the line integrals.**

**17.** Evaluate $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$, where $\vec{\mathbf{F}}(x,y) = -1\,\hat{\mathbf{j}}$, and $C$ is the part of the graph of $y = \frac{1}{2}x^3 - x$ from $(2,2)$ to $(-2,-2)$.

**18.** Evaluate $\int_\gamma (x^2+y^2+z^2)^{-1} ds$, where $\gamma$ is the helix $x = \cos t, y = \sin t, z = t$, with $0 \le t \le T$.

**19.** Evaluate $\int_C yz\,dx + xz\,dy + xy\,dz$ over the line segment from $(1,1,1)$ to $(3,2,0)$.

**20.** Let $C$ be the line segment from point (0, 1, 1) to point (2, 2, 3). Evaluate line integral $\int_C y\,ds$.

**21. [T]** Use a computer algebra system to evaluate the line integral $\int_C y^2\,dx + x\,dy$, where $C$ is the arc of the parabola $x = 4 - y^2$ from $(-5, -3)$ to $(0, 2)$.

**22. [T]** Use a computer algebra system to evaluate the line integral $\int_C (x + 3y^2)\,dy$ over the path $C$ given by $x = 2t, y = 10t$, where $0 \le t \le 1$.

**23. [T]** Use a CAS to evaluate line integral $\int_C xy\,dx + y\,dy$ over path $C$ given by $x = 2t, y = 10t$, where $0 \le t \le 1$.

**24.** Evaluate line integral $\int_C (2x - y)\,dx + (x + 3y)\,dy$, where $C$ lies along the $x$-axis from $x = 0$ to $x = 5$.

**26. [T]** Use a CAS to evaluate $\int_C \frac{y}{2x^2 - y^2}\,ds$, where $C$ is defined by the parametric equations $x = t, y = t$, for $1 \le t \le 5$.

**27. [T]** Use a CAS to evaluate $\int_C xy\,ds$, where $C$ is defined by the parametric equations $x = t^2, y = 4t$, for $0 \le t \le 1$.

**In the following exercises, find the work done by force field $\vec{\mathbf{F}}$ on an object moving along the indicated path.**

**28.** $\vec{\mathbf{F}}(x, y) = -x\,\hat{\mathbf{i}} - 2y\,\hat{\mathbf{j}}$

$C : y = x^3$ from $(0, 0)$ to $(2, 8)$

**29.** $\vec{\mathbf{F}}(x, y) = 2x\,\hat{\mathbf{i}} + y\,\hat{\mathbf{j}}$

$<C$: counterclockwise around the triangle with vertices $(0, 0), (1, 0)$, and $(1, 1)$

**30.** $\vec{\mathbf{F}}(x, y, z) = x\,\hat{\mathbf{i}} + y\,\hat{\mathbf{j}} - 5z\,\hat{\mathbf{k}}$

$C : \vec{\mathbf{r}}(t) = 2\cos t\,\hat{\mathbf{i}} + 2\sin t\,\hat{\mathbf{j}} + t\,\hat{\mathbf{k}},\ 0 \le t \le 2\pi$

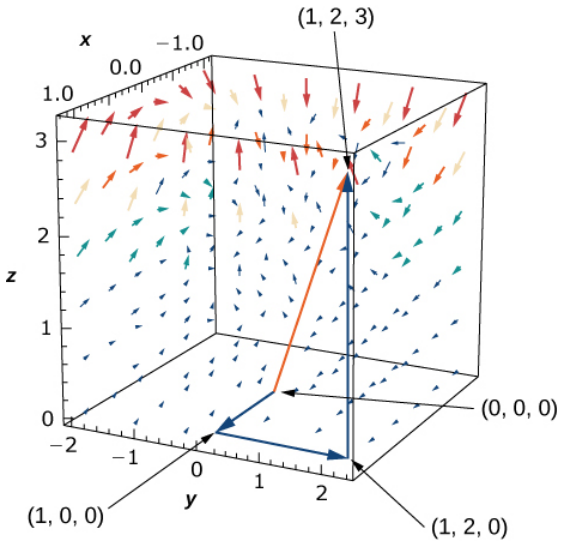
**31.** Let $\vec{\mathbf{F}}$ be vector field $\vec{\mathbf{F}}(x, y) = (y^2 + 2xe^y + 1)\,\hat{\mathbf{i}} + (2xy + x^2e^y + 2y)\,\hat{\mathbf{j}}$. Compute the work of integral $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$, where $C$ is the path $\vec{\mathbf{r}}(t) = \sin t\,\hat{\mathbf{i}} + \cos t\,\hat{\mathbf{j}}, \quad 0 \le t \le \frac{\pi}{2}$.

**32.** Compute the work done by force $\vec{\mathbf{F}}(x, y, z) = 2x\,\hat{\mathbf{i}} + 3y\,\hat{\mathbf{j}} - z\,\hat{\mathbf{k}}$ along path $\vec{\mathbf{r}}(t) = t\,\hat{\mathbf{i}} + t^2\,\hat{\mathbf{j}} + t^3\,\hat{\mathbf{k}}$, where $0 \le t \le 1$.

**33.** Evaluate $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$, where $\vec{\mathbf{F}}(x, y) = \frac{1}{x + y}\,\hat{\mathbf{i}} + \frac{1}{x + y}\,\hat{\mathbf{j}}$ and $C$ is the segment of the unit circle going counterclockwise from $(1, 0)$ to $(0, 1)$.

**34.** Force $\vec{\mathbf{F}}(x, y, z) = zy\,\hat{\mathbf{i}} + x\,\hat{\mathbf{j}} + z^2x\,\hat{\mathbf{k}}$ acts on a particle that travels from the origin to point $(1, 2, 3)$. Calculate the work done if the particle travels:

a. along the path $(0, 0, 0) \to (1, 0, 0) \to (1, 2, 0) \to (1, 2, 3)$ along straight-line segments joining each pair of endpoints;
b. along the straight line joining the initial and final points.
c. Is the work the same along the two paths?



**35.** Find the work done by vector field $\vec{\mathbf{F}}(x,y,z) = x\,\hat{\mathbf{i}} + 3xy\,\hat{\mathbf{j}} - (x+z)\,\hat{\mathbf{k}}$ on a particle moving along a line segment that goes from $(1,4,2)$ to $(0,5,1)$.

**36.** How much work is required to move an object in vector field $\vec{\mathbf{F}}(x,y) = y\,\hat{\mathbf{i}} + 3x\,\hat{\mathbf{j}}$ along the upper part of ellipse $\frac{x^2}{4} + y^2 = 1$ from $(2,0)$ to $(-2,0)$?

**37.** A vector field is given by $\vec{\mathbf{F}}(x,y) = (2x+3y)\,\hat{\mathbf{i}} + (3x+2y)\,\hat{\mathbf{j}}$. Evaluate the line integral of the field around a circle of unit radius traversed in a clockwise fashion.

**38.** Evaluate the line integral of scalar function $xy$ along parabolic path $y = x^2$ connecting the origin to point $(1,1)$.

**39.** Find $\int_C y^2\,dx + (xy - x^2)\,dy$ along $C: y = 3x$ from $(0,0)$ to $(1,3)$.

**40.** Find $\int_C y^2\,dx + (xy - x^2)\,dy$ along $C: y^2 = 9x$ from $(0,0)$ to $(1,3)$.

**For the following exercises, use a CAS to evaluate the given line integrals.**

**41. [T]** Evaluate $\vec{\mathbf{F}}(x,y,z) = x^2z\,\hat{\mathbf{i}} + 6y\,\hat{\mathbf{j}} + yz^2\,\hat{\mathbf{k}}$, where $C$ is represented by $\vec{\mathbf{r}}(t) = t\,\hat{\mathbf{i}} + t^2\,\hat{\mathbf{j}} + \ln t\,\hat{\mathbf{k}}, 1 \le t \le 3$.

**42. [T]** Evaluate line integral $\int_\gamma xe^y\,ds$ where, $\gamma$ is the arc of curve $x = e^y$ from $(1,0)$ to $(e,1)$.

**43. [T]** Evaluate the integral $\int_\gamma xy^2\,ds$, where $\gamma$ is a triangle with vertices $(0,1,2), (1,0,3)$, and $(0,-1,0)$.

**44. [T]** Evaluate line integral $\int_\gamma (y^2 - xy)\,dx$, where $\gamma$ is curve $y = \ln x$ from $(1,0)$ toward $(e,1)$.

**45. [T]** Evaluate line integral $\int_\gamma xy^4\,ds$, where $\gamma$ is the right half of circle $x^2 + y^2 = 16$.

**46. [T]** Evaluate $\int C\vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}, \int C\vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$, where $\vec{\mathbf{F}}(x,y,z) = x^2y\,\hat{\mathbf{i}} + (x-z)\,\hat{\mathbf{j}} + xyz\,\hat{\mathbf{k}}$ and

$C: \vec{\mathbf{r}}(t) = t\,\hat{\mathbf{i}} + t^2\,\hat{\mathbf{j}} + 2\,\hat{\mathbf{k}}, 0 \le t \le 1$.

**47.** Evaluate $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$, where $\vec{\mathbf{F}}(x,y) = 2x\sin y\,\hat{\mathbf{i}} + (x^2\cos y - 3y^2)\,\hat{\mathbf{j}}$ and

$C$ is any path from $(-1,0)$ to $(5,1)$.

**48.** Find the line integral of $\vec{\mathbf{F}}(x,y,z) = 12x^2\,\hat{\mathbf{i}} - 5xy\,\hat{\mathbf{j}} + xz\,\hat{\mathbf{k}}$ over path $C$ defined by $y = x^2, z = x^3$ from point $(0,0,0)$ to point $(2,4,8)$.

**49.** Find the line integral of $\int_C (1 + x^2y)\,ds$, where $C$ is ellipse $\vec{\mathbf{r}}(t) = 2\cos t\,\hat{\mathbf{i}} + 3\sin t\,\hat{\mathbf{j}}$ from $0 \le t \le \pi$.

**For the following exercises, find the flux.**

**50.** Compute the flux of $\vec{\mathbf{F}} = x^2\,\hat{\mathbf{i}} + y\,\hat{\mathbf{j}}$ across a line segment from $(0,0)$ to $(1,2)$.

**51.** Let $\vec{\mathbf{F}} = 5\,\hat{\mathbf{i}}$ and let $C$ be curve $y = 0$, with $0 \le x \le 4$. Find the flux across $C$.

**52.** Let $\vec{\mathbf{F}} = 5\,\hat{\mathbf{j}}$ and let $C$ be curve $y = 0$, with $0 \le x \le 4$. Find the flux across $C$.

**53.** Let $\vec{\mathbf{F}} = -y\,\hat{\mathbf{i}} + x\,\hat{\mathbf{j}}$ and let $C : \vec{\mathbf{r}}(t) = \cos t\,\hat{\mathbf{i}} + \sin t\,\hat{\mathbf{j}}$ for $0 \le t \le 2\pi$. Calculate the flux across $C$.

**54.** Let $\vec{\mathbf{F}} = (x^2 + y^3)\,\hat{\mathbf{i}} + (2xy)\,\hat{\mathbf{j}}$. Calculate flux $\vec{\mathbf{F}}$ orientated counterclockwise across the curve $C : x^2 + y^2 = 9$.

**Complete the rest of the exercises as stated.**

**55.** Find the line integral of $\int_C z^2\,dx + y\,dy + 2y\,dz$, where $C$ consists of two parts: $C_1$ and $C_2$. $C_1$ is the intersection of cylinder $x^2 + y^2 = 16$ and plane $z = 3$ from $(0,4,3)$ to $(-4,0,3)$. $C_2$ is a line segment from $(-4,0,3)$ to $(0,1,5)$.

**56.** A spring is made of a thin wire twisted into the shape of a circular helix $x = 2\cos t,\ y = 2\sin t,\ z = t$. Find the mass of two turns of the spring if the wire has a constant mass density of $\rho$ grams per cm.

**57.** A thin wire is bent into the shape of a semicircle of radius $a$. If the linear mass density at point $P$ is directly proportional to its distance from the line through the endpoints, find the mass of the wire.

**58.** An object moves in force field $\vec{\mathbf{F}}(x,y,z) = y^2\,\hat{\mathbf{i}} + 2(x+1)y\,\hat{\mathbf{j}}$ counterclockwise from point $(2,0)$ along elliptical path $x^2 + 4y^2 = 4$ to $(-2,0)$, and back to point $(2,0)$ along the $x$-axis. How much work is done by the force field on the object?

**59.** Find the work done when an object moves in force field $\vec{\mathbf{F}}(x,y,z) = 2x\,\hat{\mathbf{i}} - (x+z)\,\hat{\mathbf{j}} + (y-x)\,\hat{\mathbf{k}}$ along the path given by $\vec{\mathbf{r}}(t) = t^2\,\hat{\mathbf{i}} + (t^2 - t)\,\hat{\mathbf{j}} + 3\,\hat{\mathbf{k}},\ 0 \le t \le 1$.

**60.** If an inverse force field $\vec{\mathbf{F}}$ is given by $\vec{\mathbf{F}}(x,y,z) = \dfrac{k}{\|r\|^3} r$, where $k$ is a constant, find the work done by $\vec{\mathbf{F}}$ as its point of application moves along the $x$-axis from $A(1,0,0)$ to $B(2,0,0)$.

**61.** David and Sandra plan to evaluate line integral $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$ along a path in the $xy$-plane from $(0,0)$ to $(1,1)$. The force field is $\vec{\mathbf{F}}(x,y) = (x + 2y)\,\hat{\mathbf{i}} + (-x + y^2)\,\hat{\mathbf{j}}$. David chooses the path that runs along the $x$-axis from $(0,0)$ to $(1,0)$ and then runs along the vertical line $x = 1$ from $(1,0)$ to the final point $(1,1)$. Sandra chooses the direct path along the diagonal line $y = x$ from $(0,0)$ to $(1,1)$. Whose line integral is larger and by how much?

# 16.4: Conservative Vector Fields

**Learning Objectives**

- Describe simple and closed curves; define connected and simply connected regions.
- Explain how to find a potential function for a conservative vector field.
- Use the Fundamental Theorem for Line Integrals to evaluate a line integral in a vector field.
- Explain how to test a vector field to determine whether it is conservative.

In this section, we continue the study of conservative vector fields. We examine the Fundamental Theorem for Line Integrals, which is a useful generalization of the Fundamental Theorem of Calculus to line integrals of conservative vector fields. We also discover show how to test whether a given vector field is conservative, and determine how to build a potential function for a vector field known to be conservative.

## Curves and Regions

Before continuing our study of conservative vector fields, we need some geometric definitions. The theorems in the subsequent sections all rely on integrating over certain kinds of curves and regions, so we develop the definitions of those curves and regions here. We first define two special kinds of curves: closed curves and simple curves. As we have learned, a closed curve is one that begins and ends at the same point. A simple curve is one that does not cross itself. A curve that is both closed and simple is a simple closed curve (Figure 16.4.1).

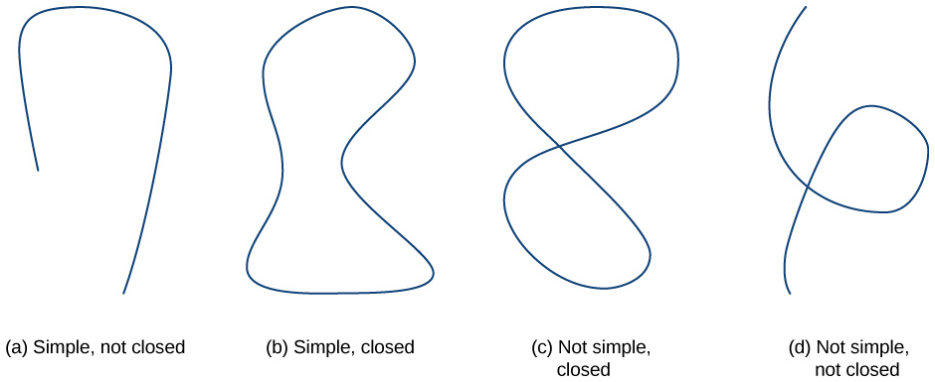

Figure 16.4.1. Types of curves that are simple or not simple and closed or not closed.

**DEFINITION: Closed Curves**

Curve $C$ is a *closed curve* if there is a parameterization $\vec{\mathbf{r}}(t)$, $a \leq t \leq b$ of $C$ such that the parameterization traverses the curve exactly once and $\vec{\mathbf{r}}(a) = \vec{\mathbf{r}}(b)$. Curve $C$ is a simple curve if $C$ does not cross itself. That is, $C$ is simple if there exists a parameterization $\vec{\mathbf{r}}(t)$, $a \leq t \leq b$ of $C$ such that $\vec{\mathbf{r}}$ is one-to-one over $(a, b)$. It is possible for $\vec{\mathbf{r}}(a) = \vec{\mathbf{r}}(b)$, meaning that the simple curve is also closed.

**Example 16.4.1: Determining Whether a Curve Is Simple and Closed**

Is the curve with parameterization $\vec{\mathbf{r}}(t) = \left\langle \cos t, \frac{\sin(2t)}{2} \right\rangle$, $0 \leq t \leq 2\pi$ a simple closed curve?

**Solution**

Note that $\vec{\mathbf{r}}(0) = \langle 1, 0 \rangle = \vec{\mathbf{r}}(2\pi)$; therefore, the curve is closed. The curve is not simple, however. To see this, note that $\vec{\mathbf{r}}\left(\frac{\pi}{2}\right) = \langle 0, 0 \rangle = \vec{\mathbf{r}}\left(\frac{3\pi}{2}\right)$, and therefore the curve crosses itself at the origin (Figure 16.4.2).

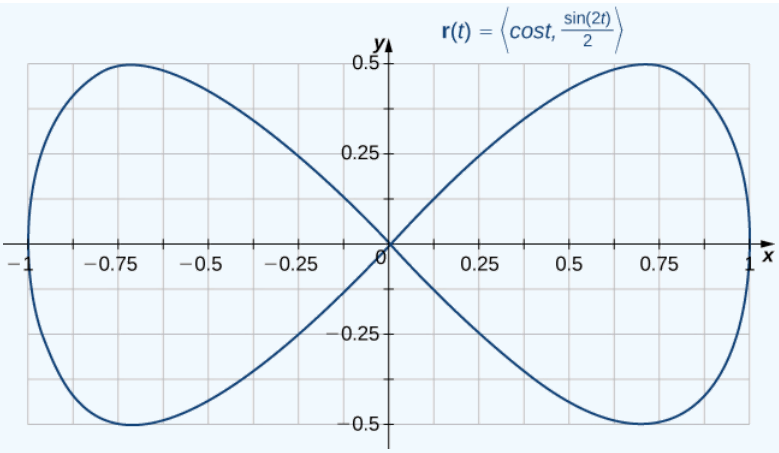

Figure **16.4.2.** *A curve that is closed but not simple.*

**? Exercise 16.4.1**

Is the curve given by parameterization $\vec{\mathbf{r}}(t) = \langle 2\cos t, 3\sin t\rangle$, $0 \le t \le 6\pi$, a simple closed curve?

**Hint**

Sketch the curve.

**Answer**

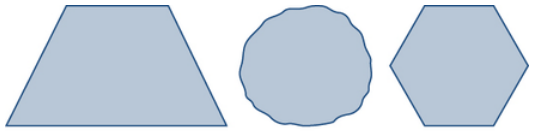
Yes

Many of the theorems in this chapter relate an integral over a region to an integral over the boundary of the region, where the region's boundary is a simple closed curve or a union of simple closed curves. To develop these theorems, we need two geometric definitions for regions: that of a connected region and that of a simply connected region. A connected region is one in which there is a path in the region that connects any two points that lie within that region. A simply connected region is a connected region that does not have any holes in it. These two notions, along with the notion of a simple closed curve, allow us to state several generalizations of the Fundamental Theorem of Calculus later in the chapter. These two definitions are valid for regions in any number of dimensions, but we are only concerned with regions in two or three dimensions.

**DEFINITION: connected regions**

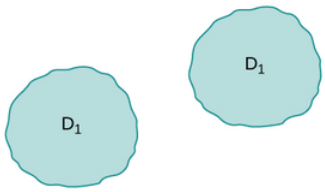
A region $D$ is a *connected region* if, for any two points $P_1$ and $P_2$, there is a path from $P_1$ to $P_2$ with a trace contained entirely inside $D$. A region $D$ is a simply connected region if $D$ is connected for any simple closed curve $C$ that lies inside $D$, and curve $C$ can be shrunk continuously to a point while staying entirely inside $D$. In two dimensions, a region is simply connected if it is connected and has no holes.

All simply connected regions are connected, but not all connected regions are simply connected (Figure **16.4.3**).



(a) Simply connected regions

(b) Connected regions that are not simply connected

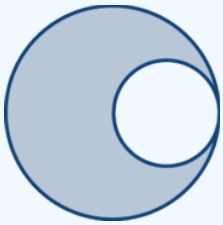


(c) A region that is not connected

Figure **16.4.3**: Not all connected regions are simply connected. (a) Simply connected regions have no holes. (b) Connected regions that are not simply connected may have holes but you can still find a path in the region between any two points. (c) A region that is not connected has some points that cannot be connected by a path in the region.

**? Exercise 16.4.2**

Is the region in the below image connected? Is the region simply connected?



**Hint**

Consider the definitions.

**Answer**

The region in the figure is connected. The region in the figure is not simply connected.

## Fundamental Theorem for Line Integrals

Now that we understand some basic curves and regions, let's generalize the Fundamental Theorem of Calculus to line integrals. Recall that the Fundamental Theorem of Calculus says that if a function $f$ has an antiderivative $F$, then the integral of $f$ from $a$ to $b$ depends only on the values of $F$ at $a$ and at $b$—that is,

$$\int_a^b f(x)\,dx = F(b) - F(a).$$

If we think of the gradient as a derivative, then the same theorem holds for vector line integrals. We show how this works using a motivational example.

### Example 16.4.2: Evaluating a Line Integral and the Antiderivatives of the Endpoints

Let $\vec{\mathbf{F}}(x,y) = \langle 2x, 4y\rangle$. Calculate $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$, where $C$ is the line segment from $(0,0)$ to $(2,2)$ (Figure 16.4.4).

**Solution**

We use the method from the previous section to calculate $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$. Curve $C$ can be parameterized by $\vec{\mathbf{r}}(t) = \langle 2t, 2t\rangle$, $0 \le t \le 1$. Then, $\vec{\mathbf{F}}(\vec{\mathbf{r}}(t)) = \langle 4t, 8t\rangle$ and $\vec{\mathbf{r}}'(t) = \langle 2, 2\rangle$, which implies that

$$\begin{aligned}\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} &= \int_0^1 \langle 4t, 8t\rangle \cdot \langle 2, 2\rangle dt \\ &= \int_0^1 (8t + 16t) dt = \int_0^1 24t dt \\ &= \left[12t^2\right]_0^1 = 12.\end{aligned}$$

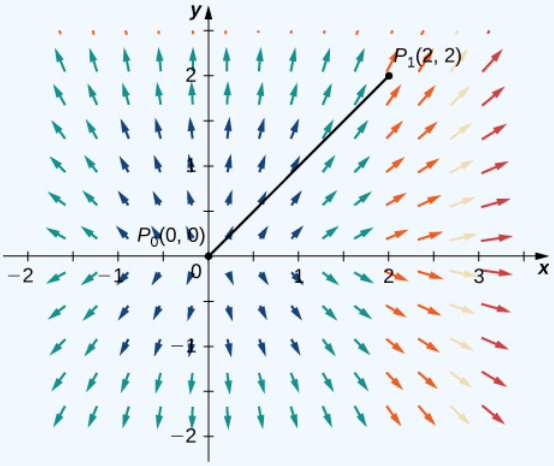


Figure 16.4.4: The value of line integral $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$ *depends only on the value of the potential function of* $\vec{\mathbf{F}}$ *at the endpoints of the curve.*

Notice that $\vec{\mathbf{F}} = \vec{\nabla} f$, where $f(x,y) = x^2 + 2y^2$. If we think of the gradient as a derivative, then $f$ is an "antiderivative" of $\vec{\mathbf{F}}$. In the case of single-variable integrals, the integral of derivative $g'(x)$ is $g(b) - g(a)$, where $a$ is the start point of the interval of integration and $b$ is the endpoint. If vector line integrals work like single-variable integrals, then we would expect integral $\vec{\mathbf{F}}$ to be $f(P_1) - f(P_0)$, where $P_1$ is the endpoint of the curve of integration and $P_0$ is the start point. Notice that this is the case for this example:

$$\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \int_C \vec{\nabla} f \cdot d\vec{\mathbf{r}} = 12$$

and

$$f(2,2) - f(0,0) = 4 + 8 - 0 = 12.$$

In other words, the integral of a "derivative" can be calculated by evaluating an "antiderivative" at the endpoints of the curve and subtracting, just as for single-variable integrals.

The following theorem says that, under certain conditions, what happened in the previous example holds for any gradient field. The same theorem holds for vector line integrals, which we call the **Fundamental Theorem for Line Integrals**.

### Theorem: THE FUNDAMENTAL THEOREM FOR LINE INTEGRALS

Let $C$ be a piecewise smooth curve with parameterization $\vec{\mathbf{r}}(t)$, $a \le t \le b$. Let $f$ be a function of two or three variables with first-order partial derivatives that exist and are continuous on $C$. Then,

$$\int_C \vec{\nabla} f \cdot d\vec{\mathbf{r}} = f(\vec{\mathbf{r}}(b)) - f(\vec{\mathbf{r}}(a)). \tag{16.4.1}$$

**Proof**

First,

$$\int_C \vec{\nabla} f \cdot d\vec{\mathbf{r}} = \int_a^b \vec{\nabla} f(\vec{\mathbf{r}}(t)) \cdot \vec{\mathbf{r}}'(t)\, dt.$$

By the chain rule,

$$\frac{d}{dt}(f(\vec{\mathbf{r}}(t)) = \vec{\nabla} f(\vec{\mathbf{r}}(t)) \cdot \vec{\mathbf{r}}'(t)$$

Therefore, by the Fundamental Theorem of Calculus,

$$\begin{aligned} \int_C \vec{\nabla} f \cdot d\vec{\mathbf{r}} &= \int_a^b \vec{\nabla} f(\vec{\mathbf{r}}(t)) \cdot \vec{\mathbf{r}}'(t) dt \\ &= \int_a^b \frac{d}{dt}(f(\vec{\mathbf{r}}(t)) dt \\ &= \left[ f(\vec{\mathbf{r}}(t)) \right]_{t=a}^{t=b} \\ &= f(\vec{\mathbf{r}}(b)) - f(\vec{\mathbf{r}}(a)). \end{aligned}$$

□

We know that if $\vec{\mathbf{F}}$ is a conservative vector field, there is a potential function $f$ such that $\vec{\nabla} f = \vec{\mathbf{F}}$. Therefore

$$\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \int_C \vec{\nabla} f \cdot d\vec{\mathbf{r}} = f(\vec{\mathbf{r}}(b)) - f(\vec{\mathbf{r}}(a)).$$

In other words, just as with the Fundamental Theorem of Calculus, computing the line integral $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$, where $\vec{\mathbf{F}}$ is conservative, is a two-step process:

1. Find a potential function ("antiderivative") $f$ for $\vec{\mathbf{F}}$ and
2. Compute the value of $f$ at the endpoints of $C$ and calculate their difference $f(\vec{\mathbf{r}}(b)) - f(\vec{\mathbf{r}}(a))$.

Keep in mind, however, there is one major difference between the Fundamental Theorem of Calculus and the Fundamental Theorem for Line Integrals:
*A function of one variable that is continuous must have an antiderivative. However, a vector field, even if it is continuous, does not need to have a potential function.*

**Example 16.4.3: Applying the Fundamental Theorem**

Calculate integral $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$, where $\vec{\mathbf{F}}(x, y, z) = \langle 2x \ln y, \frac{x^2}{y} + z^2, 2yz \rangle$ and $C$ is a curve with parameterization $\vec{\mathbf{r}}(t) = \langle t^2, t, t \rangle$, $1 \leq t \leq e$

a. without using the Fundamental Theorem of Line Integrals and
b. using the Fundamental Theorem of Line Integrals.

**Solution**

1. First, let's calculate the integral without the Fundamental Theorem for Line Integrals and instead use the method we learned in the previous section:

$$\begin{aligned}\int_C \vec{\mathbf{F}}\cdot d\mathbf{r} &= \int_1^e \vec{\mathbf{F}}(\vec{\mathbf{r}}(t))\cdot\vec{\mathbf{r}}'(t)\,dt\\ &= \int_1^e \langle 2t^2\ln t, \frac{t^4}{t}+t^2, 2t^2\rangle\cdot\langle 2t,1,1\rangle\,dt\\ &= \int_1^e (4t^3\ln t + t^3 + 3t^2)\,dt\\ &= \int_1^e 4t^3\ln t\,dt + \int_1^e (t^3+3t^2)\,dt\\ &= \int_1^e 4t^3\ln t\,dt + \left[\frac{t^4}{4}+t^3\right]_1^e\\ &= \int_1^e 4t^3\ln t\,dt + \frac{e^4}{4}+e^3-\frac{1}{4}-1\\ &= \int_1^e 4t^3\ln t\,dt + \frac{e^4}{4}+e^3-\frac{5}{4}\end{aligned}$$

Integral $\int_1^e t^3\ln t\,dt$ requires integration by parts. Let $u=\ln t$ and $dv=t^3$. Then $u=\ln t$, $dv=t^3$

and

$$du=\frac{1}{t}\,dt,\quad v=\frac{t^4}{4}.$$

Therefore,

$$\begin{aligned}\int_1^e t^3\ln t\,dt &= \left[\frac{t^4}{4}\ln t\right]_1^e - \frac{1}{4}\int_1^e t^3\,dt\\ &= \frac{e^4}{4}-\frac{1}{4}\left(\frac{e^4}{4}-\frac{1}{4}\right).\end{aligned}$$

Thus,

$$\begin{aligned}\int_C \vec{\mathbf{F}}\cdot d\vec{\mathbf{r}} &= 4\int_1^e t^3\ln t\,dt \quad + \quad \frac{e^4}{4}+e^3-\frac{5}{4}\\ &= 4\left(\frac{e^4}{4}-\frac{1}{4}\left(\frac{e^4}{4}-\frac{1}{4}\right)\right)+\frac{e^4}{4}+e^3-\frac{5}{4}\\ &= e^4-\frac{e^4}{4}+\frac{1}{4}+\frac{e^4}{4}+e^3-\frac{5}{4}\\ &= e^4+e^3-1.\end{aligned}$$

2. Given that $f(x,y,z)=x^2\ln y+yz^2$ is a potential function for $\vec{\mathbf{F}}$, let's use the Fundamental Theorem for Line Integrals to calculate the integral. Note that

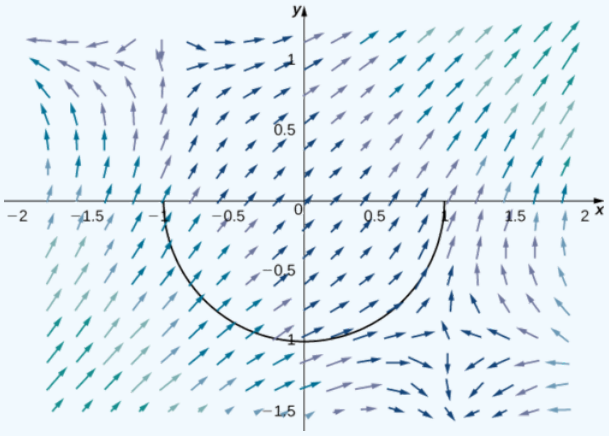
$$\begin{aligned}\int_C \vec{\mathbf{F}}\cdot d\vec{\mathbf{r}} &= \int_C \vec{\nabla} f\cdot d\vec{\mathbf{r}}\\ &= f(\vec{\mathbf{r}}(e))-f(\vec{\mathbf{r}}(1))\\ &= f(e^2,e,e)-f(1,1,1)\\ &= e^4+e^3-1.\end{aligned}$$

This calculation is much more straightforward than the calculation we did in (a). As long as we have a potential function, calculating a line integral using the Fundamental Theorem for Line Integrals is much easier than calculating without the theorem.

Example **16.4.3** illustrates a nice feature of the Fundamental Theorem of Line Integrals: it allows us to calculate more easily many vector line integrals. As long as we have a potential function, calculating the line integral is only a matter of evaluating the potential function at the endpoints and subtracting.

**Exercise 16.4.3**

Given that $f(x,y) = (x-1)^2 y + (y+1)^2 x$ is a potential function for $\vec{\mathbf{F}}(x,y) = \langle 2xy - 2y + (y+1)^2, (x-1)^2 + 2yx + 2x \rangle$, calculate integral $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$, where $C$ is the lower half of the unit circle oriented counterclockwise.



**Hint**

The Fundamental Theorem for Line Intervals says this integral depends only on the value of $f$ at the endpoints of $C$.

**Answer**

2

The Fundamental Theorem for Line Integrals has two important consequences. The first consequence is that if $\vec{\mathbf{F}}$ is conservative and $C$ is a closed curve, then the circulation of $\vec{\mathbf{F}}$ along $C$ is zero—that is, $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = 0$. To see why this is true, let $f$ be a potential function for $\vec{\mathbf{F}}$. Since $C$ is a closed curve, the terminal point $\vec{\mathbf{r}}(b)$ of $C$ is the same as the initial $\vec{\mathbf{r}}(a)$ of $C$—that is, $\vec{\mathbf{r}}(a) = \vec{\mathbf{r}}(b)$. Therefore, by the Fundamental Theorem for Line Integrals,

$$\oint_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \oint_C \vec{\nabla} f \cdot d\vec{\mathbf{r}} \tag{16.4.2}$$

$$= f(\vec{\mathbf{r}}(b)) - f(\vec{\mathbf{r}}(a)) \tag{16.4.3}$$

$$= f(\vec{\mathbf{r}}(b)) - f(\vec{\mathbf{r}}(b)) \tag{16.4.4}$$

$$= 0. \tag{16.4.5}$$

Recall that the reason a conservative vector field $\vec{\mathbf{F}}$ is called "conservative" is because such vector fields model forces in which energy is conserved. We have shown gravity to be an example of such a force. If we think of vector field $\vec{\mathbf{F}}$ in integral $\oint_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$ as a gravitational field, then the equation $\oint_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = 0$ follows. If a particle travels along a path that starts and ends at the same place, then the work done by gravity on the particle is zero.

The second important consequence of the Fundamental Theorem for Line Integrals (Equation 16.4.1) is that line integrals of conservative vector fields are independent of path—meaning, they depend only on the endpoints of the given curve, and do not depend on the path between the endpoints.

**DEFINITION: Path Independence**

Let $\vec{\mathbf{F}}$ be a vector field with domain $D$; it is independent of path (or path independent) if

$$\int_{C_1} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \int_{C_2} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$$

for any paths $C_1$ and $C_2$ in $D$ with the same initial and terminal points.

The second consequence is stated formally in the following theorem.

**Theorem: CONSERVATIVE FIELDS**

If $\vec{\mathbf{F}}$ is a *conservative vector field*, then $\vec{\mathbf{F}}$ is independent of path.

**Proof**

Let $D$ denote the domain of $\vec{\mathbf{F}}$ and let $C_1$ and $C_2$ be two paths in $D$ with the same initial and terminal points (Figure 16.4.5). Call the initial point $P_1$ and the terminal point $P_2$. Since $\vec{\mathbf{F}}$ is conservative, there is a potential function $f$ for $\vec{\mathbf{F}}$. By the Fundamental Theorem for Line Integrals,

$$\int_{C_1} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = f(P_2) - f(P_1) = \int_{C_2} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}.$$

Therefore, $\int_{C_1} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \int_{C_2} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$ and $\vec{\mathbf{F}}$ is independent of path.

□

To visualize what independence of path means, imagine three hikers climbing from base camp to the top of a mountain. Hiker 1 takes a steep route directly from camp to the top. Hiker 2 takes a winding route that is not steep from camp to the top. Hiker 3 starts by taking the steep route but halfway to the top decides it is too difficult for him. Therefore he returns to camp and takes the non-steep path to the top. All three hikers are traveling along paths in a gravitational field. Since gravity is a force in which energy is conserved, the gravitational field is conservative. By independence of path, the total amount of work done by gravity on each of the hikers is the same because they all started in the same place and ended in the same place. The work done by the hikers includes other factors such as friction and muscle movement, so the total amount of energy each one expended is not the same, but the net energy expended against gravity is the same for all three hikers.

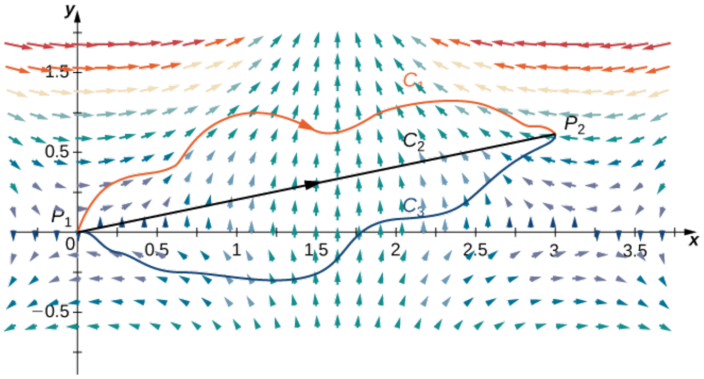


Figure 16.4.4: The vector field is conservative, and therefore independent of path.

We have shown that if $\vec{\mathbf{F}}$ is conservative, then $\vec{\mathbf{F}}$ is independent of path. It turns out that if the domain of $\vec{\mathbf{F}}$ is open and connected, then the converse is also true. That is, if $\vec{\mathbf{F}}$ is independent of path and the domain of $\vec{\mathbf{F}}$ is open and connected, then $\vec{\mathbf{F}}$ is conservative. Therefore, the set of conservative vector fields on open and connected domains is precisely the set of vector fields independent of path.

**Theorem: THE PATH INDEPENDENCE TEST FOR CONSERVATIVE FIELDS**

If $\vec{\mathbf{F}}$ is a continuous vector field that is independent of path and the domain $D$ of $\vec{\mathbf{F}}$ is open and connected, then $\vec{\mathbf{F}}$ is conservative.

**Proof**

We prove the theorem for vector fields in $\mathbb{R}^2$. The proof for vector fields in $\mathbb{R}^3$ is similar. To show that $\vec{\mathbf{F}} = \langle P, Q \rangle$ is conservative, we must find a potential function $f$ for $\vec{\mathbf{F}}$. To that end, let $X$ be a fixed point in $D$. For any point $(x, y)$ in $D$, let $C$ be a path from $X$ to $(x, y)$. Define $f(x, y)$ by $f(x, y) = \int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$. (Note that this definition of $f$ makes sense only because $\vec{\mathbf{F}}$ is

independent of path. If $\vec{\mathbf{F}}$ was not independent of path, then it might be possible to find another path $C'$ from $X$ to $(x,y)$ such that $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} \neq \int_{C'} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$, and in such a case $f(x,y)$ would not be a function.) We want to show that $f$ has the property $\vec{\nabla} f = \vec{\mathbf{F}}$.

Since domain $D$ is open, it is possible to find a disk centered at $(x,y)$ such that the disk is contained entirely inside $D$. Let $(a,y)$ with $a < x$ be a point in that disk. Let $C$ be a path from $X$ to $(x,y)$ that consists of two pieces: $C_1$ and $C_2$. The first piece, $C_1$, is any path from $C$ to $(a,y)$ that stays inside $D$; $C_2$ is the horizontal line segment from $(a,y)$ to $(x,y)$ (Figure 16.4.6). Then

$$f(x,y) = \int_{C_1} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} + \int_{C_2} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}.$$

The first integral does not depend on $x$, so

$$f_x(x,y) = \frac{\partial}{\partial x} \int_{C_2} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}.$$

If we parameterize $C_2$ by $\vec{\mathbf{r}}(t) = \langle t, y \rangle$, $a \leq t \leq x$, then

$$\begin{aligned} f_x(x,y) &= \frac{\partial}{\partial x} \int_{C_2} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} \\ &= \frac{\partial}{\partial x} \int_a^x \vec{\mathbf{F}}(\vec{\mathbf{r}}(t)) \cdot \vec{\mathbf{r}}'(t)\, dt \\ &= \frac{\partial}{\partial x} \int_a^x \vec{\mathbf{F}}(\vec{\mathbf{r}}(t)) \cdot \frac{d}{dt}(\langle t, y \rangle)\, dt \\ &= \frac{\partial}{\partial x} \int_a^x \vec{\mathbf{F}}(\vec{\mathbf{r}}(t)) \cdot \langle 1, 0 \rangle\, dt \\ &= \frac{\partial}{\partial x} \int_a^x P(t,y)\, dt. \end{aligned}$$

By the Fundamental Theorem of Calculus (part 1),

$$f_x(x,y) = \frac{\partial}{\partial x} \int_a^x P(t,y)\, dt = P(x,y).$$

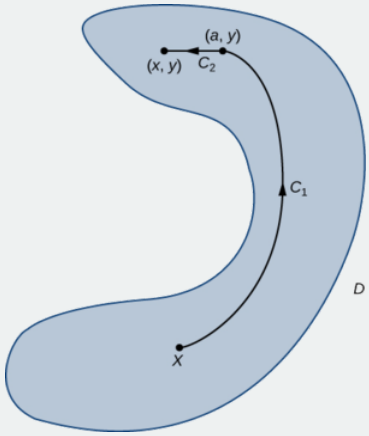

Figure 16.4.6. Here, $C_1$ is any path from $C$ to $(a,y)$ that stays inside $D$, and $C_2$ is the horizontal line segment from $(a,y)$ to $(x,y)$.

A similar argument using a vertical line segment rather than a horizontal line segment shows that $f_y(x,y) = Q(x,y)$.

Therefore $\vec{\nabla} f = \vec{\mathbf{F}}$ and $\vec{\mathbf{F}}$ is conservative.

□

We have spent a lot of time discussing and proving the theorems above, but we can summarize them simply: a vector field $\vec{\mathbf{F}}$ on an open and connected domain is conservative if and only if it is independent of path. This is important to know because conservative vector fields are extremely important in applications, and these theorems give us a different way of viewing what it means to be conservative using path independence.

## Example 16.4.4: Showing That a Vector Field Is Not Conservative

Use path independence to show that vector field $\vec{\mathbf{F}}(x,y) = \langle x^2 y, y+5\rangle$ is not conservative.

### Solution

We can indicate that $\vec{\mathbf{F}}$ is not conservative by showing that $\vec{\mathbf{F}}$ is not path independent. We do so by giving two different paths, $C_1$ and $C_2$, that both start at $(0,0)$ and end at $(1,1)$, and yet $\int_{C_1} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} \neq \int_{C_2} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$.

Let $C_1$ be the curve with parameterization $\vec{\mathbf{r}}_1(t) = \langle t, t\rangle$, $0 \leq t \leq 1$ and let $C_2$ be the curve with parameterization $\vec{\mathbf{r}}_2(t) = \langle t, t^2\rangle$, $0 \leq t \leq 1$ (Figure 16.4.7.). Then

$$\begin{aligned}\int_{C_1} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} &= \int_0^1 \vec{\mathbf{F}}(\vec{\mathbf{r}}_1(t)) \cdot \vec{\mathbf{r}}_1{}'(t)\, dt \\ &= \int_0^1 \langle t^3, t+5\rangle \cdot \langle 1,1\rangle\, dt = \int_0^1 (t^3 + t + 5)\, dt \\ &= \left[\frac{t^4}{4} + \frac{t^2}{2} + 5t\right]_0^1 = \frac{23}{4}\end{aligned}$$

and

$$\begin{aligned}\int_{C_2} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} &= \int_0^1 \vec{\mathbf{F}}(\vec{\mathbf{r}}_2(t)) \cdot \vec{\mathbf{r}}_2{}'(t)\, dt \\ &= \int_0^1 \langle t^4, t^2+5\rangle \cdot \langle 1, 2t\rangle\, dt = \int_0^1 (t^4 + 2t^3 + 10t)\, dt \\ &= \left[\frac{t^5}{5} + \frac{t^4}{2} + 5t^2\right]_0^1 = \frac{57}{10}.\end{aligned}$$

Since $\int_{C_1} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} \neq \int_{C_2} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$, the value of a line integral of $\vec{\mathbf{F}}$ depends on the path between two given points. Therefore, $\vec{\mathbf{F}}$ is not independent of path, and $\vec{\mathbf{F}}$ is not conservative.

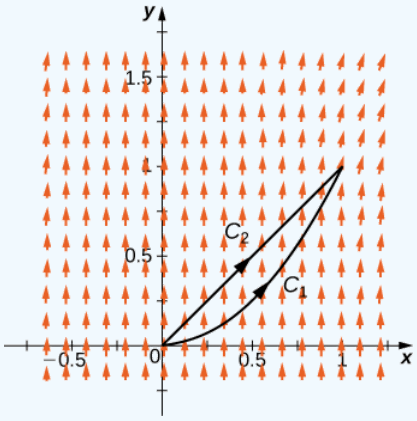

Figure 16.4.7: Curves $C_1$ and $C_2$ are both oriented from left to right.

## Exercise 16.4.4

Show that $\vec{\mathbf{F}}(x,y) = \langle xy, x^2y^2\rangle$ is not path independent by considering the line segment from $(0,0)$ to $(0,2)$ and the piece of the graph of $y = \frac{x^2}{2}$ that goes from $(0,0)$ to $(0,2)$.

**Hint**

Calculate the corresponding line integrals.

**Answer**

If $C_1$ and $C_2$ represent the two curves, then

$$\int_{C_1} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} \neq \int_{C_2} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}.$$

## Conservative Vector Fields and Potential Functions

As we have learned, the Fundamental Theorem for Line Integrals says that if $\vec{\mathbf{F}}$ is conservative, then calculating $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$ has two steps: first, find a potential function $f$ for $\vec{\mathbf{F}}$ and, second, calculate $f(P_1) - f(P_0)$, where $P_1$ is the endpoint of $C$ and $P_0$ is the starting point. To use this theorem for a conservative field $\vec{\mathbf{F}}$, we must be able to find a potential function $f$ for $\vec{\mathbf{F}}$. Therefore, we must answer the following question: Given a conservative vector field $\vec{\mathbf{F}}$, how do we find a function $f$ such that $\vec{\nabla} f = \vec{\mathbf{F}}$? Before giving a general method for finding a potential function, let's motivate the method with an example.

### Example 16.4.5: Finding a Potential Function

Find a potential function for $\vec{\mathbf{F}}(x, y) = \langle 2xy^3, 3x^2y^2 + \cos(y) \rangle$, thereby showing that $\vec{\mathbf{F}}$ is conservative.

**Solution**

Suppose that $f(x, y)$ is a potential function for $\vec{\mathbf{F}}$. Then, $\vec{\nabla} f = \vec{\mathbf{F}}$, and therefore

$$f_x(x, y) = 2xy^3 \quad \text{and} \quad f_y(x, y) = 3x^2y^2 + \cos y.$$

Integrating the equation $f_x(x, y) = 2xy^3$ with respect to $x$ yields the equation

$$f(x, y) = x^2y^3 + h(y).$$

Notice that since we are integrating a two-variable function with respect to $x$, we must add a constant of integration that is a constant with respect to $x$, but may still be a function of $y$. The equation $f(x, y) = x^2y^3 + h(y)$ can be confirmed by taking the partial derivative with respect to $x$:

$$\frac{\partial f}{\partial x} = \frac{\partial}{\partial x}(x^2y^3) + \frac{\partial}{\partial x}(h(y)) = 2xy^3 + 0 = 2xy^3.$$

Since $f$ is a potential function for $\vec{\mathbf{F}}$,

$$f_y(x, y) = 3x^2y^2 + \cos(y),$$

and therefore

$$3x^2y^2 + g'(y) = 3x^2y^2 + \cos(y).$$

This implies that $h'(y) = \cos y$, so $h(y) = \sin y + C$. Therefore, *any* function of the form $f(x, y) = x^2y^3 + \sin(y) + C$ is a potential function. Taking, in particular, $C = 0$ gives the potential function $f(x, y) = x^2y^3 + \sin(y)$.

To verify that $f$ is a potential function, note that $\vec{\nabla} f(x, y) = \langle 2xy^3, 3x^2y^2 + \cos y \rangle = \vec{\mathbf{F}}$.

### Exercise 16.4.5

Find a potential function for $\vec{\mathbf{F}}(x, y) = \langle e^x y^3 + y, 3e^x y^2 + x \rangle$.

**Hint**

Follow the steps in Example **16.4.5**.

**Answer**

$f(x, y) = e^x y^3 + xy$

The logic of the previous example extends to finding the potential function for any conservative vector field in $\mathbb{R}^2$. Thus, we have the following problem-solving strategy for finding potential functions:

**PROBLEM-SOLVING STRATEGY: FINDING A POTENTIAL FUNCTION FOR A CONSERVATIVE VECTOR FIELD $\vec{\mathbf{F}}(x,y) = \langle P(x,y), Q(x,y)\rangle$**

1. Integrate $P$ with respect to $x$. This results in a function of the form $g(x,y) + h(y)$, where $h(y)$ is unknown.
2. Take the partial derivative of $g(x,y) + h(y)$ with respect to $y$, which results in the function $g_y(x,y) + h'(y)$.
3. Use the equation $g_y(x,y) + h'(y) = Q(x,y)$ to find $h'(y)$.
4. Integrate $h'(y)$ to find $h(y)$.
5. Any function of the form $f(x,y) = g(x,y) + h(y) + C$, where $C$ is a constant, is a potential function for $\vec{\mathbf{F}}$.

We can adapt this strategy to find potential functions for vector fields in $\mathbb{R}^3$, as shown in the next example.

**Example 16.4.6: Finding a Potential Function in $\mathbb{R}^3$**

Find a potential function for $F(x,y,z) = \langle 2xy, x^2 + 2yz^3, 3y^2z^2 + 2z\rangle$, thereby showing that $\vec{\mathbf{F}}$ is conservative.

**Solution**

Suppose that $f$ is a potential function. Then, $\vec{\nabla} f = \vec{\mathbf{F}}$ and therefore $f_x(x,y,z) = 2xy$. Integrating this equation with respect to $x$ yields the equation $f(x,y,z) = x^2y + g(y,z)$ for some function $g$. Notice that, in this case, the constant of integration with respect to $x$ is a function of $y$ and $z$.

Since $f$ is a potential function,

$$x^2 + 2yz^3 = f_y(x,y,z) = x^2 + g_y(y,z).$$

Therefore,

$$g_y(y,z) = 2yz^3.$$

Integrating this function with respect to $y$ yields

$$g(y,z) = y^2z^3 + h(z)$$

for some function $h(z)$ of $z$ alone. (Notice that, because we know that $g$ is a function of only $y$ and $z$, we do not need to write $g(y,z) = y^2z^3 + h(x,z)$.) Therefore,

$$f(x,y,z) = x^2y + g(y,z) = x^2y + y^2z^3 + h(z).$$

To find $f$, we now must only find $h$. Since $f$ is a potential function,

$$3y^2z^2 + 2z = g_z(y,z) = 3y^2z^2 + h'(z).$$

This implies that $h'(z) = 2z$, so $h(z) = z^2 + C$. Letting $C = 0$ gives the potential function

$$f(x,y,z) = x^2y + y^2z^3 + z^2.$$

To verify that $f$ is a potential function, note that $\vec{\nabla} f(x,y,z) = \langle 2xy, x^2 + 2yz^3, 3y^2z^2 + 2z\rangle = \vec{\mathbf{F}}(x,y,z)$.

**Exercise 16.4.6**

Find a potential function for $\vec{\mathbf{F}}(x,y,z) = \langle 12x^2, \cos y \cos z, 1 - \sin y \sin z\rangle$.

**Hint**

Following Example 16.4.6, begin by integrating with respect to $x$.

**Answer**

$f(x,y,z) = 4x^3 + \sin y \cos z + z$

We can apply the process of finding a potential function to a gravitational force. Recall that, if an object has unit mass and is located at the origin, then the gravitational force in $\mathbb{R}^2$ that the object exerts on another object of unit mass at the point $(x,y)$ is

given by vector field

$$\vec{\mathbf{F}}(x,y) = -G\left\langle \frac{x}{(x^2+y^2)^{3/2}}, \frac{y}{(x^2+y^2)^{3/2}} \right\rangle,$$

where $G$ is the universal gravitational constant. In the next example, we build a potential function for $\vec{\mathbf{F}}$, thus confirming what we already know: that gravity is conservative.

### Example 16.4.7: Finding a Potential Function

Find a potential function $f$ for $\vec{\mathbf{F}}(x,y) = -G\left\langle \frac{x}{(x^2+y^2)^{3/2}}, \frac{y}{(x^2+y^2)^{3/2}} \right\rangle$.

**Solution**

Suppose that $f$ is a potential function. Then, $\vec{\nabla} f = \vec{\mathbf{F}}$ and therefore

$$f_x(x,y) = \frac{-Gx}{(x^2+y^2)^{3/2}}.$$

To integrate this function with respect to $x$, we can use $u$-substitution. If $u = x^2+y^2$, then $\frac{du}{2} = x\,dx$, so

$$\begin{aligned}\int \frac{-Gx}{(x^2+y^2)^{3/2}}\,dx &= \int \frac{-G}{2u^{3/2}}\,du \\ &= \frac{G}{\sqrt{u}} + h(y) \\ &= \frac{G}{\sqrt{x^2+y^2}} + h(y)\end{aligned}$$

for some function $h(y)$. Therefore,

$$f(x,y) = \frac{G}{\sqrt{x^2+y^2}} + h(y).$$

Since $f$ is a potential function for $\vec{\mathbf{F}}$,

$$f_y(x,y) = \frac{-Gy}{(x^2+y^2)^{3/2}}$$

.

Since $f(x,y) = \frac{G}{\sqrt{x^2+y^2}} + h(y)$, $f_y(x,y)$ also equals $\frac{-Gy}{(x^2+y^2)^{3/2}} + h'(y)$.

Therefore,

$$\frac{-Gy}{(x^2+y^2)^{3/2}} + h'(y) = \frac{-Gy}{(x^2+y^2)^{3/2}},$$

which implies that $h'(y) = 0$. Thus, we can take $h(y)$ to be any constant; in particular, we can let $h(y) = 0$. The function

$$f(x,y) = \frac{G}{\sqrt{x^2+y^2}}$$

is a potential function for the gravitational field $\vec{\mathbf{F}}$. To confirm that $f$ is a potential function, note that

$$\begin{aligned}\vec{\nabla} f(x,y) &= \langle -\frac{1}{2}\frac{G}{(x^2+y^2)^{3/2}}(2x), -\frac{1}{2}\frac{G}{(x^2+y^2)^{3/2}}(2y)\rangle \\ &= \langle \frac{-Gx}{(x^2+y^2)^{3/2}}, \frac{-Gy}{(x^2+y^2)^{3/2}}\rangle \\ &= \vec{\mathbf{F}}(x,y).\end{aligned}$$

**Exercise 16.4.7**

Find a potential function $f$ for the three-dimensional gravitational force $\vec{\mathbf{F}}(x,y,z) = \left\langle \frac{-Gx}{(x^2+y^2+z^2)^{3/2}}, \frac{-Gy}{(x^2+y^2+z^2)^{3/2}}, \frac{-Gz}{(x^2+y^2+z^2)^{3/2}} \right\rangle$.

**Hint**

Follow the Problem-Solving Strategy.

**Answer**

$$f(x,y,z) = \frac{G}{\sqrt{x^2+y^2+z^2}}$$

## Testing a Vector Field

Until now, we have worked with vector fields that we know are conservative, but if we are not told that a vector field is conservative, we need to be able to test whether it is conservative. Recall that, if $\vec{\mathbf{F}}$ is conservative, then $\vec{\mathbf{F}}$ has the cross-partial property (see The Cross-Partial Property of Conservative Vector Fields). That is, if $\vec{\mathbf{F}} = \langle P, Q, R \rangle$ is conservative, then $P_y = Q_x$, $P_z = R_x$, and $Q_z = R_y$. So, if $\vec{\mathbf{F}}$ has the cross-partial property, then is $\vec{\mathbf{F}}$ conservative? If the domain of $\vec{\mathbf{F}}$ is open and simply connected, then the answer is yes.

**Theorem: THE CROSS-PARTIAL TEST FOR CONSERVATIVE FIELDS**

If $\vec{\mathbf{F}} = \langle P, Q, R \rangle$ is a vector field on an open, simply connected region $D$ and $P_y = Q_x$, $P_z = R_x$, and $Q_z = R_y$ throughout $D$, then $\vec{\mathbf{F}}$ is conservative.

Although a proof of this theorem is beyond the scope of the text, we can discover its power with some examples. Later, we see why it is necessary for the region to be simply connected.

Combining this theorem with the cross-partial property, we can determine whether a given vector field is conservative:

**Theorem: CROSS-PARTIAL PROPERTY OF CONSERVATIVE FIELDS**

Let $\vec{\mathbf{F}} = \langle P, Q, R \rangle$ be a vector field on an open, simply connected region $D$. Then $P_y = Q_x$, $P_z = R_x$, and $Q_z = R_y$ throughout $D$ if and only if $\vec{\mathbf{F}}$ is conservative.

The version of this theorem in $\mathbb{R}^2$ is also true. If $\vec{\mathbf{F}}(x,y) = \langle P, Q \rangle$ is a vector field on an open, simply connected domain in $\mathbb{R}^2$, then $\vec{\mathbf{F}}$ is conservative if and only if $P_y = Q_x$.

**Example 16.4.8: Determining Whether a Vector Field Is Conservative**

Determine whether vector field $\vec{\mathbf{F}}(x,y,z) = \langle xy^2z, x^2yz, z^2 \rangle$ is conservative.

**Solution**

Note that the domain of $\vec{\mathbf{F}}$ is all of $\mathbb{R}^2$ and $\mathbb{R}^3$ is simply connected. Therefore, we can use **The Cross-Partial Property of Conservative Vector Fields** to determine whether $\vec{\mathbf{F}}$ is conservative. Let

$$P(x,y,z) = xy^2z$$

$$Q(x,y,z) = x^2yz$$

and

$$R(x,y,z) = z^2.$$

Since $Q_z(x,y,z) = x^2y$ and $R_y(x,y,z) = 0$, the vector field is not conservative.

### Example 16.4.9: Determining Whether a Vector Field Is Conservative

Determine vector field $\vec{\mathbf{F}}(x,y) = \langle x\ln(y), \frac{x^2}{2y}\rangle$ is conservative.

**Solution**

Note that the domain of $\vec{\mathbf{F}}$ is the part of $\mathbb{R}^2$ in which $y > 0$. Thus, the domain of $\vec{\mathbf{F}}$ is part of a plane above the $x$-axis, and this domain is simply connected (there are no holes in this region and this region is connected). Therefore, we can use **The Cross-Partial Property of Conservative Vector Fields** to determine whether $\vec{\mathbf{F}}$ is conservative. Let

$$P(x,y) = x\ln(y) \text{ and } Q(x,y) = \frac{x^2}{2y}.$$

Then $P_y(x,y) = \frac{x}{y} = Q_x(x,y)$ and thus $\vec{\mathbf{F}}$ is conservative.

### Exercise 16.4.8

Determine whether $\vec{\mathbf{F}}(x,y) = \langle \sin x\cos y, \cos x\sin y\rangle$ is conservative.

**Hint**

Use **The Cross-Partial Property of Conservative Vector Fields** from the previous section.

**Answer**

It is conservative.

When using **The Cross-Partial Property of Conservative Vector Fields**, it is important to remember that a theorem is a tool, and like any tool, it can be applied only under the right conditions. In the case of **The Cross-Partial Property of Conservative Vector Fields**, the theorem can be applied only if the domain of the vector field is simply connected.

To see what can go wrong when misapplying the theorem, consider the vector field from Example 16.4.4:

$$\vec{\mathbf{F}}(x,y) = \frac{y}{x^2+y^2}\,\hat{\mathbf{i}} + \frac{-x}{x^2+y^2}\,\hat{\mathbf{j}}.$$

This vector field satisfies the cross-partial property, since

$$\frac{\partial}{\partial y}\left(\frac{y}{x^2+y^2}\right) = \frac{(x^2+y^2)-y(2y)}{(x^2+y^2)^2} = \frac{x^2-y^2}{(x^2+y^2)^2}$$

and

$$\frac{\partial}{\partial x}\left(\frac{-x}{x^2+y^2}\right) = \frac{-(x^2+y^2)+x(2x)}{(x^2+y^2)^2} = \frac{x^2-y^2}{(x^2+y^2)^2}.$$

Since $\vec{\mathbf{F}}$ satisfies the cross-partial property, we might be tempted to conclude that $\vec{\mathbf{F}}$ is conservative. However, $\vec{\mathbf{F}}$ is not conservative. To see this, let

$$\vec{\mathbf{r}}(t) = \langle \cos t, \sin t\rangle, \quad 0 \le t \le \pi$$

be a parameterization of the upper half of a unit circle oriented counterclockwise (denote this $C_1$) and let

$$\vec{\mathbf{s}}(t) = \langle \cos t, -\sin t\rangle, \quad 0 \le t \le \pi$$

be a parameterization of the lower half of a unit circle oriented clockwise (denote this $C_2$). Notice that $C_1$ and $C_2$ have the same starting point and endpoint. Since $\sin^2 t + \cos^2 t = 1$,

$$\vec{\mathbf{F}}(\vec{\mathbf{r}}(t))\cdot\vec{\mathbf{r}}'(t) = \langle \sin(t), -\cos(t)\rangle \cdot \langle -\sin(t), \cos(t)\rangle = -1$$

and

$$\vec{\mathbf{F}}(\vec{\mathbf{s}}(t)) \cdot \vec{\mathbf{s}}'(t) = \langle -\sin t, -\cos t \rangle \cdot \langle -\sin t, -\cos t \rangle = \sin^2 t + \cos^2 t = 1.$$

Therefore,

$$\int_{C_1} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \int_0^{\pi} -1 \, dt = -\pi$$

and

$$\int_{C_2} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \int_0^{\pi} 1 \, dt = \pi.$$

Thus, $C_1$ and $C_2$ have the same starting point and endpoint, but $\int_{C_1} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} \neq \int_{C_2} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$. Therefore, $\vec{\mathbf{F}}$ is not independent of path and $\vec{\mathbf{F}}$ is not conservative.

To summarize: $\vec{\mathbf{F}}$ satisfies the cross-partial property and yet $\vec{\mathbf{F}}$ is not conservative. What went wrong? Does this contradict **The Cross-Partial Property of Conservative Vector Fields**? The issue is that the domain of $\vec{\mathbf{F}}$ is all of $\mathbb{R}^2$ except for the origin. In other words, the domain of $\vec{\mathbf{F}}$ has a hole at the origin, and therefore the domain is not simply connected. Since the domain is not simply connected, **The Cross-Partial Property of Conservative Vector Fields** does not apply to $\vec{\mathbf{F}}$.

We close this section by looking at an example of the usefulness of the Fundamental Theorem for Line Integrals. Now that we can test whether a vector field is conservative, we can always decide whether the Fundamental Theorem for Line Integrals can be used to calculate a vector line integral. If we are asked to calculate an integral of the form $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$, then our first question should be: Is $\vec{\mathbf{F}}$ conservative? If the answer is yes, then we should find a potential function and use the Fundamental Theorem for Line Integrals to calculate the integral. If the answer is no, then the Fundamental Theorem for Line Integrals cannot help us and we have to use other methods, such as using the method from the previous section (using $\vec{\mathbf{F}}(\vec{\mathbf{r}}(t))$ and $\vec{\mathbf{r}}'(t)$).

### Example 16.4.10: Using the Fundamental Theorem for Line Integrals

Calculate line integral $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$, where $\vec{\mathbf{F}}(x, y, z) = \langle 2xe^y z + e^x z, \; x^2 e^y z, \; x^2 e^y + e^x \rangle$ and $C$ is any smooth curve that goes from the origin to $(1, 1, 1)$.

#### Solution

Before trying to compute the integral, we need to determine whether $\vec{\mathbf{F}}$ is conservative and whether the domain of $\vec{\mathbf{F}}$ is simply connected. The domain of $\vec{\mathbf{F}}$ is all of $\mathbb{R}^3$, which is connected and has no holes. Therefore, the domain of $\vec{\mathbf{F}}$ is simply connected. Let

$$P(x, y, z) = 2xe^y z + e^x z, \quad Q(x, y, z) = x^2 e^y z, \quad \text{and} \quad R(x, y, z) = x^2 e^y + e^x$$

so that $\vec{\mathbf{F}}(x, y, z) = \langle P, Q, R \rangle$. Since the domain of $\vec{\mathbf{F}}$ is simply connected, we can check the cross partials to determine whether $\vec{\mathbf{F}}$ is conservative. Note that

$$\begin{aligned} P_y(x, y, z) &= 2xe^y z = Q_x(x, y, z) \\ P_z(x, y, z) &= 2xe^y + e^x = R_x(x, y, z) \\ Q_z(x, y, z) &= x^2 e^y = R_y(x, y, z). \end{aligned}$$

Therefore, $\vec{\mathbf{F}}$ is conservative.

To evaluate $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$ using the Fundamental Theorem for Line Integrals, we need to find a potential function $f$ for $\vec{\mathbf{F}}$. Let $f$ be a potential function for $\vec{\mathbf{F}}$. Then, $\vec{\nabla} f = \vec{\mathbf{F}}$, and therefore $f_x(x, y, z) = 2xe^y z + e^x z$. Integrating this equation with respect to $x$ gives $f(x, y, z) = x^2 e^y z + e^x z + h(y, z)$ for some function $h$. Differentiating this equation with respect to $y$ gives $x^2 e^y z + h_y(y, z) = Q(x, y, z) = x^2 e^y z$, which implies that $h_y(y, z) = 0$. Therefore, $h$ is a function of $z$ only, and $f(x, y, z) = x^2 e^y z + e^x z + h(z)$. To find $h$, note that $f_z = x^2 e^y + e^x + h'(z) = R = x^2 e^y + e^x$. Therefore, $h'(z) = 0$ and we can take $h(z) = 0$. A potential function for $\vec{\mathbf{F}}$ is $f(x, y, z) = x^2 e^y z + e^x z$.

Now that we have a potential function, we can use the Fundamental Theorem for Line Integrals to evaluate the integral. By the theorem,

$$\begin{aligned}\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} &= \int_C \vec{\nabla} f \cdot d\vec{\mathbf{r}} \\ &= f(1,1,1) - f(0,0,0) \\ &= 2e.\end{aligned}$$

### Analysis

Notice that if we hadn't recognized that $\vec{\mathbf{F}}$ is conservative, we would have had to parameterize $C$ and use the method from the previous section. Since curve $C$ is unknown, using the Fundamental Theorem for Line Integrals is much simpler.

## ? Exercise 16.4.9

Calculate integral $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$, where $\vec{\mathbf{F}}(x,y) = \langle \sin x \sin y, 5 - \cos x \cos y \rangle$ and $C$ is a semicircle with starting point $(0,\pi)$ and endpoint $(0,-\pi)$.

**Hint**

Use the Fundamental Theorem for Line Integrals.

**Answer**

$-10\pi$

## ✓ Example 16.4.11: Work Done on a Particle

Let $\vec{\mathbf{F}}(x,y) = \langle 2xy^2, 2x^2y \rangle$ be a force field. Suppose that a particle begins its motion at the origin and ends its movement at any point in a plane that is not on the $x$-axis or the $y$-axis. Furthermore, the particle's motion can be modeled with a smooth parameterization. Show that $\vec{\mathbf{F}}$ does positive work on the particle.

### Solution

We show that $\vec{\mathbf{F}}$ does positive work on the particle by showing that $\vec{\mathbf{F}}$ is conservative and then by using the Fundamental Theorem for Line Integrals.

To show that $\vec{\mathbf{F}}$ is conservative, suppose $f(x,y)$ were a potential function for $\vec{\mathbf{F}}$. Then, $\vec{\nabla} f(x,y) = \vec{\mathbf{F}}(x,y) = \langle 2xy^2, 2x^2y \rangle$ and therefore $f_x(x,y) = 2xy^2$ and $f_y(x,y) = 2x^2y$. The equation $fx(x,y) = 2xy^2$ implies that $f(x,y) = x^2y^2 + h(y)$. Deriving both sides with respect to $y$ yields $f_y(x,y) = 2x^2y + h'(y)$. Therefore, $h'(y) = 0$ and we can take $h(y) = 0$.

If $f(x,y) = x^2y^2$, then note that $\vec{\nabla} f(x,y) = \langle 2xy^2, 2x^2y \rangle = \vec{\mathbf{F}}$, and therefore $f$ is a potential function for $\vec{\mathbf{F}}$.

Let $(a,b)$ be the point at which the particle stops is motion, and let $C$ denote the curve that models the particle's motion. The work done by $\vec{\mathbf{F}}$ on the particle is $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$. By the Fundamental Theorem for Line Integrals,

$$\begin{aligned}\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} &= \int_C \nabla f \cdot d\vec{\mathbf{r}} \\ &= f(a,b) - f(0,0) \\ &= a^2b^2.\end{aligned}$$

Since $a \neq 0$ and $b \neq 0$, by assumption, $a^2b^2 > 0$. Therefore, $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} > 0$, and $\vec{\mathbf{F}}$ does positive work on the particle.

### Analysis

Notice that this problem would be much more difficult without using the Fundamental Theorem for Line Integrals. To apply the tools we have learned, we would need to give a curve parameterization and use the method from the previous section. Since the path of motion $C$ can be as exotic as we wish (as long as it is smooth), it can be very difficult to parameterize the motion of the particle.

**? Exercise 16.4.10**

Let $\vec{\mathbf{F}}(x,y) = \langle 4x^3y^4, 4x^4y^3 \rangle$, and suppose that a particle moves from point $(4,4)$ to $(1,1)$ along any smooth curve. Is the work done by $\vec{\mathbf{F}}$ on the particle positive, negative, or zero?

**Hint**

Use the Fundamental Theorem for Line Integrals.

**Answer**

Negative

## Key Concepts

- The theorems in this section require curves that are closed, simple, or both, and regions that are connected or simply connected.
- The line integral of a conservative vector field can be calculated using the Fundamental Theorem for Line Integrals. This theorem is a generalization of the Fundamental Theorem of Calculus in higher dimensions. Using this theorem usually makes the calculation of the line integral easier.
- Conservative fields are independent of path. The line integral of a conservative field depends only on the value of the potential function at the endpoints of the domain curve.
- Given vector field $\vec{\mathbf{F}}$, we can test whether $\vec{\mathbf{F}}$ is conservative by using the cross-partial property. If $\vec{\mathbf{F}}$ has the cross-partial property and the domain is simply connected, then $\vec{\mathbf{F}}$ is conservative (and thus has a potential function). If $\vec{\mathbf{F}}$ is conservative, we can find a potential function by using the Problem-Solving Strategy.
- The circulation of a conservative vector field on a simply connected domain over a closed curve is zero.

## Key Equations

- **Fundamental Theorem for Line Integrals**
  $\int_C \vec{\nabla} f \cdot d\vec{\mathbf{r}} = f(\vec{\mathbf{r}}(b)) - f(\vec{\mathbf{r}}(a))$
- **Circulation of a conservative field over curve $C$ that encloses a simply connected region**
  $\oint_C \vec{\nabla} f \cdot d\vec{\mathbf{r}} = 0$

## Glossary

**closed curve**
a curve that begins and ends at the same point

**connected region**
a region in which any two points can be connected by a path with a trace contained entirely inside the region

**Fundamental Theorem for Line Integrals**
the value of line integral $\int_C \vec{\nabla} f \cdot d\vec{\mathbf{r}}$ depends only on the value of $f$ at the endpoints of $C$: $\int_C \vec{\nabla} f \cdot d\vec{\mathbf{r}} = f(\vec{\mathbf{r}}(b)) - f(\vec{\mathbf{r}}(a))$

**independence of path**
a vector field $\vec{\mathbf{F}}$ has path independence if $\int_{C_1} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \int_{C_2} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$ for any curves $C_1$ and $C_2$ in the domain of $\vec{\mathbf{F}}$ with the same initial points and terminal points

**simple curve**
a curve that does not cross itself

**simply connected region**
a region that is connected and has the property that any closed curve that lies entirely inside the region encompasses points that are entirely inside the region

# 16.4E: Exercises for Section 16.3

**1.** *True* or *False?* If vector field $\vec{\mathbf{F}}$ is conservative on the open and connected region $D$, then line integrals of $\vec{\mathbf{F}}$ are path independent on $D$, regardless of the shape of $D$.

**2.** *True* or *False?* Function $\vec{\mathbf{r}}(t) = \vec{\mathbf{a}} + t(\vec{\mathbf{b}} - \vec{\mathbf{a}})$, where $0 \le t \le 1$, parameterizes the straight-line segment from $\vec{\mathbf{a}}$ to $\vec{\mathbf{b}}$.

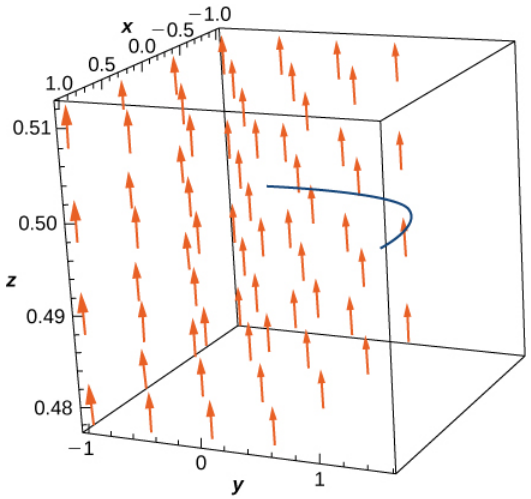
**3.** *True* or *False?* Vector field $\vec{\mathbf{F}}(x, y, z) = (y \sin z)\,\hat{\mathbf{i}} + (x \sin z)\,\hat{\mathbf{j}} + (xy \cos z)\,\hat{\mathbf{k}}$ is conservative.

**4.** *True* or *False?* Vector field $\vec{\mathbf{F}}(x, y, z) = y\,\hat{\mathbf{i}} + (x + z)\,\hat{\mathbf{j}} - y\,\hat{\mathbf{k}}$ is conservative.

**5.** Justify the Fundamental Theorem of Line Integrals for $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$ in the case when $\vec{\mathbf{F}}(x, y) = (2x + 2y)\,\hat{\mathbf{i}} + (2x + 2y)\,\hat{\mathbf{j}}$ and $C$ is a portion of the positively oriented circle $x^2 + y^2 = 25$ from $(5, 0)$ to $(3, 4)$.

**6. [T]** Find $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$, where $\vec{\mathbf{F}}(x, y) = (ye^{xy} + \cos x)\,\hat{\mathbf{i}} + \left(xe^{xy} + \frac{1}{y^2+1}\right)\hat{\mathbf{j}}$ and $C$ is a portion of curve $y = \sin x$ from $x = 0$ to $x = \frac{\pi}{2}$.

**7. [T]** Evaluate line integral $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$, where $\vec{\mathbf{F}}(x, y) = (e^x \sin y - y)\,\hat{\mathbf{i}} + (e^x \cos y - x - 2)\,\hat{\mathbf{j}}$, and $C$ is the path given by $\vec{\mathbf{r}}(t) = (t^3 \sin \frac{\pi t}{2})\,\hat{\mathbf{i}} - (\frac{\pi}{2}\cos(\frac{\pi t}{2} + \frac{\pi}{2}))\,\hat{\mathbf{j}}$ for $0 \le t \le 1$.



**For the following exercises, determine whether the vector field is conservative and, if it is, find the potential function.**

**8.** $\vec{\mathbf{F}}(x, y) = 2xy^3\,\hat{\mathbf{i}} + 3y^2x^2\,\hat{\mathbf{j}}$

**9.** $\vec{\mathbf{F}}(x, y) = (-y + e^x \sin y)\,\hat{\mathbf{i}} + ((x + 2)e^x \cos y)\,\hat{\mathbf{j}}$

**10.** $\vec{\mathbf{F}}(x, y) = (e^{2x} \sin y)\,\hat{\mathbf{i}} + (e^{2x} \cos y)\,\hat{\mathbf{j}}$

**11.** $\vec{\mathbf{F}}(x, y) = (6x + 5y)\,\hat{\mathbf{i}} + (5x + 4y)\,\hat{\mathbf{j}}$

**12.** $\vec{\mathbf{F}}(x, y) = (2x \cos(y) - y \cos(x))\,\hat{\mathbf{i}} + (-x^2 \sin(y) - \sin(x))\,\hat{\mathbf{j}}$

**13.** $\vec{\mathbf{F}}(x, y) = (ye^x + \sin(y))\,\hat{\mathbf{i}} + (e^x + x \cos(y))\,\hat{\mathbf{j}}$

**For the following exercises, evaluate the line integrals using the Fundamental Theorem of Line Integrals.**

**14.** $\oint_C (y\,\hat{\mathbf{i}} + x\,\hat{\mathbf{j}}) \cdot d\vec{\mathbf{r}}$, where $C$ is any path from $(0, 0)$ to $(2, 4)$

**15.** $\oint_C (2y\,dx + 2x\,dy)$, where $C$ is the line segment from $(0, 0)$ to $(4, 4)$

**16. [T]** $\oint_C \left[\arctan\frac{y}{x} - \frac{xy}{x^2 + y^2}\right] dx + \left[\frac{x^2}{x^2 + y^2} + e^{-y}(1 - y)\right] dy$, where $C$ is any smooth curve from $(1, 1)$ to $(-1, 2)$.

**17.** Find the conservative vector field for the potential function $f(x, y) = 5x^2 + 3xy + 10y^2$.

**For the following exercises, determine whether the vector field is conservative and, if so, find a potential function.**

**18.** $\vec{\mathbf{F}}(x,y) = (12xy)\,\hat{\mathbf{i}} + 6(x^2+y^2)\,\hat{\mathbf{j}}$

**19.** $\vec{\mathbf{F}}(x,y) = (e^x \cos y)\,\hat{\mathbf{i}} + 6(e^x \sin y)\,\hat{\mathbf{j}}$

**20.** $\vec{\mathbf{F}}(x,y) = (2xye^{x^2y})\,\hat{\mathbf{i}} + 6(x^2e^{x^2y})\,\hat{\mathbf{j}}$

**21.** $\vec{\mathbf{F}}(x,y,z) = (ye^z)\,\hat{\mathbf{i}} + (xe^z)\,\hat{\mathbf{j}} + (xye^z)\,\hat{\mathbf{k}}$

**22.** $\vec{\mathbf{F}}(x,y,z) = (\sin y)\,\hat{\mathbf{i}} - (x\cos y)\,\hat{\mathbf{j}} + \hat{\mathbf{k}}$

**23.** $\vec{\mathbf{F}}(x,y,z) = \dfrac{1}{y}\,\hat{\mathbf{i}} - \dfrac{x}{y^2}\,\hat{\mathbf{j}} + (2z-1)\,\hat{\mathbf{k}}$

**24.** $\vec{\mathbf{F}}(x,y,z) = 3z^2\,\hat{\mathbf{i}} - \cos y\,\hat{\mathbf{j}} + 2xz\,\hat{\mathbf{k}}$

**25.** $\vec{\mathbf{F}}(x,y,z) = (2xy)\,\hat{\mathbf{i}} + (x^2+2yz)\,\hat{\mathbf{j}} + y^2\,\hat{\mathbf{k}}$

**For the following exercises, determine whether the given vector field is conservative and find a potential function.**

**26.** $\vec{\mathbf{F}}(x,y) = (e^x \cos y)\,\hat{\mathbf{i}} + 6(e^x \sin y)\,\hat{\mathbf{j}}$

**27.** $\vec{\mathbf{F}}(x,y) = (2xye^{x^2y})\,\hat{\mathbf{i}} + (x^2e^{x^2y})\,\hat{\mathbf{j}}$

**For the following exercises, evaluate the integral using the Fundamental Theorem of Line Integrals.**

**28.** Evaluate $\int_C \vec{\nabla} f \cdot d\vec{\mathbf{r}}$, where $f(x,y,z) = \cos(\pi x) + \sin(\pi y) - xyz$ and $C$ is any path that starts at $(1,12,2)$ and ends at $(2,1,-1)$.

**29. [T]** Evaluate $\int_C \vec{\nabla} f \cdot d\vec{\mathbf{r}}$, where $f(x,y) = xy + e^x$ and $C$ is a straight line from $(0,0)$ to $(2,1)$.

**30. [T]** Evaluate $\int_C \vec{\nabla} f \cdot d\vec{\mathbf{r}}$, where $f(x,y) = x^2y - x$ and $C$ is any path in a plane from (1, 2) to (3, 2).

**31.** Evaluate $\int_C \vec{\nabla} f \cdot d\vec{\mathbf{r}}$, where $f(x,y,z) = xyz^2 - yz$ and $C$ has initial point $(1,2,3)$ and terminal point $(3,5,2)$.

# 16.5: Green's Theorem

**Learning Objectives**

- Apply the circulation form of Green's theorem.
- Apply the flux form of Green's theorem.
- Calculate circulation and flux on more general regions.

In this section, we examine Green's theorem, which is an extension of the Fundamental Theorem of Calculus to two dimensions. Green's theorem has two forms: a circulation form and a flux form, both of which require region $D$ in the double integral to be simply connected. However, we will extend Green's theorem to regions that are not simply connected.

Put simply, Green's theorem relates a line integral around a simply closed plane curve $C$ and a double integral over the region enclosed by $C$. The theorem is useful because it allows us to translate difficult line integrals into more simple double integrals, or difficult double integrals into more simple line integrals.

## Extending the Fundamental Theorem of Calculus

Recall that the Fundamental Theorem of Calculus says that

$$\int_a^b F'(x)\,dx = F(b) - F(a).$$

As a geometric statement, this equation says that the integral over the region below the graph of $F'(x)$ and above the line segment $[a, b]$ depends only on the value of $F$ at the endpoints $a$ and $b$ of that segment. Since the numbers $a$ and $b$ are the boundary of the line segment $[a, b]$, the theorem says we can calculate integral $\int_a^b F'(x)\,dx$ based on information about the boundary of line segment $[a, b]$ (Figure 16.5.1). The same idea is true of the Fundamental Theorem for Line Integrals:

$$\int_C \vec{\nabla} f \cdot d\vec{\mathbf{r}} = f(\vec{\mathbf{r}}(b)) - f(\vec{\mathbf{r}}(a)).$$

When we have a potential function (an "antiderivative"), we can calculate the line integral based solely on information about the boundary of curve $C$.

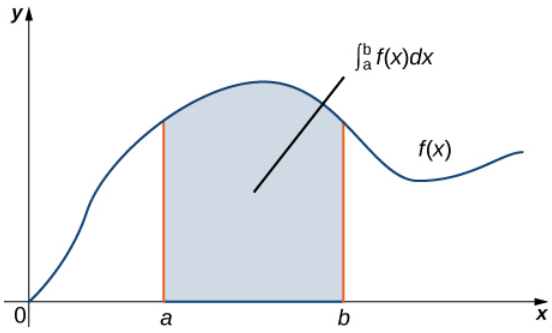

Figure 16.5.1: The Fundamental Theorem of Calculus says that the integral over line segment $[a, b]$ depends only on the values of the antiderivative at the endpoints of $[a, b]$.

Green's theorem takes this idea and extends it to calculating double integrals. Green's theorem says that we can calculate a double integral over region $D$ based solely on information about the boundary of $D$. Green's theorem also says we can calculate a line integral over a simple closed curve $C$ based solely on information about the region that $C$ encloses. In particular, Green's theorem connects a double integral over region $D$ to a line integral around the boundary of $D$.

## Circulation Form of Green's Theorem

The first form of Green's theorem that we examine is the circulation form. This form of the theorem relates the vector line integral over a simple, closed plane curve $C$ to a double integral over the region enclosed by $C$. Therefore, the circulation of a vector field along a simple closed curve can be transformed into a double integral and vice versa.

## GREEN'S THEOREM (CIRCULATION FORM)

Let $D$ be an open, simply connected region with a boundary curve $C$ that is a piecewise smooth, simple closed curve oriented counterclockwise (Figure 16.5.2). Let $\vec{\mathbf{F}} = \langle P, Q \rangle$ be a vector field with component functions that have continuous partial derivatives on $D$. Then,

$$\oint_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \oint_C P\,dx + Q\,dy \tag{16.5.1}$$

$$= \iint_D (Q_x - P_y)\,dA. \tag{16.5.2}$$

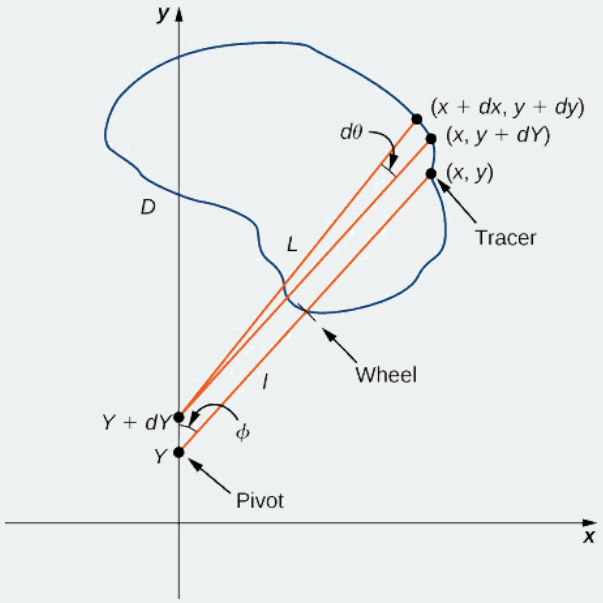

Figure 16.5.2: The circulation form of Green's theorem relates a line integral over curve $C$ to a double integral over region $D$.

Notice that Green's theorem can be used only for a two-dimensional vector field $\vec{\mathbf{F}}$. If $\vec{\mathbf{F}}$ is a three-dimensional field, then Green's theorem does not apply. Since

$$\int_C P\,dx + Q\,dy = \int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{T}}\,ds$$

this version of Green's theorem is sometimes referred to as the ***tangential form* of Green's theorem.**

The proof of Green's theorem is rather technical, and beyond the scope of this text. Here we examine a proof of the theorem in the special case that $D$ is a rectangle. For now, notice that we can quickly confirm that the theorem is true for the special case in which $\vec{\mathbf{F}} = \langle P, Q \rangle$ is conservative. In this case,

$$\oint_C P\,dx + Q\,dy = 0$$

because the circulation is zero in conservative vector fields. $\vec{\mathbf{F}}$ satisfies the cross-partial condition, so $P_y = Q_x$. Therefore,

$$\iint_D (Q_x - P_y)\,dA = \int_D 0\,dA = 0 = \oint_C P\,dx + Q\,dy$$

which confirms Green's theorem in the case of **conservative vector fields**.

### Proof

Let's now prove that the circulation form of Green's theorem is true when the region $D$ is a rectangle. Let $D$ be the rectangle $[a, b] \times [c, d]$ oriented counterclockwise. Then, the boundary $C$ of $D$ consists of four piecewise smooth pieces $C_1$, $C_2$, $C_3$, and $C_4$ (Figure 16.5.3). We parameterize each side of $D$ as follows:

$$C_1 : \vec{\mathbf{r}}_1(t) = \langle t, c \rangle,\ a \le t \le b$$

$$C_2 : \vec{\mathbf{r}}_2(t) = \langle b, t \rangle,\ c \le t \le d$$

$$-C_3 : \vec{\mathbf{r}}_3(t) = \langle t, d \rangle,\ a \le t \le b$$

$$-C_4 : \vec{\mathbf{r}}_4(t) = \langle a, t \rangle,\ c \le t \le d.$$

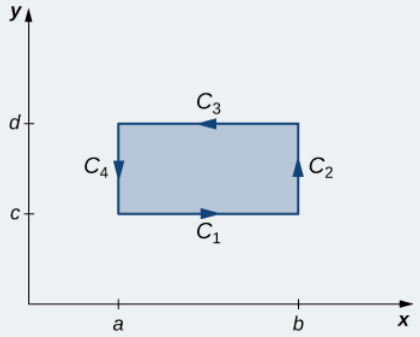

Figure **16.5.3**: Rectangle $D$ is oriented counterclockwise.

Then,

$$\begin{aligned}
\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} &= \int_{C_1} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} + \int_{C_2} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} + \int_{C_3} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} + \int_{C_4} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} \\
&= \int_{C_1} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} + \int_{C_2} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} - \int_{-C_3} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} - \int_{-C_4} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} \\
&= \int_a^b \vec{\mathbf{F}}(\vec{\mathbf{r}}_1(t)) \cdot \vec{\mathbf{r}}_1'(t)\, dt + \int_c^d \vec{\mathbf{F}}(\vec{\mathbf{r}}_2(t)) \cdot \vec{\mathbf{r}}_2'(t)\, dt \\
&\quad - \int_a^b \vec{\mathbf{F}}(\vec{\mathbf{r}}_3(t)) \cdot \vec{\mathbf{r}}_3'(t)\, dt - \int_c^d \vec{\mathbf{F}}(\vec{\mathbf{r}}_4(t)) \cdot \vec{\mathbf{r}}_4'(t)\, dt \\
&= \int_a^b P(t,c)\, dt + \int_c^d Q(b,t)\, dt - \int_a^b P(t,d)\, dt - \int_c^d Q(a,t)\, dt \\
&= \int_a^b (P(t,c) - P(t,d))\, dt + \int_c^d (Q(b,t) - Q(a,t))\, dt \\
&= -\int_a^b (P(t,d) - P(t,c))\, dt + \int_c^d (Q(b,t) - Q(a,t))\, dt.
\end{aligned}$$

By the Fundamental Theorem of Calculus,

$$P(t,d) - P(t,c) = \int_c^d \frac{\partial}{\partial y} P(t,y)\, dy$$

and

$$Q(b,t) - Q(a,t) = \int_a^b \frac{\partial}{\partial x} Q(x,t)\, dx.$$

Therefore,

$$\begin{aligned}
&-\int_a^b (P(t,d) - P(t,c))\, dt + \int_c^d (Q(b,t) - Q(a,t))\, dt \\
&= -\int_a^b \int_c^d \frac{\partial}{\partial y} P(t,y)\, dy\, dt + \int_c^d \int_a^b \frac{\partial}{\partial x} Q(x,t)\, dx\, dt.
\end{aligned}$$

But,

$$-\int_a^b \int_c^d \frac{\partial}{\partial y} P(t,y)\,dy\,dt + \int_c^d \int_a^b \frac{\partial}{\partial x} Q(x,t)\,dx\,dt = -\int_a^b \int_c^d \frac{\partial}{\partial y} P(x,y)\,dy\,dx + \int_c^d \int_a^b \frac{\partial}{\partial x} Q(x,y)\,dx\,dy$$
$$= \int_a^b \int_c^d (Q_x - P_y)\,dy\,dx$$
$$= \iint_D (Q_x - P_y)\,dA.$$

Therefore, $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \iint_D (Q_x - P_y)\,dA$ and we have proved Green's theorem in the case of a rectangle.

□

To prove Green's theorem over a general region $D$, we can decompose $D$ into many tiny rectangles and use the proof that the theorem works over rectangles. The details are technical, however, and beyond the scope of this text.

### Example 16.5.1: Applying Green's Theorem over a Rectangle

Calculate the line integral

$$\oint_C x^2 y\,dx + (y-3)\,dy,$$

where $C$ is a rectangle with vertices $(1,1)$, $(4,1)$, $(4,5)$, and $(1,5)$ oriented counterclockwise.

**Solution**

Let $\vec{\mathbf{F}}(x,y) = \langle P(x,y), Q(x,y)\rangle = \langle x^2 y, y-3\rangle$. Then, $Q_x(x,y) = 0$ and $P_y(x,y) = x^2$. Therefore, $Q_x - P_y = -x^2$.

Let $D$ be the rectangular region enclosed by $C$ (Figure 16.5.4). By Green's theorem,

$$\oint_C x^2 y\,dx + (y-3)\,dy = \iint_D (Q_x - P_y)\,dA$$
$$= \iint_D -x^2\,dA = \int_1^5 \int_1^4 -x^2\,dx\,dy$$
$$= \int_1^5 -\frac{x^3}{3}\Big|_1^4\,dy$$
$$= \int_1^5 \left(-\frac{64}{3} + \frac{1}{3}\right)\,dy$$
$$= \int_1^5 -21\,dy = -84.$$

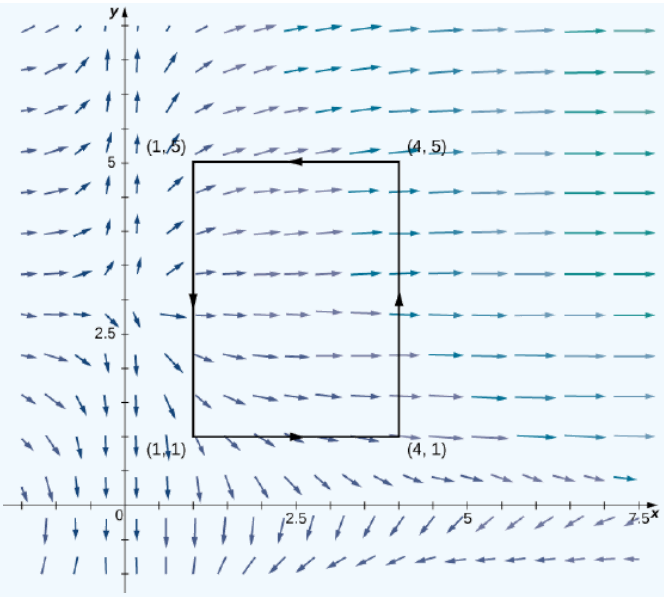

Figure **16.5.4**: The line integral over the boundary of the rectangle can be transformed into a double integral over the rectangle.

### Analysis

If we were to evaluate this line integral without using Green's theorem, we would need to parameterize each side of the rectangle, break the line integral into four separate line integrals, and use the methods from the section titled **Line Integrals** to evaluate each integral. Furthermore, since the vector field here is not conservative, we cannot apply the Fundamental Theorem for Line Integrals. Green's theorem makes the calculation much simpler.

## Example 16.5.2: Applying Green's Theorem to Calculate Work

Calculate the work done on a particle by force field

$$\vec{\mathbf{F}}(x,y) = \langle y + \sin x, e^y - x \rangle$$

as the particle traverses circle $x^2 + y^2 = 4$ exactly once in the counterclockwise direction, starting and ending at point $(2, 0)$.

### Solution

Let $C$ denote the circle and let $D$ be the disk enclosed by $C$. The work done on the particle is

$$W = \oint_C (y + \sin x)\, dx + (e^y - x)\, dy.$$

As with Example **16.5.1**, this integral can be calculated using tools we have learned, but it is easier to use the double integral given by Green's theorem (Figure **16.5.5**).

Let $\vec{\mathbf{F}}(x,y) = \langle P(x,y), Q(x,y) \rangle = \langle y + \sin x, e^y - x \rangle$. Then, $Q_x = -1$ and $P_y = 1$. Therefore, $Q_x - P_y = -2$.

By Green's theorem,

$$\begin{aligned} W &= \oint_C (y + \sin(x))dx + (e^y - x)\, dy \\ &= \iint_D (Q_x - P_y)\, dA \\ &= \iint_D -2\, dA \\ &= -2(area(D)) = -2\pi(2^2) = -8\pi. \end{aligned}$$

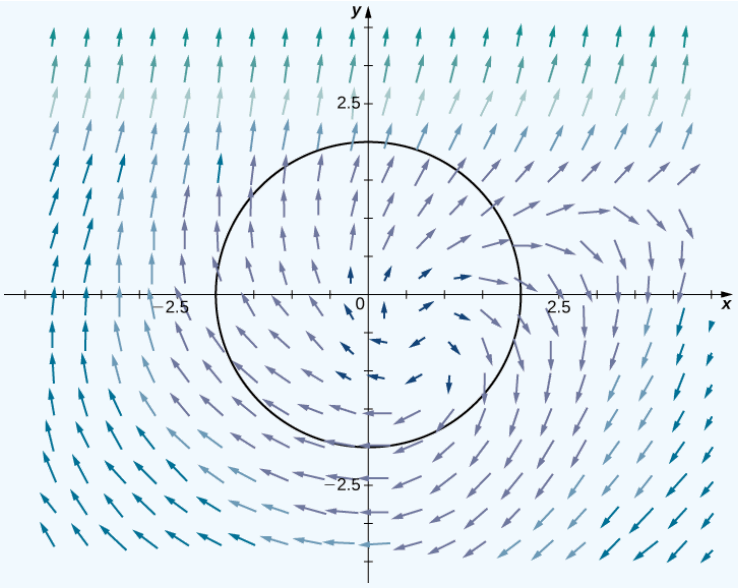

Figure 16.5.5: The line integral over the boundary circle can be transformed into a double integral over the disk enclosed by the circle.

## ? Exercise 16.5.2

Use Green's theorem to calculate line integral

$$\oint_C \sin(x^2)\,dx + (3x - y)\,dy.$$

where $C$ is a right triangle with vertices $(-1, 2)$, $(4, 2)$, and $(4, 5)$ oriented counterclockwise.

**Hint**

Transform the line integral into a double integral.

**Answer**

$\frac{45}{2}$

In the preceding two examples, the double integral in Green's theorem was easier to calculate than the line integral, so we used the theorem to calculate the line integral. In the next example, the double integral is more difficult to calculate than the line integral, so we use Green's theorem to translate a double integral into a line integral.

## ✓ Example 16.5.3: Applying Green's Theorem over an Ellipse

Calculate the area enclosed by ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ (Figure 16.5.6).

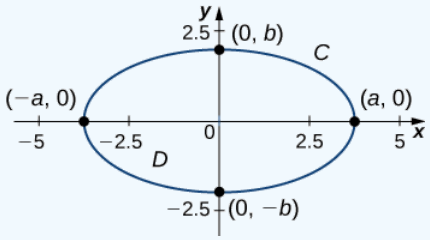

Figure 16.5.6: Ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ is denoted by $C$.

### Solution

Let $C$ denote the ellipse and let $D$ be the region enclosed by $C$. Recall that ellipse $C$ can be parameterized by

- $x = a\cos t$,
- $y = b\sin t$,
- $0 \le t \le 2\pi$.

Calculating the area of $D$ is equivalent to computing double integral $\iint_D \, dA$. To calculate this integral without Green's theorem, we would need to divide $D$ into two regions: the region above the $x$-axis and the region below. The area of the ellipse is

$$\int_{-a}^{a}\int_{0}^{\sqrt{b^2-(bx/a)^2}} \, dy\,dx + \int_{-a}^{a}\int_{-\sqrt{b^2-(bx/a)^2}}^{0} \, dy\,dx.$$

These two integrals are not straightforward to calculate (although when we know the value of the first integral, we know the value of the second by symmetry). Instead of trying to calculate them, we use Green's theorem to transform $\iint_D \, dA$ into a line integral around the boundary $C$.

Consider vector field

$$\vec{\mathbf{F}}(x,y) = \langle P, Q\rangle = \langle -\frac{y}{2}, \frac{x}{2}\rangle.$$

Then, $Q_x = \frac{1}{2}$ and $P_y = -\frac{1}{2}$, and therefore $Q_x - P_y = 1$. Notice that $\vec{\mathbf{F}}$ was chosen to have the property that $Q_x - P_y = 1$. Since this is the case, Green's theorem transforms the line integral of $\vec{\mathbf{F}}$ over $C$ into the double integral of 1 over $D$.

By Green's theorem,

$$\begin{aligned}\iint_D dA &= \iint_D (Q_x - P_y)\,dA \\ &= \int_C \vec{\mathbf{F}}\cdot d\vec{\mathbf{r}} = \frac{1}{2}\int_C -y\,dx + x\,dy \\ &= \frac{1}{2}\int_0^{2\pi} -b\sin t(-a\sin t) + a(\cos t)b\cos t\,dt \\ &= \frac{1}{2}\int_0^{2\pi} ab\cos^2 t + ab\sin^2 t\,dt \\ &= \frac{1}{2}\int_0^{2\pi} ab\,dt = \pi ab.\end{aligned}$$

Therefore, the area of the ellipse is $\pi ab$ units$^2$.

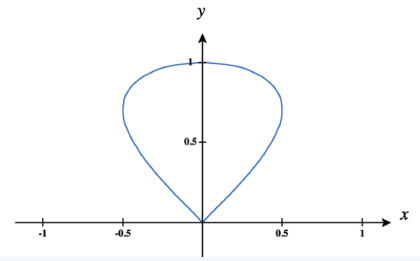
In Example 16.5.3, we used vector field $\vec{\mathbf{F}}(x,y) = \langle P, Q\rangle = \langle -\frac{y}{2}, \frac{x}{2}\rangle$ to find the area of any ellipse. The logic of the previous example can be extended to derive a formula for the area of any region $D$. Let $D$ be any region with a boundary that is a simple closed curve $C$ oriented counterclockwise. If $\vec{\mathbf{F}}(x,y) = \langle P, Q\rangle = \langle -\frac{y}{2}, \frac{x}{2}\rangle$, then $Q_x - P_y = 1$. Therefore, by the same logic as in Example 16.5.3,

$$\text{area of } D = \iint_D \, dA = \frac{1}{2}\oint_C -y\,dx + x\,dy. \tag{16.5.3}$$

It's worth noting that if $\vec{\mathbf{F}} = \langle P, Q\rangle$ is any vector field with $Q_x - P_y = 1$, then the logic of the previous paragraph works. So. Equation 16.5.3 is not the only equation that uses a vector field's mixed partials to get the area of a region.

**? Exercise 16.5.3**

Find the area of the region enclosed by the curve with parameterization $\vec{\mathbf{r}}(t) = \langle \sin t\cos t, \sin t\rangle$, $0 \le t \le \pi$.



**Hint**

Use Equation 16.5.3.

**Answer**

$\frac{2}{3}$ units$^2$.

**Solution**

For convenience, let's use the same vector field we used in Example 16.5.3, where $Q_x - P_y = 1$.

$$\vec{\mathbf{F}}(x,y) = \langle P, Q\rangle = \langle -\frac{y}{2}, \frac{x}{2}\rangle.$$

For the curve $r(t) = \langle \sin t \cos t, \sin t\rangle$ with $0 \le t \le \pi$, we have

$$\vec{\mathbf{r}}'(t) = \langle \cos^2 t - \sin^2 t, \cos t\rangle \text{ and}$$
$$\vec{\mathbf{F}}(t) = \left\langle -\frac{\sin t}{2}, \frac{\sin t \cos t}{2}\right\rangle$$

By Green's theorem,

$$
\begin{aligned}
\text{Area of the region } D = \iint_D dA &= \iint_D (Q_x - P_y)\, dA \\
&= \int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \frac{1}{2}\int_C -y\, dx + x\, dy \\
&= \frac{1}{2}\int_0^{\pi} \left( -\sin t(\cos^2 t - \sin^2 t) + \sin t \cos^2 t \right) dt \\
&= \frac{1}{2}\int_0^{\pi} \left( -\sin t \cos^2 t + \sin t \sin^2 t + \sin t \cos^2 t \right) dt \\
&= \frac{1}{2}\int_0^{\pi} \left( \cancel{-\sin t \cos^2 t} + \sin t(1 - \cos^2 t) + \cancel{\sin t \cos^2 t} \right) dt \\
&= \frac{1}{2}\int_0^{\pi} \left( \sin t - \cos^2 t \sin t \right) dt \\
&= \frac{1}{2}\left[ -\cos t + \frac{\cos^3 t}{3} \right] \Bigg|_0^{\pi} \\
&= \frac{1}{2}\left[ -\cos \pi + \frac{\cos^3 \pi}{3} + \cos 0 - \frac{\cos^3 0}{3} \right] \\
&= \frac{1}{2}\left[ 1 - \frac{1}{3} + 1 - \frac{1}{3} \right] \\
&= \frac{1}{2}\left[ 2 - \frac{2}{3} \right] \\
&= \frac{1}{2}\left[ \frac{6}{3} - \frac{2}{3} \right] \\
&= \frac{1}{2}\left[ \frac{4}{3} \right] \\
&= \frac{2}{3} \text{ units}^2
\end{aligned}
$$

Therefore the area of this region is $\frac{2}{3}$ $\text{units}^2$.

## Flux Form of Green's Theorem

The circulation form of Green's theorem relates a double integral over region $D$ to line integral $\oint_C \vec{\mathbf{F}} \cdot \vec{\mathbf{T}} ds$, where $C$ is the boundary of $D$. The flux form of Green's theorem relates a double integral over region $D$ to the flux across boundary $C$. The flux of a fluid across a curve can be difficult to calculate using the flux line integral. This form of Green's theorem allows us to translate a difficult flux integral into a double integral that is often easier to calculate.

### GREEN'S THEOREM (FLUX FORM)

Let $D$ be an open, simply connected region with a boundary curve $C$ that is a piecewise smooth, simple closed curve that is oriented counterclockwise (Figure 16.5.7). Let $\vec{\mathbf{F}} = \langle P, Q \rangle$ be a vector field with component functions that have continuous partial derivatives on an open region containing $D$. Then,

$$\oint_C \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, ds = \iint_D P_x + Q_y\, dA. \tag{16.5.4}$$

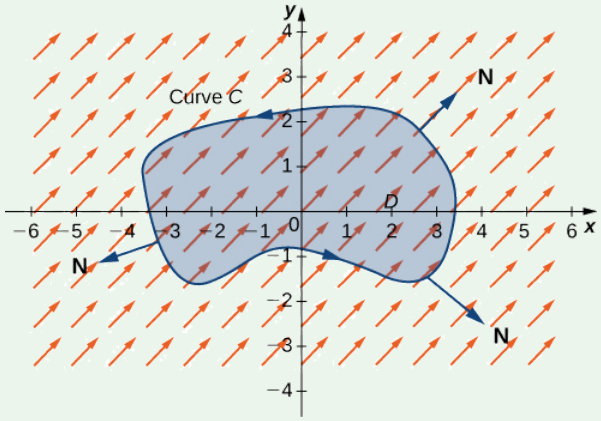


Figure 16.5.7: The flux form of Green's theorem relates a double integral over region $D$ to the flux across curve $C$.

Because this form of Green's theorem contains unit normal vector $\vec{\mathbf{N}}$, it is sometimes referred to as the *normal form* of Green's theorem.

**Proof**

Recall that $\oint_C \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, ds = \oint_C -Q\, dx + P\, dy$. Let $M = -Q$ and $N = P$. By the circulation form of Green's theorem,

$$\begin{aligned} \oint_C -Q\, dx + P\, dy &= \oint_C M\, dx + N\, dy \\ &= \iint_D N_x - M_y\, dA \\ &= \iint_D P_x - (-Q)_y\, dA \\ &= \iint_D P_x + Q_y\, dA. \end{aligned}$$

□

**Example 16.5.4A: Applying Green's Theorem for Flux across a Circle**

Let $C$ be a circle of radius $r$ centered at the origin (Figure 16.5.8) and let $\vec{\mathbf{F}}(x, y) = \langle x, y \rangle$. Calculate the flux across $C$.

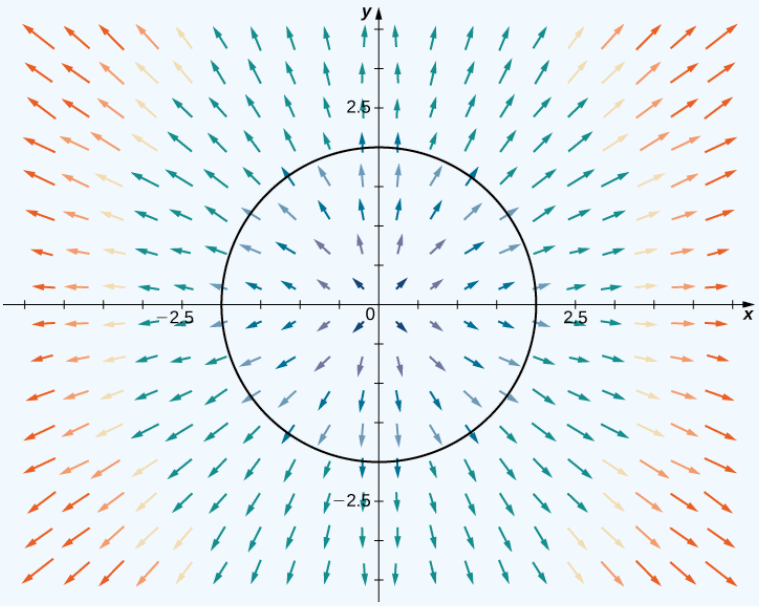

Figure 16.5.8: Curve $C$ is a circle of radius $r$ centered at the origin.

### Solution

Let $D$ be the disk enclosed by $C$. The flux across $C$ is $\oint_C \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, ds$. We could evaluate this integral using tools we have learned, but Green's theorem makes the calculation much more simple. Let $P(x,y) = x$ and $Q(x,y) = y$ so that $\vec{\mathbf{F}} = \langle P, Q \rangle$. Note that $P_x = 1 = Q_y$, and therefore $P_x + Q_y = 2$. By Green's theorem,

$$\int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, ds = \iint_D 2\, dA = 2 \iint_D dA.$$

Since $\iint_D dA$ is the area of the circle, $\iint_D dA = \pi r^2$. Therefore, the flux across $C$ is $2\pi r^2$.

## Example 16.5.4B: Applying Green's Theorem for Flux across a Triangle

Let $S$ be the triangle with vertices $(0,0)$, $(1,0)$, and $(0,3)$ oriented clockwise (Figure 16.5.9). Calculate the flux of $\vec{\mathbf{F}}(x,y) = \langle P(x,y), Q(x,y) \rangle = \langle x^2 + e^y, x + y \rangle$ across $S$.

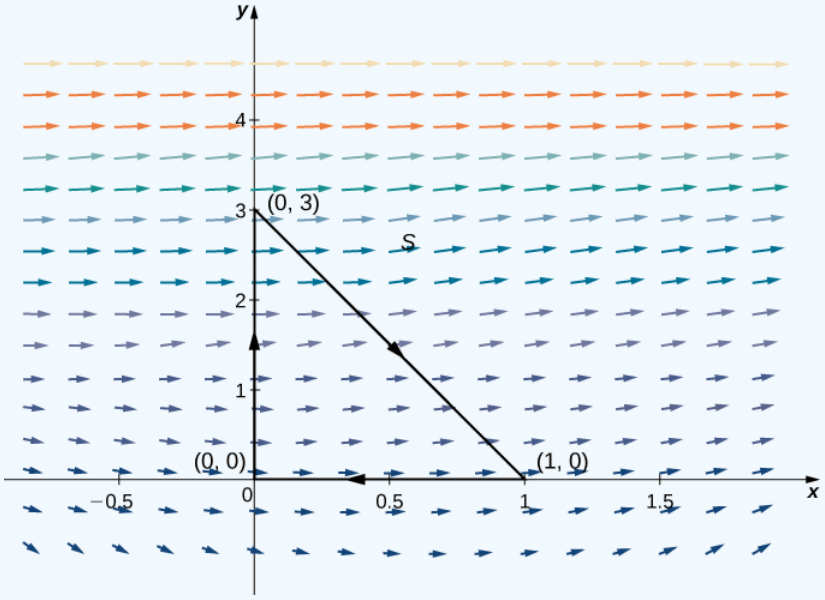

Figure 16.5.9: Curve $S$ is a triangle with vertices $(0,0)$, $(1,0)$, and $(0,3)$ oriented clockwise.

### Solution

To calculate the flux without Green's theorem, we would need to break the flux integral into three line integrals, one integral for each side of the triangle. Using Green's theorem to translate the flux line integral into a single double integral is much more simple.

Let $D$ be the region enclosed by $S$. Note that $P_x = 2x$ and $Q_y = 1$; therefore, $P_x + Q_y = 2x + 1$. Green's theorem applies only to simple closed curves oriented counterclockwise, but we can still apply the theorem because $\oint_C \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, ds = -\oint_{-S} \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, ds$ and $-S$ is oriented counterclockwise. By Green's theorem, the flux is

$$\begin{aligned} \oint_C \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, ds &= \oint_{-S} \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, ds \\ &= -\iint_D (P_x + Q_y)\, dA \\ &= -\iint_D (2x + 1)\, dA. \end{aligned}$$

Notice that the top edge of the triangle is the line $y = -3x + 3$. Therefore, in the iterated double integral, the $y$-values run from $y = 0$ to $y = -3x + 3$, and we have

$$
\begin{aligned}
-\iint_D (2x+1)\,dA &= -\int_0^1 \int_0^{-3x+3} (2x+1)\,dy\,dx \\
&= -\int_0^1 (2x+1)y\Big|_0^{-3x+3}\,dx \\
&= -\int_0^1 (2x+1)(-3x+3)\,dx \\
&= -\int_0^1 (-6x^2+3x+3)\,dx \\
&= -\left[-2x^3+\frac{3x^2}{2}+3x\right]\Big|_0^1 \\
&= -\frac{5}{2}.
\end{aligned}
$$

**Exercise 16.5.4**

Calculate the flux of $\vec{\mathbf{F}}(x,y) = \langle x^3, y^3\rangle$ across a unit circle oriented counterclockwise.

**Hint**

Apply Green's theorem and use polar coordinates.

**Answer**

$\frac{3\pi}{2}$

**Example 16.5.5: Applying Green's Theorem for Water Flow across a Rectangle**

Water flows from a spring located at the origin. The velocity of the water is modeled by vector field $\vec{\mathbf{v}}(x,y) = \langle 5x+y, x+3y\rangle$ m/sec. Find the amount of water per second that flows across the rectangle with vertices $(-1,-2)$, $(1,-2)$, $(1,3)$,and $(-1,3)$, oriented counterclockwise (Figure 16.5.10).

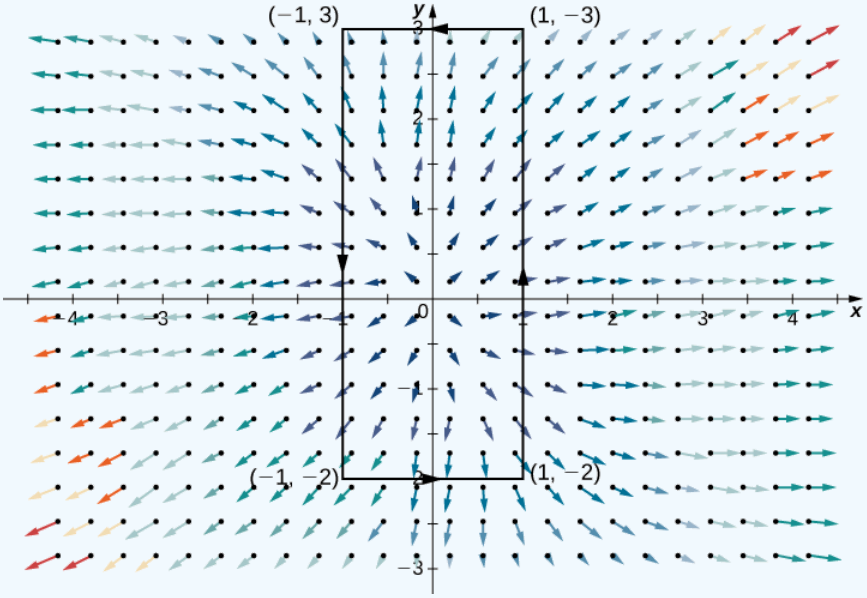

Figure 16.5.10: Water flows across the rectangle with vertices $(-1,-2)$, $(1,-2)$, $(1,3)$,and $(-1,3)$, oriented counterclockwise.

**Solution**

Let $C$ represent the given rectangle and let $D$ be the rectangular region enclosed by $C$. To find the amount of water flowing across $C$, we calculate flux $\int_C \vec{\mathbf{v}}\cdot d\vec{\mathbf{r}}$. Let $P(x,y) = 5x+y$ and $Q(x,y) = x+3y$ so that $\vec{\mathbf{v}} = \langle P, Q\rangle$. Then, $P_x = 5$ and $Q_y = 3$. By

Green's theorem,

$$\begin{aligned}\int_C \vec{\mathbf{v}} \cdot d\vec{\mathbf{r}} &= \iint_D (P_x + Q_y)\, dA \\ &= \iint_D 8\, dA \\ &= 8(\text{area of } D) = 80.\end{aligned}$$

Therefore, the water flux is 80 $m^2$/sec.

Recall that if vector field $\vec{\mathbf{F}}$ is conservative, then $\vec{\mathbf{F}}$ does no work around closed curves—that is, the circulation of $\vec{\mathbf{F}}$ around a closed curve is zero. In fact, if the domain of $\vec{\mathbf{F}}$ is simply connected, then $\vec{\mathbf{F}}$ is conservative if and only if the circulation of $\vec{\mathbf{F}}$ around any closed curve is zero. If we replace "circulation of $\vec{\mathbf{F}}$" with "flux of $\vec{\mathbf{F}}$," then we get a definition of a source-free vector field. The following statements are all equivalent ways of defining a source-free field $\vec{\mathbf{F}} = \langle P, Q \rangle$ on a simply connected domain (note the similarities with properties of conservative vector fields):

1. The flux $\oint_C \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, ds$ across any closed curve $C$ is zero.
2. If $C_1$ and $C_2$ are curves in the domain of $\vec{\mathbf{F}}$ with the same starting points and endpoints, then $\int_{C_1} \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, ds = \int_{C_2} \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, ds$. In other words, flux is independent of path.
3. There is a stream function $g(x, y)$ for $\vec{\mathbf{F}}$. A stream function for $\vec{\mathbf{F}} = \langle P, Q \rangle$ is a function $g$ such that $P = g_y$ and $Q = -g_x$.Geometrically, $\vec{\mathbf{F}} = \langle a, b \rangle$ is tangential to the level curve of $g$ at $(a, b)$. Since the gradient of $g$ is perpendicular to the level curve of $g$ at $(a, b)$, stream function $g$ has the property $\vec{\mathbf{F}}(a, b) \cdot \vec{\nabla} g(a, b) = 0$ for any point $(a, b)$ in the domain of $g$. (Stream functions play the same role for source-free fields that potential functions play for conservative fields.)
4. $P_x + Q_y = 0$

### Example 16.5.6: Finding a Stream Function

Verify that rotation vector field $\vec{\mathbf{F}}(x, y) = \langle y, -x \rangle$ is source free, and find a stream function for $\vec{\mathbf{F}}$.

#### Solution

Note that the domain of $\vec{\mathbf{F}}$ is all of $\mathbb{R}^2$, which is simply connected. Therefore, to show that $\vec{\mathbf{F}}$ is source free, we can show any of items 1 through 4 from the previous list to be true. In this example, we show that item 4 is true. Let $P(x, y) = y$ and $Q(x, y) = -x$. Then $P_x = 0 = Q_y$, and therefore $P_x + Q_y = 0$. Thus, $\vec{\mathbf{F}}$ is source free.

To find a stream function for $\vec{\mathbf{F}}$, proceed in the same manner as finding a potential function for a conservative field. Let $g$ be a stream function for $\vec{\mathbf{F}}$. Then $g_y = y$, which implies that

$$g(x, y) = \frac{y^2}{2} + h(x).$$

Since $-g_x = Q = -x$, we have $h'(x) = x$. Therefore,

$$h(x) = \frac{x^2}{2} + C.$$

Letting $C = 0$ gives stream function

$$g(x, y) = \frac{x^2}{2} + \frac{y^2}{2}.$$

To confirm that $g$ is a stream function for $\vec{\mathbf{F}}$, note that $g_y = y = P$ and $-g_x = -x = Q$.

Notice that source-free rotation vector field $\vec{\mathbf{F}}(x, y) = \langle y, -x \rangle$ is perpendicular to conservative radial vector field $\vec{\nabla} g = \langle x, y \rangle$ (Figure 16.5.11).

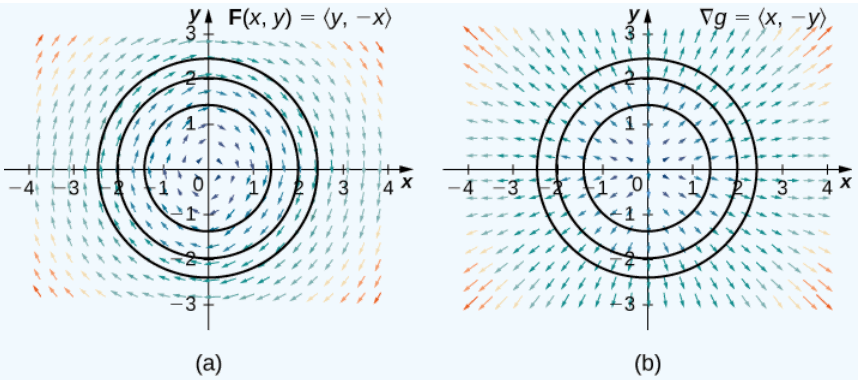

Figure **16.5.11**: (a) In this image, we see the three-level curves of $g$ and vector field $\vec{\mathbf{F}}$. Note that the $\vec{\mathbf{F}}$ vectors on a given level curve are tangent to the level curve. (b) In this image, we see the three-level curves of $g$ and vector field $\vec{\nabla} g$. The gradient vectors are perpendicular to the corresponding level curve. Therefore, $\vec{\mathbf{F}}(a,b) \cdot \vec{\nabla} g(a,b) = 0$ for any point in the domain of $g$.

## ? Exercise 16.5.6

Find a stream function for vector field $\vec{\mathbf{F}}(x,y) = \langle x \sin y, \cos y \rangle$.

**Hint**

Follow the outline provided in the previous example.

**Answer**

$g(x,y) = -x \cos y$

Vector fields that are both conservative and source free are important vector fields. One important feature of conservative and source-free vector fields on a simply connected domain is that any potential function $f$ of such a field satisfies Laplace's equation $f_{xx} + f_{yy} = 0$. Laplace's equation is foundational in the field of partial differential equations because it models such phenomena as gravitational and magnetic potentials in space, and the velocity potential of an ideal fluid. A function that satisfies Laplace's equation is called a *harmonic* function. Therefore any potential function of a conservative and source-free vector field is harmonic.

To see that any potential function of a conservative and source-free vector field on a simply connected domain is harmonic, let $f$ be such a potential function of vector field $\vec{\mathbf{F}} = \langle P, Q \rangle$. Then, $f_x = P$ and $f_x = Q$ because $\vec{\nabla} f = \vec{\mathbf{F}}$. Therefore, $f_{xx} = P_x$ and $f_{yy} = Q_y$. Since $\vec{\mathbf{F}}$ is source free, $f_{xx} + f_{yy} = P_x + Q_y = 0$, and we have that $f$ is harmonic.

## ✓ Example 16.5.7: Satisfying Laplace's Equation

For vector field $\vec{\mathbf{F}}(x,y) = \langle e^x \sin y, e^x \cos y \rangle$, verify that the field is both conservative and source free, find a potential function for $\vec{\mathbf{F}}$, and verify that the potential function is harmonic.

### Solution

Let $P(x,y) = e^x \sin y$ and $Q(x,y) = e^x \cos y$. Notice that the domain of $\vec{\mathbf{F}}$ is all of two-space, which is simply connected. Therefore, we can check the cross-partials of $\vec{\mathbf{F}}$ to determine whether $\vec{\mathbf{F}}$ is conservative. Note that $P_y = e^x \cos y = Q_x$, so $\vec{\mathbf{F}}$ is conservative. Since $P_x = e^x \sin y$ and $Q_y = e^x \sin y$, $P_x + Q_y = 0$ and the field is source free.

To find a potential function for $\vec{\mathbf{F}}$, let $f$ be a potential function. Then, $\vec{\nabla} f = \vec{\mathbf{F}}$, so $f_x(x,y) = e^x \sin y$. Integrating this equation with respect to $x$ gives $f(x,y) = e^x \sin y + h(y)$. Since $f_y(x,y) = e^x \cos y$, differentiating $f$ with respect to $y$ gives $e^x \cos y = e^x \cos y + h'(y)$. Therefore, we can take $h(y) = 0$, and $f(x,y) = e^x \sin y$ is a potential function for $f$.

To verify that $f$ is a harmonic function, note that $f_{xx}(x,y) = \dfrac{\partial}{\partial x}(e^x \sin y) = e^x \sin y$ and

$f_{yy}(x,y) = \dfrac{\partial}{\partial x}(e^x \cos y) = -e^x \sin y$. Therefore, $f_{xx} + f_{yy} = 0$, and $f$ satisfies Laplace's equation.

**? Exercise 16.5.7**

Is the function $f(x,y) = e^{x+5y}$ harmonic?

**Hint**

Determine whether the function satisfies Laplace's equation.

**Answer**

No

## Green's Theorem on General Regions

Green's theorem, as stated, applies only to regions that are simply connected—that is, Green's theorem as stated so far cannot handle regions with holes. Here, we extend Green's theorem so that it does work on regions with finitely many holes (Figure 16.5.12).

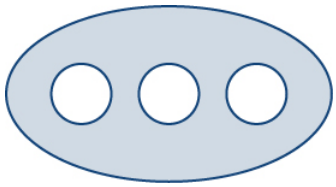

Figure 16.5.12: Green's theorem, as stated, does not apply to a nonsimply connected region with three holes like this one.

Before discussing extensions of Green's theorem, we need to go over some terminology regarding the boundary of a region. Let $D$ be a region and let $C$ be a component of the boundary of $D$. We say that $C$ is *positively oriented* if, as we walk along $C$ in the direction of orientation, region $D$ is always on our left. Therefore, the counterclockwise orientation of the boundary of a disk is a positive orientation, for example. Curve $C$ is *negatively oriented* if, as we walk along $C$ in the direction of orientation, region $D$ is always on our right. The clockwise orientation of the boundary of a disk is a negative orientation, for example.

Let $D$ be a region with finitely many holes (so that $D$ has finitely many boundary curves), and denote the boundary of $D$ by $\partial D$ (Figure 16.5.13). To extend Green's theorem so it can handle $D$, we divide region $D$ into two regions, $D_1$ and $D_2$ (with respective boundaries $\partial D_1$ and $\partial D_2$), in such a way that $D = D_1 \cup D_2$ and neither $D_1$ nor $D_2$ has any holes (Figure 16.5.13).

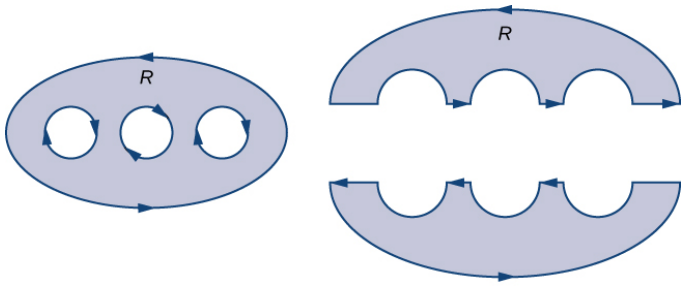

Figure 16.5.13: (a) Region $D$ with an oriented boundary has three holes. (b) Region $D$ split into two simply connected regions has no holes.

Assume the boundary of $D$ is oriented as in the figure, with the inner holes given a negative orientation and the outer boundary given a positive orientation. The boundary of each simply connected region $D_1$ and $D_2$ is positively oriented. If $\vec{\mathbf{F}}$ is a vector field defined on $D$, then Green's theorem says that

$$\oint_{\partial D} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \oint_{\partial D_1} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} + \oint_{\partial D_2} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} \tag{16.5.5}$$

$$= \iint_{D_1} Q_x - P_y \, dA + \iint_{D_2} Q_x - P_y \, dA \tag{16.5.6}$$

$$= \iint_{D} (Q_x - P_y) \, dA. \tag{16.5.7}$$

Therefore, Green's theorem still works on a region with holes.

To see how this works in practice, consider annulus $D$ in Figure 16.5.14 and suppose that $F = \langle P, Q \rangle$ is a vector field defined on this annulus. Region $D$ has a hole, so it is not simply connected. Orient the outer circle of the annulus counterclockwise and the inner circle clockwise (Figure 16.5.14) so that, when we divide the region into $D_1$ and $D_2$, we are able to keep the region on our left as we walk along a path that traverses the boundary. Let $D_1$ be the upper half of the annulus and $D_2$ be the lower half. Neither of these regions has holes, so we have divided $D$ into two simply connected regions.

We label each piece of these new boundaries as $P_i$ for some $i$, as in Figure 16.5.14. If we begin at $P$ and travel along the oriented boundary, the first segment is $P_1$, then $P_2$, $P_3$, and $P_4$. Now we have traversed $D_1$ and returned to $P$. Next, we start at $P$ again and traverse $D_2$. Since the first piece of the boundary is the same as $P_4$ in $D_1$, but oriented in the opposite direction, the first piece of $D_2$ is $-P_4$. Next, we have $P_5$, then $-P_2$, and finally $P_6$.

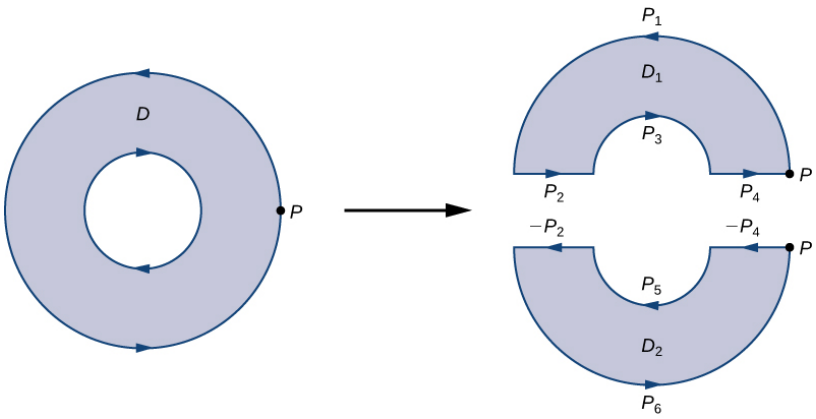

Figure 16.5.14: Breaking the annulus into two separate regions gives us two simply connected regions. The line integrals over the common boundaries cancel out.

Figure 16.5.14 shows a path that traverses the boundary of $D$. Notice that this path traverses the boundary of region $D_1$, returns to the starting point, and then traverses the boundary of region $D_2$. Furthermore, as we walk along the path, the region is always on our left. Notice that this traversal of the $P_i$ paths covers the entire boundary of region $D$. If we had only traversed one portion of the boundary of $D$, then we cannot apply Green's theorem to $D$.

The boundary of the upper half of the annulus, therefore, is $P_1 \cup P_2 \cup P_3 \cup P_4$ and the boundary of the lower half of the annulus is $-P_4 \cup P_5 \cup -P_2 \cup P_6$. Then, Green's theorem implies

$$\begin{aligned}
\oint_{\partial D} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} &= \int_{P_1} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} + \int_{P_2} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} + \int_{P_3} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} + \int_{P_4} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} + \int_{-P_4} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} && (16.5.8)\\
&\quad + \int_{P_5} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} + \int_{-P_2} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} + \int_{P_6} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} \\
&= \int_{P_1} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} + \int_{P_2} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} + \int_{P_3} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} + \int_{P_4} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} + \int_{P_4} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} && (16.5.9)\\
&\quad + \int_{P_5} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} + \int_{-P_2} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} + \int_{P_6} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} \\
&= \int_{P_1} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} + \int_{P_3} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} + \int_{P_5} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} + \int_{P_6} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} && (16.5.10)\\
&= \oint_{\partial D_1} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} + \oint_{\partial D_2} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} && (16.5.11)\\
&= \iint_{D_1} (Q_x - P_y)\, dA + \iint_{D_2} (Q_x - P_y)\, dA && (16.5.12)\\
&= \iint_{D} (Q_x - P_y)\, dA. && (16.5.13)
\end{aligned}$$

Therefore, we arrive at the equation found in Green's theorem—namely,

$$\oint_{\partial D} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \iint_{D} (Q_x - P_y)\, dA.$$

The same logic implies that the flux form of Green's theorem can also be extended to a region with finitely many holes:

$$\oint_C \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, ds = \iint_D (P_x + Q_y)\, dA.$$

### Example 16.5.8A: Using Green's Theorem on a Region with Holes

Calculate the integral

$$\oint_{\partial D} (\sin x - \frac{y^3}{3})dx + (\frac{y^3}{3} + \sin y)dy,$$

where $D$ is the annulus given by the polar inequalities $1 \leq r \leq 2$, $0 \leq \theta \leq 2\pi$.

**Solution**

Although $D$ is not simply connected, we can use the extended form of Green's theorem to calculate the integral. Since the integration occurs over an annulus, we convert to polar coordinates:

$$\begin{aligned}\oint_{\partial D} (\sin x - \frac{y^3}{3})\, dx + (\frac{x^3}{3} + \sin y)\, dy &= \iint_D (Q_x - P_y)\, dA \\ &= \iint_D (x^2 + y^2)\, dA \\ &= \int_0^{2\pi} \int_1^2 r^3\, dr d\theta = \int_0^{2\pi} \frac{15}{4}\, d\theta \\ &= \frac{15\pi}{2}.\end{aligned}$$

### Example 16.5.8B: Using the Extended Form of Green's Theorem

Let $\vec{\mathbf{F}} = \langle P, Q\rangle = \left\langle \frac{y}{x^2+y^2}, -\frac{x}{x^2+y^2} \right\rangle$ and let $C$ be any simple closed curve in a plane oriented counterclockwise. What are the possible values of $\oint_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$?

**Solution**

We use the extended form of Green's theorem to show that $\oint_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$ is either 0 or $-2\pi$—that is, no matter how crazy curve $C$ is, the line integral of $\vec{\mathbf{F}}$ along $C$ can have only one of two possible values. We consider two cases: the case when $C$ encompasses the origin and the case when $C$ does not encompass the origin.

#### Case 1: *C* Does Not Encompass the Origin

In this case, the region enclosed by $C$ is simply connected because the only hole in the domain of $\vec{\mathbf{F}}$ is at the origin. We showed in our discussion of cross-partials that $\vec{\mathbf{F}}$ satisfies the cross-partial condition. If we restrict the domain of $\vec{\mathbf{F}}$ just to $C$ and the region it encloses, then $\vec{\mathbf{F}}$ with this restricted domain is now defined on a simply connected domain. Since $\vec{\mathbf{F}}$ satisfies the cross-partial property on its restricted domain, the field $\vec{\mathbf{F}}$ is conservative on this simply connected region and hence the circulation $\oint_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$ is zero.

#### Case 2: *C* Does Encompass the Origin

In this case, the region enclosed by $C$ is not simply connected because this region contains a hole at the origin. Let $C_1$ be a circle of radius $a$ centered at the origin so that $C_1$ is entirely inside the region enclosed by $C$ (Figure **16.5.15**). Give $C_1$ a clockwise orientation.

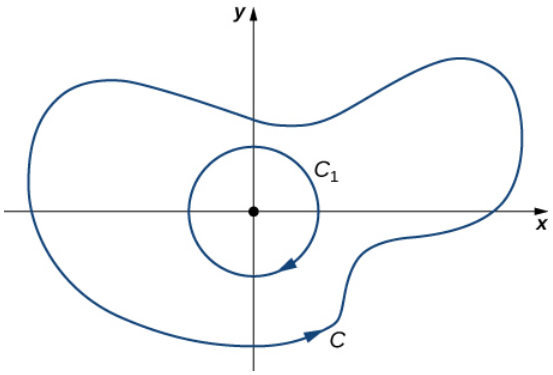

Figure **16.5.15**: Choose circle $C_1$ centered at the origin that is contained entirely inside $C$.

Let $D$ be the region between $C_1$ and $C$, and $C$ is orientated counterclockwise. By the extended version of Green's theorem,

$$\begin{aligned}\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} + \int_{C_1} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} &= \iint_D Qx_P_y \, dA \\ &= \iint_D -\frac{y^2 - x^2}{(x^2+y^2)^2} + \frac{y^2 - x^2}{(x^2+y^2)^2} dA \\ &= 0,\end{aligned}$$

and therefore

$$\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = -\int_{C_1} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}.$$

Since $C_1$ is a specific curve, we can evaluate $\int_{C_1} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$. Let

$$x = a\cos t, \quad y = a\sin t, \quad 0 \le t \le 2\pi$$

be a parameterization of $C_1$. Then,

$$\begin{aligned}\int_{C_1} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} &= \int_0^{2\pi} \vec{\mathbf{F}}(\vec{\mathbf{r}}(t)) \cdot \vec{\mathbf{r}}'(t) \, dt \\ &= \int_0^{2\pi} \langle -\frac{\sin(t)}{a}, -\frac{\cos(t)}{a} \rangle \cdot \langle -a\sin(t), -a\cos(t) \rangle \, dt \\ &= \int_0^{2\pi} \sin^2(t) + \cos^2(t) \, dt \\ &= \int_0^{2\pi} dt = 2\pi.\end{aligned}$$

Therefore, $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = -2\pi$.

**? Exercise 16.5.8**

Calculate integral $\oint_{\partial D} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$, where $D$ is the annulus given by the polar inequalities $2 \le r \le 5$, $0 \le \theta \le 2\pi$, and $\vec{\mathbf{F}}(x, y) = \langle x^3, 5x + e^y \sin y \rangle$.

**Hint**

Use the extended version of Green's theorem.

**Answer**

$105\pi$

## MEASURING AREA FROM A BOUNDARY: THE PLANIMETER

Imagine you are a doctor who has just received a magnetic resonance image of your patient's brain. The brain has a tumor (Figure **16.5.16**). How large is the tumor? To be precise, what is the area of the red region? The red cross-section of the tumor has an irregular shape, and therefore it is unlikely that you would be able to find a set of equations or inequalities for the region and then be able to calculate its area by conventional means. You could approximate the area by chopping the region into tiny squares (a Riemann sum approach), but this method always gives an answer with some error.

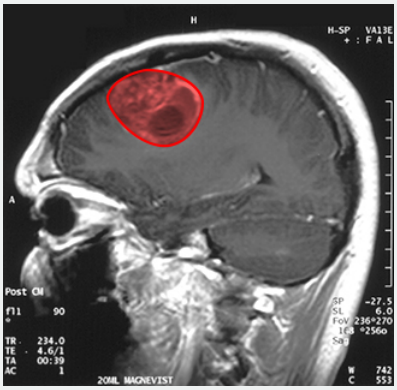

Figure **16.5.16**: This magnetic resonance image of a patient's brain shows a tumor, which is highlighted in red. (credit: modification of work by Christaras A, Wikimedia Commons)

Instead of trying to measure the area of the region directly, we can use a device called a *rolling planimeter* to calculate the area of the region exactly, simply by measuring its boundary. In this project you investigate how a planimeter works, and you use Green's theorem to show the device calculates area correctly.

A rolling planimeter is a device that measures the area of a planar region by tracing out the boundary of that region (Figure **16.5.17**). To measure the area of a region, we simply run the tracer of the planimeter around the boundary of the region. The planimeter measures the number of turns through which the wheel rotates as we trace the boundary; the area of the shape is proportional to this number of wheel turns. We can derive the precise proportionality equation using Green's theorem. As the tracer moves around the boundary of the region, the tracer arm rotates and the roller moves back and forth (but does not rotate).

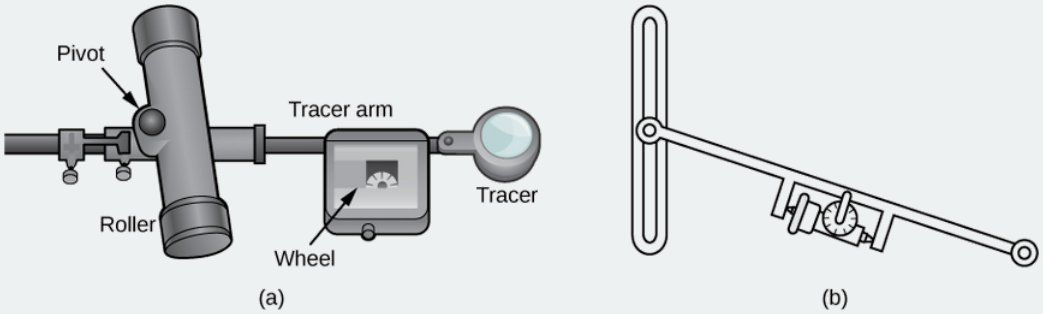

Figure **16.5.17**: (a) A rolling planimeter. The pivot allows the tracer arm to rotate. The roller itself does not rotate; it only moves back and forth. (b) An interior view of a rolling planimeter. Notice that the wheel cannot turn if the planimeter is moving back and forth with the tracer arm perpendicular to the roller.

Let $C$ denote the boundary of region $D$, the area to be calculated. As the tracer traverses curve $C$, assume the roller moves along the $y$-axis (since the roller does not rotate, one can assume it moves along a straight line). Use the coordinates $(x, y)$ to represent points on boundary $C$, and coordinates $(0, Y)$ to represent the position of the pivot. As the planimeter traces $C$, the pivot moves along the $y$-axis while the tracer arm rotates on the pivot.

Watch a short animation of a planimeter in action.

Begin the analysis by considering the motion of the tracer as it moves from point $(x, y)$ counterclockwise to point $(x + dx, y + dy)$ that is close to $(x, y)$ (Figure **16.5.18**). The pivot also moves, from point $(0, Y)$ to nearby point $(0, Y + dY)$. How much does the wheel turn as a result of this motion? To answer this question, break the motion into two parts. First, roll the pivot along the $y$-axis from $(0, Y)$ to $(0, Y + dY)$ without rotating the tracer arm. The tracer arm then ends up at point $(x, y + dY)$ while

maintaining a constant angle $\phi$ with the $x$-axis. Second, rotate the tracer arm by an angle $d\theta$ without moving the roller. Now the tracer is at point $(x + dx, y + dy)$. Let ll be the distance from the pivot to the wheel and let $L$ be the distance from the pivot to the tracer (the length of the tracer arm).

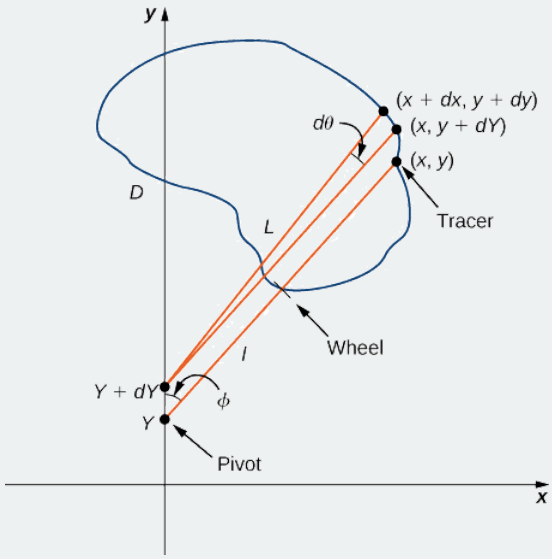

Figure **16.5.18**: Mathematical analysis of the motion of the planimeter.

1. Explain why the total distance through which the wheel rolls the small motion just described is $\sin\phi dY + ld\theta = \frac{x}{L}dY + ld\theta$.
2. Show that $\oint_C d\theta = 0$.
3. Use step 2 to show that the total rolling distance of the wheel as the tracer traverses curve $C$ is

   Total wheel roll $= \frac{1}{L}\oint_C x dY$.

   Now that you have an equation for the total rolling distance of the wheel, connect this equation to Green's theorem to calculate area $D$ enclosed by $C$.
4. Show that $x^2 + (y - Y)^2 = L^2$.
5. Assume the orientation of the planimeter is as shown in Figure **16.5.18**. Explain why $Y \le y$, and use this inequality to show there is a unique value of $Y$ for each point $(x, y)$: $Y = y = \sqrt{L^2 - x^2}$.
6. Use step 5 to show that $dY = dy + \frac{x}{L^2 - x^2}dx$.
7. Use Green's theorem to show that $\oint_C \frac{x}{L^2 - x^2}dx = 0$.
8. Use step 7 to show that the total wheel roll is

$$\text{Total wheel roll} \quad = \quad 1L\oint_C x\,dy.$$

   It took a bit of work, but this equation says that the variable of integration $Y$ in step 3 can be replaced with $y$.
9. Use Green's theorem to show that the area of $D$ is $\oint_C x\,dy$. The logic is similar to the logic used to show that the area of $D$ $= 12\oint_C -y\,dx + x\,dy$.
10. Conclude that the area of $D$ equals the length of the tracer arm multiplied by the total rolling distance of the wheel.

You now know how a planimeter works and you have used Green's theorem to justify that it works. To calculate the area of a planar region $D$, use a planimeter to trace the boundary of the region. The area of the region is the length of the tracer arm multiplied by the distance the wheel rolled.

## Key Concepts

- Green's theorem relates the integral over a connected region to an integral over the boundary of the region. Green's theorem is a version of the Fundamental Theorem of Calculus in one higher dimension.

- Green's Theorem comes in two forms: a circulation form and a flux form. In the circulation form, the integrand is $\vec{\mathbf{F}} \cdot \vec{\mathbf{T}}$. In the flux form, the integrand is $\vec{\mathbf{F}} \cdot \vec{\mathbf{N}}$.
- Green's theorem can be used to transform a difficult line integral into an easier double integral, or to transform a difficult double integral into an easier line integral.
- A vector field is source free if it has a stream function. The flux of a source-free vector field across a closed curve is zero, just as the circulation of a conservative vector field across a closed curve is zero.

## Key Equations

- **Green's theorem, circulation form**
  $\oint_C P\,dx + Q\,dy = \iint_D Q_x - P_y\,dA$, where $C$ is the boundary of $D$
- **Green's theorem, flux form**
  $\oint_C \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\,ds = \iint_D P_x + Q_y\,dA$, where $C$ is the boundary of $D$
- **Green's theorem, extended version**
  $\oint_{\partial D} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \iint_D Q_x - P_y\,dA$

## Glossary

**Green's theorem**

relates the integral over a connected region to an integral over the boundary of the region

**stream function**

if $\vec{\mathbf{F}} = \langle P, Q \rangle$ is a source-free vector field, then stream function $g$ is a function such that $P = g_y$ and $Q = -g_x$

## Contributions

Paul Seeburger created a corrected image and the worked out solution for Exercise 16.5.3.

# 16.5E: Exercises for Section 16.4

**For the following exercises, evaluate the line integrals by applying Green's theorem.**

**1.** $\int_C 2xy\,dx + (x+y)\,dy$, where $C$ is the path from $(0,0)$ to $(1,1)$ along the graph of $y = x^3$ and from $(1,1)$ to $(0,0)$ along the graph of $y = x$ oriented in the counterclockwise direction

**2.** $\int_C 2xy\,dx + (x+y)\,dy$, where $C$ is the boundary of the region lying between the graphs of $y = 0$ and $y = 4 - x^2$ oriented in the counterclockwise direction

**3.** $\int_C 2\arctan\left(\frac{y}{x}\right)\,dx + \ln(x^2+y^2)\,dy$, where $C$ is defined by $x = 4 + 2\cos\theta$, $y = 4\sin\theta$ oriented in the counterclockwise direction

**4.** $\int_C \sin x\cos y\,dx + (xy + \cos x\sin y)\,dy$, where $C$ is the boundary of the region lying between the graphs of $y = x$ and $y = \sqrt{x}$ oriented in the counterclockwise direction

**5.** $\int_C xy\,dx + (x+y)\,dy$, where $C$ is the boundary of the region lying between the graphs of $x^2 + y^2 = 1$ and $x^2 + y^2 = 9$ oriented in the counterclockwise direction

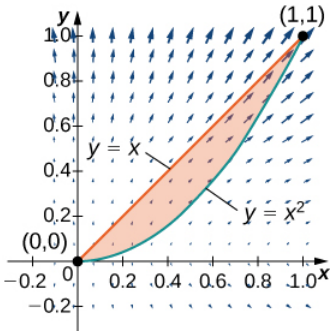
**6.** $\oint_C (-y\,dx + x\,dy)$, where $C$ consists of line segment $C_1$ from $(-1,0)$ to $(1,0)$, followed by the semicircular arc $C_2$ from $(1,0)$ back to $(-1,0)$

**For the following exercises, use Green's theorem.**

**7.** Let $C$ be the curve consisting of line segments from $(0,0)$ to $(1,1)$ to $(0,1)$ and back to $(0,0)$. Find the value of $\int_C xy\,dx + \sqrt{y^2+1}\,dy$.

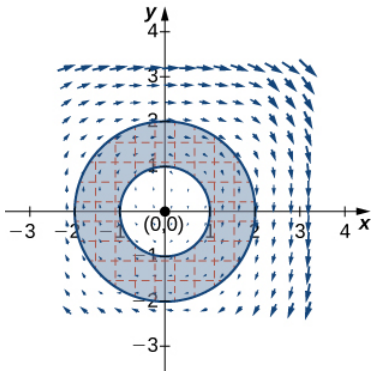
**8.** Evaluate line integral $\int_C xe^{-2x}\,dx + (x^4 + 2x^2y^2)\,dy$, where $C$ is the boundary of the region between circles $x^2 + y^2 = 1$ and $x^2 + y^2 = 4$, and is a positively oriented curve.

**9.** Find the counterclockwise circulation of field $\vec{\mathbf{F}}(x,y) = xy\,\hat{\mathbf{i}} + y^2\,\hat{\mathbf{j}}$ around and over the boundary of the region enclosed by curves $y = x^2$ and $y = x$ in the first quadrant and oriented in the counterclockwise direction.



**10.** Evaluate $\oint_C y^3\,dx - x^3y^2\,dy$, where $C$ is the positively oriented circle of radius $2$ centered at the origin.

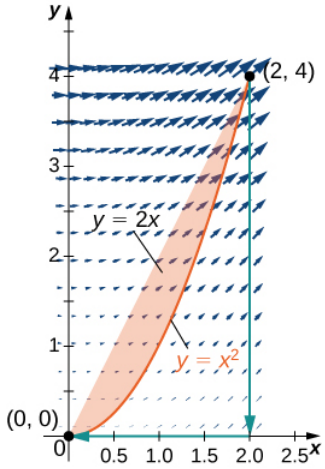
**11.** Evaluate $\oint_C y^3\,dx - x^3\,dy$, where $C$ includes the two circles of radius $2$ and radius $1$ centered at the origin, both with positive orientation.



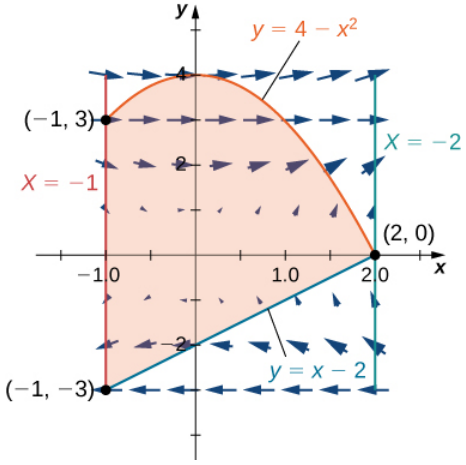
**12.** Calculate $\oint_C -x^2y\,dx + xy^2\,dy$, where $C$ is a circle of radius $2$ centered at the origin and oriented in the counterclockwise direction.

**13.** Calculate integral $\oint_C 2[y + x\sin(y)]\,dx + [x^2\cos(y) - 3y^2]\,dy$ along triangle $C$ with vertices $(0,0)$, $(1,0)$ and $(1,1)$, oriented counterclockwise, using Green's theorem.

**14.** Evaluate integral $\oint_C (x^2 + y^2)\,dx + 2xy\,dy$, where $C$ is the curve that follows parabola $y = x^2$ from $(0,0)$, $(2,4)$, then the line from $(2,4)$ to $(2,0)$, and finally the line from $(2,0)$ to $(0,0)$.



**15.** Evaluate line integral $\oint_C (y - \sin(y)\cos(y))\,dx + 2x\sin^2(y)\,dy$, where $C$ is oriented in a counterclockwise path around the region bounded by $x = -1$, $x = 2$, $y = 4 - x^2$, and $y = x - 2$.

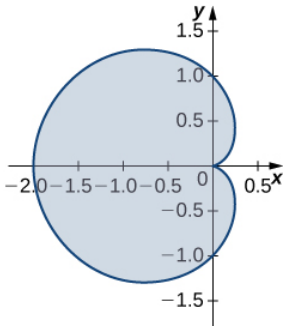


**For the following exercises, use Green's theorem to find the area.**

**16.** Find the area between ellipse $\frac{x^2}{9} + \frac{y^2}{4} = 1$ and circle $x^2 + y^2 = 25$.

**17.** Find the area of the region enclosed by parametric equation

$$\vec{\mathbf{p}}(\theta) = (\cos(\theta) - \cos^2(\theta))\,\hat{\mathbf{i}} + (\sin(\theta) - \cos(\theta)\sin(\theta))\,\hat{\mathbf{j}} \text{ for } 0 \le \theta \le 2\pi.$$



**18.** Find the area of the region bounded by hypocycloid $\vec{\mathbf{r}}(t) = \cos^3(t)\,\hat{\mathbf{i}} + \sin^3(t)\,\hat{\mathbf{j}}$. The curve is parameterized by $t \in [0, 2\pi]$.

**19.** Find the area of a pentagon with vertices $(0, 4)$, $(4, 1)$, $(3, 0)$, $(-1, -1)$, and $(-2, 2)$.

**20.** Use Green's theorem to evaluate $\int_{C^+} (y^2 + x^3)\,dx + x^4\,dy$, where $C^+$ is the perimeter of square $[0, 1] \times [0, 1]$ oriented counterclockwise.

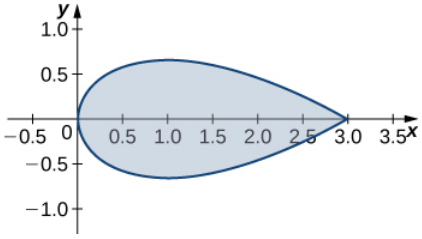
**21.** Use Green's theorem to prove the area of a disk with radius $a$ is $A = \pi a^2$ units$^2$.

**22.** Use Green's theorem to find the area of one loop of a four-leaf rose $r = 3\sin 2\theta$. (*Hint*: $x\,dy - y\,dx = r^2\,d\theta$).

**23.** Use Green's theorem to find the area under one arch of the cycloid given by the parametric equations: $x = t - \sin t,\ y = 1 - \cos t,\ t \ge 0$.

**24.** Use Green's theorem to find the area of the region enclosed by curve

$$\vec{\mathbf{r}}(t) = t^2\,\hat{\mathbf{i}} + \left(\tfrac{t^3}{3} - t\right)\hat{\mathbf{j}}, \text{ for } -\sqrt{3} \le t \le \sqrt{3}.$$



**25. [T]** Evaluate Green's theorem using a computer algebra system to evaluate the integral $\int_C xe^y\,dx + e^x\,dy$, where $C$ is the circle given by $x^2 + y^2 = 4$ and is oriented in the counterclockwise direction.

**26.** Evaluate $\int_C (x^2y - 2xy + y^2)\,ds$, where $C$ is the boundary of the unit square $0 \le x \le 1,\ 0 \le y \le 1$, traversed counterclockwise.

**27.** Evaluate $\int_C \frac{-(y+2)\,dx + (x-1)\,dy}{(x-1)^2 + (y+2)^2}$, where $C$ is any simple closed curve with an interior that does not contain point $(1, -2)$ traversed counterclockwise.

**28.** Evaluate $\int_C \frac{x\,dx + y\,dy}{x^2 + y^2}$, where $C$ is any piecewise, smooth simple closed curve enclosing the origin, traversed counterclockwise.

**For the following exercises, use Green's theorem to calculate the work done by force $\vec{\mathbf{F}}$ on a particle that is moving counterclockwise around closed path $C$.**

**29.** $\vec{\mathbf{F}}(x,y) = xy\,\hat{\mathbf{i}} + (x+y)\,\hat{\mathbf{j}}, \quad C: x^2+y^2=4$

**30.** $\vec{\mathbf{F}}(x,y) = (x^{3/2}-3y)\,\hat{\mathbf{i}} + (6x+5\sqrt{y})\,\hat{\mathbf{j}}, \quad C$: boundary of a triangle with vertices $(0,0)$, $(5,0)$, and $(0,5)$

**31.** Evaluate $\int_C (2x^3-y^3)\,dx + (x^3+y^3)\,dy$, where $C$ is a unit circle oriented in the counterclockwise direction.

**32.** A particle starts at point $(-2,0)$, moves along the $x$-axis to $(2,0)$, and then travels along semicircle $y=\sqrt{4-x^2}$ to the starting point. Use Green's theorem to find the work done on this particle by force field $\vec{\mathbf{F}}(x,y) = x\,\hat{\mathbf{i}} + (x^3+3xy^2)\,\hat{\mathbf{j}}$.

**33.** David and Sandra are skating on a frictionless pond in the wind. David skates on the inside, going along a circle of radius $2$ in a counterclockwise direction. Sandra skates once around a circle of radius $3$, also in the counterclockwise direction. Suppose the force of the wind at point $(x,y)$ is $\vec{\mathbf{F}}(x,y) = (x^2y+10y)\,\hat{\mathbf{i}} + (x^3+2xy^2)\,\hat{\mathbf{j}}$. Use Green's theorem to determine who does more work.

**34.** Use Green's theorem to find the work done by force field $\vec{\mathbf{F}}(x,y) = (3y-4x)\,\hat{\mathbf{i}} + (4x-y)\,\hat{\mathbf{j}}$ when an object moves once counterclockwise around ellipse $4x^2+y^2=4$.

**35.** Use Green's theorem to evaluate line integral $\oint_C e^{2x}\sin 2y\,dx + e^{2x}\cos 2y\,dy$, where $C$ is ellipse $9(x-1)^2+4(y-3)^2=36$ oriented counterclockwise.

**36.** Evaluate line integral $\oint_C y^2\,dx + x^2\,dy$, where $C$ is the boundary of a triangle with vertices $(0,0)$, $(1,1)$, and $(1,0)$, with the counterclockwise orientation.

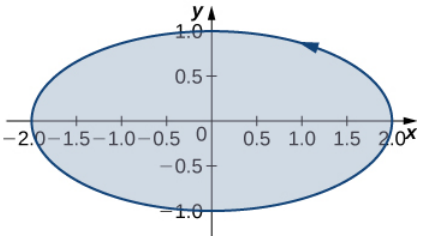
**37.** Use Green's theorem to evaluate line integral $\int_C \vec{\mathbf{h}}\cdot d\vec{\mathbf{r}}$ if $\vec{\mathbf{h}}(x,y) = e^y\,\hat{\mathbf{i}} - \sin \pi x\,\hat{\mathbf{j}}$, where $C$ is a triangle with vertices $(1,0)$, $(0,1)$, and $(-1,0)$, traversed counterclockwise.

**38.** Use Green's theorem to evaluate line integral $\int_C \sqrt{1+x^3}\,dx + 2xy\,dy$ where $C$ is a triangle with vertices $(0,0)$, $(1,0)$, and $(1,3)$ oriented clockwise.

**39.** Use Green's theorem to evaluate line integral $\int_C x^2y\,dx - xy^2\,dy$ where $C$ is a circle $x^2+y^2=4$ oriented counterclockwise.

**40.** Use Green's theorem to evaluate line integral $\int_C \left(3y-e^{\sin x}\right)dx + \left(7x+\sqrt{y^4+1}\right)dy$ where $C$ is circle $x^2+y^2=9$ oriented in the counterclockwise direction.

**41.** Use Green's theorem to evaluate line integral $\int_C (3x-5y)\,dx + (x-6y)\,dy$, where $C$ is ellipse $\frac{x^2}{4}+y^2=1$ and is oriented in the counterclockwise direction.



**42.** Let $C$ be a triangular closed curve from $(0,0)$ to $(1,0)$ to $(1,1)$ and finally back to $(0,0)$. Let $\vec{\mathbf{F}}(x,y) = 4y\,\hat{\mathbf{i}} + 6x^2\,\hat{\mathbf{j}}$. Use Green's theorem to evaluate $\oint_C \vec{\mathbf{F}}\cdot d\vec{\mathbf{r}}$.

**43.** Use Green's theorem to evaluate line integral $\oint_C y\,dx - x\,dy$, where $C$ is circle $x^2+y^2=a^2$ oriented in the clockwise direction.

**44.** Use Green's theorem to evaluate line integral $\oint_C (y+x)\,dx + (x+\sin y)\,dy$, where $C$ is any smooth simple closed curve joining the origin to itself oriented in the counterclockwise direction.

**45.** Use Green's theorem to evaluate line integral $\oint_C \left(y - \ln(x^2 + y^2)\right)\, dx + \left(2\arctan\frac{y}{x}\right)\, dy$, where $C$ is the positively oriented circle $(x-2)^2 + (y-3)^2 = 1$.

**46.** Use Green's theorem to evaluate $\oint_C xy\, dx + x^3y^3\, dy$, where $C$ is a triangle with vertices $(0,0)$, $(1,0)$, and $(1,2)$ with positive orientation.

**47.** Use Green's theorem to evaluate line integral $\int_C \sin y\, dx + x\cos y\, dy$, where $C$ is ellipse $x^2 + xy + y^2 = 1$ oriented in the counterclockwise direction.

**48.** Let $\vec{\mathbf{F}}(x,y) = \left(\cos(x^5) - 13y^3\right)\hat{\mathbf{i}} + 13x^3\hat{\mathbf{j}}$. Find the counterclockwise circulation $\oint_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$, where $C$ is a curve consisting of the line segment joining $(-2,0)$ and $(-1,0)$, half circle $y = \sqrt{1-x^2}$, the line segment joining $(1,0)$ and $(2,0)$, and half circle $y = \sqrt{4-x^2}$.

**49.** Use Green's theorem to evaluate line integral $\int_C \sin(x^3)\, dx + 2ye^{x^2}\, dy$, where $C$ is a triangular closed curve that connects the points $(0,0)$, $(2,2)$, and $(0,2)$ counterclockwise.

**50.** Let $C$ be the boundary of square $0 \le x \le \pi,\ 0 \le y \le \pi$, traversed counterclockwise. Use Green's theorem to find $\int_C \sin(x + y)\, dx + \cos(x+y)\, dy$.

**51.** Use Green's theorem to evaluate line integral $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$, where $\vec{\mathbf{F}}(x,y) = \left(y^2 - x^2\right)\hat{\mathbf{i}} + \left(x^2 + y^2\right)\hat{\mathbf{j}}$, and $C$ is a triangle bounded by $y = 0,\ x = 3$, and $y = x$, oriented counterclockwise.

**52.** Use Green's Theorem to evaluate integral $\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$, where $\vec{\mathbf{F}}(x,y) = \left(xy^2\right)\hat{\mathbf{i}} + x\hat{\mathbf{j}}$, and $C$ is a unit circle oriented in the counterclockwise direction.

**53.** Use Green's theorem in a plane to evaluate line integral $\oint_C \left(xy + y^2\right)\, dx + x^2\, dy$, where $C$ is a closed curve of a region bounded by $y = x$ and $y = x^2$ oriented in the counterclockwise direction.

**54.** Calculate the outward flux of $\vec{\mathbf{F}}(x,y) = -x\hat{\mathbf{i}} + 2y\hat{\mathbf{j}}$ over a square with corners $(\pm 1, \pm 1)$, where the unit normal is outward pointing and oriented in the counterclockwise direction.

**55.** **[T]** Let $C$ be circle $x^2 + y^2 = 4$ oriented in the counterclockwise direction. Evaluate $\oint_C \left[\left(3y - e^{\arctan x}\right)dx + \left(7x + \sqrt{y^4+1}\right)\, dy\right]$ using a computer algebra system.

**56.** Find the flux of field $\vec{\mathbf{F}}(x,y) = -x\hat{\mathbf{i}} + y\hat{\mathbf{j}}$ across $x^2 + y^2 = 16$ oriented in the counterclockwise direction.

**57.** Let $\vec{\mathbf{F}} = \left(y^2 - x^2\right)\hat{\mathbf{i}} + \left(x^2 + y^2\right)\hat{\mathbf{j}}$, and let $C$ be a triangle bounded by $y = 0,\ x = 3$, and $y = x$ oriented in the counterclockwise direction. Find the outward flux of $\vec{\mathbf{F}}$ through $C$.

**58.** **[T]** Let $C$ be unit circle $x^2 + y^2 = 1$ traversed once counterclockwise. Evaluate $\int_C \left[-y^3 + \sin(xy) + xy\cos(xy)\right]\, dx + \left[x^3 + x^2\cos(xy)\right]\, dy$ by using a computer algebra system.

**59.** **[T]** Find the outward flux of vector field $\vec{\mathbf{F}}(x,y) = xy^2\hat{\mathbf{i}} + x^2y\hat{\mathbf{j}}$ across the boundary of annulus $R = \left\{(x,y) : 1 \le x^2 + y^2 \le 4\right\} = \left\{(r,\theta) : 1 \le r \le 2,\ 0 \le \theta \le 2\pi\right\}$ using a computer algebra system.

**60.** Consider region $R$ bounded by parabolas $y = x^2$ and $x = y^2$. Let $C$ be the boundary of $R$ oriented counterclockwise. Use Green's theorem to evaluate $\oint_C \left(y + e^{\sqrt{x}}\right)\, dx + \left(2x + \cos(y^2)\right)\, dy$.

# 16.6: Divergence and Curl

**Learning Objectives**

- Determine divergence from the formula for a given vector field.
- Determine curl from the formula for a given vector field.
- Use the properties of curl and divergence to determine whether a vector field is conservative.

In this section, we examine two important operations on a vector field: divergence and curl. They are important to the field of calculus for several reasons, including the use of curl and divergence to develop some higher-dimensional versions of the Fundamental Theorem of Calculus. In addition, curl and divergence appear in mathematical descriptions of fluid mechanics, electromagnetism, and elasticity theory, which are important concepts in physics and engineering. We can also apply curl and divergence to other concepts we already explored. For example, under certain conditions, a vector field is conservative if and only if its curl is zero.

In addition to defining curl and divergence, we look at some physical interpretations of them, and show their relationship to conservative and source-free vector fields.

## Divergence

Divergence is an operation on a vector field that tells us how the field behaves toward or away from a point. Locally, the divergence of a vector field $\vec{\mathbf{F}}$ in $\mathbb{R}^2$ or $\mathbb{R}^3$ at a particular point $P$ is a measure of the "outflowing-ness" of the vector field at $P$. If $\vec{\mathbf{F}}$ represents the velocity of a fluid, then the divergence of $\vec{\mathbf{F}}$ at $P$ measures the net rate of change with respect to time of the amount of fluid flowing away from $P$ (the tendency of the fluid to flow "out of" P). In particular, if the amount of fluid flowing into $P$ is the same as the amount flowing out, then the divergence at $P$ is zero.

**Definition: divergence in $\mathbb{R}^3$**

If $\vec{\mathbf{F}} = \langle P, Q, R \rangle$ is a vector field in $\mathbb{R}^3$ and $P_x$, $Q_y$, and $R_z$ all exist, then the divergence of $\vec{\mathbf{F}}$ is defined by

$$\operatorname{div} F = P_x + Q_y + R_z \tag{16.6.1}$$

$$= \frac{\partial P}{\partial x} + \frac{\partial Q}{\partial y} + \frac{\partial R}{\partial z}. \tag{16.6.2}$$

Note the divergence of a vector field is not a vector field, but a scalar function. In terms of the gradient operator

$$\vec{\nabla} = \left\langle \frac{\partial}{\partial x}, \frac{\partial}{\partial y}, \frac{\partial}{\partial z} \right\rangle$$

divergence can be written symbolically as the dot product

$$\operatorname{div} \vec{\mathbf{F}} = \vec{\nabla} \cdot \vec{\mathbf{F}}.$$

Note this is merely helpful notation, because the dot product of a vector of operators and a vector of functions is not meaningfully defined given our current definition of dot product.

If $\vec{\mathbf{F}} = \langle P, Q \rangle$ is a vector field in $\mathbb{R}^2$, and $P_x$ and $Q_y$ both exist, then the divergence of $\vec{\mathbf{F}}$ is defined similarly as

$$\begin{aligned} \operatorname{div} \vec{\mathbf{F}} &= P_x + Q_y \\ &= \frac{\partial P}{\partial x} + \frac{\partial Q}{\partial y} \\ &= \vec{\nabla} \cdot \vec{\mathbf{F}}. \end{aligned}$$

To illustrate this point, consider the two vector fields in Figure **16.6.1**. At any particular point, the amount flowing in is the same as the amount flowing out, so at every point the "outflowing-ness" of the field is zero. Therefore, we expect the divergence of both fields to be zero, and this is indeed the case, as

$$\text{div}(\langle 1,2\rangle) = \frac{\partial}{\partial x}(1) + \frac{\partial}{\partial y}(2) = 0$$

and

$$\text{div}(\langle -y,x\rangle) = \frac{\partial}{\partial x}(-y) + \frac{\partial}{\partial y}(x) = 0.$$

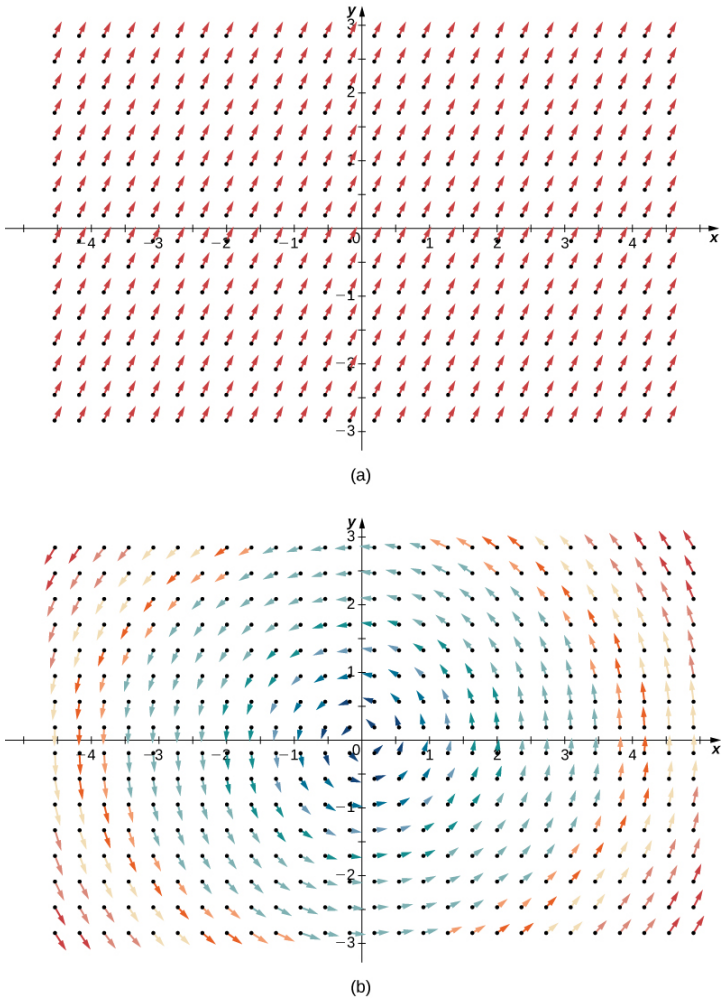

Figure 16.6.1: (a) Vector field $\langle 1,2\rangle$ has zero divergence. (b) Vector field $\langle -y,x\rangle$ also has zero divergence.

By contrast, consider radial vector field $\vec{\mathbf{R}}(x,y) = \langle -x,-y\rangle$ in Figure 16.6.2. At any given point, more fluid is flowing in than is flowing out, and therefore the "outgoingness" of the field is negative. We expect the divergence of this field to be negative, and this is indeed the case, as

$$\text{div}(\vec{\mathbf{R}}) = \frac{\partial}{\partial x}(-x) + \frac{\partial}{\partial y}(-y) = -2.$$

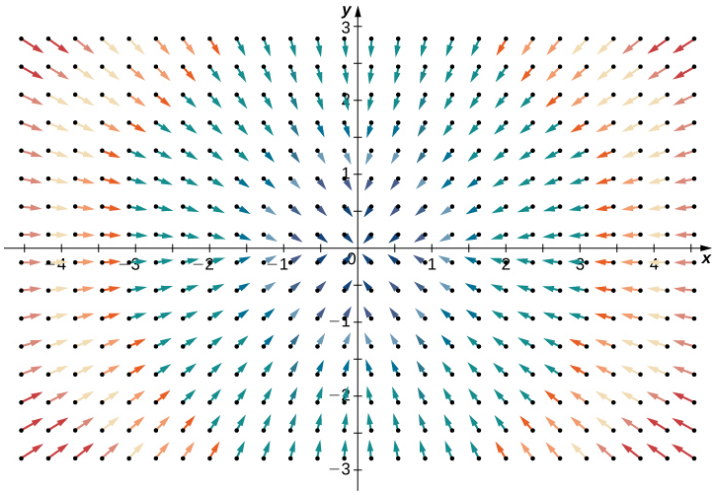

Figure 16.6.2: This vector field has negative divergence.

To get a global sense of what divergence is telling us, suppose that a vector field in $\mathbb{R}^2$ represents the velocity of a fluid. Imagine taking an elastic circle (a circle with a shape that can be changed by the vector field) and dropping it into a fluid. If the circle maintains its exact area as it flows through the fluid, then the divergence is zero. This would occur for both vector fields in Figure 16.6.1. On the other hand, if the circle's shape is distorted so that its area shrinks or expands, then the divergence is not zero. Imagine dropping such an elastic circle into the radial vector field in Figure 16.6.2 so that the center of the circle lands at point $(3, 3)$. The circle would flow toward the origin, and as it did so the front of the circle would travel more slowly than the back, causing the circle to "scrunch" and lose area. This is how you can see a negative divergence.

### Example 16.6.1: Calculating Divergence at a Point

If $\vec{\mathbf{F}}(x, y, z) = e^x\hat{i} + yz\hat{j} - yz^2\hat{k}$, then find the divergence of $\vec{\mathbf{F}}$ at $(0, 2, -1)$.

**Solution**

The divergence of $\vec{\mathbf{F}}$ is

$$\frac{\partial}{\partial x}(e^x) + \frac{\partial}{\partial y}(yz) - \frac{\partial}{\partial z}(yz^2) = e^x + z - 2yz.$$

Therefore, the divergence at $(0, 2, -1)$ is $e^0 - 1 + 4 = 4$. If $\vec{\mathbf{F}}$ represents the velocity of a fluid, then more fluid is flowing out than flowing in at point $(0, 2, -1)$.

### Exercise 16.6.1

Find $\mathbf{div}\ \vec{\mathbf{F}}$ for

$$\vec{\mathbf{F}}(x, y, z) = \langle xy,\ 5 - z^2,\ x^2 + y^2 \rangle.$$

**Hint**

Follow Example 16.6.1.

**Answer**

$\mathbf{div}\ \vec{\mathbf{F}} = y$

One application for divergence occurs in physics, when working with magnetic fields. A magnetic field is a vector field that models the influence of electric currents and magnetic materials. Physicists use divergence in Gauss's law for magnetism, which states that if $\vec{\mathbf{B}}$ is a magnetic field, then $\vec{\nabla} \cdot \vec{\mathbf{B}} = 0$; in other words, the divergence of a magnetic field is zero.

### Example 16.6.2: Determining Whether a Field Is Magnetic

Is it possible for $\vec{\mathbf{F}}(x,y) = \langle x^2 y,\ y - xy^2 \rangle$ to be a magnetic field?

**Solution**

If $\vec{\mathbf{F}}$ were magnetic, then its divergence would be zero. The divergence of $\vec{\mathbf{F}}$ is

$$\frac{\partial}{\partial x}(x^2 y) + \frac{\partial}{\partial y}(y - xy^2) = 2xy + 1 - 2xy = 1$$

and therefore $\vec{\mathbf{F}}$ cannot model a magnetic field (Figure 16.6.3).

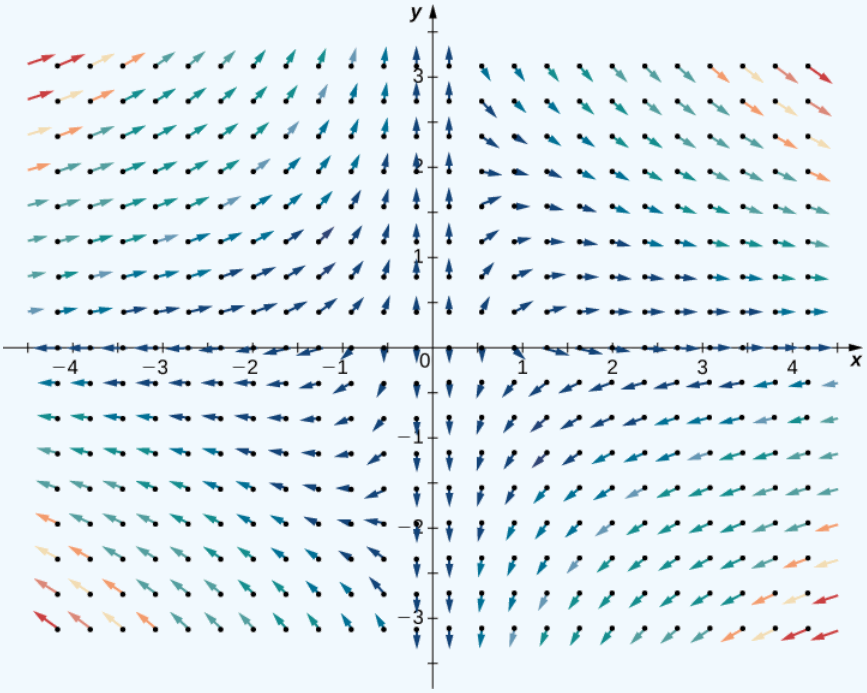

Figure 16.6.3: The divergence of vector field $\vec{\mathbf{F}}(x,y) = \langle x^2 y,\ y - xy^2 \rangle$ is one, so it cannot model a magnetic field.

Another application for divergence is detecting whether a field is source free. Recall that a source-free field is a vector field that has a stream function; equivalently, a source-free field is a field with a flux that is zero along any closed curve. The next two theorems say that, under certain conditions, source-free vector fields are precisely the vector fields with zero divergence.

### Theorem: Divergence of a Source-Free Vector Field

If $\vec{\mathbf{F}} = \langle P, Q \rangle$ is a source-free continuous vector field with differentiable component functions, then $\operatorname{div} \vec{\mathbf{F}} = 0$.

### Proof

Since $\vec{\mathbf{F}}$ is source free, there is a function $g(x,y)$ with $g_y = P$ and $-g_x = Q$. Therefore, $\vec{\mathbf{F}} = \langle g_y, -g_x \rangle$ and $\operatorname{div} \vec{\mathbf{F}} = g_{yx} - g_{xy} = 0$ by Clairaut's theorem.

□

The converse of Divergence of a Source-Free Vector Field is true on simply connected regions, but the proof is too technical to include here. Thus, we have the following theorem, which can test whether a vector field in $\mathbb{R}^2$ is source free.

**Theorem: Divergence Test for Source-Free Vector Fields**

Let $\vec{\mathbf{F}} = \langle P, Q \rangle$ be a continuous vector field with differentiable component functions with a domain that is simply connected. Then, $\operatorname{div} \vec{\mathbf{F}} = 0$ if and only if $\vec{\mathbf{F}}$ is source free.

**Example 16.6.3: Determining Whether a Field Is Source Free**

Is field $\vec{\mathbf{F}}(x, y) = \langle x^2 y,\ 5 - xy^2 \rangle$ source free?

**Solution**

Note the domain of $\vec{\mathbf{F}}$ is $\mathbb{R}^2$ which is simply connected. Furthermore, $\vec{\mathbf{F}}$ is continuous with differentiable component functions. Therefore, we can use the Divergence Test for Source-Free Vector Fields to analyze $\vec{\mathbf{F}}$. The divergence of $\vec{\mathbf{F}}$ is

$$\frac{\partial}{\partial x}(x^2 y) + \frac{\partial}{\partial y}(5 - xy^2) = 2xy - 2xy = 0.$$

Therefore, $\vec{\mathbf{F}}$ is source free by the Divergence Test for Source-Free Vector Fields.

**Exercise 16.6.2**

Let $\vec{\mathbf{F}}(x, y) = \langle -ay, bx \rangle$ be a rotational field where $a$ and $b$ are positive constants. Is $\vec{\mathbf{F}}$ source free?

**Hint**

Calculate the divergence.

**Answer**

Yes

Recall that the flux form of Green's theorem says that

$$\oint_C \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, ds = \iint_D P_x + Q_y\, dA,$$

where $C$ is a simple closed curve and $D$ is the region enclosed by $C$. Since $P_x + Q_y = \operatorname{div} \vec{\mathbf{F}}$, Green's theorem is sometimes written as

$$\oint_C \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, ds = \iint_D \operatorname{div} \vec{\mathbf{F}}\, dA.$$

Therefore, Green's theorem can be written in terms of divergence. If we think of divergence as a derivative of sorts, then Green's theorem says the "derivative" of $\vec{\mathbf{F}}$ on a region can be translated into a line integral of $\vec{\mathbf{F}}$ along the boundary of the region. This is analogous to the Fundamental Theorem of Calculus, in which the derivative of a function $f$ on a line segment $[a, b]$ can be translated into a statement about $f$ on the boundary of $[a, b]$. Using divergence, we can see that Green's theorem is a higher-dimensional analog of the Fundamental Theorem of Calculus.

We can use all of what we have learned in the application of divergence. Let $\vec{\mathbf{v}}$ be a vector field modeling the velocity of a fluid. Since the divergence of $\vec{\mathbf{v}}$ at point $P$ measures the "outflowing-ness" of the fluid at $P$, $\operatorname{div} v(P) > 0$ implies that more fluid is flowing out of $P$ than flowing in. Similarly, $\operatorname{div} v(P) < 0$ implies the more fluid is flowing in to $P$ than is flowing out, and $\operatorname{div} \vec{\mathbf{v}}(P) = 0$ implies the same amount of fluid is flowing in as flowing out.

**Example 16.6.4: Determining Flow of a Fluid**

Suppose $\vec{\mathbf{v}}(x, y) = \langle -xy, y \rangle$, $y > 0$ models the flow of a fluid. Is more fluid flowing into point $(1, 4)$ than flowing out?

**Solution**

To determine whether more fluid is flowing into $(1, 4)$ than is flowing out, we calculate the divergence of $\vec{\mathbf{v}}$ at $(1, 4)$:

$$div(\vec{\mathbf{v}}) = \frac{\partial}{\partial x}(-xy) + \frac{\partial}{\partial y}(y) = -y + 1.$$

To find the divergence at $(1, 4)$ substitute the point into the divergence: $-4 + 1 = -3$. Since the divergence of $\vec{\mathbf{v}}$ at $(1, 4)$ is negative, more fluid is flowing in than flowing out (Figure **16.6.4**).

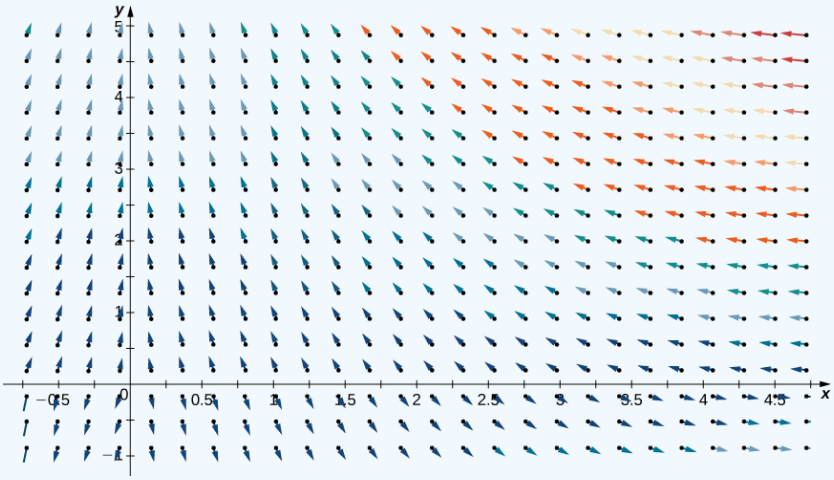

Figure **16.6.4**: Vector field $\vec{\mathbf{v}}(x, y) = \langle -xy, y \rangle$ has negative divergence at $(1, 4)$

## ? Exercise 16.6.3

For vector field $\vec{\mathbf{v}}(x, y) = \langle -xy, y \rangle$, $y > 0$, find all points $P$ such that the amount of fluid flowing in to $P$ equals the amount of fluid flowing out of $P$.

**Hint**

Find where the divergence is zero.

**Answer**

All points on line $y = 1$.

## Curl

The second operation on a vector field that we examine is the curl, which measures the extent of rotation of the field about a point. Suppose that $\vec{\mathbf{F}}$ represents the velocity field of a fluid. Then, the curl of $\vec{\mathbf{F}}$ at point $P$ is a vector that measures the tendency of particles near $P$ to rotate about the axis that points in the direction of this vector. The magnitude of the curl vector at $P$ measures how quickly the particles rotate around this axis. In other words, the curl at a point is a measure of the vector field's "spin" at that point. Visually, imagine placing a paddlewheel into a fluid at $P$, with the axis of the paddlewheel aligned with the curl vector (Figure **16.6.5**). The curl measures the tendency of the paddlewheel to rotate.

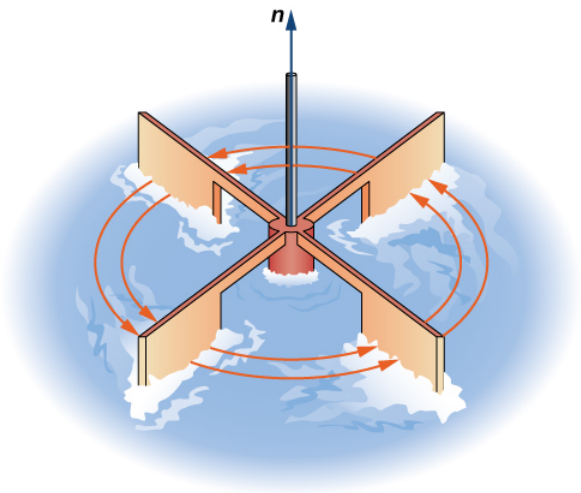

Figure **16.6.5**: To visualize curl at a point, imagine placing a small paddlewheel into the vector field at a point.

Consider the vector fields in Figure **16.6.1**. In part (a), the vector field is constant and there is no spin at any point. Therefore, we expect the curl of the field to be zero, and this is indeed the case. Part (b) shows a rotational field, so the field has spin. In particular, if you place a paddlewheel into a field at any point so that the axis of the wheel is perpendicular to a plane, the wheel rotates counterclockwise. Therefore, we expect the curl of the field to be nonzero, and this is indeed the case (the curl is $2\hat{\mathbf{k}}$).

To see what curl is measuring globally, imagine dropping a leaf into the fluid. As the leaf moves along with the fluid flow, the curl measures the tendency of the leaf to rotate. If the curl is zero, then the leaf doesn't rotate as it moves through the fluid.

**Definition: Curl**

If $\vec{\mathbf{F}} = \langle P, Q, R \rangle$ is a vector field in $\mathbb{R}^3$, and $P_x$, $Q_y$, and $R_z$ all exist, then the curl of $\vec{\mathbf{F}}$ is defined by

$$\operatorname{curl} \vec{\mathbf{F}} = (R_y - Q_z)\hat{\mathbf{i}} + (P_z - R_x)\hat{\mathbf{j}} + (Q_x - P_y)\hat{\mathbf{k}} \tag{16.6.3}$$

$$= \left(\frac{\partial R}{\partial y} - \frac{\partial Q}{\partial z}\right)\hat{\mathbf{i}} + \left(\frac{\partial P}{\partial z} - \frac{\partial R}{\partial x}\right)\hat{\mathbf{j}} + \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y}\right)\hat{\mathbf{k}}. \tag{16.6.4}$$

Note that the curl of a vector field is a vector field, in contrast to divergence.

The definition of curl can be difficult to remember. To help with remembering, we use the notation $\vec{\nabla} \times \vec{\mathbf{F}}$ to stand for a "determinant" that gives the curl formula:

$$\begin{vmatrix} \hat{i} & \hat{j} & \hat{k} \\ \dfrac{\partial}{\partial x} & \dfrac{\partial}{\partial y} & \dfrac{\partial}{\partial z} \\ P & Q & R \end{vmatrix}.$$

The determinant of this matrix is

$$(R_y - Q_z)\hat{\mathbf{i}} - (R_x - P_z)\hat{\mathbf{j}} + (Q_x - P_y)\hat{\mathbf{k}} = (R_y - Q_z)\hat{\mathbf{i}} + (P_z - R_x)\hat{\mathbf{j}} + (Q_x - P_y)\hat{\mathbf{k}} = \operatorname{curl} \vec{\mathbf{F}}.$$

Thus, this matrix is a way to help remember the formula for curl. Keep in mind, though, that the word *determinant* is used very loosely. A determinant is not really defined on a matrix with entries that are three vectors, three operators, and three functions.

If $\vec{\mathbf{F}} = \langle P, Q \rangle$ is a vector field in $\mathbb{R}^2$, then the curl of $\vec{\mathbf{F}}$, by definition, is

$$\operatorname{curl} \vec{\mathbf{F}} = (Q_x - P_y)\hat{\mathbf{k}} = \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y}\right)\hat{\mathbf{k}}.$$

### Example 16.6.5: Finding the Curl of a Three-Dimensional Vector Field

Find the curl of $\vec{\mathbf{F}}(x,y,z) = \langle P, Q, R\rangle = \langle x^2 z, e^y + xz, xyz\rangle$.

**Solution**

The curl is

$$\begin{aligned}\operatorname{curl}\vec{\mathbf{F}} &= \vec{\nabla}\times\vec{\mathbf{F}} \\ &= \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ \partial/\partial x & \partial/\partial y & \partial/\partial z \\ P & Q & R \end{vmatrix} \\ &= (R_y - Q_z)\hat{\mathbf{i}} + (P_z - R_x)\hat{\mathbf{j}} + (Q_x - P_y)\hat{\mathbf{k}} \\ &= (xz - x)\hat{\mathbf{i}} + (x^2 - yz)\hat{\mathbf{j}} + z\hat{\mathbf{k}}.\end{aligned}$$

### Exercise 16.6.4

Find the curl of $\vec{\mathbf{F}}(x,y,z) = \langle \sin x \cos z, \sin y \sin z, \cos x \cos y\rangle$ at point $\left(0, \frac{\pi}{2}, \frac{\pi}{2}\right)$.

**Hint**

Find the determinant of matrix $\vec{\nabla}\times\vec{\mathbf{F}}$.

**Answer**

$-\hat{i}$

### Example 16.6.6: Finding the Curl of a Two-Dimensional Vector Field

Find the curl of $\vec{\mathbf{F}}(x,y) = \langle P, Q\rangle = \langle y, 0\rangle$.

**Solution**

Notice that this vector field consists of vectors that are all parallel. In fact, each vector in the field is parallel to the $x$-axis. This fact might lead us to the conclusion that the field has no spin and that the curl is zero. To test this theory, note that

$$\operatorname{curl}\vec{\mathbf{F}} = (Q_x - P_y)\hat{\mathbf{k}} = -\hat{\mathbf{k}} \neq \vec{\mathbf{0}}.$$

Therefore, this vector field does have spin. To see why, imagine placing a paddlewheel at any point in the first quadrant (Figure **16.6.6**). The larger magnitudes of the vectors at the top of the wheel cause the wheel to rotate. The wheel rotates in the clockwise (negative) direction, causing the coefficient of the curl to be negative.

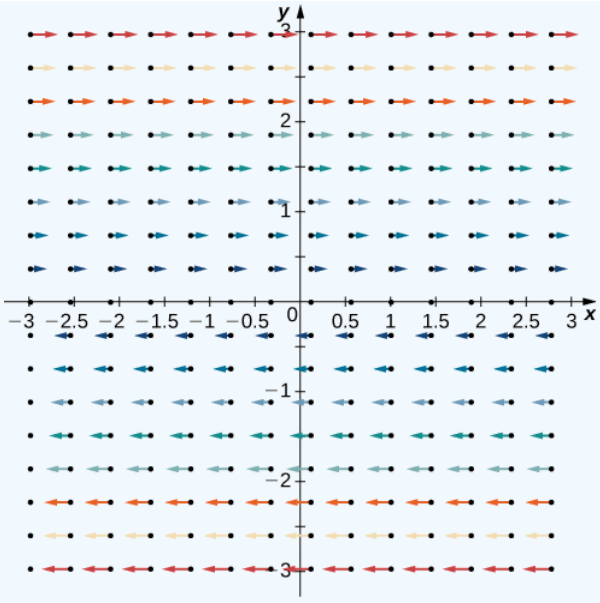

Figure **16.6.6**: Vector field $\vec{\mathbf{F}}(x,y) = \langle y, 0\rangle$ consists of vectors that are all parallel.

Note that if $\vec{\mathbf{F}} = \langle P, Q\rangle$ is a vector field in a plane, then $\text{curl}\,\vec{\mathbf{F}} \cdot \hat{\mathbf{k}} = (Q_x - P_y)\,\hat{\mathbf{k}} \cdot \hat{\mathbf{k}} = Q_x - P_y$. Therefore, the circulation form of Green's theorem is sometimes written as

$$\oint_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \iint_D \text{curl}\,\vec{\mathbf{F}} \cdot \hat{\mathbf{k}}\, dA,$$

where $C$ is a simple closed curve and $D$ is the region enclosed by $C$. Therefore, the circulation form of Green's theorem can be written in terms of the curl. If we think of curl as a derivative of sorts, then Green's theorem says that the "derivative" of $\vec{\mathbf{F}}$ on a region can be translated into a line integral of $\vec{\mathbf{F}}$ along the boundary of the region. This is analogous to the Fundamental Theorem of Calculus, in which the derivative of a function $f$ on line segment $[a,b]$ can be translated into a statement about $f$ on the boundary of $[a,b]$. Using curl, we can see the circulation form of Green's theorem is a higher-dimensional analog of the Fundamental Theorem of Calculus.

We can now use what we have learned about curl to show that gravitational fields have no "spin." Suppose there is an object at the origin with mass $m_1$ at the origin and an object with mass $m_2$. Recall that the gravitational force that object 1 exerts on object 2 is given by field

$$\vec{\mathbf{F}}(x,y,z) = -Gm_1m_2 \left\langle \frac{x}{(x^2+y^2+z^2)^{3/2}}, \frac{y}{(x^2+y^2+z^2)^{3/2}}, \frac{z}{(x^2+y^2+z^2)^{3/2}} \right\rangle.$$

### Example 16.6.7: Determining the Spin of a Gravitational Field

Show that a gravitational field has no spin.

**Solution**

To show that $\vec{\mathbf{F}}$ has no spin, we calculate its curl. Let

- $P(x,y,z) = \dfrac{x}{(x^2+y^2+z^2)^{3/2}}$,
- $Q(x,y,z) = \dfrac{y}{(x^2+y^2+z^2)^{3/2}}$, and
- $R(x,y,z) = \dfrac{z}{(x^2+y^2+z^2)^{3/2}}$.

Then,

$$\begin{aligned}\operatorname{curl}\vec{\mathbf{F}} &= -Gm_1m_2[(R_y-Q_z)\hat{\mathbf{i}}+(P_z-R_x)\hat{\mathbf{j}}+(Q_x-P_y)\hat{\mathbf{k}}] \\ &= -Gm_1m_2\begin{pmatrix}\left(\frac{-3yz}{(x^2+y^2+z^2)^{5/2}}-\left(\frac{-3yz}{(x^2+y^2+z^2)^{5/2}}\right)\right)\hat{\mathbf{i}} \\ +\left(\frac{-3xz}{(x^2+y^2+z^2)^{5/2}}-\left(\frac{-3xz}{(x^2+y^2+z^2)^{5/2}}\right)\right)\hat{\mathbf{j}} \\ +\left(\frac{-3xy}{(x^2+y^2+z^2)^{5/2}}-\left(\frac{-3xy}{(x^2+y^2+z^2)^{5/2}}\right)\right)\hat{\mathbf{k}}\end{pmatrix} \\ &= \vec{\mathbf{0}}.\end{aligned}$$

Since the curl of the gravitational field is zero, the field has no spin.

**? Exercise 16.6.7**

Field $\vec{\mathbf{v}}(x,y)=\langle -\frac{y}{x^2+y^2},\frac{x}{x^2+y^2}\rangle$ models the flow of a fluid. Show that if you drop a leaf into this fluid, as the leaf moves over time, the leaf does not rotate.

**Hint**

Calculate the curl.

**Answer**

$\operatorname{curl}\vec{\mathbf{v}}=\vec{\mathbf{0}}$

## Using Divergence and Curl

Now that we understand the basic concepts of divergence and curl, we can discuss their properties and establish relationships between them and conservative vector fields.

If $\vec{\mathbf{F}}$ is a vector field in $\mathbb{R}^3$ then the curl of $\vec{\mathbf{F}}$ is also a vector field in $\mathbb{R}^3$. Therefore, we can take the divergence of a curl. The next theorem says that the result is always zero. This result is useful because it gives us a way to show that some vector fields are not the curl of any other field. To give this result a physical interpretation, recall that divergence of a velocity field $\vec{\mathbf{v}}$ at point $P$ measures the tendency of the corresponding fluid to flow out of $P$. Since $\operatorname{div}(\operatorname{curl}\vec{\mathbf{v}})=0$, the net rate of flow in vector field $\operatorname{curl}\vec{\mathbf{v}}$ at any point is zero. Taking the curl of vector field $\vec{\mathbf{F}}$ eliminates whatever divergence was present in $\vec{\mathbf{F}}$.

**Theorem: Divergence of the Curl**

Let $\vec{\mathbf{F}}=\langle P,Q,R\rangle$ be a vector field in $\mathbb{R}^3$ such that the component functions all have continuous second-order partial derivatives. Then,

$$\operatorname{div}(\operatorname{curl}\vec{\mathbf{F}})=\vec{\nabla}\cdot(\vec{\nabla}\times\vec{\mathbf{F}})=0.$$

**Proof**

By the definitions of divergence and curl, and by Clairaut's theorem,

$$\begin{aligned}\operatorname{div}(\operatorname{curl}\vec{\mathbf{F}}) &= \operatorname{div}[(R_y-Q_z)\hat{\mathbf{i}}+(P_z-R_x)\hat{\mathbf{j}}+(Q_x-P_y)\hat{\mathbf{k}}] \\ &= R_{yx}-Q_{xz}+P_{yz}-R_{yx}+Q_{xz}-P_{zy} \\ &= 0.\end{aligned}$$

□

### Example 16.6.8: Showing That a Vector Field Is Not the Curl of Another

Show that $\vec{\mathbf{F}}(x,y,z) = e^x\,\hat{\mathbf{i}} + yz\,\hat{\mathbf{j}} + xz^2\,\hat{\mathbf{k}}$ is not the curl of another vector field. That is, show that there is no other vector $\vec{\mathbf{G}}$ with $\text{curl}\,\vec{\mathbf{G}} = \vec{\mathbf{F}}$.

**Solution**

Notice that the domain of $\vec{\mathbf{F}}$ is all of $\mathbb{R}^3$ and the second-order partials of $\vec{\mathbf{F}}$ are all continuous. Therefore, we can apply the previous theorem to $\vec{\mathbf{F}}$.

The divergence of $\vec{\mathbf{F}}$ is $e^x + z + 2xz$. If $\vec{\mathbf{F}}$ were the curl of vector field $\vec{\mathbf{G}}$, then $\text{div}\,\vec{\mathbf{F}} = \text{div}(\text{curl}\,\vec{\mathbf{G}}) = 0$. But, the divergence of $\vec{\mathbf{F}}$ is not zero, and therefore $\vec{\mathbf{F}}$ is not the curl of any other vector field.

### Exercise 16.6.8

Is it possible for $\vec{\mathbf{G}}(x,y,z) = \langle \sin x,\ \cos y,\ \sin(xyz)\rangle$ to be the curl of a vector field?

**Hint**

Find the divergence of $\vec{\mathbf{G}}$.

**Answer**

No.

With the next two theorems, we show that if $\vec{\mathbf{F}}$ is a conservative vector field then its curl is zero, and if the domain of $\vec{\mathbf{F}}$ is simply connected then the converse is also true. This gives us another way to test whether a vector field is conservative.

### Theorem: Curl of a Conservative Vector Field

If $\vec{\mathbf{F}} = \langle P, Q, R\rangle$ is conservative, then $\text{curl}\,\vec{\mathbf{F}} = \vec{\mathbf{0}}$.

### Proof

Since conservative vector fields satisfy the cross-partials property, all the cross-partials of $\vec{\mathbf{F}}$ are equal. Therefore,

$$\begin{aligned}\text{curl}\,\vec{\mathbf{F}} &= (R_y - Q_z)\,\hat{\mathbf{i}} + (P_z - R_x)\,\hat{\mathbf{j}} + (Q_x - P_y)\,\hat{\mathbf{k}} \\ &= \vec{\mathbf{0}}.\end{aligned}$$

□

The same theorem is true for vector fields in a plane.

Since a conservative vector field is the gradient of a scalar function, the previous theorem says that $\text{curl}\,(\vec{\nabla} f) = \vec{\mathbf{0}}$ for any scalar function $f$. In terms of our curl notation, $\vec{\nabla} \times \vec{\nabla}(f) = \vec{\mathbf{0}}$. This equation makes sense because the cross product of a vector with itself is always the zero vector. Sometimes equation $\vec{\nabla} \times \vec{\nabla}(f) = \vec{\mathbf{0}}$ is simplified as $\vec{\nabla} \times \vec{\nabla} = \vec{\mathbf{0}}$.

### Theorem: Curl Test for a Conservative Field

Let $\vec{\mathbf{F}} = \langle P, Q, R\rangle$ be a vector field in space on a simply connected domain. If $\text{curl}\,\vec{\mathbf{F}} = \vec{\mathbf{0}}$, then $\vec{\mathbf{F}}$ is conservative.

### Proof

Since $\text{curl}\,\vec{\mathbf{F}} = \vec{\mathbf{0}}$, we have that $R_y = Q_z$, $P_z = R_x$, and $Q_x = P_y$. Therefore, $\vec{\mathbf{F}}$ satisfies the cross-partials property on a simply connected domain, and the Cross-Partial Property of Conservative Fields implies that $\vec{\mathbf{F}}$ is conservative.

□

The same theorem is also true in a plane. Therefore, if $\vec{\mathbf{F}}$ is a vector field in a plane or in space and the domain is simply connected, then $\vec{\mathbf{F}}$ is conservative if and only if $\text{curl}\,\vec{\mathbf{F}} = \vec{\mathbf{0}}$.

### Example 16.6.9: Testing Whether a Vector Field Is Conservative

Use the curl to determine whether $\vec{\mathbf{F}}(x, y, z) = \langle yz, xz, xy \rangle$ is conservative.

#### Solution

Note that the domain of $\vec{\mathbf{F}}$ is all of $\mathbb{R}^3$ which is simply connected (Figure 16.6.7). Therefore, we can test whether $\vec{\mathbf{F}}$ is conservative by calculating its curl.

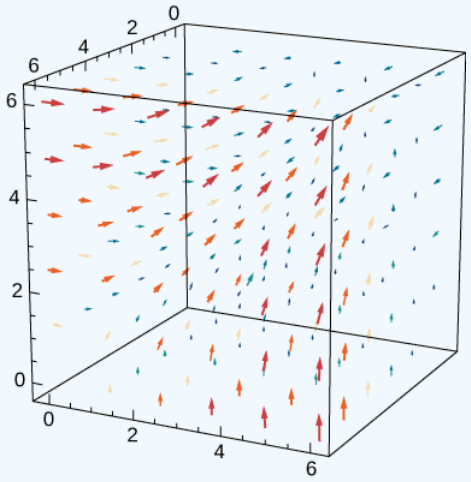

Figure 16.6.7: The curl of vector field $\vec{\mathbf{F}}(x, y, z) = \langle yz, xz, xy \rangle$ is zero.

The curl of $\vec{\mathbf{F}}$ is

$$\left(\frac{\partial}{\partial y}xy - \frac{\partial}{\partial z}xz\right)\hat{\mathbf{i}} + \left(\frac{\partial}{\partial y}yz - \frac{\partial}{\partial z}xy\right)\hat{\mathbf{j}} + \left(\frac{\partial}{\partial y}xz - \frac{\partial}{\partial z}yz\right)\hat{\mathbf{k}}$$
$$= (x - x)\hat{\mathbf{i}} + (y - y)\hat{\mathbf{j}} + (z - z)\hat{\mathbf{k}} = \vec{\mathbf{0}}.$$

Thus, $\vec{\mathbf{F}}$ is conservative.

We have seen that the curl of a gradient is zero. What is the divergence of a gradient? If $f$ is a function of two variables, then $\text{div}(\vec{\nabla} f) = \vec{\nabla} \cdot (\vec{\nabla} f) = f_{xx} + f_{yy}$. We abbreviate this "double dot product" as $\vec{\nabla}^2$. This operator is called the *Laplace operator*, and in this notation Laplace's equation becomes $\vec{\nabla}^2 f = 0$. Therefore, a harmonic function is a function that becomes zero after taking the divergence of a gradient.

Similarly, if $f$ is a function of three variables then

$$\text{div}(\vec{\nabla} f) = \vec{\nabla} \cdot (\vec{\nabla} f) = f_{xx} + f_{yy} + f_{zz}.$$

Using this notation we get Laplace's equation for harmonic functions of three variables:

$$\vec{\nabla}^2 f = 0.$$

Harmonic functions arise in many applications. For example, the potential function of an electrostatic field in a region of space that has no static charge is harmonic.

### Example 16.6.10: Finding a Potential Function

Is it possible for $f(x, y) = x^2 + x - y$ to be the potential function of an electrostatic field that is located in a region of $\mathbb{R}^2$ free of static charge?

**Solution**

If $f$ were such a potential function, then $f$ would be harmonic. Note that $f_{xx} = 2$ and $f_{yy} = 0$, and so $f_{xx} + f_{yy} \neq 0$. Therefore, $f$ is not harmonic and $f$ cannot represent an electrostatic potential.

**? Exercise 16.6.10**

Is it possible for function $f(x, y) = x^2 - y^2 + x$ to be the potential function of an electrostatic field located in a region of $\mathbb{R}^2$ free of static charge?

**Hint**

Determine whether the function is harmonic.

**Answer**

Yes.

## Key Concepts

- The divergence of a vector field is a scalar function. Divergence measures the "outflowing-ness" of a vector field. If $\vec{\mathbf{v}}$ is the velocity field of a fluid, then the divergence of $\vec{\mathbf{v}}$ at a point is the outflow of the fluid less the inflow at the point.
- The curl of a vector field is a vector field. The curl of a vector field at point $P$ measures the tendency of particles at $P$ to rotate about the axis that points in the direction of the curl at $P$.
- A vector field with a simply connected domain is conservative if and only if its curl is zero.

## Key Equations

- **Curl**

$$\vec{\nabla} \times \vec{\mathbf{F}} = (R_y - Q_z)\hat{\mathbf{i}} + (P_z - R_x)\hat{\mathbf{j}} + (Q_x - P_y)\hat{\mathbf{k}}$$

- **Divergence**

$$\vec{\nabla} \cdot \vec{\mathbf{F}} = P_x + Q_y + R_z$$

- **Divergence of curl is zero**

$$\vec{\nabla} \cdot (\vec{\nabla} \times \vec{\mathbf{F}}) = 0$$

- **Curl of a gradient is the zero vector**

$$\vec{\nabla} \times (\vec{\nabla} f) = 0$$

## Glossary

**curl**

the curl of vector field $\vec{\mathbf{F}} = \langle P, Q, R \rangle$, denoted $\vec{\nabla} \times \vec{\mathbf{F}}$ is the "determinant" of the matrix

$$\begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ \dfrac{\partial}{\partial x} & \dfrac{\partial}{\partial y} & \dfrac{\partial}{\partial z} \\ P & Q & R \end{vmatrix}.$$

and is given by the expression $(R_y - Q_z)\hat{\mathbf{i}} + (P_z - R_x)\hat{\mathbf{j}} + (Q_x - P_y)\hat{\mathbf{k}}$; it measures the tendency of particles at a point to rotate about the axis that points in the direction of the curl at the point

**divergence**

the divergence of a vector field $\vec{\mathbf{F}} = \langle P, Q, R \rangle$, denoted $\vec{\nabla} \times \vec{\mathbf{F}}$, is $P_x + Q_y + R_z$; it measures the "outflowing-ness" of a vector field

# 16.6E: Exercises for Section 16.5

**For the following exercises, determine whether the statement is *True* or *False*.**

**1.** If the coordinate functions of $\vec{\mathbf{F}} : \mathbb{R}^3 \to \mathbb{R}^3$ have continuous second partial derivatives, then $\textbf{curl}\,(\textbf{div}\,\vec{\mathbf{F}})$ equals zero.

**2.** $\vec{\nabla} \cdot (x\,\hat{\mathbf{i}} + y\,\hat{\mathbf{j}} + z\,\hat{\mathbf{k}}) = 1$.

**Answer**

False

**3.** All vector fields of the form $\vec{\mathbf{F}}(x, y, z) = f(x)\,\hat{\mathbf{i}} + g(y)\,\hat{\mathbf{j}} + h(z)\,\hat{\mathbf{k}}$ are conservative.

**4.** If $\textbf{curl}\,\vec{\mathbf{F}} = \vec{\mathbf{0}}$, then $\vec{\mathbf{F}}$ is conservative.

**Answer**

True

**5.** If $\vec{\mathbf{F}}$ is a constant vector field then $\textbf{div}\,\vec{\mathbf{F}} = 0$.

**6.** If $\vec{\mathbf{F}}$ is a constant vector field then $\textbf{curl}\,\vec{\mathbf{F}} = \vec{\mathbf{0}}$.

**Answer**

True

**For the following exercises, find the curl of $\vec{\mathbf{F}}$.**

**7.** $\vec{\mathbf{F}}(x, y, z) = xy^2z^4\,\hat{\mathbf{i}} + (2x^2y + z)\,\hat{\mathbf{j}} + y^3z^2\,\hat{\mathbf{k}}$

**8.** $\vec{\mathbf{F}}(x, y, z) = x^2z\,\hat{\mathbf{i}} + y^2x\,\hat{\mathbf{j}} + (y + 2z)\,\hat{\mathbf{k}}$

**Answer**

$\textbf{curl}\,\vec{\mathbf{F}} = \hat{\mathbf{i}} + x^2\,\hat{\mathbf{j}} + y^2\,\hat{\mathbf{k}}$

**9.** $\vec{\mathbf{F}}(x, y, z) = 3xyz^2\,\hat{\mathbf{i}} + y^2 \sin z\,\hat{\mathbf{j}} + xe^{2z}\,\hat{\mathbf{k}}$

**10.** $\vec{\mathbf{F}}(x, y, z) = x^2yz\,\hat{\mathbf{i}} + xy^2z\,\hat{\mathbf{j}} + xyz^2\,\hat{\mathbf{k}}$

**Answer**

$\textbf{curl}\,\vec{\mathbf{F}} = (xz^2 - xy^2)\,\hat{\mathbf{i}} + (x^2y - yz^2)\,\hat{\mathbf{j}} + (y^2z - x^2z)\,\hat{\mathbf{k}}$

**11.** $\vec{\mathbf{F}}(x, y, z) = (x \cos y)\,\hat{\mathbf{i}} + xy^2\,\hat{\mathbf{j}}$

**12.** $\vec{\mathbf{F}}(x, y, z) = (x - y)\,\hat{\mathbf{i}} + (y - z)\,\hat{\mathbf{j}} + (z - x)\,\hat{\mathbf{k}}$

**Answer**

$\textbf{curl}\ \vec{\mathbf{F}} = \hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}$

**13.** $\vec{\mathbf{F}}(x, y, z) = xyz\,\hat{\mathbf{i}} + x^2y^2z^2\,\hat{\mathbf{j}} + y^2z^3\,\hat{\mathbf{k}}$

**14.** $\vec{\mathbf{F}}(x, y, z) = xy\,\hat{\mathbf{i}} + yz\,\hat{\mathbf{j}} + xz\,\hat{\mathbf{k}}$

**Answer**

$\textbf{curl}\ \vec{\mathbf{F}} = -y\,\hat{\mathbf{i}} - z\,\hat{\mathbf{j}} - x\,\hat{\mathbf{k}}$

**15.** $\vec{\mathbf{F}}(x, y, z) = x^2\,\hat{\mathbf{i}} + y^2\,\hat{\mathbf{j}} + z^2\,\hat{\mathbf{k}}$

**16.** $\vec{\mathbf{F}}(x, y, z) = ax\,\hat{\mathbf{i}} + by\,\hat{\mathbf{j}} + c\,\hat{\mathbf{k}}$ for constants $a$, $b$, $c$.

**Answer**

$$\text{curl } \vec{\mathbf{F}} = \vec{\mathbf{0}}$$

**For the following exercises, find the divergence of $\vec{\mathbf{F}}$.**

**17.** $\vec{\mathbf{F}}(x,y,z) = x^2z\,\hat{\mathbf{i}} + y^2x\,\hat{\mathbf{j}} + (y+2z)\,\hat{\mathbf{k}}$

**18.** $\vec{\mathbf{F}}(x,y,z) = 3xyz^2\,\hat{\mathbf{i}} + y^2\sin z\,\hat{\mathbf{j}} + xe^{2z}z\,\hat{\mathbf{k}}$

**Answer**

$\text{div}\,\vec{\mathbf{F}} = 3yz^2 + 2y\sin z + 2xe^{2z}$

**19.** $\vec{\mathbf{F}}(x,y) = (\sin x)\,\hat{\mathbf{i}} + (\cos y)\,\hat{\mathbf{j}}$

**20.** $\vec{\mathbf{F}}(x,y,z) = x^2\,\hat{\mathbf{i}} + y^2\,\hat{\mathbf{j}} + z^2\,\hat{\mathbf{k}}$

**Answer**

$\text{div}\,\vec{\mathbf{F}} = 2(x+y+z)$

**21.** $\vec{\mathbf{F}}(x,y,z) = (x-y)\,\hat{\mathbf{i}} + (y-z)\,\hat{\mathbf{j}} + (z-x)\,\hat{\mathbf{k}}$

**22.** $\vec{\mathbf{F}}(x,y) = \dfrac{x}{\sqrt{x^2+y^2}}\,\hat{\mathbf{i}} + \dfrac{y}{\sqrt{x^2+y^2}}\,\hat{\mathbf{j}}$

**Answer**

$\text{div}\,\vec{\mathbf{F}} = \dfrac{1}{\sqrt{x^2+y^2}}$

**23.** $\vec{\mathbf{F}}(x,y) = x\,\hat{\mathbf{i}} - y\,\hat{\mathbf{j}}$

**24.** $\vec{\mathbf{F}}(x,y,z) = ax\,\hat{\mathbf{i}} + by\,\hat{\mathbf{j}} + c\,\hat{\mathbf{k}}$ for constants $a$, $b$, $c$.

**Answer**

$\text{div}\,\vec{\mathbf{F}} = a + b$

**25.** $\vec{\mathbf{F}}(x,y,z) = xyz\,\hat{\mathbf{i}} + x^2y^2z^2\,\hat{\mathbf{j}} + y^2z^3\,\hat{\mathbf{k}}$

**26.** $\vec{\mathbf{F}}(x,y,z) = xy\,\hat{\mathbf{i}} + yz\,\hat{\mathbf{j}} + xz\,\hat{\mathbf{k}}$

**Answer**

$\text{div}\,\vec{\mathbf{F}} = x + y + z$

**For exercises 27 & 28, determine whether each of the given scalar functions is harmonic.**

**27.** $u(x,y,z) = e^{-x}(\cos y - \sin y)$

**28.** $w(x,y,z) = (x^2+y^2+z^2)^{-1/2}$

**Answer**

Harmonic

**29.** If $\vec{\mathbf{F}}(x,y,z) = 2\,\hat{\mathbf{i}} + 2xj + 3yk$ and $\vec{\mathbf{G}}(x,y,z) = x\,\hat{\mathbf{i}} - y\,\hat{\mathbf{j}} + z\,\hat{\mathbf{k}}$, find $\text{curl}\,(\vec{\mathbf{F}} \times \vec{\mathbf{G}})$.

**30.** If $\vec{\mathbf{F}}(x,y,z) = 2\,\hat{\mathbf{i}} + 2xj + 3yk$ and $\vec{\mathbf{G}}(x,y,z) = x\,\hat{\mathbf{i}} - y\,\hat{\mathbf{j}} + z\,\hat{\mathbf{k}}$, find $\text{div}\,(\vec{\mathbf{F}} \times \vec{\mathbf{G}})$.

**Answer**

$\text{div}\,(\vec{\mathbf{F}} \times \vec{\mathbf{G}}) = 2z + 3x$

**31.** Find $\text{div}\,\vec{\mathbf{F}}$, given that $\vec{\mathbf{F}} = \vec{\nabla} f$, where $f(x,y,z) = xy^3z^2$.

**32.** Find the divergence of $\vec{\mathbf{F}}$ for vector field $\vec{\mathbf{F}}(x,y,z) = (y^2+z^2)(x+y)\,\hat{\mathbf{i}} + (z^2+x^2)(y+z)\,\hat{\mathbf{j}} + (x^2+y^2)(z+x)\,\hat{\mathbf{k}}$.

**Answer**

$\text{div}\,\vec{\mathbf{F}} = 2r^2$

**33.** Find the divergence of $\vec{\mathbf{F}}$ for vector field $\vec{\mathbf{F}}(x,y,z) = f_1(y,z)\,\hat{\mathbf{i}} + f_2(x,z)\,\hat{\mathbf{j}} + f_3(x,y)\,\hat{\mathbf{k}}$.

**For exercises 34 - 36, use $r = |\vec{\mathbf{r}}|$ and $\vec{\mathbf{r}}(x,y,z) = \langle x,y,z\rangle$.**

**34.** Find the $\text{curl}\,\vec{\mathbf{r}}$

**Answer**

$\text{curl}\,\vec{\mathbf{r}} = \vec{\mathbf{0}}$

**35.** Find the $\text{curl}\,\dfrac{\vec{\mathbf{r}}}{r}$.

**36.** Find the $\text{curl}\,\dfrac{\vec{\mathbf{r}}}{r^3}$.

**Answer**

$\text{curl}\,\dfrac{\vec{\mathbf{r}}}{r^3} = \vec{\mathbf{0}}$

**37.** Let $\vec{\mathbf{F}}(x,y) = \dfrac{-y\,\hat{\mathbf{i}} + x\,\hat{\mathbf{j}}}{x^2+y^2}$, where $\vec{\mathbf{F}}$ is defined on $\{(x,y) \in \mathbb{R} | (x,y) \neq (0,0)\}$. Find $\text{curl}\,\vec{\mathbf{F}}$.

**For the following exercises, use a computer algebra system to find the curl of the given vector fields.**

**38.** [T] $\vec{\mathbf{F}}(x,y,z) = \arctan\left(\dfrac{x}{y}\right)\,\hat{\mathbf{i}} + \ln\sqrt{x^2+y^2}\,\hat{\mathbf{j}} + \hat{\mathbf{k}}$

**Answer**

$\text{curl}\;\vec{\mathbf{F}} = \dfrac{2x}{x^2+y^2}\,\hat{\mathbf{k}}$

**39.** [T] $\vec{\mathbf{F}}(x,y,z) = \sin(x-y)\,\hat{\mathbf{i}} + \sin(y-z)\,\hat{\mathbf{j}} + \sin(z-x)\,\hat{\mathbf{k}}$

**For the following exercises, find the divergence of $\vec{\mathbf{F}}$ at the given point.**

**40.** $\vec{\mathbf{F}}(x,y,z) = \hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}$ at $(2,-1,3)$

**Answer**

$\text{div}\,\vec{\mathbf{F}} = 0$

**41.** $\vec{\mathbf{F}}(x,y,z) = xyz\,\hat{\mathbf{i}} + y\,\hat{\mathbf{j}} + z\,\hat{\mathbf{k}}$ at $(1,2,3)$

**42.** $\vec{\mathbf{F}}(x,y,z) = e^{-xy}\,\hat{\mathbf{i}} + e^{xz}\,\hat{\mathbf{j}} + e^{yz}\,\hat{\mathbf{k}}$ at $(3,2,0)$

**Answer**

$\text{div}\,\vec{\mathbf{F}} = 2 - 2e^{-6}$

**43.** $\vec{\mathbf{F}}(x,y,z) = xyz\,\hat{\mathbf{i}} + y\,\hat{\mathbf{j}} + z\,\hat{\mathbf{k}}$ at $(1,2,1)$

**44.** $\vec{\mathbf{F}}(x,y,z) = e^x \sin y\,\hat{\mathbf{i}} - e^x \cos y\,\hat{\mathbf{j}}$ at $(0,0,3)$

**Answer**

$\text{div}\,\vec{\mathbf{F}} = 0$

**For exercises 45- 49, find the curl of $\vec{\mathbf{F}}$ at the given point.**

**45.** $\vec{\mathbf{F}}(x,y,z) = \hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}$ at $(2,-1,3)$

**46.** $\vec{\mathbf{F}}(x,y,z) = xyz\,\hat{\mathbf{i}} + y\,\hat{\mathbf{j}} + x\,\hat{\mathbf{k}}$ at $(1,2,3)$

**Answer**

$\text{curl } \vec{\mathbf{F}} = \hat{\mathbf{j}} - 3\hat{\mathbf{k}}$

**47.** $\vec{\mathbf{F}}(x, y, z) = e^{-xy}\,\hat{\mathbf{i}} + e^{xz}\,\hat{\mathbf{j}} + e^{yz}\,\hat{\mathbf{k}}$ at $(3, 2, 0)$

**48.** $\vec{\mathbf{F}}(x, y, z) = xyz\,\hat{\mathbf{i}} + y\,\hat{\mathbf{j}} + z\,\hat{\mathbf{k}}$ at $(1, 2, 1)$

**Answer**

$\text{curl } \vec{\mathbf{F}} = 2\hat{\mathbf{j}} - \hat{\mathbf{k}}$

**49.** $\vec{\mathbf{F}}(x, y, z) = e^{x} \sin y\,\hat{\mathbf{i}} - e^{x} \cos y\,\hat{\mathbf{j}}$ at $(0, 0, 3)$

**50.** Let $\vec{\mathbf{F}}(x, y, z) = (3x^2y + az)\,\hat{\mathbf{i}} + x^3\,\hat{\mathbf{j}} + (3x + 3z^2)\,\hat{\mathbf{k}}$. For what value of $a$ is $\vec{\mathbf{F}}$ conservative?

**Answer**

$a = 3$

**51.** Given vector field $\vec{\mathbf{F}}(x, y) = \dfrac{1}{x^2 + y^2}\langle -y, x\rangle$ on domain $D = \dfrac{\mathbb{R}^2}{\{(0,0)\}} = \{(x, y) \in \mathbb{R}^2 | (x, y) \neq (0, 0)\}$, is $\vec{\mathbf{F}}$ conservative?

**52.** Given vector field $\vec{\mathbf{F}}(x, y) = \dfrac{1}{x^2 + y^2}\langle x, y\rangle$ on domain $D = \dfrac{\mathbb{R}^2}{\{(0,0)\}}$, is $\vec{\mathbf{F}}$ conservative?

**Answer**

$\vec{\mathbf{F}}$ is conservative.

**53.** Find the work done by force field $\vec{\mathbf{F}}(x, y) = e^{-y}\,\hat{\mathbf{i}} - xe^{-y}\,\hat{\mathbf{j}}$ in moving an object from $P(0, 1)$ to $Q(2, 0)$. Is the force field conservative?

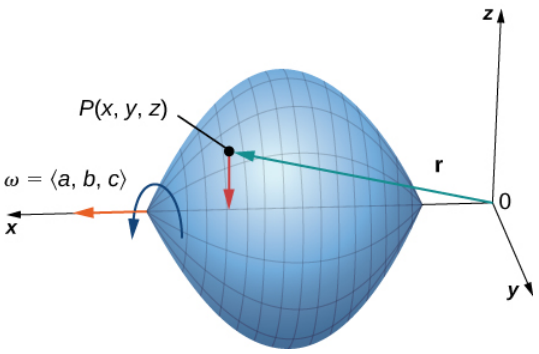
**54.** Compute divergence $\vec{\mathbf{F}}(x, y, z) = (\sinh x)\,\hat{\mathbf{i}} + (\cosh y)\,\hat{\mathbf{j}} - xyz\,\hat{\mathbf{k}}$.

**Answer**

$\text{div } \vec{\mathbf{F}} = \cosh x + \sinh y - xy$

**55.** Compute $\text{curl } \vec{\mathbf{F}} = (\sinh x)\,\hat{\mathbf{i}} + (\cosh y)\,\hat{\mathbf{j}} - xyz\,\hat{\mathbf{k}}$.

**For the following exercises, consider a rigid body that is rotating about the $x$-axis counterclockwise with constant angular velocity $\vec{\omega} = \langle a, b, c\rangle$. If $P$ is a point in the body located at $\vec{\mathbf{r}} = x\,\hat{\mathbf{i}} + y\,\hat{\mathbf{j}} + z\,\hat{\mathbf{k}}$, the velocity at $P$ is given by vector field $\vec{\mathbf{F}} = \vec{\omega} \times \vec{\mathbf{r}}$.**



**56.** Express $\vec{\mathbf{F}}$ in terms of $\hat{\mathbf{i}}$, $\hat{\mathbf{j}}$, and $\hat{\mathbf{k}}$ vectors.

**Answer**

$\vec{\mathbf{F}} = (bz - cy)\,\hat{\mathbf{i}} + (cx - az)\,\hat{\mathbf{j}} + (ay - bx)\,\hat{\mathbf{k}}$

**57.** Find $\text{div } F$.

**58.** Find $\text{curl } F$

**Answer**

$$\text{curl } \vec{\mathbf{F}} = 2\vec{\omega}$$

**In the following exercises, suppose that $\vec{\nabla} \cdot \vec{\mathbf{F}} = 0$ and $\vec{\nabla} \cdot \vec{\mathbf{G}} = 0$.**

**59.** Does $\vec{\mathbf{F}} + \vec{\mathbf{G}}$ necessarily have zero divergence?

**60.** Does $\vec{\mathbf{F}} \times \vec{\mathbf{G}}$ necessarily have zero divergence?

**Answer**

$\vec{\mathbf{F}} \times \vec{\mathbf{G}}$ does not have zero divergence.

**In the following exercises, suppose a solid object in $\mathbb{R}^3$ has a temperature distribution given by $T(x, y, z)$. The heat flow vector field in the object is $\vec{\mathbf{F}} = -k\vec{\nabla}T$, where $k > 0$ is a property of the material. The heat flow vector points in the direction opposite to that of the gradient, which is the direction of greatest temperature decrease. The divergence of the heat flow vector is $\vec{\nabla} \cdot \vec{\mathbf{F}} = -k\vec{\nabla} \cdot \vec{\nabla}T = -k\vec{\nabla}^2 T$.**

**61.** Compute the heat flow vector field.

**62.** Compute the divergence.

**Answer**

$\vec{\nabla} \cdot \vec{\mathbf{F}} = -200k[1 + 2(x^2 + y^2 + z^2)]e^{-x^2+y^2+z^2}$

**63.** [T] Consider rotational velocity field $\vec{\mathbf{v}} = \langle 0, 10z, -10y \rangle$. If a paddlewheel is placed in plane $x + y + z = 1$ with its axis normal to this plane, using a computer algebra system, calculate how fast the paddlewheel spins in revolutions per unit time.

# 16.7: Surface Integrals

**Learning Objectives**

- Find the parametric representations of a cylinder, a cone, and a sphere.
- Describe the surface integral of a scalar-valued function over a parametric surface.
- Use a surface integral to calculate the area of a given surface.
- Explain the meaning of an oriented surface, giving an example.
- Describe the surface integral of a vector field.
- Use surface integrals to solve applied problems.

We have seen that a line integral is an integral over a path in a plane or in space. However, if we wish to integrate over a surface (a two-dimensional object) rather than a path (a one-dimensional object) in space, then we need a new kind of integral that can handle integration over objects in higher dimensions. We can extend the concept of a line integral to a surface integral to allow us to perform this integration.

Surface integrals are important for the same reasons that line integrals are important. They have many applications to physics and engineering, and they allow us to develop higher dimensional versions of the Fundamental Theorem of Calculus. In particular, surface integrals allow us to generalize Green's theorem to higher dimensions, and they appear in some important theorems we discuss in later sections.

## Parametric Surfaces

A surface integral is similar to a line integral, except the integration is done over a surface rather than a path. In this sense, surface integrals expand on our study of line integrals. Just as with line integrals, there are two kinds of surface integrals: a surface integral of a scalar-valued function and a surface integral of a vector field.

However, before we can integrate over a surface, we need to consider the surface itself. Recall that to calculate a scalar or vector line integral over curve $C$, we first need to parameterize $C$. In a similar way, to calculate a surface integral over surface $S$, we need to parameterize $S$. That is, we need a working concept of a *parameterized surface* (or a *parametric surface*), in the same way that we already have a concept of a parameterized curve.

A parameterized surface is given by a description of the form

$$\vec{\mathbf{r}}(u,v) = \langle x(u,v),\, y(u,v),\, z(u,v)\rangle.$$

Notice that this parameterization involves two parameters, $u$ and $v$, because a surface is two-dimensional, and therefore two variables are needed to trace out the surface. The parameters $u$ and $v$ vary over a region called the parameter domain, or parameter space—the set of points in the $uv$-plane that can be substituted into $\vec{\mathbf{r}}$. Each choice of $u$ and $v$ in the parameter domain gives a point on the surface, just as each choice of a parameter $t$ gives a point on a parameterized curve. The entire surface is created by making all possible choices of $u$ and $v$ over the parameter domain.

**Definition: Parameter Domain**

Given a parameterization of surface

$$\vec{\mathbf{r}}(u,v) = \langle x(u,v),\, y(u,v),\, z(u,v)\rangle.$$

the *parameter domain* of the parameterization is the set of points in the $uv$-plane that can be substituted into $\vec{\mathbf{r}}$.

**Example 16.7.1: Parameterizing a Cylinder**

Describe surface $S$ parameterized by

$$\vec{\mathbf{r}}(u,v) = \langle \cos u,\, \sin u,\, v\rangle,\ -\infty < u < \infty,\ -\infty < v < \infty.$$

**Solution**

To get an idea of the shape of the surface, we first plot some points. Since the parameter domain is all of $\mathbb{R}^2$, we can choose any value for $u$ and $v$ and plot the corresponding point. If $u = v = 0$, then $\vec{\mathbf{r}}(0,0) = \langle 1,0,0\rangle$, so point (1, 0, 0) is on $S$. Similarly, points $\vec{\mathbf{r}}(\pi,2) = (-1,0,2)$ and $\vec{\mathbf{r}}\left(\frac{\pi}{2},4\right) = (0,1,4)$ are on $S$.

Although plotting points may give us an idea of the shape of the surface, we usually need quite a few points to see the shape. Since it is time-consuming to plot dozens or hundreds of points, we use another strategy. To visualize $S$, we visualize two families of curves that lie on $S$. In the first family of curves we hold $u$ constant; in the second family of curves we hold $v$ constant. This allows us to build a "skeleton" of the surface, thereby getting an idea of its shape.

- Suppose that $u$ is a constant $K$. Then the curve traced out by the parameterization is $\langle \cos K, \sin K, v\rangle$, which gives a vertical line that goes through point $(\cos K, \sin K, v\rangle$ in the $xy$-plane.
- Suppose that $v$ is a constant $K$. Then the curve traced out by the parameterization is $\langle \cos u, \sin u, K\rangle$, which gives a circle in plane $z = K$ with radius 1 and center $(0,0,K)$.

If $u$ is held constant, then we get vertical lines; if $v$ is held constant, then we get circles of radius 1 centered around the vertical line that goes through the origin. Therefore the surface traced out by the parameterization is cylinder $x^2 + y^2 = 1$ (Figure 16.7.1).

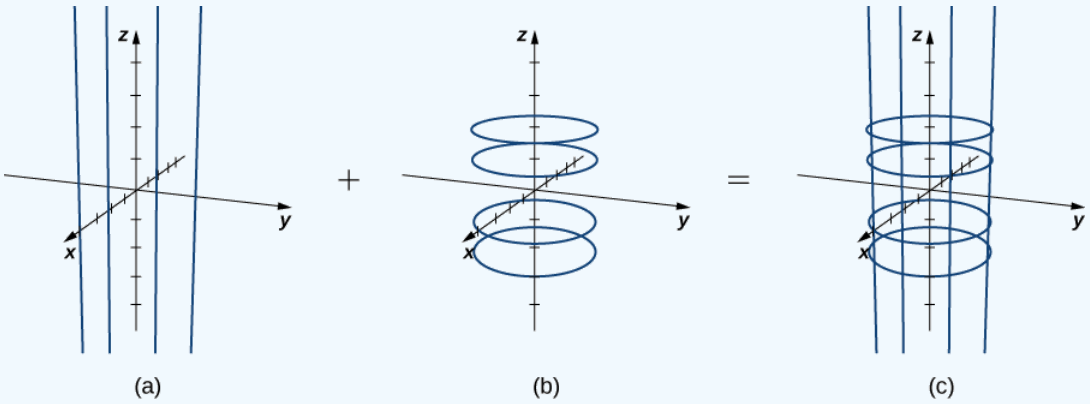

Figure 16.7.1: (a) Lines $\langle \cos K, \sin K, v\rangle$ for $K = 0$, $\frac{\pi}{2}$, $\pi$, and $\frac{3\pi}{2}$. (b) Circles $\langle \cos u, \sin u, K\rangle$ for $K = -2, -1, 1$, and 2 (c) The lines and circles together. As $u$ and $v$ vary, they describe a cylinder.

Notice that if $x = \cos u$ and $y = \sin u$, then $x^2 + y^2 = 1$, so points from $S$ do indeed lie on the cylinder. Conversely, each point on the cylinder is contained in some circle $\langle \cos u, \sin u, k\rangle$ for some $k$, and therefore each point on the cylinder is contained in the parameterized surface (Figure 16.7.2).

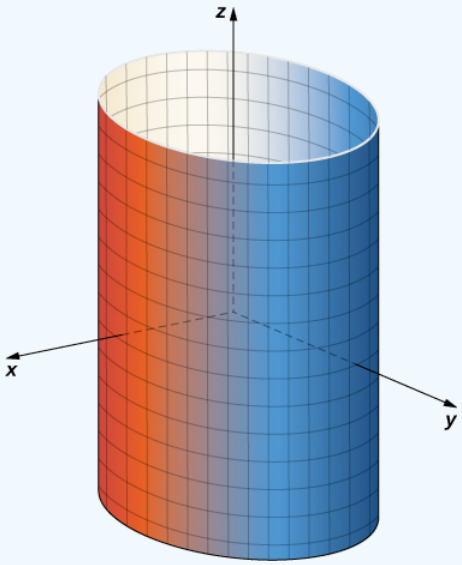

Figure 16.7.2: Cylinder $x^2 + y^2 = r^2$ has parameterization $\vec{\mathbf{r}}(u,v) = \langle r\cos u, r\sin u, v\rangle$, $0 \le u \le 2\pi$, $-\infty < v < \infty$.

### Analysis

Notice that if we change the parameter domain, we could get a different surface. For example, if we restricted the domain to $0 \leq u \leq \pi$, $-\infty < v < 6$, then the surface would be a half-cylinder of height 6.

**? Exercise 16.7.1**

Describe the surface with parameterization

$$\vec{\mathbf{r}}(u,v) = \langle 2\cos u,\ 2\sin u,\ v\rangle,\ 0 \leq u \leq 2\pi,\ -\infty < v < \infty$$

**Hint**

Hold $u$ and $v$ constant, and see what kind of curves result.

**Answer**

Cylinder $x^2 + y^2 = 4$

It follows from Example 16.7.1 that we can parameterize all cylinders of the form $x^2 + y^2 = R^2$. If $S$ is a cylinder given by equation $x^2 + y^2 = R^2$, then a parameterization of $S$ is $\vec{\mathbf{r}}(u,v) = \langle R\cos u,\ R\sin u,\ v\rangle$, $0 \leq u \leq 2\pi$, $-\infty < v < \infty$.

We can also find different types of surfaces given their parameterization, or we can find a parameterization when we are given a surface.

**✓ Example 16.7.2: Describing a Surface**

Describe surface $S$ parameterized by $\vec{\mathbf{r}}(u,v) = \langle u\cos v,\ u\sin v,\ u^2\rangle$, $0 \leq u < \infty$, $0 \leq v < 2\pi$.

### Solution

Notice that if $u$ is held constant, then the resulting curve is a circle of radius $u$ in plane $z = u$. Therefore, as $u$ increases, the radius of the resulting circle increases. If $v$ is held constant, then the resulting curve is a vertical parabola. Therefore, we expect the surface to be an elliptic paraboloid. To confirm this, notice that

$$\begin{aligned} x^2 + y^2 &= (u\cos v)^2 + (u\sin v)^2 \\ &= u^2\cos^2 v + u^2 sin^2 v \\ &= u^2 \\ &= z \end{aligned}$$

Therefore, the surface is the elliptic paraboloid $x^2 + y^2 = z$ (Figure 16.7.3).

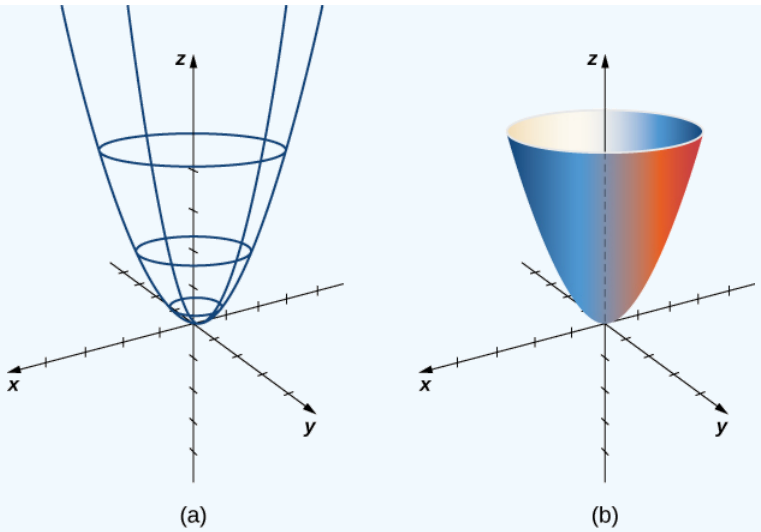

Figure 16.7.3: (a) Circles arise from holding $u$ constant; the vertical parabolas arise from holding $v$ constant. (b) An elliptic paraboloid results from all choices of $u$ and $v$ in the parameter domain.

## ? Exercise 16.7.2

Describe the surface parameterized by $\vec{\mathbf{r}}(u,v) = \langle u\cos v, u\sin v, u\rangle$, $-\infty < u < \infty$, $0 \le v < 2\pi$.

**Hint**

Hold $u$ constant and see what kind of curves result. Imagine what happens as $u$ increases or decreases.

**Answer**

Cone $x^2 + y^2 = z^2$

## ✓ Example 16.7.3: Finding a Parameterization

Give a parameterization of the cone $x^2 + y^2 = z^2$ lying on or above the plane $z = -2$.

### Solution

The horizontal cross-section of the cone at height $z = u$ is circle $x^2 + y^2 = u^2$. Therefore, a point on the cone at height $u$ has coordinates $(u\cos v, u\sin v, u)$ for angle $v$. Hence, a parameterization of the cone is $\vec{\mathbf{r}}(u,v) = \langle u\cos v, u\sin v, u\rangle$. Since we are not interested in the entire cone, only the portion on or above plane $z = -2$, the parameter domain is given by $-2 < u < \infty$, $0 \le v < 2\pi$ (Figure 16.7.4).

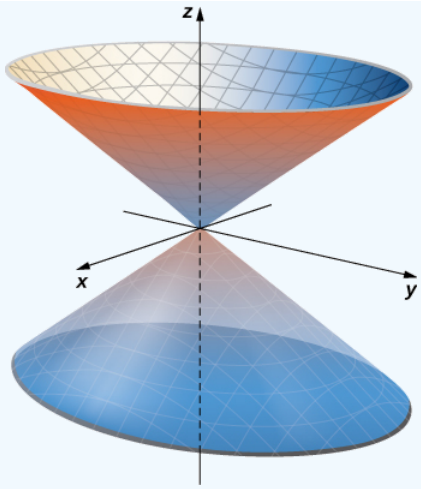

Figure 16.7.4: Cone $x^2 + y^2 = z^2$ has parametrization $\vec{\mathbf{r}}(u, v) = \langle u \cos v, u \sin v \rangle$, $-\infty < u < \infty$, $0 \leq v \leq 2\pi$.

**? Exercise 16.7.3**

Give a parameterization for the portion of cone $x^2 + y^2 = z^2$ lying in the first octant.

**Hint**

Consider the parameter domain for this surface.

**Answer**

$\vec{\mathbf{r}}(u, v) = \langle u \cos v, u \sin v, u \rangle$, $0 < u < \infty$, $0 \leq v < \dfrac{\pi}{2}$

We have discussed parameterizations of various surfaces, but two important types of surfaces need a separate discussion: spheres and graphs of two-variable functions. To parameterize a sphere, it is easiest to use spherical coordinates. The sphere of radius $\rho$ centered at the origin is given by the parameterization

$$\vec{\mathbf{r}}(\phi, \theta) = \langle \rho \cos\theta \sin\phi, \rho \sin\theta \sin\phi, \rho \cos\phi \rangle, \; 0 \leq \theta \leq 2\pi, \; 0 \leq \phi \leq \pi.$$

The idea of this parameterization is that as $\phi$ sweeps downward from the positive $z$-axis, a circle of radius $\rho \sin\phi$ is traced out by letting $\theta$ run from 0 to $2\pi$. To see this, let $\phi$ be fixed. Then

$$\begin{aligned} x^2 + y^2 &= (\rho \cos\theta \sin\phi)^2 + (\rho \sin\theta \sin\phi)^2 \\ &= \rho^2 \sin^2\phi(\cos^2\theta + \sin^2\theta) \\ &= \rho^2 \sin^2\phi \\ &= (\rho \sin\phi)^2. \end{aligned}$$

This results in the desired circle (Figure 16.7.5).

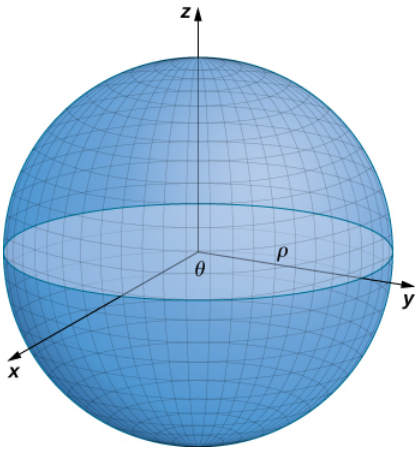

Figure 16.7.5: The sphere of radius $\rho$ has parameterization $\vec{\mathbf{r}}(\phi,\theta) = \langle \rho\cos\theta\sin\phi,\ \rho\sin\theta\sin\phi,\ \rho\cos\phi\rangle$, $0 \le \theta \le 2\pi$, $0 \le \phi \le \pi$.

Finally, to parameterize the graph of a two-variable function, we first let $z = f(x,y)$ be a function of two variables. The simplest parameterization of the graph of $f$ is $\vec{\mathbf{r}}(x,y) = \langle x, y, f(x,y)\rangle$, where $x$ and $y$ vary over the domain of $f$ (Figure 16.7.6). For example, the graph of $f(x,y) = x^2y$ can be parameterized by $\vec{\mathbf{r}}(x,y) = \langle x, y, x^2y\rangle$, where the parameters $x$ and $y$ vary over the domain of $f$. If we only care about a piece of the graph of $f$ - say, the piece of the graph over rectangle $[1,3] \times [2,5]$ - then we can restrict the parameter domain to give this piece of the surface:

$$\vec{\mathbf{r}}(x,y) = \langle x, y, x^2y\rangle,\ 1 \le x \le 3,\ 2 \le y \le 5.$$

Similarly, if $S$ is a surface given by equation $x = g(y,z)$ or equation $y = h(x,z)$, then a parameterization of $S$ is $\vec{\mathbf{r}}(y,z) = \langle g(y,z),\ y, z\rangle$ or $\vec{\mathbf{r}}(x,z) = \langle x, h(x,z), z\rangle$, respectively. For example, the graph of paraboloid $2y = x^2 + z^2$ can be parameterized by $\vec{\mathbf{r}}(x,y) = \left\langle x, \dfrac{x^2+z^2}{2}, z\right\rangle$, $0 \le x < \infty$, $0 \le z < \infty$. Notice that we do not need to vary over the entire domain of $y$ because $x$ and $z$ are squared.

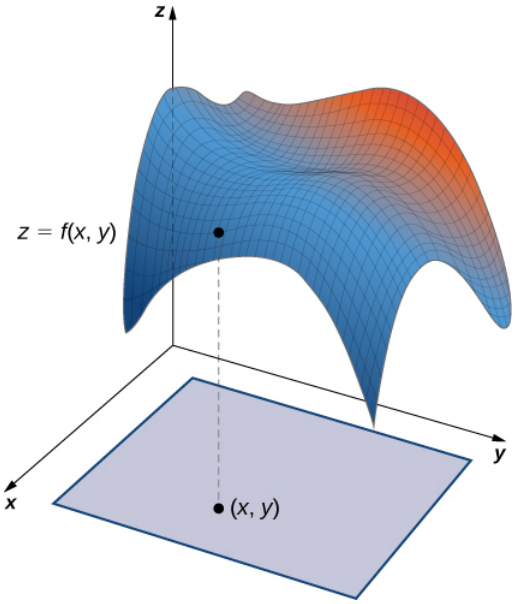

Figure 16.7.6: The simplest parameterization of the graph of a function is $\vec{\mathbf{r}}(x,y) = \langle x, y, f(x,y)\rangle$.

Let's now generalize the notions of smoothness and regularity to a parametric surface. Recall that curve parameterization $\vec{\mathbf{r}}(t)$, $a \le t \le b$ is regular (or **smooth**) if $\vec{\mathbf{r}}'(t) \neq \vec{\mathbf{0}}$ for all $t$ in $[a,b]$. For a curve, this condition ensures that the image of $\vec{\mathbf{r}}$ really is a curve, and not just a point. For example, consider curve parameterization $\vec{\mathbf{r}}(t) = \langle 1, 2\rangle$, $0 \le t \le 5$. The image of this parameterization is simply point $(1,2)$, which is not a curve. Notice also that $\vec{\mathbf{r}}'(t) = \vec{\mathbf{0}}$. The fact that the derivative is the zero vector indicates we are not actually looking at a curve.

Analogously, we would like a notion of regularity (or smoothness) for surfaces so that a surface parameterization really does trace out a surface. To motivate the definition of regularity of a surface parameterization, consider the parameterization

$$\vec{\mathbf{r}}(u,v) = \langle 0,\ \cos v,\ 1\rangle,\ 0 \le u \le 1,\ 0 \le v \le \pi.$$

Although this parameterization appears to be the parameterization of a surface, notice that the image is actually a line (Figure 16.7.7). How could we avoid parameterizations such as this? Parameterizations that do not give an actual surface? Notice that $\vec{\mathbf{r}}_u = \langle 0,0,0\rangle$ and $\vec{\mathbf{r}}_v = \langle 0,-\sin v,0\rangle$, and the corresponding cross product is zero. The analog of the condition $\vec{\mathbf{r}}'(t) = \vec{\mathbf{0}}$ is that $\vec{\mathbf{r}}_u \times \vec{\mathbf{r}}_v$ is not zero for point $(u,v)$ in the parameter domain, which is a regular parameterization.

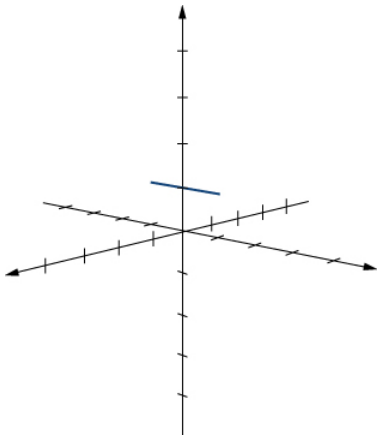

Figure 16.7.7: The image of parameterization $\vec{\mathbf{r}}(u,v) = \langle 0,\cos v,1\rangle,\ 0 \le u \le 1,\ 0 \le v \le \pi$ is a line.

**Definition: Regular Parameterization**

Parameterization $\vec{\mathbf{r}}(u,v) = \langle x(u,v), y(u,v), z(u,v)\rangle$ is a **regular parameterization** if $\vec{\mathbf{r}}_u \times \vec{\mathbf{r}}_v$ is not zero for point $(u,v)$ in the parameter domain.

If parameterization $\vec{r}$ is regular, then the image of $\vec{r}$ is a two-dimensional object, as a surface should be. Throughout this chapter, parameterizations $\vec{\mathbf{r}}(u,v) = \langle x(u,v), y(u,v), z(u,v)\rangle$are assumed to be regular.

Recall that curve parameterization $\vec{\mathbf{r}}(t),\ a \le t \le b$ is smooth if $\vec{\mathbf{r}}'(t)$ is continuous and $\vec{\mathbf{r}}'(t) \ne \vec{\mathbf{0}}$ for all $t$ in $[a,b]$. Informally, a curve parameterization is smooth if the resulting curve has no sharp corners. The definition of a smooth surface parameterization is similar. Informally, a surface parameterization is *smooth* if the resulting surface has no sharp corners.

**Definition: Smooth Surfaces**

A surface parameterization $\vec{\mathbf{r}}(u,v) = \langle x(u,v), y(u,v), z(u,v)\rangle$ is *smooth* if vector $\vec{\mathbf{r}}_u \times \vec{\mathbf{r}}_v$ is not zero for any choice of $u$ and $v$ in the parameter domain.

A surface may also be *piecewise smooth* if it has smooth faces but also has locations where the directional derivatives do not exist.

**Example 16.7.4: Identifying Smooth and Nonsmooth Surfaces**

Which of the figures in Figure 16.7.8 is smooth?

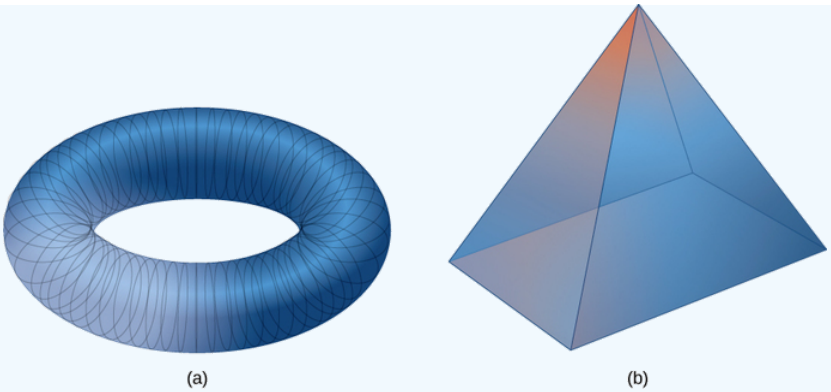

Figure 16.7.8: (a) This surface is smooth. (b) This surface is piecewise smooth.

### Solution

The surface in Figure 16.7.8*a* can be parameterized by

$$\vec{\mathbf{r}}(u,v) = \langle (2+\cos v)\cos u,\ (2+\cos v)\sin u,\ \sin v\rangle,\ 0 \le u < 2\pi,\ 0 \le v < 2\pi$$

(we can use technology to verify). Notice that vectors

$$\vec{\mathbf{r}}_u = \langle -(2+\cos v)\sin u,\ (2+\cos v)\cos u, 0\rangle$$

and

$$\vec{\mathbf{r}}_v = \langle -\sin v\cos u,\ -\sin v\sin u,\ \cos v\rangle$$

exist for any choice of $u$ and $v$ in the parameter domain, and

$$\begin{aligned}\vec{\mathbf{r}}_u \times \vec{\mathbf{r}}_v &= \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ -(2+\cos v)\sin u & (2+\cos v)\cos u & 0 \\ -\sin v\cos u & -\sin v\sin u & \cos v \end{vmatrix} \\ &= [(2+\cos v)\cos u\cos v]\hat{\mathbf{i}} + [2+\cos v)\sin u\cos v]\hat{\mathbf{j}} \\ &\quad + [(2+\cos v)\sin v\sin^2 u + (2+\cos v)\sin v\cos^2 u]\hat{\mathbf{k}} \\ &= [(2+\cos v)\cos u\cos v]\hat{\mathbf{i}} + [(2+\cos v)\sin u\cos v]\hat{\mathbf{j}} + [(2+\cos v)\sin v]\hat{\mathbf{k}}.\end{aligned}$$

The $\hat{\mathbf{k}}$ component of this vector is zero only if $v = 0$ or $v = \pi$. If $v = 0$ or $v = \pi$, then the only choices for $u$ that make the $\hat{\mathbf{j}}$ component zero are $u = 0$ or $u = \pi$. But, these choices of $u$ do not make the $\hat{\mathbf{i}}$ component zero. Therefore, $\vec{\mathbf{r}}_u \times \vec{\mathbf{r}}_v$ is not zero for any choice of $u$ and $v$ in the parameter domain, and the parameterization is smooth. Notice that the corresponding surface has no sharp corners.

In the pyramid in Figure 16.7.8*b*, the sharpness of the corners ensures that directional derivatives do not exist at those locations. Therefore, the pyramid has no smooth parameterization. However, the pyramid consists of four smooth faces, and thus this surface is piecewise smooth.

## ? Exercise 16.7.4

Is the surface parameterization $\vec{\mathbf{r}}(u,v) = \langle u^{2v}, v+1, \sin u\rangle$, $0 \le u \le 2$, $0 \le v \le 3$ smooth?

**Hint**

Investigate the cross product $\vec{\mathbf{r}}_u \times \vec{\mathbf{r}}_v$.

**Answer**

Yes

## Surface Area of a Parametric Surface

Our goal is to define a surface integral, and as a first step we have examined how to parameterize a surface. The second step is to define the surface area of a parametric surface. The notation needed to develop this definition is used throughout the rest of this chapter.

Let $S$ be a surface with parameterization $\vec{\mathbf{r}}(u,v) = \langle x(u,v),\ y(u,v),\ z(u,v)\rangle$ over some parameter domain $D$. We assume here and throughout that the surface parameterization $\vec{\mathbf{r}}(u,v) = \langle x(u,v),\ y(u,v),\ z(u,v)\rangle$ is continuously differentiable—meaning, each component function has continuous partial derivatives. Assume for the sake of simplicity that $D$ is a rectangle (although the following material can be extended to handle nonrectangular parameter domains). Divide rectangle $D$ into subrectangles $D_{ij}$ with horizontal width $\Delta u$ and vertical length $\Delta v$. Suppose that $i$ ranges from 1 to $m$ and $j$ ranges from 1 to $n$ so that $D$ is subdivided into $mn$ rectangles. This division of $D$ into subrectangles gives a corresponding division of surface $S$ into pieces $S_{ij}$. Choose point $P_{ij}$ in each piece $S_{ij}$. Point $P_{ij}$ corresponds to point $(u_i, v_j)$ in the parameter domain.

Note that we can form a grid with lines that are parallel to the $u$-axis and the $v$-axis in the $uv$-plane. These grid lines correspond to a set of grid curves on surface $S$ that is parameterized by $\vec{\mathbf{r}}(u,v)$. Without loss of generality, we assume that $P_{ij}$ is located at the corner of two grid curves, as in Figure **16.7.9**. If we think of $\vec{\mathbf{r}}$ as a mapping from the $uv$-plane to $\mathbb{R}^3$, the grid curves are the image of the grid lines under $\vec{\mathbf{r}}$. To be precise, consider the grid lines that go through point $(u_i, v_j)$. One line is given by $x = u_i,\ y = v$; the other is given by $x = u,\ y = v_j$. In the first grid line, the horizontal component is held constant, yielding a vertical line through $(u_i, v_j)$. In the second grid line, the vertical component is held constant, yielding a horizontal line through $(u_i, v_j)$. The corresponding grid curves are $\vec{\mathbf{r}}(u_i, v)$ and $(u, v_j)$ and these curves intersect at point $P_{ij}$.

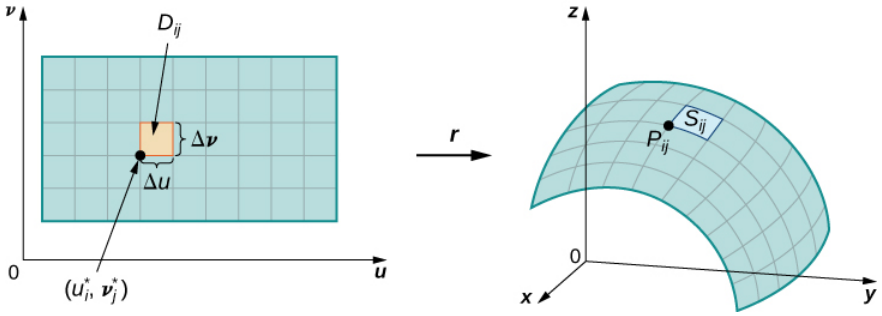

Figure **16.7.9**: Grid lines on a parameter domain correspond to grid curves on a surface.

Now consider the vectors that are tangent to these grid curves. For grid curve $\vec{\mathbf{r}}(u_i, v)$, the tangent vector at $P_{ij}$ is

$$\vec{\mathbf{t}}_v(P_{ij}) = \vec{\mathbf{r}}_v(u_i, v_j) = \langle x_v(u_i, v_j),\ y_v(u_i, v_j),\ z_v(u_i, v_j)\rangle.$$

For grid curve $\vec{\mathbf{r}}(u, v_j)$, the tangent vector at $P_{ij}$ is

$$\vec{\mathbf{t}}_u(P_{ij}) = \vec{\mathbf{r}}_u(u_i, v_j) = \langle x_u(u_i, v_j),\ y_u(u_i, v_j),\ z_u(u_i, v_j)\rangle.$$

If vector $\vec{\mathbf{N}} = \vec{\mathbf{t}}_u(P_{ij}) \times \vec{\mathbf{t}}_v(P_{ij})$ exists and is not zero, then the tangent plane at $P_{ij}$ exists (Figure **16.7.10**). If piece $S_{ij}$ is small enough, then the tangent plane at point $P_{ij}$ is a good approximation of piece $S_{ij}$.

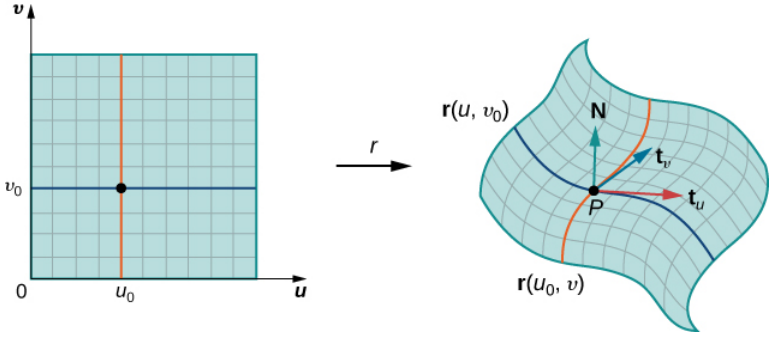

Figure **16.7.10**: If the cross product of vectors $\vec{\mathbf{t}}_u$ and $\vec{\mathbf{t}}_v$ exists, then there is a tangent plane.

The tangent plane at $P_{ij}$ contains vectors $\vec{\mathbf{t}}_u(P_{ij})$ and $\vec{\mathbf{t}}_v(P_{ij})$ and therefore the parallelogram spanned by $\vec{\mathbf{t}}_u(P_{ij})$ and $\vec{\mathbf{t}}_v(P_{ij})$ is in the tangent plane. Since the original rectangle in the $uv$-plane corresponding to $S_{ij}$ has width $\Delta u$ and length $\Delta v$, the parallelogram that we use to approximate $S_{ij}$ is the parallelogram spanned by $\Delta u\vec{\mathbf{t}}_u(P_{ij})$ and $\Delta v\vec{\mathbf{t}}_v(P_{ij})$. In other words, we scale the tangent vectors by the constants $\Delta u$ and $\Delta v$ to match the scale of the original division of rectangles in the parameter domain. Therefore, the area of the parallelogram used to approximate the area of $S_{ij}$ is

$$\Delta S_{ij} \approx ||(\Delta u\vec{\mathbf{t}}_u(P_{ij})) \times (\Delta v\vec{\mathbf{t}}_v(P_{ij}))|| = ||\vec{\mathbf{t}}_u(P_{ij}) \times \vec{\mathbf{t}}_v(P_{ij})||\Delta u\,\Delta v.$$

Varying point $P_{ij}$ over all pieces $S_{ij}$ and the previous approximation leads to the following definition of surface area of a parametric surface (Figure **16.7.11**).

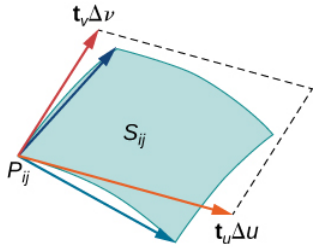

Figure **16.7.11**: The parallelogram spanned by $\vec{\mathbf{t}}_u$ *and* $\vec{\mathbf{t}}_v$ *approximates the piece of surface* $S_{ij}$.

### Definition: Smooth Parameterization of Surface

Let $\vec{\mathbf{r}}(u,v) = \langle x(u,v),\, y(u,v),\, z(u,v)\rangle$ with parameter domain $D$ be a **smooth parameterization of surface** $S$. Furthermore, assume that $S$ is traced out only once as $(u,v)$ varies over $D$. The surface area of $S$ is

$$\iint_D ||\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v||\,dA, \tag{16.7.1}$$

where $\vec{\mathbf{t}}_u = \left\langle \frac{\partial x}{\partial u}, \frac{\partial y}{\partial u}, \frac{\partial z}{\partial u}\right\rangle$

and

$$\vec{\mathbf{t}}_v = \left\langle \frac{\partial x}{\partial v}, \frac{\partial y}{\partial v}, \frac{\partial z}{\partial v}\right\rangle.$$

### Example 16.7.5: Calculating Surface Area

Calculate the lateral surface area (the area of the "side," not including the base) of the right circular cone with height $h$ and radius $r$.

#### Solution

Before calculating the surface area of this cone using Equation 16.7.1, we need a parameterization. We assume this cone is in $\mathbb{R}^3$ with its vertex at the origin (Figure **16.7.12**). To obtain a parameterization, let $\alpha$ be the angle that is swept out by starting at the positive $z$-axis and ending at the cone, and let $k = \tan\alpha$. For a height value $v$ with $0 \le v \le h$, the radius of the circle formed by intersecting the cone with plane $z = v$ is $kv$. Therefore, a parameterization of this cone is

$$\vec{\mathbf{s}}(u,v) = \langle kv\cos u,\, kv\sin u,\, v\rangle,\ 0 \le u < 2\pi,\ 0 \le v \le h.$$

The idea behind this parameterization is that for a fixed $v$-value, the circle swept out by letting $u$ vary is the circle at height $v$ and radius $kv$. As $v$ increases, the parameterization sweeps out a "stack" of circles, resulting in the desired cone.

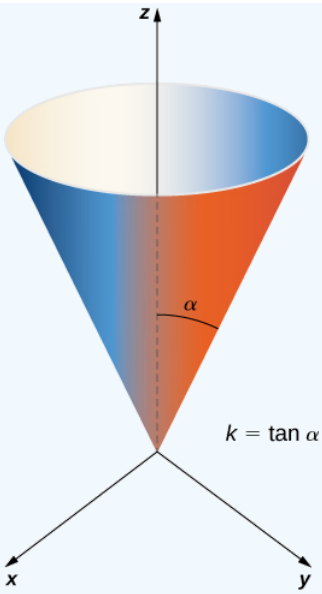

Figure 16.7.12: The right circular cone with radius $r = kh$ and height $h$ has parameterization $\vec{\mathbf{s}}(u,v) = \langle kv\cos u,\ kv\sin u,\ v\rangle$, $0 \le u < 2\pi$, $0 \le v \le h$.

With a parameterization in hand, we can calculate the surface area of the cone using Equation 16.7.1. The tangent vectors are $\vec{\mathbf{t}}_u = \langle -kv\sin u,\ kv\cos u,\ 0\rangle$ and $\vec{\mathbf{t}}_v = \langle k\cos u,\ k\sin u,\ 1\rangle$. Therefore,

$$\begin{aligned}\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v &= \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ -kv\sin u & kv\cos u & 0 \\ k\cos u & k\sin u & 1 \end{vmatrix} \\ &= \langle kv\cos u,\ kv\sin u,\ -k^2v\sin^2 u - k^2v\cos^2 u\rangle \\ &= \langle kv\cos u,\ kv\sin u,\ -k^2v\rangle.\end{aligned}$$

The magnitude of this vector is

$$\begin{aligned}||\langle kv\cos u,\ kv\sin u,\ -k^2v\rangle|| &= \sqrt{k^2v^2\cos^2 u + k^2v^2\sin^2 u + k^4v^2} \\ &= \sqrt{k^2v^2 + k^4v^2} \\ &= kv\sqrt{1+k^2}.\end{aligned}$$

By Equation 16.7.1, the surface area of the cone is

$$\begin{aligned}\iint_D ||\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v||\,dA &= \int_0^h \int_0^{2\pi} kv\sqrt{1+k^2}\,du\,dv \\ &= 2\pi k\sqrt{1+k^2}\int_0^h v\,dv \\ &= 2\pi k\sqrt{1+k^2}\left[\frac{v^2}{2}\right]_0^h \\ &= \pi kh^2\sqrt{1+k^2}.\end{aligned}$$

Since $k = \tan\alpha = r/h$,

$$\begin{aligned}\pi k h^2\sqrt{1+k^2} &= \pi\frac{r}{h}h^2\sqrt{1+\frac{r^2}{h^2}}\\ &= \pi r h\sqrt{1+\frac{r^2}{h^2}}\\ &= \pi r\sqrt{h^2+h^2\left(\frac{r^2}{h^2}\right)}\\ &= \pi r\sqrt{h^2+r^2}.\end{aligned}$$

Therefore, the lateral surface area of the cone is $\pi r\sqrt{h^2+r^2}$.

**Analysis**

The surface area of a right circular cone with radius $r$ and height $h$ is usually given as $\pi r^2+\pi r\sqrt{h^2+r^2}$. The reason for this is that the circular base is included as part of the cone, and therefore the area of the base $\pi r^2$ is added to the lateral surface area $\pi r\sqrt{h^2+r^2}$ that we found.

**? Exercise 16.7.5**

Find the surface area of the surface with parameterization $\vec{\mathbf{r}}(u,v)=\langle u+v,\, u^2,\, 2v\rangle$, $0\le u\le 3$, $0\le v\le 2$.

**Hint**

Use Equation 16.7.1.

**Answer**

$\approx 43.02$

**✓ Example 16.7.6: Calculating Surface Area**

Show that the surface area of the sphere $x^2+y^2+z^2=r^2$ is $4\pi r^2$.

**Solution**

The sphere has parameterization

$$r\cos\theta\sin\phi,\, r\sin\theta\sin\phi,\, r\cos\phi\rangle,\ 0\le\theta<2\pi,\ 0\le\phi\le\pi.$$

The tangent vectors are

$$\vec{\mathbf{t}}_\theta=\langle -r\sin\theta\sin\phi,\, r\cos\theta\sin\phi,\, 0\rangle$$

and

$$\vec{\mathbf{t}}_\phi=\langle r\cos\theta\cos\phi,\, r\sin\theta\cos\phi,\, -r\sin\phi\rangle.$$

Therefore,

$$\begin{aligned}\vec{\mathbf{t}}_\phi\times\vec{\mathbf{t}}_\theta &= \langle r^2\cos\theta\sin^2\phi,\, r^2\sin\theta\sin^2\phi,\, r^2\sin^2\theta\sin\phi\cos\phi+r^2\cos^2\theta\sin\phi\cos\phi\rangle\\ &= \langle r^2\cos\theta\sin^2\phi,\, r^2\sin\theta\sin^2\phi,\, r^2\sin\phi\cos\phi\rangle.\end{aligned}$$

Now,

$$\begin{aligned}||\vec{\mathbf{t}}_\phi\times\vec{\mathbf{t}}_\theta|| &= \sqrt{r^4\sin^4\phi\cos^2\theta+r^4\sin^4\phi\sin^2\theta+r^4\sin^2\phi\cos^2\phi}\\ &= \sqrt{r^4\sin^4\phi+r^4\sin^2\phi\cos^2\phi}\\ &= r^2\sqrt{\sin^2\phi}\\ &= r\sin\phi.\end{aligned}$$

Notice that $\sin\phi \geq 0$ on the parameter domain because $0 \leq \phi < \pi$, and this justifies equation $\sqrt{\sin^2\phi} = \sin\phi$. The surface area of the sphere is

$$\int_0^{2\pi}\int_0^{\pi} r^2 \sin\phi \, d\phi \, d\theta = r^2 \int_0^{2\pi} 2 \, d\theta = 4\pi r^2.$$

We have derived the familiar formula for the surface area of a sphere using surface integrals.

**? Exercise 16.7.6**

Show that the surface area of cylinder $x^2 + y^2 = r^2$, $0 \leq z \leq h$ is $2\pi rh$. Notice that this cylinder does not include the top and bottom circles.

**Hint**

Use the standard parameterization of a cylinder and follow the previous example.

**Answer**

With the standard parameterization of a cylinder, Equation 16.7.1 shows that the surface area is $2\pi rh$.

In addition to parameterizing surfaces given by equations or standard geometric shapes such as cones and spheres, we can also parameterize surfaces of revolution. Therefore, we can calculate the surface area of a surface of revolution by using the same techniques. Let $y = f(x) \geq 0$ be a positive single-variable function on the domain $a \leq x \leq b$ and let $S$ be the surface obtained by rotating $f$ about the $x$-axis (Figure 16.7.13). Let $\theta$ be the angle of rotation. Then, $S$ can be parameterized with parameters $x$ and $\theta$ by

$$\vec{\mathbf{r}}(x,\theta) = \langle x, f(x)\cos\theta, f(x)\sin\theta\rangle, \; a \leq x \leq b, \; 0 \leq x \leq 2\pi.$$

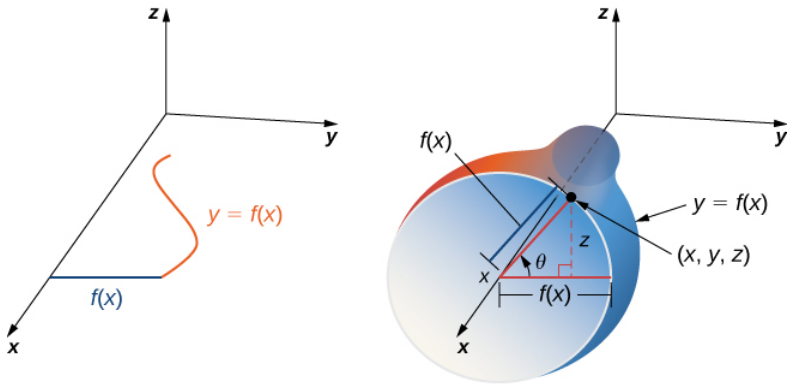

Figure 16.7.13: We can parameterize a surface of revolution by $\vec{\mathbf{r}}(x,\theta) = \langle x, f(x)\cos\theta, f(x)\sin\theta\rangle$, $a \leq x \leq b$, $0 \leq x < 2\pi$.

**✓ Example 16.7.7: Calculating Surface Area**

Find the area of the surface of revolution obtained by rotating $y = x^2$, $0 \leq x \leq b$ about the $x$-axis (Figure 16.7.14).

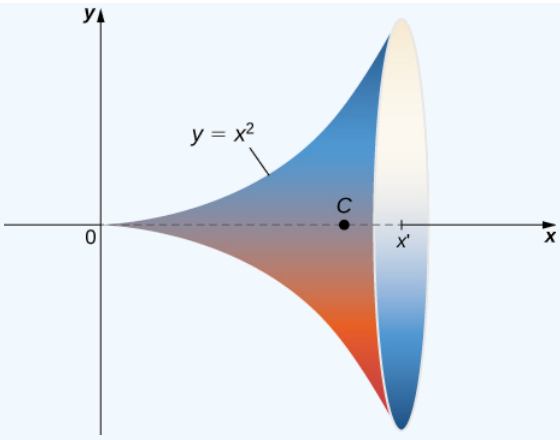

Figure 16.7.14: A surface integral can be used to calculate the surface area of this solid of revolution.

**Solution**

This surface has parameterization $\vec{\mathbf{r}}(x,\theta) = \langle x,\, x^2\cos\theta,\, x^2\sin\theta\rangle$, $0 \le x \le b$, $0 \le x < 2\pi$.

The tangent vectors are $\vec{\mathbf{t}}_x = \langle 1,\, 2x\,\cos\theta,\, 2x\,\sin\theta\rangle$ and $\vec{\mathbf{t}}_\theta = \langle 0,\, -x^2\sin\theta,\, -x^2\cos\theta\rangle$.

Therefore,

$$\begin{aligned}\vec{\mathbf{t}}_x \times \vec{\mathbf{t}}_\theta &= \langle 2x^3\cos^2\theta + 2x^3\sin^2\theta,\, -x^2\cos\theta,\, -x^2\sin\theta\rangle \\ &= \langle 2x^3,\, -x^2\cos\theta,\, -x^2\sin\theta\rangle\end{aligned}$$

and

$$\begin{aligned}\vec{\mathbf{t}}_x \times \vec{\mathbf{t}}_\theta &= \sqrt{4x^6 + x^4\cos^2\theta + x^4\sin^2\theta} \\ &= \sqrt{4x^6 + x^4} \\ &= x^2\sqrt{4x^2+1}\end{aligned}$$

The area of the surface of revolution is

$$\begin{aligned}\int_0^b \int_0^{2\pi} x^2\sqrt{4x^2+1}\,d\theta\,dx &= 2\pi\int_0^b x^2\sqrt{4x^2+1}\,dx \\ &= 2\pi\left[\frac{1}{64}\left(2\sqrt{4x^2+1}(8x^3+x)\,\sinh^{-1}(2x)\right)\right]_0^b \\ &= 2\pi\left[\frac{1}{64}\left(2\sqrt{4b^2+1}(8b^3+b)\,\sinh^{-1}(2b)\right)\right].\end{aligned}$$

**? Exercise 16.7.7**

Use Equation 16.7.1 to find the area of the surface of revolution obtained by rotating curve $y = \sin x$, $0 \le x \le \pi$ about the $x$-axis.

**Hint**

Use the parameterization of surfaces of revolution given before Example 16.7.7.

**Answer**

$2\pi(\sqrt{2} + \sinh^{-1}(1))$

## Surface Integral of a Scalar-Valued Function

Now that we can parameterize surfaces and we can calculate their surface areas, we are able to define surface integrals. First, let's look at the surface integral of a scalar-valued function. Informally, the surface integral of a scalar-valued function is an analog of a scalar line integral in one higher dimension. The domain of integration of a scalar line integral is a parameterized curve (a one-

dimensional object); the domain of integration of a scalar surface integral is a parameterized surface (a two-dimensional object). Therefore, the definition of a surface integral follows the definition of a line integral quite closely. For scalar line integrals, we chopped the domain curve into tiny pieces, chose a point in each piece, computed the function at that point, and took a limit of the corresponding Riemann sum. For scalar surface integrals, we chop the domain *region* (no longer a curve) into tiny pieces and proceed in the same fashion.

Let $S$ be a piecewise smooth surface with parameterization $\vec{\mathbf{r}}(u,v) = \langle x(u,v),\ y(u,v),\ z(u,v)\rangle$ with parameter domain $D$ and let $f(x,y,z)$ be a function with a domain that contains $S$. For now, assume the parameter domain $D$ is a rectangle, but we can extend the basic logic of how we proceed to any parameter domain (the choice of a rectangle is simply to make the notation more manageable). Divide rectangle $D$ into subrectangles $D_{ij}$ with horizontal width $\Delta u$ and vertical length $\Delta v$. Suppose that $i$ ranges from 1 to $m$ and $j$ ranges from 1 to $n$ so that $D$ is subdivided into $mn$ rectangles. This division of $D$ into subrectangles gives a corresponding division of $S$ into pieces $S_{ij}$. Choose point $P_{ij}$ in each piece $S_{ij}$ evaluate $P_{ij}$ at $f$, and multiply by area $S_{ij}$ to form the Riemann sum

$$\sum_{i=1}^{m}\sum_{j=1}^{n} f(P_{ij})\,\Delta S_{ij}.$$

To define a surface integral of a scalar-valued function, we let the areas of the pieces of $S$ shrink to zero by taking a limit.

**Definition: Surface Integral of a Scalar-Valued Function**

The **surface integral of a scalar-valued function** of $f$ over a piecewise smooth surface $S$ is

$$\iint_S f(x,y,z)dA = \lim_{m,n\to\infty}\sum_{i=1}^{m}\sum_{j=1}^{n} f(P_{ij})\Delta S_{ij}.$$

Again, notice the similarities between this definition and the definition of a scalar line integral. In the definition of a line integral we chop a curve into pieces, evaluate a function at a point in each piece, and let the length of the pieces shrink to zero by taking the limit of the corresponding Riemann sum. In the definition of a surface integral, we chop a surface into pieces, evaluate a function at a point in each piece, and let the area of the pieces shrink to zero by taking the limit of the corresponding Riemann sum. Thus, a surface integral is similar to a line integral but in one higher dimension.

The definition of a scalar line integral can be extended to parameter domains that are not rectangles by using the same logic used earlier. The basic idea is to chop the parameter domain into small pieces, choose a sample point in each piece, and so on. The exact shape of each piece in the sample domain becomes irrelevant as the areas of the pieces shrink to zero.

Scalar surface integrals are difficult to compute from the definition, just as scalar line integrals are. To develop a method that makes surface integrals easier to compute, we approximate surface areas $\Delta S_{ij}$ with small pieces of a tangent plane, just as we did in the previous subsection. Recall the definition of vectors $\vec{\mathbf{t}}_u$ and $\vec{\mathbf{t}}_v$:

$$\vec{\mathbf{t}}_u = \left\langle \frac{\partial x}{\partial u}, \frac{\partial y}{\partial u}, \frac{\partial z}{\partial u}\right\rangle \text{ and } \vec{\mathbf{t}}_v = \left\langle \frac{\partial x}{\partial v}, \frac{\partial y}{\partial v}, \frac{\partial z}{\partial v}\right\rangle.$$

From the material we have already studied, we know that

$$\Delta S_{ij} \approx ||\vec{\mathbf{t}}_u(P_{ij}) \times \vec{\mathbf{t}}_v(P_{ij})||\,\Delta u\,\Delta v.$$

Therefore,

$$\iint_S f(x,y,z)\,dS \approx \lim_{m,n\to\infty}\sum_{i=1}^{m}\sum_{j=1}^{n} f(P_{ij})||\vec{\mathbf{t}}_u(P_{ij}) \times \vec{\mathbf{t}}_v(P_{ij})||\,\Delta u\,\Delta v.$$

This approximation becomes arbitrarily close to $\lim_{m,n\to\infty}\sum_{i=1}^{m}\sum_{j=1}^{n} f(P_{ij})\Delta S_{ij}$ as we increase the number of pieces $S_{ij}$ by letting $m$ and $n$ go to infinity. Therefore, we have the following equation to calculate **scalar surface integrals**:

$$\iint_S f(x,y,z)\,dS = \iint_D f(\vec{\mathbf{r}}(u,v))||\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v||\,dA. \tag{16.7.2}$$

Equation 16.7.2 allows us to calculate a surface integral by transforming it into a double integral. This equation for surface integrals is analogous to the equation for line integrals:

$$\iint_C f(x,y,z)\,ds = \int_a^b f(\vec{\mathbf{r}}(t))||\vec{\mathbf{r}}'(t)||\,dt.$$

In this case, vector $\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v$ is perpendicular to the surface, whereas vector $\vec{\mathbf{r}}'(t)$ is tangent to the curve.

### Example 16.7.8: Calculating a Surface Integral

Calculate surface integral

$$\iint_S 5\,dS,$$

where $S$ is the surface with parameterization $\vec{\mathbf{r}}(u,v) = \langle u, u^2, v\rangle$ for $0 \le u \le 2$ and $0 \le v \le u$.

#### Solution

Notice that this parameter domain $D$ is a triangle, and therefore the parameter domain is not rectangular. This is not an issue though, because Equation 16.7.2 does not place any restrictions on the shape of the parameter domain.

To use Equation 16.7.2 to calculate the surface integral, we first find vectors $\vec{\mathbf{t}}_u$ and $\vec{\mathbf{t}}_v$. Note that $\vec{\mathbf{t}}_u = \langle 1, 2u, 0\rangle$ and $\vec{\mathbf{t}}_v = \langle 0, 0, 1\rangle$. Therefore,

$$\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 1 & 2u & 0 \\ 0 & 0 & 1 \end{vmatrix} = \langle 2u, -1, 0\rangle$$

and

$$||\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v|| = \sqrt{1+4u^2}.$$

By Equation 16.7.2,

$$\begin{aligned} \iint_S 5\,dS &= 5\iint_D \sqrt{1+4u^2}\,dA \\ &= 5\int_0^2 \int_0^u \sqrt{1+4u^2}\,dv\,du = 5\int_0^2 u\sqrt{1+4u^2}\,du \\ &= 5\left[\frac{(1+4u^2)^{3/2}}{3}\right]_0^2 \\ &= \frac{5(17^{3/2}-1)}{3} \approx 115.15. \end{aligned}$$

### Example 16.7.9: Calculating the Surface Integral of a Cylinder

Calculate surface integral

$$\iint_S (x+y^2)\,dS,$$

where $S$ is cylinder $x^2+y^2=4$, $0 \le z \le 3$ (Figure 16.7.15).

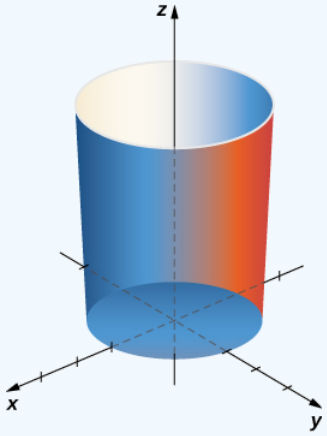

Figure 16.7.15: Integrating function $f(x,y,z)=x+y^2$ over a cylinder.

### Solution

To calculate the surface integral, we first need a parameterization of the cylinder. A parameterization is $\vec{\mathbf{r}}(u,v)=\langle\cos u,\ \sin u,\ v\rangle, 0\le u\le 2\pi,\ 0\le v\le 3.$

The tangent vectors are $\vec{\mathbf{t}}_u=\langle\sin u,\ \cos u,\ 0\rangle$ and $\vec{\mathbf{t}}_v=\langle 0,0,1\rangle$. Then,

$$\vec{\mathbf{t}}_u\times\vec{\mathbf{t}}_v=\begin{vmatrix}\hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}}\\ -\sin u & \cos u & 0\\ 0 & 0 & 1\end{vmatrix}=\langle\cos u,\ \sin u,\ 0\rangle$$

and $||\vec{\mathbf{t}}_u\times\vec{\mathbf{t}}_v||=\sqrt{\cos^2 u+\sin^2 u}=1$. By Equation 16.7.2,

$$\begin{aligned}\iint_S f(x,y,z)dS &= \iint_D f(\vec{\mathbf{r}}(u,v))||\vec{\mathbf{t}}_u\times\vec{\mathbf{t}}_v||\,dA\\ &= \int_0^3\int_0^{2\pi}(\cos u+\sin^2 u)\,du\,dv\\ &= \int_0^3\left[\sin u+\frac{u}{2}-\frac{\sin(2u)}{4}\right]_0^{2\pi}dv\\ &= \int_0^3 \pi\,dv=3\pi.\end{aligned}$$

## Exercise 16.7.8

Calculate

$$\iint_S (x^2-z)\,dS,$$

where $S$ is the surface with parameterization $\vec{\mathbf{r}}(u,v)=\langle v,\ u^2+v^2,\ 1\rangle,\ 0\le u\le 2,\ 0\le v\le 3.$

**Hint**

Use Equation 16.7.2.

**Answer**

24

## Example 16.7.10: Calculating the Surface Integral of a Piece of a Sphere

Calculate surface integral

$$\iint_S f(x,y,z)\,dS,$$

where $f(x,y,z) = z^2$ and $S$ is the surface that consists of the piece of sphere $x^2 + y^2 + z^2 = 4$ that lies on or above plane $z = 1$ and the disk that is enclosed by intersection plane $z = 1$ and the given sphere (Figure 16.7.16).

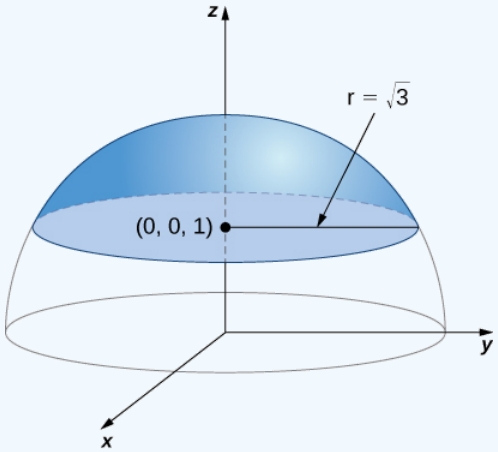

Figure 16.7.16: Calculating a surface integral over surface $S$.

### Solution

Notice that $S$ is not smooth but is piecewise smooth; $S$ can be written as the union of its base $S_1$ and its spherical top $S_2$, and both $S_1$ and $S_2$ are smooth. Therefore, to calculate

$$\iint_S z^2 dS,$$

we write this integral as

$$\iint_{S_1} z^2\, dS + \iint_{S_2} z^2\, dS$$

and we calculate integrals

$$\iint_{S_1} z^2\, dS$$

and

$$\iint_{S_2} Z^2\, dS.$$

First, we calculate $\iint_{S_1} z^2\, dS$. To calculate this integral we need a parameterization of $S_1$. This surface is a disk in plane $z = 1$ centered at $(0,0,1)$. To parameterize this disk, we need to know its radius. Since the disk is formed where plane $z = 1$ intersects sphere $x^2 + y^2 + z^2 = 4$, we can substitute $z = 1$ into equation $x^2 + y^2 + z^2 = 4$:

$$x^2 + y^2 + 1 = 4 \Rightarrow x^2 + y^2 = 3.$$

Therefore, the radius of the disk is $\sqrt{3}$ and a parameterization of $S_1$ is $\vec{\mathbf{r}}(u,v) = \langle u\, \cos v,\, u\, \sin v,\, 1\rangle$, $0 \le u \le \sqrt{3}$, $0 \le v \le 2\pi$. The tangent vectors are $\vec{\mathbf{t}}_u = \langle \cos v,\, \sin v,\, 0\rangle$ and $\vec{\mathbf{t}}_v = \langle -u\, \sin v,\, u\, \cos v,\, 0\rangle$, and thus

$$\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ \cos v & \sin v & 0 \\ -u \sin v & u \cos v & 0 \end{vmatrix} = \langle 0,\, 0,\, u\, \cos^2 v + u\, \sin^2 v\rangle = \langle 0, 0, u\rangle.$$

The magnitude of this vector is $u$. Therefore,

$$\begin{aligned}\iint_{S_1} z^2\,dS &= \int_0^{\sqrt{3}}\int_0^{2\pi} f(r(u,v))||t_u \times t_v||\,dv\,du \\ &= \int_0^{\sqrt{3}}\int_0^{2\pi} u\,dv\,du \\ &= 2\pi\int_0^{\sqrt{3}} u\,du \\ &= 2\pi\sqrt{3}.\end{aligned}$$

Now we calculate

$$\iint_{S_2} dS.$$

To calculate this integral, we need a parameterization of $S_2$. The parameterization of full sphere $x^2+y^2+z^2=4$ is

$$\vec{\mathbf{r}}(\phi,\theta) = \langle 2\cos\theta\sin\phi,\ 2\sin\theta\sin\phi,\ 2\cos\phi\rangle,\ 0\le\theta\le 2\pi, 0\le\phi\le\pi.$$

Since we are only taking the piece of the sphere on or above plane $z=1$, we have to restrict the domain of $\phi$. To see how far this angle sweeps, notice that the angle can be located in a right triangle, as shown in Figure **16.7.17** (the $\sqrt{3}$ comes from the fact that the base of $S$ is a disk with radius $\sqrt{3}$). Therefore, the tangent of $\phi$ is $\sqrt{3}$, which implies that $\phi$ is $\pi/6$. We now have a parameterization of $S_2$:

$$\vec{\mathbf{r}}(\phi,\theta) = \langle 2\cos\theta\sin\phi,\ 2\sin\theta\sin\phi,\ 2\cos\phi\rangle,\ 0\le\theta\le 2\pi,\ 0\le\phi\le\pi/3.$$

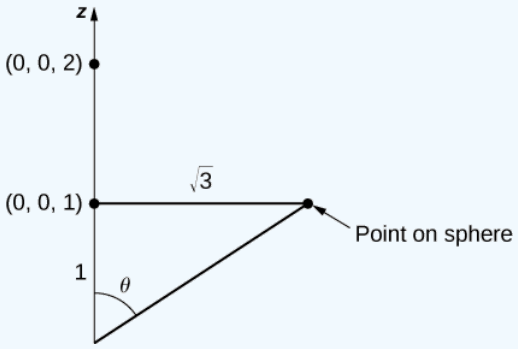

Figure **16.7.17**: The maximum value of $\phi$ has a tangent value of $\sqrt{3}$.

The tangent vectors are $\vec{\mathbf{t}}_\phi = \langle 2\cos\theta\cos\phi,\ 2\sin\theta\cos\phi,\ -2\sin\phi\rangle$ and $\vec{\mathbf{t}}_\theta = \langle -2\sin\theta\sin\phi,\ u\cos\theta\sin\phi,\ 0\rangle$, and thus

$$\begin{aligned}\vec{\mathbf{t}}_\phi \times \vec{\mathbf{t}}_\theta &= \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 2\cos\theta\cos\phi & 2\sin\theta\cos\phi & -2\sin\phi \\ -2\sin\theta\sin\phi & 2\cos\theta\sin\phi & 0 \end{vmatrix} \\ &= \langle 4\cos\theta\sin^2\phi,\ 4\sin\theta\sin^2\phi,\ 4\cos^2\theta\cos\phi\sin\phi + 4\sin^2\theta\cos\phi\sin\phi\rangle \\ &= \langle 4\cos\theta\sin^2\phi,\ 4\sin\theta\sin^2\phi,\ 4\cos\phi\sin\phi\rangle.\end{aligned}$$

The magnitude of this vector is

$$\begin{aligned}\vec{\mathbf{t}}_\phi \times \vec{\mathbf{t}}_\theta &= \sqrt{16\cos^2\theta\sin^4\phi + 16\sin^2\theta\sin^4\phi + 16\cos^2\phi\sin^2\phi} \\ &= 4\sqrt{\sin^4\phi + \cos^2\phi\sin^2\phi}.\end{aligned}$$

Therefore,

$$\begin{aligned}\iint_{S_2} z\,dS &= \int_0^{\pi/6}\int_0^{2\pi} f(\vec{\mathbf{r}}(\phi,\theta))\|\vec{\mathbf{t}}_\phi \times \vec{\mathbf{t}}_\theta\|\,d\theta\,d\phi \\ &= \int_0^{\pi/6}\int_0^{2\pi} 16\cos^2\phi\sqrt{\sin^4\phi+\cos^2\phi\sin^2\phi}\,d\theta\,d\phi \\ &= 32\pi\int_0^{\pi/6}\cos^2\phi\sqrt{\sin^4\phi+\cos^2\phi\sin^2\phi}\,d\phi \\ &= 32\pi\int_0^{\pi/6}\cos^2\phi\sin\phi\sqrt{\sin^2\phi+\cos^2\phi}\,d\phi \\ &= 32\pi\int_0^{\pi/6}\cos^2\phi\sin\phi\,d\phi \\ &= 32\pi\left[-\frac{\cos^3\phi}{3}\right]_0^{\pi/6} \\ &= 32\pi\left[\frac{1}{3}-\frac{\sqrt{3}}{8}\right] = \frac{32\pi}{3}-4\sqrt{3}.\end{aligned}$$

Since

$$\iint_S z^2\,dS = \iint_{S_1} z^2\,dS + \iint_{S_2} z^2\,dS,$$

we have

$$\iint_S z^2\,dS = (2\pi-4)\sqrt{3}+\frac{32\pi}{3}.$$

### Analysis

In this example we broke a surface integral over a piecewise surface into the addition of surface integrals over smooth subsurfaces. There were only two smooth subsurfaces in this example, but this technique extends to finitely many smooth subsurfaces.

**? Exercise 16.7.9**

Calculate line integral $\iint_S (x-y)\,dS$, where $S$ is cylinder $x^2+y^2=1$, $0\le z\le 2$, including the circular top and bottom.

**Hint**

Break the integral into three separate surface integrals.

**Answer**

0

Scalar surface integrals have several real-world applications. Recall that scalar line integrals can be used to compute the mass of a wire given its density function. In a similar fashion, we can use scalar surface integrals to compute the mass of a sheet given its density function. If a thin sheet of metal has the shape of surface $S$ and the density of the sheet at point $(x,y,z)$ is $\rho(x,y,z)$ then mass $m$ of the sheet is

$$m = \iint_S \rho(x,y,z)\,dS. \tag{16.7.3}$$

**✓ Example 16.7.11: Calculating the Mass of a Sheet**

A flat sheet of metal has the shape of surface $z=1+x+2y$ that lies above rectangle $0\le x\le 4$ and $0\le y\le 2$. If the density of the sheet is given by $\rho(x,y,z)=x^2yz$, what is the mass of the sheet?

**Solution**

Let $S$ be the surface that describes the sheet. Then, the mass of the sheet is given by $m = \iint_S x^2yx\,dS$. To compute this surface integral, we first need a parameterization of $S$. Since $S$ is given by the function $f(x,y) = 1 + x + 2y$, a parameterization of $S$ is $\vec{\mathbf{r}}(x,y) = \langle x, y, 1 + x + 2y\rangle$, $0 \le x \le 4$, $0 \le y \le 2$.

The tangent vectors are $\vec{\mathbf{t}}_x = \langle 1, 0, 1\rangle$ and $\vec{\mathbf{t}}_y = \langle 1, 0, 2\rangle$. Therefore, $\vec{\mathbf{t}}_x + \vec{\mathbf{t}}_y = \langle -1, -2, 1\rangle$ and $||\vec{\mathbf{t}}_x \times \vec{\mathbf{t}}_y|| = \sqrt{6}$.

By the definition of the line integral (Section 16.2),

$$\begin{aligned} m &= \iint_S x^2yz\,dS \\ &= \sqrt{6}\int_0^4 \int_0^2 x^2y(1 + x + 2y)\,dy\,dx \\ &= \sqrt{6}\int_0^4 \frac{22x^2}{3} + 2x^3\,dx \\ &= \frac{2560\sqrt{6}}{9} \approx 696.74. \end{aligned}$$

**? Exercise 16.7.10**

A piece of metal has a shape that is modeled by paraboloid $z = x^2 + y^2$, $0 \le z \le 4$, and the density of the metal is given by $\rho(x,y,z) = z + 1$. Find the mass of the piece of metal.

**Hint**

The mass of a sheet is given by Equation 16.7.3. A useful parameterization of a paraboloid was given in a previous example.

**Answer**

$38.401\pi \approx 120.640$

## Orientation of a Surface

Recall that when we defined a scalar line integral, we did not need to worry about an orientation of the curve of integration. The same was true for scalar surface integrals: we did not need to worry about an "orientation" of the surface of integration.

On the other hand, when we defined vector line integrals, the curve of integration needed an orientation. That is, we needed the notion of an oriented curve to define a vector line integral without ambiguity. Similarly, when we define a surface integral of a vector field, we need the notion of an oriented surface. An oriented surface is given an "upward" or "downward" orientation or, in the case of surfaces such as a sphere or cylinder, an "outward" or "inward" orientation.

Let $S$ be a smooth surface. For any point $(x,y,z)$ on $S$, we can identify two unit normal vectors $\vec{\mathbf{N}}$ and $-\vec{\mathbf{N}}$. If it is possible to choose a unit normal vector $\vec{\mathbf{N}}$ at every point $(x,y,z)$ on $S$ so that $\vec{\mathbf{N}}$ varies continuously over $S$, then $S$ is "*orientable*." Such a choice of unit normal vector at each point gives the **orientation of a surface** $S$. If you think of the normal field as describing water flow, then the side of the surface that water flows toward is the "negative" side and the side of the surface at which the water flows away is the "positive" side. Informally, a choice of orientation gives $S$ an "outer" side and an "inner" side (or an "upward" side and a "downward" side), just as a choice of orientation of a curve gives the curve "forward" and "backward" directions.

Closed surfaces such as spheres are orientable: if we choose the outward normal vector at each point on the surface of the sphere, then the unit normal vectors vary continuously. This is called the *positive orientation of the closed surface* (Figure 16.7.18). We also could choose the inward normal vector at each point to give an "inward" orientation, which is the negative orientation of the surface.

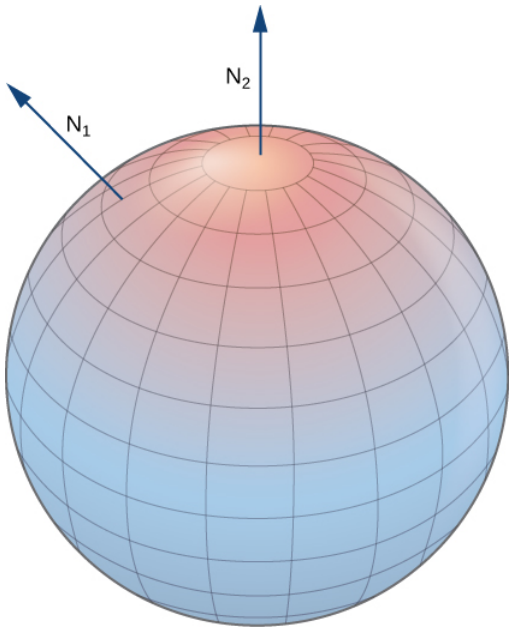

Figure 16.7.18: An oriented sphere with positive orientation.

A portion of the graph of any smooth function $z = f(x, y)$ is also orientable. If we choose the unit normal vector that points "above" the surface at each point, then the unit normal vectors vary continuously over the surface. We could also choose the unit normal vector that points "below" the surface at each point. To get such an orientation, we parameterize the graph of $f$ in the standard way: $\vec{\mathbf{r}}(x, y) = \langle x,\ y,\ f(x, y)\rangle$, where $x$ and $y$ vary over the domain of $f$. Then, $\vec{\mathbf{t}}_x = \langle 1, 0, f_x\rangle$ and $\vec{\mathbf{t}}_y = \langle 0, 1, f_y\rangle$, and therefore the cross product $\vec{\mathbf{t}}_x \times \vec{\mathbf{t}}_y$ (which is normal to the surface at any point on the surface) is $\langle -f_x, -f_y, 1\rangle$Since the $z$-component of this vector is one, the corresponding unit normal vector points "upward," and the upward side of the surface is chosen to be the "positive" side.

Let $S$ be a smooth orientable surface with parameterization $\vec{\mathbf{r}}(u, v)$. For each point $\vec{\mathbf{r}}(a, b)$ on the surface, vectors $\vec{\mathbf{t}}_u$ and $\vec{\mathbf{t}}_v$ lie in the tangent plane at that point. Vector $\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v$ is normal to the tangent plane at $\vec{\mathbf{r}}(a, b)$ and is therefore normal to $S$ at that point. Therefore, the choice of unit normal vector

$$\vec{\mathbf{N}} = \frac{\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v}{||\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v||}$$

gives an orientation of surface $S$.

### Example 16.7.12: Choosing an Orientation

Give an orientation of cylinder $x^2 + y^2 = r^2$, $0 \le z \le h$.

#### Solution

This surface has parameterization $\vec{\mathbf{r}}(u, v) = \langle r\cos u,\ r\sin u,\ v\rangle$, $0 \le u < 2\pi$, $0 \le v \le h$.

The tangent vectors are $\vec{\mathbf{t}}_u = \langle -r\sin u,\ r\cos u,\ 0\rangle$ and $\vec{\mathbf{t}}_v = \langle 0, 0, 1\rangle$. To get an orientation of the surface, we compute the unit normal vector

$$\vec{\mathbf{N}} = \frac{\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v}{||\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v||}$$

In this case, $\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v = \langle r\cos u,\ r\sin u,\ 0\rangle$ and therefore

$$||\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v|| = \sqrt{r^2\cos^2 u + r^2\sin^2 u} = r.$$

An orientation of the cylinder is

$$\vec{\mathbf{N}}(u, v) = \frac{\langle r\cos u,\ r\sin u,\ 0\rangle}{r} = \langle \cos u,\ \sin u,\ 0\rangle.$$

Notice that all vectors are parallel to the $xy$-plane, which should be the case with vectors that are normal to the cylinder. Furthermore, all the vectors point outward, and therefore this is an outward orientation of the cylinder (Figure 16.7.19).

Figure 16.7.19: If all the vectors normal to a cylinder point outward, then this is an outward orientation of the cylinder.

**? Exercise 16.7.11**

Give the "upward" orientation of the graph of $f(x,y) = xy$.

**Hint**

Parameterize the surface and use the fact that the surface is the graph of a function.

**Answer**

$$\vec{\mathbf{N}}(x,y) = \left\langle \frac{-y}{\sqrt{1+x^2+y^2}}, \frac{-x}{\sqrt{1+x^2+y^2}}, \frac{1}{\sqrt{1+x^2+y^2}} \right\rangle$$

Since every curve has a "forward" and "backward" direction (or, in the case of a closed curve, a clockwise and counterclockwise direction), it is possible to give an orientation to any curve. Hence, it is possible to think of every curve as an oriented curve. This is not the case with surfaces, however. Some surfaces cannot be oriented; such surfaces are called *nonorientable*. Essentially, a surface can be oriented if the surface has an "inner" side and an "outer" side, or an "upward" side and a "downward" side. Some surfaces are twisted in such a fashion that there is no well-defined notion of an "inner" or "outer" side.

The classic example of a nonorientable surface is the Möbius strip. To create a Möbius strip, take a rectangular strip of paper, give the piece of paper a half-twist, and the glue the ends together (Figure 16.7.20). Because of the half-twist in the strip, the surface has no "outer" side or "inner" side. If you imagine placing a normal vector at a point on the strip and having the vector travel all the way around the band, then (because of the half-twist) the vector points in the opposite direction when it gets back to its original position. Therefore, the strip really only has one side.

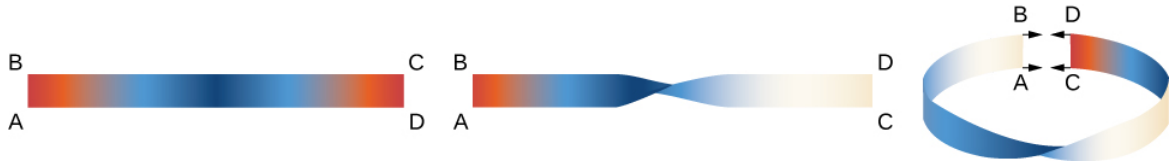

Figure 16.7.20: The construction of a Möbius strip.

Since some surfaces are *nonorientable*, it is not possible to define a vector surface integral on all piecewise smooth surfaces. This is in contrast to vector line integrals, which can be defined on any piecewise smooth curve.

## Surface Integral of a Vector Field

With the idea of orientable surfaces in place, we are now ready to define a surface integral of a vector field. The definition is analogous to the definition of the flux of a vector field along a plane curve. Recall that if $\vec{\mathbf{F}}$ is a two-dimensional vector field and $C$ is a plane curve, then the definition of the flux of $\vec{\mathbf{F}}$ along $C$ involved chopping $C$ into small pieces, choosing a point inside each piece, and calculating $\vec{\mathbf{F}} \cdot \vec{\mathbf{N}}$ at the point (where $\vec{\mathbf{N}}$ is the unit normal vector at the point). The definition of a surface integral of a vector field proceeds in the same fashion, except now we chop surface $S$ into small pieces, choose a point in the small (two-dimensional) piece, and calculate $\vec{\mathbf{F}} \cdot \vec{\mathbf{N}}$ at the point.

To place this definition in a real-world setting, let $S$ be an oriented surface with unit normal vector $\vec{\mathbf{N}}$. Let $\vec{\mathbf{v}}$ be a velocity field of a fluid flowing through $S$, and suppose the fluid has density $\rho(x,y,z)$ Imagine the fluid flows through $S$, but $S$ is completely

permeable so that it does not impede the fluid flow (Figure 16.7.21). The mass flux of the fluid is the rate of mass flow per unit area. The mass flux is measured in mass per unit time per unit area. How could we calculate the mass flux of the fluid across $S$?

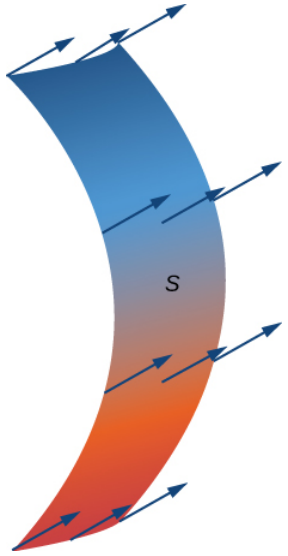

Figure 16.7.21: Fluid flows across a completely permeable surface $S$.

The rate of flow, measured in mass per unit time per unit area, is $\rho\vec{\mathbf{N}}$. To calculate the mass flux across $S$, chop $S$ into small pieces $S_{ij}$. If $S_{ij}$ is small enough, then it can be approximated by a tangent plane at some point $P$ in $S_{ij}$. Therefore, the unit normal vector at $P$ can be used to approximate $\vec{\mathbf{N}}(x,y,z)$ across the entire piece $S_{ij}$ because the normal vector to a plane does not change as we move across the plane. The component of the vector $\rho v$ at $P$ in the direction of $\vec{\mathbf{N}}$ is $\rho\vec{\mathbf{v}}\cdot\vec{\mathbf{N}}$ at $P$. Since $S_{ij}$ is small, the dot product $\rho v\cdot N$ changes very little as we vary across $S_{ij}$ and therefore $\rho\vec{\mathbf{v}}\cdot\vec{\mathbf{N}}$ can be taken as approximately constant across $S_{ij}$. To approximate the mass of fluid per unit time flowing across $S_{ij}$ (and not just locally at point $P$), we need to multiply $(\rho\vec{\mathbf{v}}\cdot\vec{\mathbf{N}})(P)$ by the area of $S_{ij}$. Therefore, the mass of fluid per unit time flowing across $S_{ij}$ in the direction of $\vec{\mathbf{N}}$ can be approximated by $(\rho\vec{\mathbf{v}}\cdot\vec{\mathbf{N}})\Delta S_{ij}$ where $\vec{\mathbf{N}}$, $\rho$ and $\vec{\mathbf{v}}$ are all evaluated at $P$ (Figure 16.7.22). This is analogous to the flux of two-dimensional vector field $\vec{\mathbf{F}}$ across plane curve $C$, in which we approximated flux across a small piece of $C$ with the expression $(\vec{\mathbf{F}}\cdot\vec{\mathbf{N}})\,\Delta s$. To approximate the mass flux across $S$, form the sum

$$\sum_{i=1}^{m}\sum_{j=1}^{n}(\rho\vec{\mathbf{v}}\cdot\vec{\mathbf{N}})\Delta S_{ij}.$$

As pieces $S_{ij}$ get smaller, the sum

$$\sum_{i=1}^{m}\sum_{j=1}^{n}(\rho\vec{\mathbf{v}}\cdot\vec{\mathbf{N}})\Delta S_{ij}$$

gets arbitrarily close to the mass flux. Therefore, the mass flux is

$$\iint_S \rho\vec{\mathbf{v}}\cdot\vec{\mathbf{N}}\,dS=\lim_{m,n\to\infty}\sum_{i=1}^{m}\sum_{j=1}^{n}(\rho\vec{\mathbf{v}}\cdot\vec{\mathbf{N}})\Delta S_{ij}.$$

This is a surface integral of a vector field. Letting the vector field $\rho\vec{\mathbf{v}}$ be an arbitrary vector field $\vec{\mathbf{F}}$ leads to the following definition.

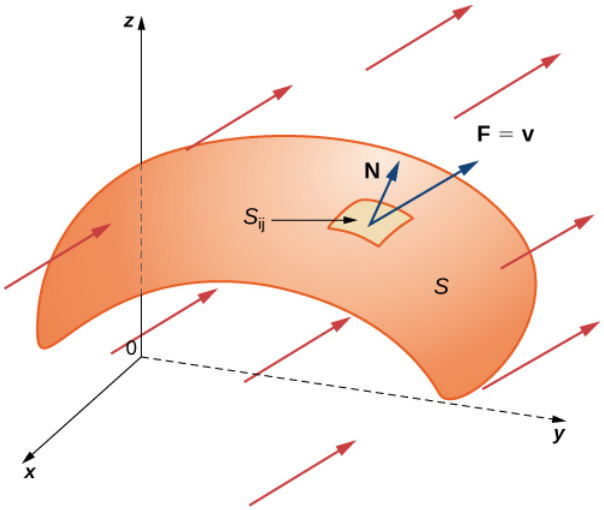

Figure 16.7.22: The mass of fluid per unit time flowing across $S_{ij}$ in the direction of $\vec{\mathbf{N}}$ can be approximated by $(\rho\vec{\mathbf{v}} \cdot \vec{\mathbf{N}})\Delta S_{ij}$.

**Definition: Surface Integrals**

Let $\vec{\mathbf{F}}$ be a continuous vector field with a domain that contains oriented surface $S$ with unit normal vector $\vec{\mathbf{N}}$. The surface integral of $\vec{\mathbf{F}}$ over $S$ is

$$\iint_S \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}} = \iint_S \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, dS. \tag{16.7.4}$$

Notice the parallel between this definition and the definition of vector line integral $\int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, dS$. A surface integral of a vector field is defined in a similar way to a flux line integral across a curve, except the domain of integration is a surface (a two-dimensional object) rather than a curve (a one-dimensional object). Integral $\iint_S \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, dS$ is called the *flux of* $\vec{\mathbf{F}}$ *across* $S$, just as integral $\int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, dS$ is the flux of $\vec{\mathbf{F}}$ across curve $C$. A surface integral over a vector field is also called a **flux integral**.

Just as with vector line integrals, surface integral $\iint_S \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, dS$ is easier to compute after surface $S$ has been parameterized. Let $\vec{\mathbf{r}}(u,v)$ be a parameterization of $S$ with parameter domain $D$. Then, the unit normal vector is given by $\vec{\mathbf{N}} = \dfrac{\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v}{||\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v||}$ and, from Equation 16.7.4, we have

$$\begin{aligned}\int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, dS &= \iint_S \vec{\mathbf{F}} \cdot \frac{\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v}{||\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v||}\, dS \\ &= \iint_D \left(\vec{\mathbf{F}}(\vec{\mathbf{r}}(u,v)) \cdot \frac{\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v}{||\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v||}\right) ||\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v||\, dA \\ &= \iint_D (\vec{\mathbf{F}}(\vec{\mathbf{r}}(u,v)) \cdot (\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v))\, dA.\end{aligned}$$

Therefore, to compute a surface integral over a vector field we can use the equation

$$\iint_S \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, dS = \iint_D (\vec{\mathbf{F}}(\vec{\mathbf{r}}(u,v)) \cdot (\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v))\, dA. \tag{16.7.5}$$

**Example 16.7.13: Calculating a Surface Integral**

Calculate the surface integral

$$\iint_S \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, dS,$$

where $\vec{\mathbf{F}} = \langle -y, x, 0\rangle$ and $S$ is the surface with parameterization

$$\vec{\mathbf{r}}(u,v) = \langle u, v^2 - u, u + v\rangle,\ 0 \le u \le 3,\ 0 \le v \le 4.$$

**Solution**

The tangent vectors are $\vec{\mathbf{t}}_u = \langle 1, -1, 1\rangle$ and $\vec{\mathbf{t}}_v = \langle 0, 2v, 1\rangle$. Therefore,

$$\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v = \langle -1 - 2v, -1, 2v\rangle.$$

By Equation 16.7.5,

$$\begin{aligned}
\iint_S \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}} &= \int_0^4 \int_0^3 F(\vec{\mathbf{r}}(u,v)) \cdot (\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v)\, du\, dv \\
&= \int_0^4 \int_0^3 \langle u - v^2,\ u,\ 0\rangle \cdot \langle -1 - 2v,\ -1,\ 2v\rangle\, du\, dv \\
&= \int_0^4 \int_0^3 [(u - v^2)(-1 - 2v) - u]\, du\, dv \\
&= \int_0^4 \int_0^3 (2v^3 + v^2 - 2uv - 2u)\, du\, dv \\
&= \int_0^4 [2v^3 u + v^2 u - vu^2 - u^2]\Big|_0^3\, dv \\
&= \int_0^4 (6v^3 + 3v^2 - 9v - 9)\, dv \\
&= \left[\frac{3v^4}{2} + v^3 - \frac{9v^2}{2} - 9v\right]_0^4 \\
&= 340.
\end{aligned}$$

Therefore, the flux of $\vec{\mathbf{F}}$ across $S$ is 340.

## Exercise 16.7.12

Calculate surface integral

$$\iint_S \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, dS,$$

where $\vec{\mathbf{F}} = \langle 0, -z, y\rangle$ and $S$ is the portion of the unit sphere in the first octant with outward orientation.

**Hint**

Use Equation 16.7.5.

**Answer**

0

## Example 16.7.14: Calculating Mass Flow Rate

Let $\vec{\mathbf{v}}(x,y,z) = \langle 2x,\ 2y,\ z\rangle$ represent a velocity field (with units of meters per second) of a fluid with constant density 80 kg/m$^3$. Let $S$ be hemisphere $x^2 + y^2 + z^2 = 9$ with $z \le 0$ such that $S$ is oriented outward. Find the mass flow rate of the fluid across $S$.

**Solution**

A parameterization of the surface is

$$\vec{\mathbf{r}}(\phi,\theta) = \langle 3\cos\theta\sin\phi,\ 3\sin\theta\sin\phi,\ 3\cos\phi\rangle,\ 0 \le \theta \le 2\pi,\ 0 \le \phi \le \pi/2.$$

As in Example 16.7.7, the tangent vectors are $\vec{\mathbf{t}}_\theta = \langle -3\sin\theta\sin\phi,\ 3\cos\theta\sin\phi,\ 0\rangle$ and $\vec{\mathbf{t}}_\phi = \langle 3\cos\theta\cos\phi,\ 3\sin\theta\cos\phi,\ -3\sin\phi\rangle$, and their cross product is

$$\vec{\mathbf{t}}_\phi \times \vec{\mathbf{t}}_\theta = \langle 9\cos\theta\sin^2\phi,\ 9\sin\theta\sin^2\phi,\ 9\sin\phi\cos\phi\rangle.$$

Notice that each component of the cross product is positive, and therefore this vector gives the outward orientation. Therefore we use the orientation

$\vec{\mathbf{N}} = \langle 9\cos\theta\sin^2\phi,\ 9\sin\theta\sin^2\phi,\ 9\sin\phi\cos\phi\rangle$

for the sphere.

By Equation 16.7.4,

$$\begin{aligned}\iint_S \rho v\cdot dS &= 80\int_0^{2\pi}\int_0^{\pi/2} v(r(\phi,\theta))\cdot(t_\phi\times t_\theta)\,d\phi\,d\theta\\ &= 80\int_0^{2\pi}\int_0^{\pi/2}\langle 6\cos\theta\sin\phi,\ 6\sin\theta\sin\phi,\ 3\cos\phi\rangle\\ &\quad\cdot\langle 9\cos\theta\sin^2\phi,\ 9\sin\theta\sin^2\phi,\ 9\sin\phi\cos\phi\rangle\,d\phi\,d\theta\\ &= 80\int_0^{2\pi}\int_0^{\pi/2} 54\sin^3\phi + 27\cos^2\phi\sin\phi\,d\phi\,d\theta\\ &= 80\int_0^{2\pi}\int_0^{\pi/2} 54(1-\cos^2\phi)\sin\phi + 27\cos^2\phi\sin\phi\,d\phi\,d\theta\\ &= 80\int_0^{2\pi}\int_0^{\pi/2} 54\sin\phi - 27\cos^2\phi\sin\phi\,d\phi\,d\theta\\ &= 80\int_0^{2\pi}\Big[-54\cos\phi + 9\cos^3\phi\Big]_{\phi=0}^{\phi=2\pi}\,d\theta\\ &= 80\int_0^{2\pi} 45\,d\theta\\ &= 7200\pi.\end{aligned}$$

Therefore, the mass flow rate is $7200\pi\ \text{kg/sec/m}^2$.

## ? Exercise 16.7.13

Let $\vec{\mathbf{v}}(x,y,z) = \langle x^2+y^2,\ z,\ 4y\rangle$ m/sec represent a velocity field of a fluid with constant density 100 kg/m$^3$. Let $S$ be the half-cylinder $\vec{\mathbf{r}}(u,v) = \langle\cos u,\ \sin u,\ v\rangle$, $0\le u\le\pi$, $0\le v\le 2$ oriented outward. Calculate the mass flux of the fluid across $S$.

**Hint**

Use Equation 16.7.4.

**Answer**

400 kg/sec/m

In Example 16.7.14, we computed the mass flux, which is the rate of mass flow per unit area. If we want to find the flow rate (measured in volume per time) instead, we can use flux integral

$$\iint_S \vec{\mathbf{v}}\cdot\vec{\mathbf{N}}\,dS,$$

which leaves out the density. Since the flow rate of a fluid is measured in volume per unit time, flow rate does not take mass into account. Therefore, we have the following characterization of the flow rate of a fluid with velocity $\vec{\mathbf{v}}$ across a surface $S$:

$$\text{Flow rate of fluid across S} = \iint_S \vec{\mathbf{v}}\cdot d\vec{\mathbf{S}}.$$

To compute the flow rate of the fluid in Example 16.7.14, we simply remove the density constant, which gives a flow rate of $90\pi\ m^3/sec$.

Both mass flux and flow rate are important in physics and engineering. Mass flux measures how much mass is flowing across a surface; flow rate measures how much volume of fluid is flowing across a surface.

In addition to modeling fluid flow, surface integrals can be used to model heat flow. Suppose that the temperature at point $(x,y,z)$ in an object is $T(x,y,z)$. Then the heat flow is a vector field proportional to the negative temperature gradient in the object. To be

precise, the heat flow is defined as vector field $F = -k\nabla T$, where the constant $k$ is the *thermal conductivity* of the substance from which the object is made (this constant is determined experimentally). The rate of heat flow across surface $S$ in the object is given by the flux integral

$$\iint_S \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}} = \iint_S -k\vec{\nabla} T \cdot d\vec{\mathbf{S}}.$$

**Example 16.7.15: Calculating Heat Flow**

A cast-iron solid cylinder is given by inequalities $x^2 + y^2 \leq 1$, $1 \leq z \leq 4$. The temperature at point $(x, y, z)$ in a region containing the cylinder is $T(x, y, z) = (x^2 + y^2)z$. Given that the thermal conductivity of cast iron is 55, find the heat flow across the boundary of the solid if this boundary is oriented outward.

### Solution

Let $S$ denote the boundary of the object. To find the heat flow, we need to calculate flux integral

$$\iint_S -k\vec{\nabla} T \cdot d\vec{\mathbf{S}}.$$

Notice that $S$ is not a smooth surface but is piecewise smooth, since $S$ is the union of three smooth surfaces (the circular top and bottom, and the cylindrical side). Therefore, we calculate three separate integrals, one for each smooth piece of $S$. Before calculating any integrals, note that the gradient of the temperature is $\vec{\nabla} T = \langle 2xz, 2yz, x^2 + y^2 \rangle$.

First we consider the circular bottom of the object, which we denote $S_1$. We can see that $S_1$ is a circle of radius 1 centered at point $(0, 0, 1)$ sitting in plane $z = 1$. This surface has parameterization $\vec{\mathbf{r}}(u, v) = \langle v \cos u, v \sin u, 1 \rangle$, $0 \leq u < 2\pi$, $0 \leq v \leq 1$.

Therefore,

$\vec{\mathbf{t}}_u = \langle -v \sin u, v \cos u, 0 \rangle$ and $\vec{\mathbf{t}}_v = \langle \cos u, v \sin u, 0 \rangle$, and $\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v = \langle 0, 0, -v \sin^2 u - v \cos^2 u \rangle = \langle 0, 0, -v \rangle$.

Since the surface is oriented outward and $S_1$ is the bottom of the object, it makes sense that this vector points downward. By Equation 16.7.5 the heat flow across $S_1$ is

$$\begin{aligned}
\iint_{S_1} -k\vec{\nabla} T \cdot d\vec{\mathbf{S}} &= -55 \int_0^{2\pi} \int_0^1 \vec{\nabla} T(u, v) \cdot (\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v)\, dv\, du \\
&= -55 \int_0^{2\pi} \int_0^1 \langle 2v \cos u, 2v \sin u, v^2 \cos^2 u + v^2 \sin^2 u \rangle \cdot \langle 0, 0, -v \rangle\, dv\, du \\
&= -55 \int_0^{2\pi} \int_0^1 \langle 2v \cos u, 2v \sin u, v^2 \rangle \cdot \langle 0, 0, -v \rangle\, dv\, du \\
&= -55 \int_0^{2\pi} \int_0^1 -v^3\, dv\, du \\
&= -55 \int_0^{2\pi} -\frac{1}{4}\, du \\
&= \frac{55\pi}{2}.
\end{aligned}$$

Now let's consider the circular top of the object, which we denote $S_2$. We see that $S_2$ is a circle of radius 1 centered at point $(0, 0, 4)$, sitting in plane $z = 4$. This surface has parameterization $\vec{\mathbf{r}}(u, v) = \langle v \cos u, v \sin u, 4 \rangle$, $0 \leq u < 2\pi$, $0 \leq v \leq 1$.

Therefore, $\vec{\mathbf{t}}_u = \langle -v \sin u, v \cos u, 0 \rangle$ and $\vec{\mathbf{t}}_v = \langle \cos u, v \sin u, 0 \rangle$, and $\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v = \langle 0, 0, -v \sin^2 u - v \cos^2 u \rangle = \langle 0, 0, -v \rangle$.

Since the surface is oriented outward and $S_1$ is the top of the object, we instead take vector $\vec{\mathbf{t}}_v \times \vec{\mathbf{t}}_u = \langle 0, 0, v \rangle$. By Equation 16.7.5, the heat flow across $S_1$ is

$$\begin{aligned}\iint_{S_2} -k\vec{\nabla}T \cdot d\vec{\mathbf{S}} &= -55\int_0^{2\pi}\int_0^1 \vec{\nabla}T(u,v)\cdot(\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v)\,dv\,du \\ &= -55\int_0^{2\pi}\int_0^1 \langle 8v\cos u,\ 8v\sin u,\ v^2\cos^2 u + v^2\sin^2 u\rangle \cdot \langle 0,0,-v\rangle\,dv\,du \\ &= -55\int_0^{2\pi}\int_0^1 \langle 8v\cos u,\ 8v\sin u,\ v^2\rangle \cdot \langle 0,0,-v\rangle\ dv\,du \\ &= -55\int_0^{2\pi}\int_0^1 -v^3\,dv\,du = -55\int_0^{2\pi} -\frac{1}{4}\,du = -\frac{55\pi}{2}.\end{aligned}$$

Last, let's consider the cylindrical side of the object. This surface has parameterization $\vec{\mathbf{r}}(u,v) = \langle \cos u,\ \sin u,\ v\rangle$, $0 \le u < 2\pi$, $1 \le v \le 4$. By Example 16.7.9, we know that $\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v = \langle \cos u,\ \sin u,\ 0\rangle$. By Equation 16.7.5,

$$\begin{aligned}\iint_{S_3} -k\vec{\nabla}T \cdot d\vec{\mathbf{S}} &= -55\int_0^{2\pi}\int_1^4 \vec{\nabla}T(u,v)\cdot(\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v)\,dv\,du \\ &= -55\int_0^{2\pi}\int_1^4 \langle 2v\cos u,\ 2v\sin u,\ \cos^2 u + \sin^2 u\rangle \cdot \langle \cos u,\ \sin u,\ 0\rangle\,dv\,du \\ &= -55\int_0^{2\pi}\int_0^1 \langle 2v\cos^2 u,\ 2v\sin u,\ 1\rangle \cdot \langle \cos u,\ \sin u,\ 0\rangle\,dv\ du \\ &= -55\int_0^{2\pi}\int_0^1 (2v\cos^2 u + 2v\sin^2 u)\,dv\,du \\ &= -55\int_0^{2\pi}\int_0^1 2v\,dv\,du \\ &= -55\int_0^{2\pi} du \\ &= -110\pi.\end{aligned}$$

Therefore, the rate of heat flow across $S$ is

$$\frac{55\pi}{2} - \frac{55\pi}{2} - 110\pi = -110\pi.$$

## ? Exercise 16.7.14

A cast-iron solid ball is given by inequality $x^2 + y^2 + z^2 \le 1$. The temperature at a point in a region containing the ball is $T(x,y,z) = \frac{1}{3}(x^2 + y^2 + z^2)$. Find the heat flow across the boundary of the solid if this boundary is oriented outward.

**Hint**

Follow the steps of Example 16.7.15.

**Answer**

$$-\frac{440\pi}{3}$$

## Key Concepts

- Surfaces can be parameterized, just as curves can be parameterized. In general, surfaces must be parameterized with two parameters.
- Surfaces can sometimes be oriented, just as curves can be oriented. Some surfaces, such as a Möbius strip, cannot be oriented.
- A surface integral is like a line integral in one higher dimension. The domain of integration of a surface integral is a surface in a plane or space, rather than a curve in a plane or space.
  - The integrand of a surface integral can be a scalar function or a vector field. To calculate a surface integral with an integrand that is a function, use Equation 16.7.2. To calculate a surface integral with an integrand that is a vector field, use Equation 16.7.5.

- If $S$ is a surface, then the area of $S$ is

$$\iint_S dS.$$

## Key Equations

- **Scalar surface integral**

$$\iint_S f(x,y,z)\,dS = \iint_D f(\vec{\mathbf{r}}(u,v))||\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v||\,dA$$

- **Flux integral**

$$\iint_S \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\,dS = \iint_S \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}} = \iint_D \vec{\mathbf{F}}(\vec{\mathbf{r}}(u,v)) \cdot (\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v)\,dA$$

## Glossary

**flux integral**
another name for a surface integral of a vector field; the preferred term in physics and engineering

**grid curves**
curves on a surface that are parallel to grid lines in a coordinate plane

**heat flow**
a vector field proportional to the negative temperature gradient in an object

**mass flux**
the rate of mass flow of a fluid per unit area, measured in mass per unit time per unit area

**orientation of a surface**
if a surface has an “inner” side and an “outer” side, then an orientation is a choice of the inner or the outer side; the surface could also have “upward” and “downward” orientations

**parameter domain (parameter space)**
the region of the $uv$-plane over which the parameters $u$ and $v$ vary for parameterization $\vec{\mathbf{r}}(u,v) = \langle x(u,v),\, y(u,v),\, z(u,v)\rangle$

**parameterized surface (parametric surface)**
a surface given by a description of the form $\vec{\mathbf{r}}(u,v) = \langle x(u,v),\, y(u,v),\, z(u,v)\rangle$, where the parameters $u$ and $v$ vary over a parameter domain in the $uv$-plane

**regular parameterization**
parameterization $\vec{\mathbf{r}}(u,v) = \langle x(u,v),\, y(u,v),\, z(u,v)\rangle$ such that $r_u \times r_v$ is not zero for point $(u,v)$ in the parameter domain

**surface area**
the area of surface $S$ given by the surface integral

$$\iint_S dS$$

**surface integral**
an integral of a function over a surface

**surface integral of a scalar-valued function**
a surface integral in which the integrand is a scalar function

**surface integral of a vector field**

a surface integral in which the integrand is a vector field

# 16.7E: Exercises for Section 16.6

**In exercises 1 - 4, determine whether the statements are *true or false*.**

1. If surface $S$ is given by $\{(x, y, z) : 0 \le x \le 1, 0 \le y \le 1, z = 10\}$, then $\iint_S f(x, y, z)\, dS = \int_0^1 \int_0^1 f(x, y, 10)\, dx\, dy$.

**Answer**

True

2. If surface $S$ is given by $\{(x, y, z) : 0 \le x \le 1, 0 \le y \le 1, z = x\}$, then $\iint_S f(x, y, z)\, dS = \int_0^1 \int_0^1 f(x, y, x)\, dx\, dy$.

3. Surface $\vec{\mathbf{r}} = \langle v \cos u,\ v \sin u,\ v^2 \rangle$, for $0 \le u \le \pi$, $0 \le v \le 2$ is the same surface $\vec{\mathbf{r}} = \langle \sqrt{v} \cos 2u,\ \sqrt{v} \sin 2u,\ v \rangle$, for $0 \le u \le \frac{\pi}{2}$, $0 \le v \le 4$.

**Answer**

True

4. Given the standard parameterization of a sphere, normal vectors $\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v$ are outward normal vectors.

**In exercises 5 - 10, find parametric descriptions for the following surfaces.**

5. Plane $3x - 2y + z = 2$

**Answer**

$\vec{\mathbf{r}}(u, v) = \langle u,\ v,\ 2 - 3u + 2v \rangle$ for $-\infty \le u < \infty$ and $-\infty \le v < \infty$.

6. Paraboloid $z = x^2 + y^2$, for $0 \le z \le 9$.

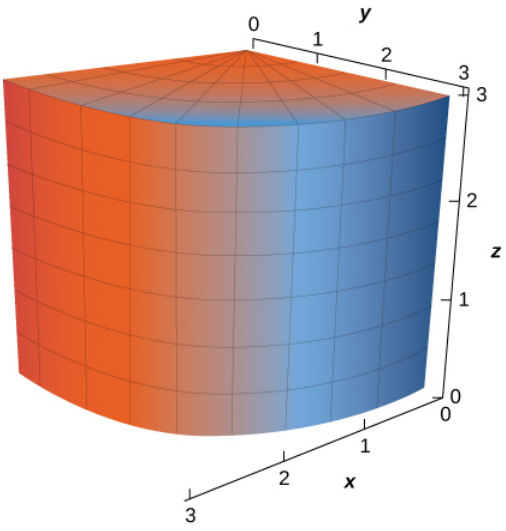
7. Plane $2x - 4y + 3z = 16$

**Answer**

$\vec{\mathbf{r}}(u, v) = \langle u,\ v,\ \frac{1}{3}(16 - 2u + 4v) \rangle$ for $|u| < \infty$ and $|v| < \infty$.

8. The frustum of cone $z^2 = x^2 + y^2$, for $2 \le z \le 8$

9. The portion of cylinder $x^2 + y^2 = 9$ in the first octant, for $0 \le z \le 3$



**Answer**

$\vec{\mathbf{r}}(u, v) = \langle 3 \cos u,\ 3 \sin u,\ v \rangle$ for $0 \le u \le \frac{\pi}{2}$, $0 \le v \le 3$

10. A cone with base radius $r$ and height $h$, where $r$ and $h$ are positive constants.

**For exercises 11 - 12, use a computer algebra system to approximate the area of the following surfaces using a parametric description of the surface.**

11. [T] Half cylinder $\{(r, \theta, z) : r = 4, 0 \leq \theta \leq \pi, 0 \leq z \leq 7\}$

**Answer**

$A = 87.9646$

12. [T] Plane $z = 10 - z - y$ above square $|x| \leq 2, |y| \leq 2$

**In exercises 13 - 15, let $S$ be the hemisphere $x^2 + y^2 + z^2 = 4$, with $z \geq 0$, and evaluate each surface integral, in the counterclockwise direction.**

13. $\iint_S z\, dS$

**Answer**

$\iint_S z\, dS = 8\pi$

14. $\iint_S (x - 2y)\, dS$

15. $\iint_S (x^2 + y^2)\, dS$

**Answer**

$\iint_S (x^2 + y^2)\, dS = 16\pi$

**In exercises 16 - 18, evaluate $\int \int_S \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, dS$ for vector field $\vec{\mathbf{F}}$ where $\vec{\mathbf{N}}$ is an outward normal vector to surface $S$.**

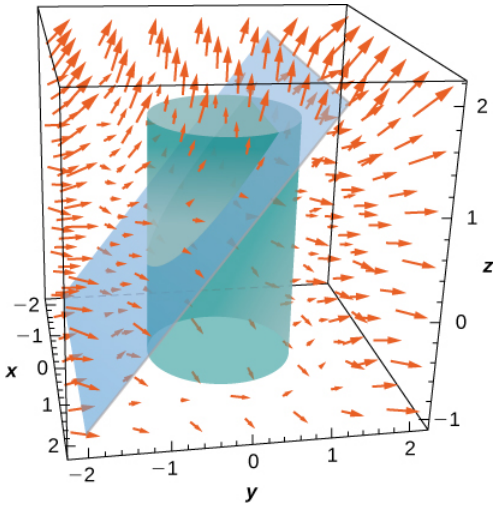
16. $\vec{\mathbf{F}}(x, y, z) = x\,\hat{\mathbf{i}} + 2y\,\hat{\mathbf{j}} = 3z\,\hat{\mathbf{k}}$, and $S$ is that part of plane $15x - 12y + 3z = 6$ that lies above unit square $0 \leq x \leq 1, 0 \leq y \leq 1$.

17. $\vec{\mathbf{F}}(x, y) = x\,\hat{\mathbf{i}} + y\,\hat{\mathbf{j}}$, and $S$ is hemisphere $z = \sqrt{1 - x^2 - y^2}$.

**Answer**

$\iint_S \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, dS = \frac{4\pi}{3}$

18. $\vec{\mathbf{F}}(x, y, z) = x^2\,\hat{\mathbf{i}} + y^2\,\hat{\mathbf{j}} + z^2\,\hat{\mathbf{k}}$, and $S$ is the portion of plane $z = y + 1$ that lies inside cylinder $x^2 + y^2 = 1$.



**In exercises 19 - 20, approximate the mass of the homogeneous lamina that has the shape of given surface $S$. Round to four decimal places.**

19. [T] $S$ is surface $z = 4 - x - 2y$, with $z \geq 0$, $x \geq 0$, $y \geq 0$; $\xi = x$.

**Answer**

$m \approx 13.0639$

20. [T] $S$ is surface $z = x^2 + y^2$, with $z \leq 1$; $\xi = z$.

21. [T] $S$ is surface $x^2 + y^2 + x^2 = 5$, with $z \geq 1$; $\xi = \theta^2$.

**Answer**

$m \approx 228.5313$

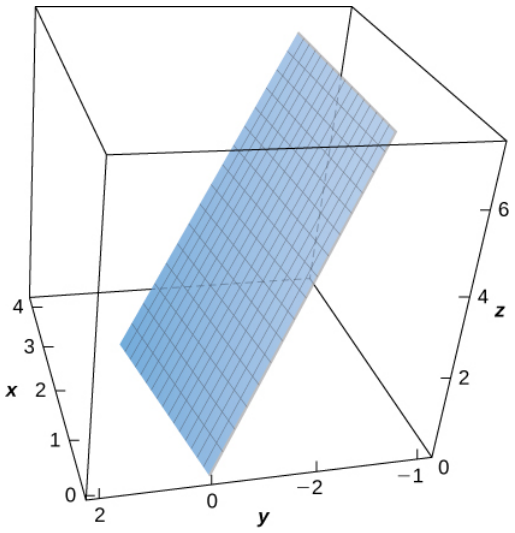
22. Evaluate $\iint_S (y^2 z\,\hat{\mathbf{i}} + y^3\,\hat{\mathbf{j}} + xz\,\hat{\mathbf{k}}) \cdot dS$, where $S$ is the surface of cube $-1 \leq x \leq 1$, $-1 \leq y \leq 1$, and $0 \leq z \leq 2$ in a counterclockwise direction.

23. Evaluate surface integral $\iint_S g\,dS$, where $g(x, y, z) = xz + 2x^2 - 3xy$ and $S$ is the portion of plane $2x - 3y + z = 6$ that lies over unit square $R : 0 \leq x \leq 1$, $0 \leq y \leq 1$.

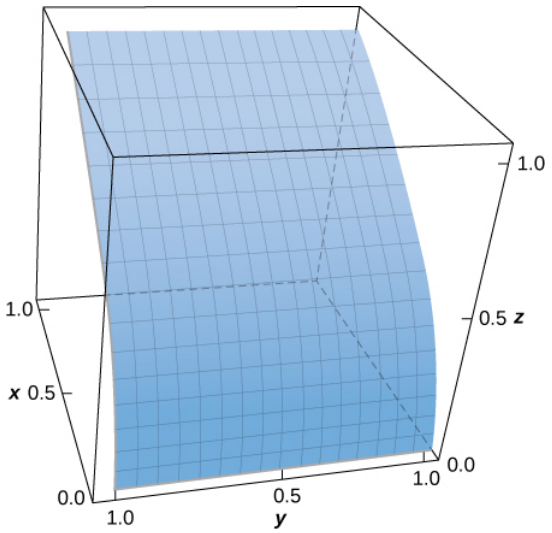
**Answer**

$\iint_S g\,dS = 3\sqrt{4}$

24. Evaluate $\iint_S (x + y + z)\,dS$, where $S$ is the surface defined parametrically by $\vec{\mathbf{R}}(u, v) = (2u + v)\,\hat{\mathbf{i}} + (u - 2v)\,\hat{\mathbf{j}} + (u + 3v)\,\hat{\mathbf{k}}$ for $0 \leq u \leq 1$, and $0 \leq v \leq 2$.



25. [T] Evaluate $\iint_S (x - y^2 + z)\,dS$, where $S$ is the surface defined parametrically by $\vec{\mathbf{R}}(u, v) = u^2\,\hat{\mathbf{i}} + v\,\hat{\mathbf{j}} + u\,\hat{\mathbf{k}}$ for $0 \leq u \leq 1$, $0 \leq v \leq 1$.



**Answer**

$$\iint_S (x^2 + y - z)\, dS \approx 0.9617$$

26. [T] Evaluate where $S$ is the surface defined by $\vec{\mathbf{R}}(u, v) = u\,\hat{\mathbf{i}} - u^2\,\hat{\mathbf{j}} + v\hat{\mathbf{k}}$, $0 \le u \le 2$, $0 \le v \le 1$ for $0 \le u \le 1$, $0 \le v \le 2$.

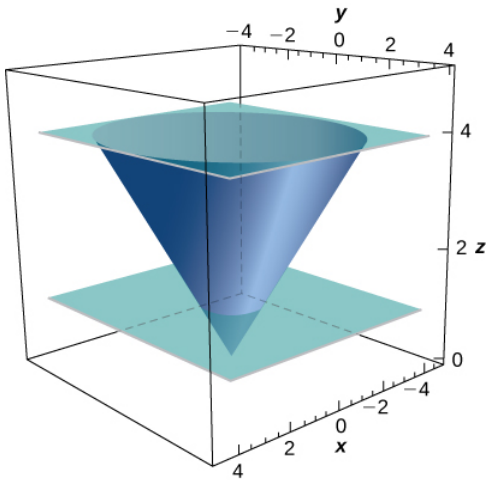
27. Evaluate $\iint_S (x^2 + y^2)\, dS$, where $S$ is the surface bounded above hemisphere $z = \sqrt{1 - x^2 - y^2}$, and below by plane $z = 0$.

**Answer**

$$\iint_S (x^2 + y^2)\, dS = \frac{4\pi}{3}$$

28. Evaluate $\iint_S (x^2 + y^2 + z^2)\, dS$, where $S$ is the portion of plane that lies inside cylinder $x^2 + y^2 = 1$.

29. [T] Evaluate $\iint_S x^2 z\, dS$, where $S$ is the portion of cone $z^2 = x^2 + y^2$ that lies between planes $z = 1$ and $z = 4$.

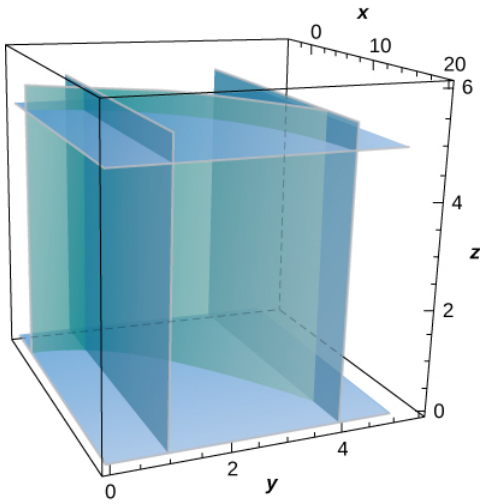


**Answer**

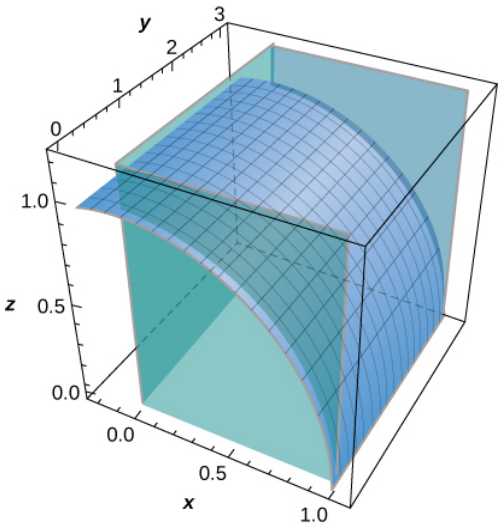
$$\operatorname{div} \vec{\mathbf{F}} = a + b$$

$$\iint_S x^2 z\, dS = \frac{1023\sqrt{2\pi}}{5}$$

30. [T] Evaluate $\iint_S \frac{xz}{y}\,dS$, where $S$ is the portion of cylinder $x = y^2$ that lies in the first octant between planes $z = 0$, $z = 5$, and $y = 4$.



31. [T] Evaluate $\iint_S (z + y)\,dS$, where $S$ is the part of the graph of $z = \sqrt{1 - x^2}$ in the first octant between the $xy$-plane and plane $y = 3$.



**Answer**

$\iint_S (z + y)\,dS \approx 10.1$

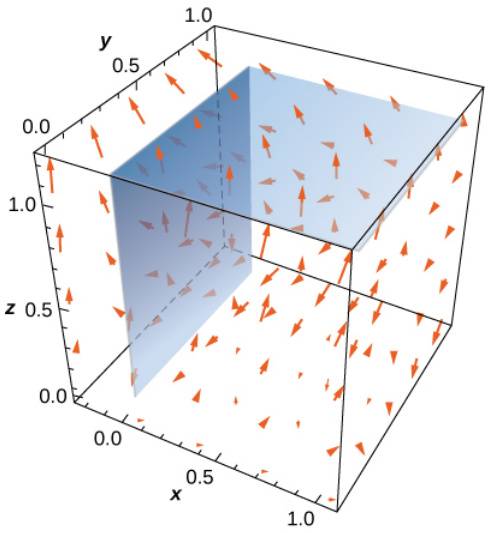
32. Evaluate $\iint_S xyz\,dS$ if $S$ is the part of plane $z = x + y$ that lies over the triangular region in the $xy$-plane with vertices (0, 0, 0), (1, 0, 0), and (0, 2, 0).

33. Find the mass of a lamina of density $\xi(x, y, z) = z$ in the shape of hemisphere $z = (a^2 - x^2 - y^2)^{1/2}$.

**Answer**

$m = \pi a^3$

34. Compute $\int\int_S \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\,dS$, where $\vec{\mathbf{F}}(x, y, z) = x\,\hat{\mathbf{i}} - 5y\,\hat{\mathbf{j}} + 4z\,\hat{\mathbf{k}}$ and $\vec{\mathbf{N}}$ is an outward normal vector $S$, where $S$ is the union of two squares $S_1 : x = 0,\ 0 \le y \le 1,\ 0 \le z \le 1$ and $S_2 : x = 0,\ 0 \le x \le 1,\ 0 \le y \le 1$.



35. Compute $\iint_S \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, dS$, where $\vec{\mathbf{F}}(x,y,z) = xy\,\hat{\mathbf{i}} + z\,\hat{\mathbf{j}} + (x+y)\,\hat{\mathbf{k}}$ and $\vec{\mathbf{N}}$ is an outward normal vector $S$, where $S$ is the triangular region cut off from plane $x+y+z=1$ by the positive coordinate axes.

**Answer**

$$\iint_S \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, dS = \frac{13}{24}$$

36. Compute $\iint_S \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, dS$, where $\vec{\mathbf{F}}(x,y,z) = 2yz\,\hat{\mathbf{i}} + (\tan^{-1} xz)\,\hat{\mathbf{j}} + e^{xy}\,\hat{\mathbf{k}}$ and $\vec{\mathbf{N}}$ is an outward normal vector $S$, where $S$ is the surface of sphere $x^2+y^2+z^2=1$.

37. Compute $\iint_S \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, dS$, where $\vec{\mathbf{F}}(x,y,z) = xyz\,\hat{\mathbf{i}} + xyz\,\hat{\mathbf{j}} + xyz\,\hat{\mathbf{k}}$ and $\vec{\mathbf{N}}$ is an outward normal vector $S$, where $S$ is the surface of the five faces of the unit cube $0 \le x \le 1$, $0 \le y \le 1$, $0 \le z \le 1$ missing $z=0$.

**Answer**

$$\iint_S \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, dS = \frac{3}{4}$$

**For exercises 38 - 39, express the surface integral as an iterated double integral by using a projection on $S$ on the $yz$-plane.**

38. $\iint_S xy^2z^3\, dS$; $S$ is the first-octant portion of plane $2x+3y+4z=12$.

39. $\iint_S (x^2-2y+z)\, dS$; $S$ is the portion of the graph of $4x+y=8$ bounded by the coordinate planes and plane $z=6$.

**Answer**

$$\int_0^8 \int_0^6 \left(4-3y+\frac{1}{16}y^2+z\right)\left(\frac{1}{4}\sqrt{17}\right) dz\, dy$$

**For exercises 40 - 41, express the surface integral as an iterated double integral by using a projection on $S$ on the $xz$-plane.**

40. $\iint_S xy^2z^3\, dS$; $S$ is the first-octant portion of plane $2x+3y+4z=12$.

41. $\iint_S (x^2-2y+z)\, dS$; is the portion of the graph of $4x+y=8$ bounded by the coordinate planes and plane $z=6$.

**Answer**

$$\int_0^2 \int_0^6 \left[x^2-2(8-4x)+z\right]\sqrt{17}\, dz\, dx$$

42. Evaluate surface integral $\iint_S yz\, dS$, where $S$ is the first-octant part of plane $x+y+z=\lambda$, where $\lambda$ is a positive constant.

43. Evaluate surface integral $\iint_S (x^2z + y^2z)\, dS$, where $S$ is hemisphere $x^2 + y^2 + z^2 = a^2$, $z \geq 0$.

**Answer**

$$\iint_S (x^2z + y^2z)\, dS = \frac{\pi a^5}{2}$$

44. Evaluate surface integral $\iint_S z\, dA$, where $S$ is surface $z = \sqrt{x^2 + y^2}$, $0 \leq z \leq 2$.

45. Evaluate surface integral $\iint_S x^2yz\, dS$, where $S$ is the part of plane $z = 1 + 2x + 3y$ that lies above rectangle $0 \leq x \leq 3$ and $0 \leq y \leq 2$.

**Answer**

$$\iint_S x^2yz\, dS = 171\sqrt{14}$$

46. Evaluate surface integral $\iint_S yz\, dS$, where $S$ is plane $x + y + z = 1$ that lies in the first octant.

47. Evaluate surface integral $\iint_S yz\, dS$, where $S$ is the part of plane $z = y + 3$ that lies inside cylinder $x^2 + y^2 = 1$.

**Answer**

$$\iint_S yz\, dS = \frac{\sqrt{2}\pi}{4}$$

**For exercises 48 - 50, use geometric reasoning to evaluate the given surface integrals.**

48. $\iint_S \sqrt{x^2 + y^2 + z^2}\, dS$, where $S$ is surface $x^2 + y^2 + z^2 = 4$, $z \geq 0$

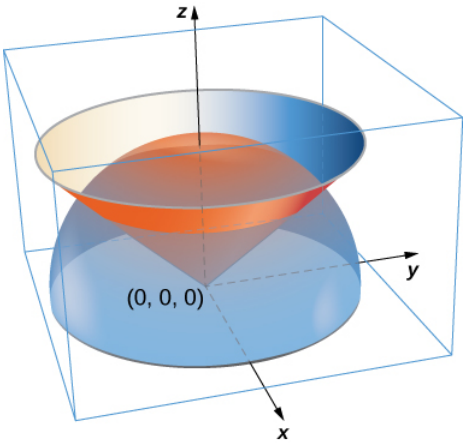
49. $\iint_S (x\,\hat{\mathbf{i}} + y\,\hat{\mathbf{j}}) \cdot dS$, where $S$ is surface $x^2 + y^2 = 4$, $1 \leq z \leq 3$, oriented with unit normal vectors pointing outward

**Answer**

$$\iint_S (x\,\hat{\mathbf{i}} + y\,\hat{\mathbf{j}}) \cdot dS = 16\pi$$

50. $\iint_S (z\,\hat{\mathbf{k}}) \cdot dS$, where $S$ is disc $x^2 + y^2 \leq 9$ on plane $z = 4$ oriented with unit normal vectors pointing upward

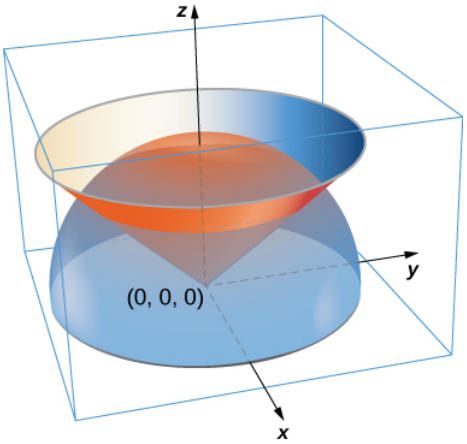
51. A lamina has the shape of a portion of sphere $x^2 + y^2 + z^2 = a^2$ that lies within cone $z = \sqrt{x^2 + y^2}$. Let $S$ be the spherical shell centered at the origin with radius $a$, and let $C$ be the right circular cone with a vertex at the origin and an axis of symmetry that coincides with the $z$-axis. Determine the mass of the lamina if $\delta(x, y, z) = x^2y^2z$.



**Answer**

$$m = \frac{\pi a^7}{192}$$

52. A lamina has the shape of a portion of sphere $x^2 + y^2 + z^2 = a^2$ that lies within cone $z = \sqrt{x^2 + y^2}$. Let $S$ be the spherical shell centered at the origin with radius $a$, and let $C$ be the right circular cone with a vertex at the origin and an axis of symmetry that coincides with the $z$-axis. Suppose the vertex angle of the cone is $\phi_0$, with $0 \leq \phi_0 < \frac{\pi}{2}$. Determine the mass of that portion of the shape enclosed in the intersection of $S$ and $C$. Assume $\delta(x, y, z) = x^2 y^2 z$.



53. A paper cup has the shape of an inverted right circular cone of height 6 in. and radius of top 3 in. If the cup is full of water weighing $62.5\, lb/ft^3$, find the magnitude of the total force exerted by the water on the inside surface of the cup.

**Answer**

$F \approx 4.57\, lb$

**For exercises 54 - 55, the heat flow vector field for conducting objects is $\vec{\mathbf{F}} = -k\vec{\nabla}T$, where $T(x, y, z)$ is the temperature in the object and $k > 0$ is a constant that depends on the material. Find the outward flux of $\vec{\mathbf{F}}$ across the following surfaces $S$ for the given temperature distributions and assume $k = 1$.**

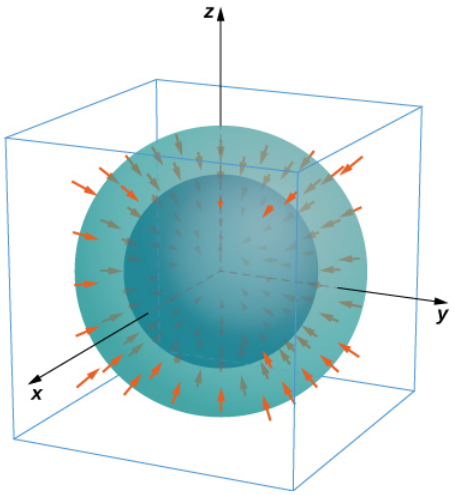
54. $T(x, y, z) = 100e^{-x-y}$; $S$ consists of the faces of cube $|x| \leq 1$, $|y| \leq 1$, $|z| \leq 1$.

55. $T(x, y, z) = -\ln(x^2 + y^2 + z^2)$; $S$ is sphere $x^2 + y^2 + z^2 = a^2$.

**Answer**

$8\pi a$

**For exercises 56 - 57, consider the radial fields $\vec{\mathbf{F}} = \frac{\langle x, y, z \rangle}{(x^2 + y^2 + z^2)^{p/2}} = \frac{r}{|r|^p}$, where $p$ is a real number. Let $S$ consist of spheres $A$ and $B$ centered at the origin with radii $0 < a < b$. The total outward flux across $S$ consists of the outward flux across the outer sphere $B$ less the flux into $S$ across inner sphere $A$.**



56. Find the total flux across $S$ with $p = 0$.

57. Show that for $p = 3$ the flux across $S$ is independent of $a$ and $b$.

**Answer**

The net flux is zero.

# 16.8: Stokes' Theorem

**Learning Objectives**

- Explain the meaning of Stokes' theorem.
- Use Stokes' theorem to evaluate a line integral.
- Use Stokes' theorem to calculate a surface integral.
- Use Stokes' theorem to calculate a curl.

In this section, we study Stokes' theorem, a higher-dimensional generalization of Green's theorem. This theorem, like the Fundamental Theorem for Line Integrals and Green's theorem, is a generalization of the Fundamental Theorem of Calculus to higher dimensions. Stokes' theorem relates a vector surface integral over surface $S$ in space to a line integral around the boundary of $S$. Therefore, just as the theorems before it, Stokes' theorem can be used to reduce an integral over a geometric object $S$ to an integral over the boundary of $S$. In addition to allowing us to translate between line integrals and surface integrals, Stokes' theorem connects the concepts of curl and circulation. Furthermore, the theorem has applications in fluid mechanics and electromagnetism. We use Stokes' theorem to derive Faraday's law, an important result involving electric fields.

## Stokes' Theorem

Stokes' theorem says we can calculate the flux of $curl\,\vec{\mathbf{F}}$ across surface $S$ by knowing information only about the values of $\vec{\mathbf{F}}$ along the boundary of $S$. Conversely, we can calculate the line integral of vector field $\vec{\mathbf{F}}$ along the boundary of surface $S$ by translating to a double integral of the curl of $\vec{\mathbf{F}}$ over $S$.

Let $S$ be an oriented smooth surface with unit normal vector $\vec{\mathbf{N}}$. Furthermore, suppose the boundary of $S$ is a simple closed curve $C$. The orientation of $S$ induces the positive orientation of $C$ if, as you walk in the positive direction around $C$ with your head pointing in the direction of $\vec{\mathbf{N}}$, the surface is always on your left. With this definition in place, we can state *Stokes' theorem*.

**Theorem 16.8.1: Stokes' Theorem**

Let $S$ be a piecewise smooth oriented surface with a boundary that is a simple closed curve $C$ with positive orientation (Figure 16.8.1). If $\vec{\mathbf{F}}$ is a vector field with component functions that have continuous partial derivatives on an open region containing $S$, then

$$\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \iint_S curl\,\vec{\mathbf{F}} \cdot d\vec{\mathbf{S}}. \tag{16.8.1}$$

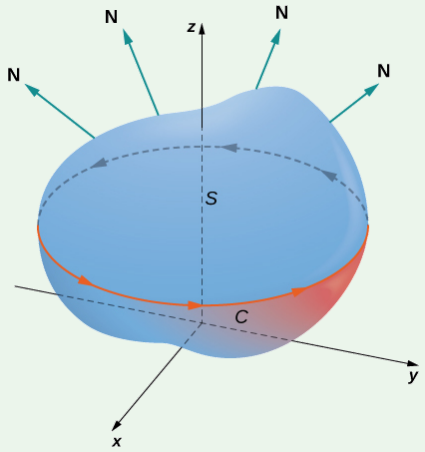

Figure 16.8.1: Stokes' theorem relates the flux integral over the surface to a line integral around the boundary of the surface. Note that the orientation of the curve is positive.

Suppose surface $S$ is a flat region in the $xy$-plane with upward orientation. Then the unit normal vector is $\vec{\mathbf{k}}$ and surface integral

$$\iint_S curl\,\vec{\mathbf{F}} \cdot d\vec{\mathbf{S}}$$

is actually the double integral

$$\iint_S curl\,\vec{\mathbf{F}} \cdot \vec{\mathbf{k}}\, dA.$$

In this special case, Stokes' theorem gives

$$\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \iint_S curl\,\vec{\mathbf{F}} \cdot \vec{\mathbf{k}}\, dA.$$

However, this is the flux form of Green's theorem, which shows us that Green's theorem is a special case of Stokes' theorem. Green's theorem can only handle surfaces in a plane, but Stokes' theorem can handle surfaces in a plane or in space.

The complete proof of Stokes' theorem is beyond the scope of this text. We look at an intuitive explanation for the truth of the theorem and then see proof of the theorem in the special case that surface $S$ is a portion of a graph of a function, and $S$, the boundary of $S$, and $\vec{\mathbf{F}}$ are all fairly tame.

**Proof**

First, we look at an informal proof of the theorem. This proof is not rigorous, but it is meant to give a general feeling for why the theorem is true. Let $S$ be a surface and let $D$ be a small piece of the surface so that $D$ does not share any points with the boundary of $S$. We choose $D$ to be small enough so that it can be approximated by an oriented square $E$. Let $D$ inherit its orientation from $S$, and give $E$ the same orientation. This square has four sides; denote them $E_l$, $E_r$, $E_u$, and $E_d$ for the left, right, up, and down sides, respectively. On the square, we can use the flux form of Green's theorem:

$$\int_{E_l+E_d+E_r+E_u} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \iint_E curl\,\vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, d\vec{\mathbf{S}} = \iint_E curl\,\vec{\mathbf{F}} \cdot d\vec{\mathbf{S}}.$$

To approximate the flux over the entire surface, we add the values of the flux on the small squares approximating small pieces of the surface (Figure 16.8.2).

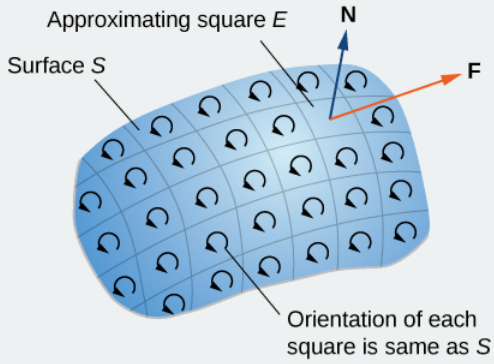

Figure 16.8.2: Chop the surface into small pieces. The pieces should be small enough that they can be approximated by a square.

By Green's theorem, the flux across each approximating square is a line integral over its boundary. Let $F$ be an approximating square with an orientation inherited from $S$ and with a right side $E_l$ (so $F$ is to the left of $E$). Let $F_r$ denote the right side of $F$; then, $E_l = -F_r$. In other words, the right side of $F$ is the same curve as the left side of $E$, just oriented in the opposite direction. Therefore,

$$\int_{E_l} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = -\int_{F_r} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}.$$

As we add up all the fluxes over all the squares approximating surface $S$, line integrals

$$\int_{E_l} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$$

and

$$\int_{F_r} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$$

cancel each other out. The same goes for the line integrals over the other three sides of $E$. These three line integrals cancel out with the line integral of the lower side of the square above $E$, the line integral over the left side of the square to the right of $E$, and the line integral over the upper side of the square below $E$ (Figure 16.8.3). After all this cancelation occurs over all the approximating squares, the only line integrals that survive are the line integrals over sides approximating the boundary of $S$. Therefore, the sum of all the fluxes (which, by Green's theorem, is the sum of all the line integrals around the boundaries of approximating squares) can be approximated by a line integral over the boundary of $S$. In the limit, as the areas of the approximating squares go to zero, this approximation gets arbitrarily close to the flux.

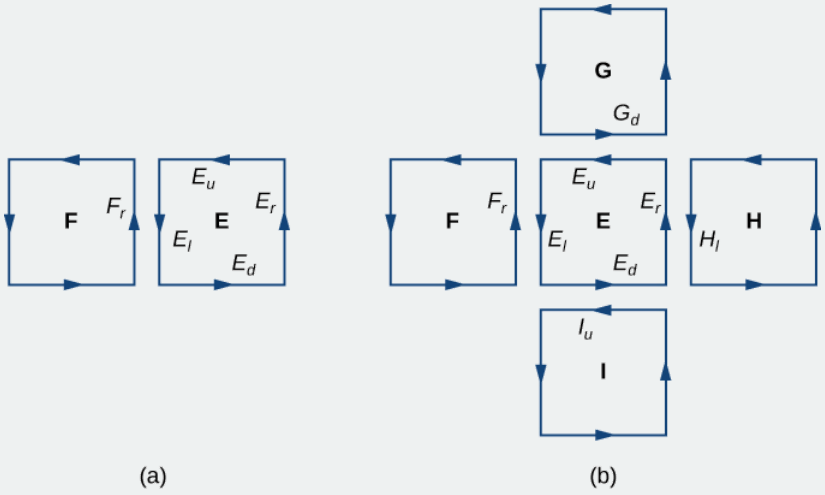

Figure 16.8.3: (a) The line integral along $E_l$ cancels out the line integral along $F_r$ because $E_l = -F_r$. (b) The line integral along any of the sides of $E$ cancels out with the line integral along a side of an adjacent approximating square.

Let's now look at a rigorous proof of the theorem in the special case that $S$ is the graph of function $z = f(x, y)$, where $x$ and $y$ vary over a bounded, simply connected region $D$ of finite area (Figure 16.8.4). Furthermore, assume that $f$ has continuous second-order partial derivatives. Let $C$ denote the boundary of $S$ and let $C'$ denote the boundary of $D$. Then, $D$ is the "shadow" of $S$ in the plane and $C'$ is the "shadow" of $C$. Suppose that $S$ is oriented upward. The counterclockwise orientation of $C$ is positive, as is the counterclockwise orientation of $C'$. Let $\vec{\mathbf{F}}(x, y, z) = \langle P, Q, R \rangle$ be a vector field with component functions that have continuous partial derivatives.

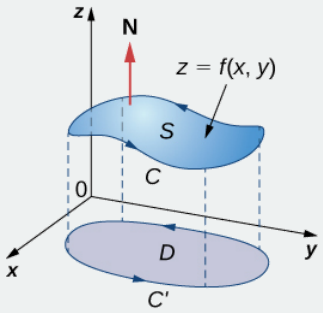

Figure 16.8.4: $D$ is the "shadow," or projection, of $S$ in the plane and $C'$ is the projection of $C$.

We take the standard parameterization of $S: x = x,\ y = y,\ z = g(x, y)$. The tangent vectors are $\vec{\mathbf{t}}_x = \langle 1, 0, g_x \rangle$ and $\vec{\mathbf{t}}_y = \langle 0, 1, g_y \rangle$, and therefore $\vec{\mathbf{t}}_x \times \vec{\mathbf{t}}_y = \langle -g_x, -g_y, 1 \rangle$.

$$\iint_S curl\, \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}} = \iint_D [-(R_y - Q_z)z_x - (P_z - R_x)z_y + (Q_x - P_y)]\, dA,$$

where the partial derivatives are all evaluated at $(x, y, g(x, y))$, making the integrand depend on $x$ and $y$ only. Suppose $\langle x(t), y(t) \rangle$, $a \le t \le b$ is a parameterization of $C'$. Then, a parameterization of $C$ is $\langle x(t), y(t), g(x(t), y(t)) \rangle$, $a \le t \le b$. Armed with

these parameterizations, the Chain rule, and Green's theorem, and keeping in mind that $P$, $Q$ and $R$ are all functions of $x$ and $y$, we can evaluate line integral

$$\begin{aligned}\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} &= \int_a^b (Px'(t) + Qy'(t) + Rz'(t))\, dt \\ &= \int_a^b \left[Px'(t) + Qy'(t) + R\left(\frac{\partial z}{\partial x}\frac{dx}{dt} + \frac{\partial z}{\partial y}\frac{dy}{dt}\right)\right] dt \\ &= \int_a^b \left[\left(P + R\frac{\partial z}{\partial x}\right)x'(t) + \left(Q + R\frac{\partial z}{\partial y}\right)y'(t)\right] dt \\ &= \int_{C'} \left(P + R\frac{\partial z}{\partial x}\right) dx + \left(Q + R\frac{\partial z}{\partial y}\right) dy \\ &= \iint_D \left[\frac{\partial}{\partial x}\left(Q + R\frac{\partial z}{\partial y}\right) - \frac{\partial}{\partial y}\left(P + R\frac{\partial z}{\partial x}\right)\right] dA \\ &= \iint_D \left(\frac{\partial Q}{\partial x} + \frac{\partial Q}{\partial z}\frac{\partial z}{\partial x} + \frac{\partial R}{\partial x}\frac{\partial z}{\partial y} + \frac{\partial R}{\partial z}\frac{\partial z}{\partial x}\frac{\partial z}{\partial y} + R\frac{\partial^2 z}{\partial x \partial y}\right) \\ &\quad - \left(\frac{\partial P}{\partial y} + \frac{\partial P}{\partial z}\frac{\partial z}{\partial y} + \frac{\partial R}{\partial z}\frac{\partial z}{\partial y}\frac{\partial z}{\partial x} + R\frac{\partial^2 z}{\partial y \partial x}\right)\end{aligned}$$

By Clairaut's theorem,

$$\frac{\partial^2 z}{\partial x \partial y} = \frac{\partial^2 z}{\partial y \partial x}$$

Therefore, four of the terms disappear from this double integral, and we are left with

$$\iint_D [-(R_y - Q_z)Z_x - (P_z - R_x)z_y + (Q_x - P_y)]\, dA,$$

which equals

$$\iint_S curl\, \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}}.$$

□

We have shown that Stokes' theorem is true in the case of a function with a domain that is a simply connected region of finite area. We can quickly confirm this theorem for another important case: when vector field $\vec{\mathbf{F}}$ is a conservative field. If $\vec{\mathbf{F}}$ is conservative, the curl of $\vec{\mathbf{F}}$ is zero, so

$$\iint_S curl\, \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}} = 0.$$

Since the boundary of $S$ is a closed curve, the integral

$$\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}.$$

is also zero.

### Example 16.8.1: Verifying Stokes' Theorem for a Specific Case

Verify that Stokes' theorem is true for vector field $\vec{\mathbf{F}}(x, y) = \langle -z, x, 0\rangle$ and surface $S$, where $S$ is the hemisphere, oriented outward, with parameterization $\vec{\mathbf{r}}(\phi, \theta) = \langle \sin\phi\cos\theta, \sin\phi\sin\theta, \cos\phi\rangle$, $0 \le \theta \le \pi$, $0 \le \phi \le \pi$ as shown in Figure 16.8.5.

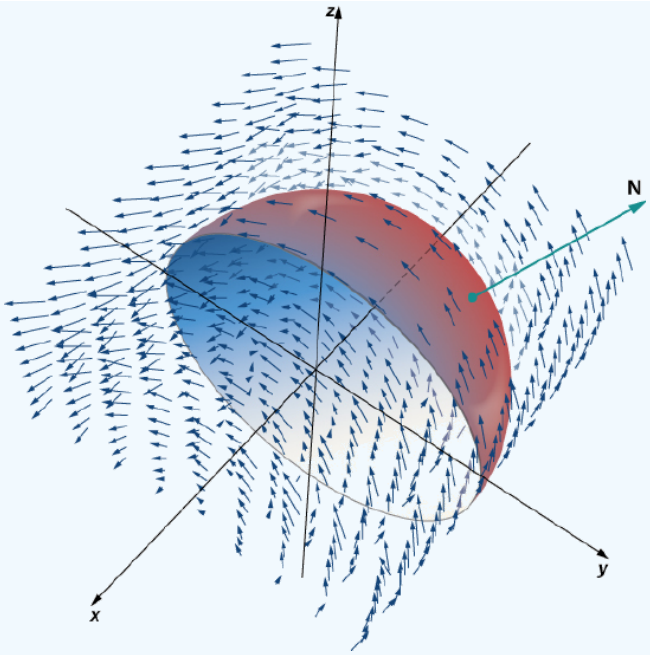

Figure 16.8.5: Verifying Stokes' theorem for a hemisphere in a vector field.

### Solution

Let $C$ be the boundary of $S$. Note that $C$ is a circle of radius 1, centered at the origin, sitting in plane $y = 0$. This circle has parameterization $\langle \cos t, 0, \sin t \rangle$, $0 \le t \le 2\pi$. the equation for scalar surface integrals

$$\begin{aligned} \int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} &= \int_0^{2\pi} \langle -\sin t, \cos t, 0 \rangle \cdot \langle -\sin t, 0, \cos t \rangle \, dt \\ &= \int_0^{2\pi} \sin^2 t \, dt \\ &= \pi. \end{aligned}$$

By the equation for vector line integrals,

$$\begin{aligned} \iint_S curl\, \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}} &= \iint_D curl\, \vec{\mathbf{F}}(\vec{\mathbf{r}}(\phi, \theta)) \cdot (\vec{\mathbf{t}}_\phi \times \vec{\mathbf{t}}_\theta) \, dA \\ &= \iint_D \langle 0, -1, 1 \rangle \cdot \langle \cos\theta \sin^2\phi, \sin\theta \sin^2\phi, \sin\phi \cos\phi \rangle \, dA \\ &= \int_0^{\pi} \int_0^{\pi} (\sin\phi \cos\phi - \sin\theta \sin^2\phi) \, d\phi d\theta \\ &= \frac{\pi}{2} \int_0^{\pi} \sin\theta \, d\theta \\ &= \pi. \end{aligned}$$

Therefore, we have verified Stokes' theorem for this example.

### ? Exercise 16.8.1

Verify that Stokes' theorem is true for vector field $\vec{\mathbf{F}}(x, y, z) = \langle y, x, -z \rangle$ and surface $S$, where $S$ is the upwardly oriented portion of the graph of $f(x, y) = x^2 y$ over a triangle in the $xy$-plane with vertices $(0, 0)$, $(2, 0)$, and $(0, 2)$.

**Hint**

Calculate the double integral and line integral separately.

**Answer**

Both integrals give $-\frac{136}{45}$:

## Applying Stokes' Theorem

Stokes' theorem translates between the flux integral of surface $S$ to a line integral around the boundary of $S$. Therefore, the theorem allows us to compute surface integrals or line integrals that would ordinarily be quite difficult by translating the line integral into a surface integral or vice versa. We now study some examples of each kind of translation.

### Example 16.8.2: Calculating a Surface Integral

Calculate surface integral

$$\iint_S curl\, \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}},$$

where $S$ is the surface, oriented outward, in Figure 16.8.6 and $\vec{\mathbf{F}} = \langle z,\ 2xy,\ x + y \rangle$.

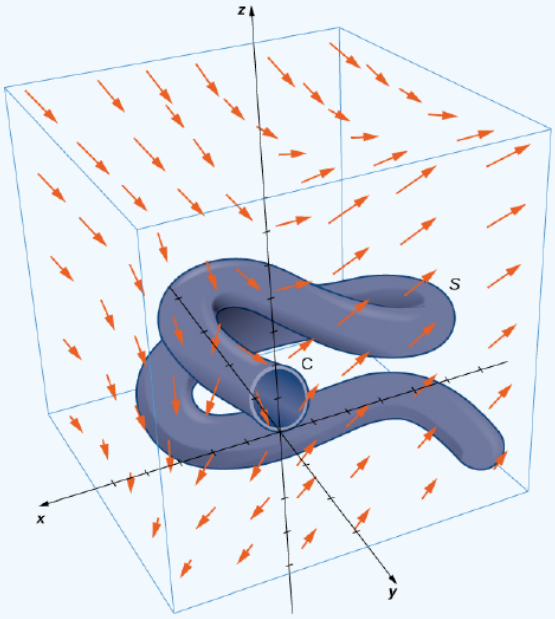

Figure 16.8.6: A complicated surface in a vector field.

**Solution**

Note that to calculate

$$\iint_S curl\, \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}}$$

without using Stokes' theorem, we would need the equation for scalar surface integrals. Use of this equation requires a parameterization of $S$. Surface $S$ is complicated enough that it would be extremely difficult to find a parameterization. Therefore, the methods we have learned in previous sections are not useful for this problem. Instead, we use Stokes' theorem, noting that the boundary $C$ of the surface is merely a single circle with radius 1.

The curl of $\vec{\mathbf{F}}$ is $\langle 1, 1, 2y \rangle$. By Stokes' theorem,

$$\iint_S curl\, \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}} = \int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}},$$

where $C$ has parameterization $\langle \cos t,\ \sin t,\ 1 \rangle, 0 \le t \le 2\pi$. By the equation for vector line integrals,

$$\begin{aligned}\iint_S curl\, F \cdot d\vec{\mathbf{S}} &= \int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} \\ &= \int_0^2 \langle 1,\, \sin t \cos t,\, \cos t + \sin t \rangle \cdot \langle -\sin t,\, \cos t,\, 0 \rangle \, dt \\ &= \int_0^{2\pi} (-\sin t + 2 \sin t \cos^2 t) \, dt \\ &= \left[ \cos t - \frac{2\cos^3 t}{3} \right]_0^{2\pi} \\ &= \cos(2\pi) - \frac{2\cos^3(2\pi)}{3} - \left( \cos(0) - \frac{2\cos^3(0)}{3} \right) \\ &= 0.\end{aligned}$$

An amazing consequence of Stokes' theorem is that if $S'$ is any other smooth surface with boundary $C$ and the same orientation as $S$, then

$$\iint_S curl\, \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}} = \int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = 0$$

because Stokes' theorem says the surface integral depends on the line integral around the boundary only.

In Example 16.8.2, we calculated a surface integral simply by using information about the boundary of the surface. In general, let $S_1$ and $S_2$ be smooth surfaces with the same boundary $C$ and the same orientation. By Stokes' theorem,

$$\iint_{S_1} curl\, \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}} = \int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \iint_{S_2} curl\, \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}}. \tag{16.8.2}$$

Therefore, if

$$\iint_{S_1} curl\, \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}}$$

is difficult to calculate but

$$\iint_{S_2} curl\, \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}}$$

is easy to calculate, Stokes' theorem allows us to calculate the easier surface integral. In Example 16.8.2, we could have calculated

$$\iint_S curl\, \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}}$$

by calculating

$$\iint_{S'} curl\, \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}},$$

where $\vec{\mathbf{S}}'$ is the disk enclosed by boundary curve $C$ (a much more simple surface with which to work).

Equation 16.8.2 shows that flux integrals of curl vector fields are surface independent in the same way that line integrals of gradient fields are path independent. Recall that if $\vec{\mathbf{F}}$ is a two-dimensional conservative vector field defined on a simply connected domain, $f$ is a *potential function* for $\vec{\mathbf{F}}$, and $C$ is a curve in the domain of $\vec{\mathbf{F}}$, then

$$\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$$

depends only on the endpoints of $C$. Therefore if $C'$ is any other curve with the same starting point and endpoint as $C$ (that is, $C'$ has the same orientation as $C$), then

$$\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \int_{C'} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$$

In other words, the value of the integral depends on the boundary of the path only; it does not really depend on the path itself.

Analogously, suppose that $S$ and $S'$ are surfaces with the same boundary and same orientation, and suppose that $\vec{\mathbf{G}}$ is a three-dimensional vector field that can be written as the curl of another vector field $\vec{\mathbf{F}}$ (so that $\vec{\mathbf{F}}$ is like a "potential field" of $\vec{\mathbf{G}}$). By Equation 16.8.2,

$$\iint_S \vec{\mathbf{G}} \cdot d\vec{\mathbf{S}} = \iint_S curl\, \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}} = \int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \iint_{S'} curl\, \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}} = \iint_{S'} \vec{\mathbf{G}} \cdot d\vec{\mathbf{S}}.$$

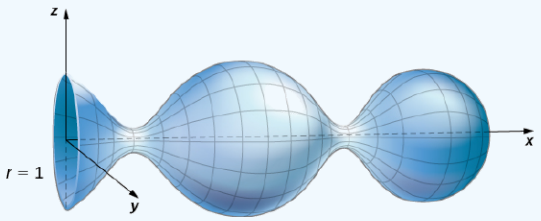
Therefore, the flux integral of $\vec{\mathbf{G}}$ does not depend on the surface, only on the boundary of the surface. Flux integrals of vector fields that can be written as the curl of a vector field are surface independent in the same way that line integrals of vector fields that can be written as the gradient of a scalar function are path independent.

**? Exercise 16.8.2**

Use Stokes' theorem to calculate surface integral

$$\iint_S curl\, \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}},$$

where $\vec{\mathbf{F}}(x, y, z) = \langle z, x, y \rangle$ and $S$ is the surface as shown in the following figure. The boundary curve, $C$ is oriented clockwise when looking along the positive $y$-axis.



**Hint**

Parameterize the boundary of $S$ and translate to a line integral.

**Answer**

$-\pi$

**✓ Example 16.8.3: Calculating a Line Integral**

Calculate the line integral

$$\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}},$$

where $\vec{\mathbf{F}} = \langle xy,\ x^2 + y^2 + z^2,\ yz \rangle$ and $C$ is the boundary of the parallelogram with vertices $(0, 0, 1)$, $(0, 1, 0)$, $(2, 0, -1)$, and $(2, 1, -2)$.

**Solution**

To calculate the line integral directly, we need to parameterize each side of the parallelogram separately, calculate four separate line integrals, and add the result. This is not overly complicated, but it is time-consuming.

By contrast, let's calculate the line integral using Stokes' theorem. Let $S$ denote the surface of the parallelogram. Note that $S$ is the portion of the graph of $z = 1 - x - y$ for $(x, y)$ varying over the rectangular region with vertices $(0, 0)$, $(0, 1)$, $(2, 0)$, and $(2, 1)$ in the $xy$-plane. Therefore, a parameterization of $S$ is $\langle x, y,\ 1 - x - y \rangle$, $0 \le x \le 2$, $0 \le y \le 1$. The curl of $\vec{\mathbf{F}}$ is $\langle -z,\ 0,\ x \rangle$,and Stokes' theorem and the equation for scalar surface integrals

$$\begin{aligned}\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} &= \iint_S curl\, \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}} \\ &= \int_0^2 \int_0^1 curl\, \vec{\mathbf{F}}(x,y) \cdot (\vec{\mathbf{t}}_x \times \vec{\mathbf{t}}_y)\, dy\, dx \\ &= \int_0^2 \int_0^1 \langle -(1-x-y),\, 0,\, x\rangle \cdot (\langle 1,\, 0, -1\rangle \times \langle 0,\, 1,\, -1\rangle)\, dy\, dx \\ &= \int_0^2 \int_0^1 \langle x+y-1,\, 0,\, x\rangle \cdot \langle 1,1,1\rangle\, dy\, dx \\ &= \int_0^2 \int_0^1 2x+y-1\, dy\, dx \\ &= 3.\end{aligned}$$

**? Exercise 16.8.3**

Use Stokes' theorem to calculate line integral

$$\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}},$$

where $\vec{\mathbf{F}} = \langle z, x, y\rangle$ and $C$ is the boundary of a triangle with vertices $(0,0,1)$, $(3,0,-2)$, and $(0,1,2)$.

**Hint**

This triangle lies in plane $z = 1 - x + y$.

**Answer**

$\frac{3}{2}$

## Interpretation of Curl

In addition to translating between line integrals and flux integrals, Stokes' theorem can be used to justify the physical interpretation of curl that we have learned. Here we investigate the relationship between curl and circulation, and we use Stokes' theorem to state Faraday's law—an important law in electricity and magnetism that relates the curl of an electric field to the rate of change of a magnetic field.

Recall that if $C$ is a closed curve and $\vec{\mathbf{F}}$ is a vector field defined on $C$, then the circulation of $\vec{\mathbf{F}}$ around $C$ is line integral

$$\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}.$$

If $\vec{\mathbf{F}}$ represents the velocity field of a fluid in space, then the circulation measures the tendency of the fluid to move in the direction of $C$.

Let $\vec{\mathbf{F}}$ be a continuous vector field and let $D_r$ be a small disk of radius $r$ with center $P_0$ (Figure 16.8.7). If $D_r$ is small enough, then $(curl\, \vec{\mathbf{F}})(P) \approx (curl\, \vec{\mathbf{F}})(P_0)$ for all points $P$ in $D_r$ because the curl is continuous. Let $C_r$ be the boundary circle of $D_r$: By Stokes' theorem,

$$\int_{C_r} \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \iint_{D_r} curl\, \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, d\vec{\mathbf{S}} \approx \iint_{D_r} (curl\, \vec{\mathbf{F}})(P_0) \cdot \vec{\mathbf{N}}(P_0)\, d\vec{\mathbf{S}}.$$

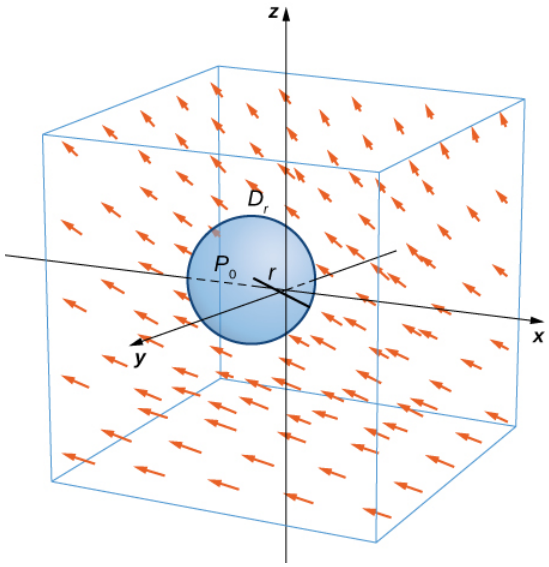


Figure 16.8.7: Disk $D_r$ is a small disk in a continuous vector field.

The quantity $(curl\,\vec{\mathbf{F}})(P_0)\cdot\vec{\mathbf{N}}(P_0)$ is constant, and therefore

$$\iint_{D_r}(curl\,\vec{\mathbf{F}})(P_0)\cdot\vec{\mathbf{N}}(P_0)\,d\vec{\mathbf{S}}=\pi r^2[(curl\,\vec{\mathbf{F}})(P_0)\cdot\vec{\mathbf{N}}(P_0)].$$

Thus

$$\int_{C_r}\vec{\mathbf{F}}\cdot d\vec{\mathbf{r}}\approx\pi r^2[(curl\,\vec{\mathbf{F}})(P_0)\cdot\vec{\mathbf{N}}(P_0)],$$

and the approximation gets arbitrarily close as the radius shrinks to zero. Therefore Stokes' theorem implies that

$$(curl\,\vec{\mathbf{F}})(P_0)\cdot\vec{\mathbf{N}}(P_0)=\lim_{r\to0^+}\frac{1}{\pi r^2}\int_{C_r}\vec{\mathbf{F}}\cdot d\vec{\mathbf{r}}.$$

This equation relates the curl of a vector field to the circulation. Since the area of the disk is $\pi r^2$, this equation says we can view the curl (in the limit) as the circulation per unit area. Recall that if $\vec{\mathbf{F}}$ is the velocity field of a fluid, then circulation

$$\oint_{C_r}\vec{\mathbf{F}}\cdot d\vec{\mathbf{r}}=\oint_{C_r}\vec{\mathbf{F}}\cdot\vec{\mathbf{T}}\,ds$$

is a measure of the tendency of the fluid to move around $C_r$: The reason for this is that $\vec{\mathbf{F}}\cdot\vec{\mathbf{T}}$ is a component of $\vec{\mathbf{F}}$ in the direction of $\vec{\mathbf{T}}$, and the closer the direction of $\vec{\mathbf{F}}$ is to $\vec{\mathbf{T}}$, the larger the value of $\vec{\mathbf{F}}\cdot\vec{\mathbf{T}}$ (remember that if $\vec{\mathbf{a}}$ and $\vec{\mathbf{b}}$ are vectors and $\vec{\mathbf{b}}$ is fixed, then the dot product $\vec{\mathbf{a}}\cdot\vec{\mathbf{b}}$ is maximal when $\vec{\mathbf{a}}$ points in the same direction as $\vec{\mathbf{b}}$). Therefore, if $\vec{\mathbf{F}}$ is the velocity field of a fluid, then $curl\,\vec{\mathbf{F}}\cdot\vec{\mathbf{N}}$ is a measure of how the fluid rotates about axis $\vec{\mathbf{N}}$. The effect of the curl is largest about the axis that points in the direction of $\vec{\mathbf{N}}$, because in this case $curl\,\vec{\mathbf{F}}\cdot\vec{\mathbf{N}}$ is as large as possible.

To see this effect in a more concrete fashion, imagine placing a tiny paddlewheel at point $P_0$ (Figure 16.8.8). The paddlewheel achieves its maximum speed when the axis of the wheel points in the direction of curl $\vec{\mathbf{F}}$. This justifies the interpretation of the curl we have learned: curl is a measure of the rotation in the vector field about the axis that points in the direction of the normal vector $\vec{\mathbf{N}}$, and Stokes' theorem justifies this interpretation.

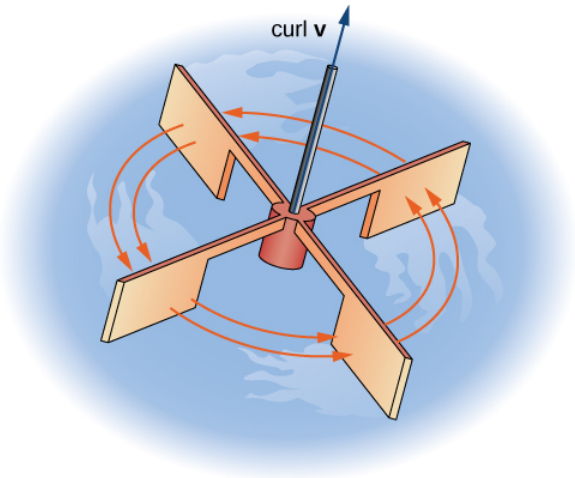

Figure **16.8.8**: To visualize curl at a point, imagine placing a tiny paddlewheel at that point in the vector field.

Now that we have learned about Stokes' theorem, we can discuss applications in the area of electromagnetism. In particular, we examine how we can use Stokes' theorem to translate between two equivalent forms of Faraday's law. Before stating the two forms of Faraday's law, we need some background terminology.

Let $C$ be a closed curve that models a thin wire. In the context of electric fields, the wire may be moving over time, so we write $C(t)$ to represent the wire. At a given time $t$, curve $C(t)$ may be different from original curve $C$ because of the movement of the wire, but we assume that $C(t)$ is a closed curve for all times $t$. Let $D(t)$ be a surface with $C(t)$ as its boundary, and orient $C(t)$ so that $D(t)$ has positive orientation. Suppose that $C(t)$is in a magnetic field $\vec{\mathbf{B}}(t)$ that can also change over time. In other words, $\vec{\mathbf{B}}$ has the form

$$\vec{\mathbf{B}}(x,y,z) = \langle P(x,y,z),\, Q(x,y,z),\, R(x,y,z)\rangle,$$

where $P$, $Q$, and $R$ can all vary continuously over time. We can produce current along the wire by changing field $\vec{\mathbf{B}}(t)$ (this is a consequence of Ampere's law). Flux $\phi(t) = \iint_{D(t)} \vec{\mathbf{B}}(t)\cdot d\vec{\mathbf{S}}$ creates electric field $\vec{\mathbf{E}}(t)$ that does work. The integral form of Faraday's law states that

$$Work = \int_{C(t)} \vec{\mathbf{E}}(t)\cdot d\vec{\mathbf{r}} = -\frac{\partial \phi}{\partial t}.$$

In other words, the work done by $\vec{\mathbf{E}}$ is the line integral around the boundary, which is also equal to the rate of change of the flux with respect to time. The differential form of Faraday's law states that

$$curl\, \vec{\mathbf{E}} = -\frac{\partial \vec{\mathbf{B}}}{\partial t}.$$

Using Stokes' theorem, we can show that the differential form of Faraday's law is a consequence of the integral form. By Stokes' theorem, we can convert the line integral in the integral form into surface integral

$$-\frac{\partial \phi}{\partial t} = \int_{C(t)} \vec{\mathbf{E}}(t)\cdot d\vec{\mathbf{r}} = \iint_{D(t)} curl\, \vec{\mathbf{E}}(t)\cdot d\vec{\mathbf{S}}.$$

Since

$$\phi(t) = \iint_{D(t)} B(t)\cdot d\vec{\mathbf{S}},$$

then as long as the integration of the surface does not vary with time we also have

$$-\frac{\partial \phi}{\partial t} = \iint_{D(t)} -\frac{\partial \vec{\mathbf{B}}}{\partial t}\cdot d\vec{\mathbf{S}}.$$

Therefore,

$$\iint_{D(t)} -\frac{\partial \vec{\mathbf{B}}}{\partial t} \cdot d\vec{\mathbf{S}} = \iint_{D(t)} curl\, \vec{\mathbf{E}} \cdot d\vec{\mathbf{S}}.$$

To derive the differential form of Faraday's law, we would like to conclude that $curl\, \vec{\mathbf{E}} = -\frac{\partial \vec{\mathbf{B}}}{\partial t}$: In general, the equation

$$\iint_{D(t)} -\frac{\partial \vec{\mathbf{B}}}{\partial t} \cdot d\vec{\mathbf{S}} = \iint_{D(t)} curl\, \vec{\mathbf{E}} \cdot d\vec{\mathbf{S}}$$

is not enough to conclude that $curl\, \vec{\mathbf{E}} = -\frac{\partial \vec{\mathbf{B}}}{\partial t}$: The integral symbols do not simply "cancel out," leaving equality of the integrands. To see why the integral symbol does not just cancel out in general, consider the two single-variable integrals $\int_0^1 x\, dx$ and $\int_0^1 f(x)\, dx$, where

$$f(x) = \begin{cases} 1, & \text{if } 0 \le x \le 1/2 \\ 0, & \text{if } 1/2 \le x \le 1. \end{cases}$$

Both of these integrals equal $\frac{1}{2}$, so $\int_0^1 x\, dx = \int_0^1 f(x)\, dx$.

However, $x \neq f(x)$. Analogously, with our equation

$$\iint_{D(t)} -\frac{\partial \vec{\mathbf{B}}}{\partial t} \cdot d\vec{\mathbf{S}} = \iint_{D(t)} curl\, \vec{\mathbf{E}} \cdot d\vec{\mathbf{S}},$$

we cannot simply conclude that $curl\, \vec{\mathbf{E}} = -\frac{\partial \vec{\mathbf{B}}}{\partial t}$ just because their integrals are equal. However, in our context, equation

$$\iint_{D(t)} -\frac{\partial \vec{\mathbf{B}}}{\partial t} \cdot d\vec{\mathbf{S}} = \iint_{D(t)} curl\, \vec{\mathbf{E}} \cdot d\vec{\mathbf{S}}$$

is true for *any* region, however small (this is in contrast to the single-variable integrals just discussed). If $\vec{\mathbf{F}}$ and $\vec{\mathbf{G}}$ are three-dimensional vector fields such that

$$\iint_S \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}} = \iint_S \vec{\mathbf{G}} \cdot d\vec{\mathbf{S}}$$

for any surface $S$, then it is possible to show that $\vec{\mathbf{F}} = \vec{\mathbf{G}}$ by shrinking the area of $S$ to zero by taking a limit (the smaller the area of $S$, the closer the value of $\iint_S \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}}$ to the value of $\vec{\mathbf{F}}$ at a point inside $S$). Therefore, we can let area $D(t)$ shrink to zero by taking a limit and obtain the differential form of Faraday's law:

$$curl\, \vec{\mathbf{E}} = -\frac{\partial \vec{\mathbf{B}}}{\partial t}.$$

In the context of electric fields, the curl of the electric field can be interpreted as the negative of the rate of change of the corresponding magnetic field with respect to time.

### Example 16.8.4: Using Faraday's Law

Calculate the curl of electric field $\vec{\mathbf{E}}$ if the corresponding magnetic field is constant field $\vec{\mathbf{B}}(t) = \langle 1, -4, 2 \rangle$.

**Solution**

Since the magnetic field does not change with respect to time, $-\frac{\partial \vec{\mathbf{B}}}{\partial t} = \vec{\mathbf{0}}$. By Faraday's law, the curl of the electric field is therefore also zero.

**Analysis**

A consequence of Faraday's law is that the curl of the electric field corresponding to a constant magnetic field is always zero.

**? Exercise 16.8.4**

Calculate the curl of electric field $\vec{\mathbf{E}}$ if the corresponding magnetic field is $\vec{\mathbf{B}}(t) = \langle tx, ty, -2tz \rangle$, $0 \leq t < \infty$.

**Hint**

- Use the differential form of Faraday's law.
- Notice that the curl of the electric field does not change over time, although the magnetic field does change over time.

**Answer**

$curl\, \vec{\mathbf{E}} = \langle x, y, -2z \rangle$

## Key Concepts

- Stokes' theorem relates a flux integral over a surface to a line integral around the boundary of the surface. Stokes' theorem is a higher dimensional version of Green's theorem, and therefore is another version of the Fundamental Theorem of Calculus in higher dimensions.
- Stokes' theorem can be used to transform a difficult surface integral into an easier line integral, or a difficult line integral into an easier surface integral.
- Through Stokes' theorem, line integrals can be evaluated using the simplest surface with boundary $C$.
- Faraday's law relates the curl of an electric field to the rate of change of the corresponding magnetic field. Stokes' theorem can be used to derive Faraday's law.

## Key Equations

- **Stokes' theorem**

$$\int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = \iint_S curl\, \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}}$$

## Glossary

**Stokes' theorem**

relates the flux integral over a surface $S$ to a line integral around the boundary $C$ of the surface $S$

**surface independent**

flux integrals of curl vector fields are surface independent if their evaluation does not depend on the surface but only on the boundary of the surface

# 16.8E: Exercises for Section 16.7

**In exercises 1 - 6, without using Stokes' theorem, calculate directly both the flux of $curl\,\vec{\mathbf{F}}\cdot\vec{\mathbf{N}}$ over the given surface and the circulation integral around its boundary, assuming all are oriented clockwise.**

1. $\vec{\mathbf{F}}(x,y,z)=y^2\,\hat{\mathbf{i}}+z^2\,\hat{\mathbf{j}}+x^2\,\hat{\mathbf{k}}$; $S$ is the first-octant portion of plane $x+y+z=1$.

2. $\vec{\mathbf{F}}(x,y,z)=z\,\hat{\mathbf{i}}+x\,\hat{\mathbf{j}}+y\,\hat{\mathbf{k}}$; $S$ is hemisphere $z=(a^2-x^2-y^2)^{1/2}$.

**Answer**

$$\iint_S (curl\,\vec{\mathbf{F}}\cdot\vec{\mathbf{N}})\,dS=\pi a^2$$

3. $\vec{\mathbf{F}}(x,y,z)=y^2\,\hat{\mathbf{i}}+2x\,\hat{\mathbf{j}}+5\,\hat{\mathbf{k}}$; $S$ is hemisphere $z=(4-x^2-y^2)^{1/2}$.

4. $\vec{\mathbf{F}}(x,y,z)=z\,\hat{\mathbf{i}}+2x\,\hat{\mathbf{j}}+3y\,\hat{\mathbf{k}}$; $S$ is upper hemisphere $z=\sqrt{9-x^2-y^2}$.

**Answer**

$$\iint_S (curl\,\vec{\mathbf{F}}\cdot\vec{\mathbf{N}})\,dS=18\pi$$

5. $\vec{\mathbf{F}}(x,y,z)=(x+2z)\,\hat{\mathbf{i}}+(y-x)\,\hat{\mathbf{j}}+(z-y)\,\hat{\mathbf{k}}$; $S$ is a triangular region with vertices $(3,0,0)$, $(0,3/2,0)$, and $(0,0,3)$.

6. $\vec{\mathbf{F}}(x,y,z)=2y\,\hat{\mathbf{i}}+6z\,\hat{\mathbf{j}}+3x\,\hat{\mathbf{k}}$; $S$ is a portion of paraboloid $z=4-x^2-y^2$ and is above the $xy$-plane.

**Answer**

$$\iint_S (curl\,\vec{\mathbf{F}}\cdot\vec{\mathbf{N}})\,dS=-8\pi$$

**In exercises 7 - 9, use Stokes' theorem to evaluate $\iint_S (curl\,\vec{\mathbf{F}}\cdot\vec{\mathbf{N}})\,dS$ for the vector fields and surface.**

7. $\vec{\mathbf{F}}(x,y,z)=xy\,\hat{\mathbf{i}}-z\,\hat{\mathbf{j}}$ and $S$ is the surface of the cube $0\le x\le 1$, $0\le y\le 1$, $0\le z\le 1$, except for the face where $z=0$ and using the outward unit normal vector.

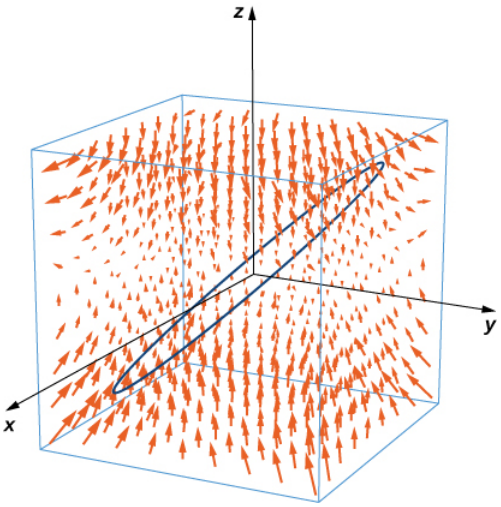
8. $\vec{\mathbf{F}}(x,y,z)=xy\,\hat{\mathbf{i}}+x^2\,\hat{\mathbf{j}}+z^2\,\hat{\mathbf{k}}$; and $C$ is the intersection of paraboloid $z=x^2+y^2$ and plane $z=y$, and using the outward normal vector.

**Answer**

$$\iint_S (curl\,\vec{\mathbf{F}}\cdot\vec{\mathbf{N}})\,dS=0$$

9. $\vec{\mathbf{F}}(x,y,z)=4y\,\hat{\mathbf{i}}+z\,\hat{\mathbf{j}}+2y\,\hat{\mathbf{k}}$; and $C$ is the intersection of sphere $x^2+y^2+z^2=4$ with plane $z=0$, and using the outward normal vector.

10. Use Stokes' theorem to evaluate $\int_C \left[2xy^2z\,dx+2x^2yz\,dy+(x^2y^2-2z)\,dz\right]$, where $C$ is the curve given by $x=\cos t$, $y=\sin t$, $0\le t\le 2\pi$, traversed in the direction of increasing $t$.



**Answer**

$$\int_C \vec{\mathbf{F}} \cdot d\vec{S} = 0$$

11. [T] Use a computer algebraic system (CAS) and Stokes' theorem to approximate line integral $\int_C (y\,dx + z\,dy + x\,dz)$, where $C$ is the intersection of plane $x + y = 2$ and surface $x^2 + y^2 + z^2 = 2(x + y)$, traversed counterclockwise viewed from the origin.

12. [T] Use a CAS and Stokes' theorem to approximate line integral $\int_C (3y\,dx + 2z\,dy - 5x\,dz)$, where $C$ is the intersection of the $xy$-plane and hemisphere $z = \sqrt{1 - x^2 - y^2}$, traversed counterclockwise viewed from the top—that is, from the positive $z$-axis toward the $xy$-plane.

**Answer**

$$\int_C \vec{\mathbf{F}} \cdot d\vec{S} = -9.4248$$

13. [T] Use a CAS and Stokes' theorem to approximate line integral $\int_C [(1 + y)\,z\,dx + (1 + z)x\,dy + (1 + x)y\,dz]$, where $C$ is a triangle with vertices $(1, 0, 0)$, $(0, 1, 0)$, and $(0, 0, 1)$ oriented counterclockwise.

14. Use Stokes' theorem to evaluate $\iint_S curl\ \vec{\mathbf{F}} \cdot d\vec{S}$, where $\vec{\mathbf{F}}(x, y, z) = e^{xy} cos\ z\ \hat{\mathbf{i}} + x^2 z\ \hat{\mathbf{j}} + xy\ \hat{\mathbf{k}}$, and $S$ is half of sphere $x = \sqrt{1 - y^2 - z^2}$, oriented out toward the positive $x$-axis.

**Answer**

$$\iint_S \vec{\mathbf{F}} \cdot d\vec{S} = 0$$

15. [T] Use a CAS and Stokes' theorem to evaluate $\iint_S (curl\ \vec{\mathbf{F}} \cdot \vec{\mathbf{N}})\,dS$, where $\vec{\mathbf{F}}(x, y, z) = x^2 y\,\hat{\mathbf{i}} + xy^2\,\hat{\mathbf{j}} + z^3\,\hat{\mathbf{k}}$ and $C$ is the curve of the intersection of plane $3x + 2y + z = 6$ and cylinder $x^2 + y^2 = 4$, oriented clockwise when viewed from above.

16. [T] Use a CAS and Stokes' theorem to evaluate $\iint_S curl\ \vec{\mathbf{F}} \cdot d\vec{S}$, where $\vec{\mathbf{F}}(x, y, z) = \left(\sin(y + z) - yx^2 - \frac{y^3}{3}\right)\hat{\mathbf{i}} + x\ \cos(y + z)\,\hat{\mathbf{j}} + \cos(2y)\,\hat{\mathbf{k}}$ and $S$ consists of the top and the four sides but not the bottom of the cube with vertices $(\pm 1, \pm 1, \pm 1)$, oriented outward.

**Answer**

$$\iint_S curl\ \vec{\mathbf{F}} \cdot d\vec{S} = 2.6667$$

17. [T] Use a CAS and Stokes' theorem to evaluate $\iint_S curl\ \vec{\mathbf{F}} \cdot d\vec{S}$, where $\vec{\mathbf{F}}(x, y, z) = z^2\,\hat{\mathbf{i}} + 3xy\,\hat{\mathbf{j}} + x^3 y^3\,\hat{\mathbf{k}}$ and $S$ is the top part of $z = 5 - x^2 - y^2$ above plane $z = 1$ and $S$ is oriented upward.

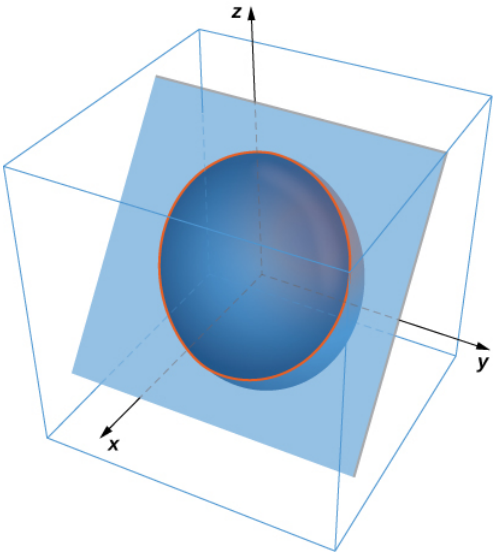
18. Use Stokes' theorem to evaluate $\iint_S (curl\, \vec{\mathbf{F}} \cdot \vec{\mathbf{N}})dS$, where $\vec{\mathbf{F}}(x,y,z) = z^2\,\hat{\mathbf{i}} + y^2\,\hat{\mathbf{j}} + x\,\hat{\mathbf{k}}$ and $S$ is a triangle with vertices $(1,0,0)$, $(0,1,0)$ and $(0,0,1)$ with counterclockwise orientation.

**Answer**

$$\iint_S (curl\, \vec{\mathbf{F}} \cdot \vec{\mathbf{N}})dS = -\frac{1}{6}$$

19. Use Stokes' theorem to evaluate line integral $\int_C (z\,dx + x\,dy + y\,dz)$, where $C$ is a triangle with vertices $(3,0,0)$, $(0,0,2)$, and $(0,6,0)$ traversed in the given order.

20. Use Stokes' theorem to evaluate $\int_C \left(\frac{1}{2}y^2\,dx + z\,dy + x\,dz\right)$, where $C$ is the curve of intersection of plane $x + z = 1$ and ellipsoid $x^2 + 2y^2 + z^2 = 1$, oriented clockwise from the origin.



**Answer**

$$\int_C \left(\frac{1}{2}y^2\,dx + z\,dy + x\,dz\right) = -\frac{\pi}{4}$$

21. Use Stokes' theorem to evaluate $\iint_S (curl\, \vec{\mathbf{F}} \cdot \vec{\mathbf{N}})dS$, where $\vec{\mathbf{F}}(x,y,z) = x\,\hat{\mathbf{i}} + y^2\,\hat{\mathbf{j}} + ze^{xy}\,\hat{\mathbf{k}}$ and $S$ is the part of surface $z = 1 - x^2 - 2y^2$ with $z \geq 0$, oriented counterclockwise.

22. Use Stokes' theorem for vector field $\vec{\mathbf{F}}(x,y,z) = z\,\hat{\mathbf{i}} + 3x\,\hat{\mathbf{j}} + 2z\hat{\mathbf{k}}$ where $S$ is surface $z = 1 - x^2 - 2y^2$, $z \geq 0$, $C$ is boundary circle $x^2 + y^2 = 1$, and $S$ is oriented in the positive $z$-direction.

**Answer**

$$\iint_S (curl\, \vec{\mathbf{F}} \cdot \vec{\mathbf{N}})dS = -3\pi$$

23. Use Stokes' theorem for vector field $\vec{\mathbf{F}}(x,y,z) = -\frac{3}{2}y^2\,\hat{\mathbf{i}} - 2xy\,\hat{\mathbf{j}} + yz\hat{\mathbf{k}}$, where $S$ is that part of the surface of plane $x + y + z = 1$ contained within triangle $C$ with vertices $(1,0,0)$, $(0,1,0)$, and $(0,0,1)$, traversed counterclockwise as viewed from above.

24. A certain closed path $C$ in plane $2x + 2y + z = 1$ is known to project onto unit circle $x^2 + y^2 = 1$ in the $xy$-plane. Let $C$ be a constant and let $\vec{\mathbf{R}}(x,y,z) = x\,\hat{\mathbf{i}} + y\,\hat{\mathbf{j}} + z\,\hat{\mathbf{k}}$. Use Stokes' theorem to evaluate $\int_C (c\,\hat{\mathbf{k}} \times \vec{\mathbf{R}}) \cdot dS$.

**Answer**

$$\int_C (c\,\hat{\mathbf{k}} \times \vec{\mathbf{R}}) \cdot dS = 2\pi c$$

25. Use Stokes' theorem and let $C$ be the boundary of surface $z = x^2 + y^2$ with $0 \le x \le 2$ and $0 \le y \le 1$ oriented with upward facing normal. Define $\vec{\mathbf{F}}(x, y, z) = \left(\sin(x^3) + xz\right)\hat{\mathbf{i}} + (x - yz)\hat{\mathbf{j}} + \cos(z^4)\hat{\mathbf{k}}$ and evaluate $\int_C \vec{\mathbf{F}} \cdot d\vec{S}$.

26. Let $S$ be hemisphere $x^2 + y^2 + z^2 = 4$ with $z \ge 0$, oriented upward. Let $\vec{\mathbf{F}}(x, y, z) = x^2 e^{yz}\hat{\mathbf{i}} + y^2 e^{xz}\hat{\mathbf{j}} + z^2 e^{xy}\hat{\mathbf{k}}$ be a vector field. Use Stokes' theorem to evaluate $\iint_S curl\, \vec{\mathbf{F}} \cdot d\vec{S}$.

**Answer**

$$\iint_S curl\, \vec{\mathbf{F}} \cdot d\vec{S} = 0$$

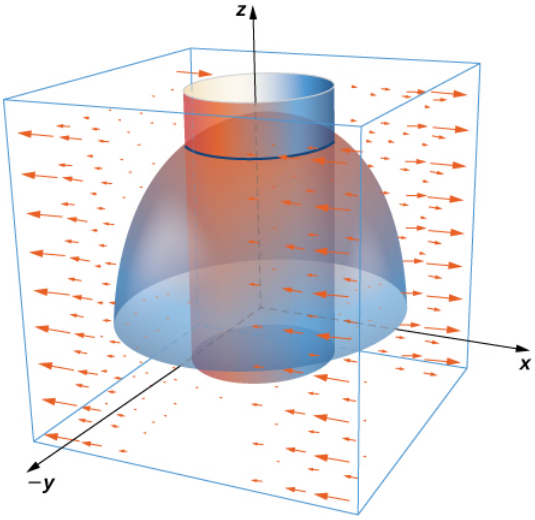
27. Let $\vec{\mathbf{F}}(x, y, z) = xy\,\hat{\mathbf{i}} + (e^{z^2} + y)\,\hat{\mathbf{j}} + (x + y)\,\hat{\mathbf{k}}$ and let $S$ be the graph of function $y = \frac{x^2}{9} + \frac{z^2}{9} - 1$ with $z \le 0$ oriented so that the normal vector $S$ has a positive $y$ component. Use Stokes' theorem to compute integral $\iint_S curl\, \vec{\mathbf{F}} \cdot d\vec{S}$.

28. Use Stokes' theorem to evaluate $\oint \vec{\mathbf{F}} \cdot d\vec{S}$, where $\vec{\mathbf{F}}(x, y, z) = y\,\hat{\mathbf{i}} + z\,\hat{\mathbf{j}} + x\,\hat{\mathbf{k}}$ and $C$ is a triangle with vertices $(0, 0, 0)$, $(2, 0, 0)$ and $0, -2, 2)$ oriented counterclockwise when viewed from above.

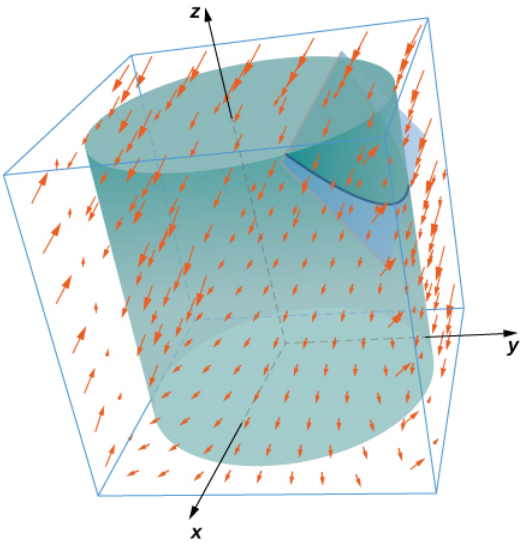
**Answer**

$$\oint \vec{\mathbf{F}} \cdot d\vec{S} = -4$$

29. Use the surface integral in Stokes' theorem to calculate the circulation of field $\vec{\mathbf{F}}$, $\vec{\mathbf{F}}(x, y, z) = x^2 y^3\,\hat{\mathbf{i}} + \hat{\mathbf{j}} + z\hat{\mathbf{k}}$ around $C$, which is the intersection of cylinder $x^2 + y^2 = 4$ and hemisphere $x^2 + y^2 + z^2 = 16$, $z \ge 0$, oriented counterclockwise when viewed from above.



30. Use Stokes' theorem to compute $\iint_S curl\, \vec{\mathbf{F}} \cdot d\vec{S}$. where $\vec{\mathbf{F}}(x, y, z) = \hat{\mathbf{i}} + xy^2\,\hat{\mathbf{j}} + xy^2\,\hat{\mathbf{k}}$ and $S$ is a part of plane $y + z = 2$ inside cylinder $x^2 + y^2 = 1$ and oriented counterclockwise.



**Answer**

$$\iint_S curl\, \vec{\mathbf{F}} \cdot dS = 0$$

31. Use Stokes' theorem to evaluate $\iint_S curl\, \vec{\mathbf{F}} \cdot dS$, where $\vec{\mathbf{F}}(x, y, z) = -y^2\,\hat{\mathbf{i}} + x\,\hat{\mathbf{j}} + z^2\,\hat{\mathbf{k}}$ and $S$ is the part of plane $x + y + z = 1$ in the positive octant and oriented counterclockwise $x \geq 0,\ y \geq 0,\ z \geq 0$.

32. Let $\vec{\mathbf{F}}(x, y, z) = xy\,\hat{\mathbf{i}} + 2z\,\hat{\mathbf{j}} - 2y\,\hat{\mathbf{k}}$ and let $C$ be the intersection of plane $x + z = 5$ and cylinder $x^2 + y^2 = 9$, which is oriented counterclockwise when viewed from the top. Compute the line integral of $\vec{\mathbf{F}}$ over $C$ using Stokes' theorem.

**Answer**

$$\iint_S curl\, \vec{\mathbf{F}} \cdot dS = -36\pi$$

33. [T] Use a CAS and let $\vec{\mathbf{F}}(x, y, z) = xy^2\,\hat{\mathbf{i}} + (yz - x)\,\hat{\mathbf{j}} + e^{yxz}\,\hat{\mathbf{k}}$. Use Stokes' theorem to compute the surface integral of curl $\vec{\mathbf{F}}$ over surface $S$ with inward orientation consisting of cube $[0, 1] \times [0, 1] \times [0, 1]$ with the right side missing.

34. Let $S$ be ellipsoid $\frac{x^2}{4} + \frac{y^2}{9} + z^2 = 1$ oriented counterclockwise and let $\vec{\mathbf{F}}$ be a vector field with component functions that have continuous partial derivatives.

**Answer**

$$\iint_S curl\, \vec{\mathbf{F}} \cdot \vec{\mathbf{N}} = 0$$

35. Let $S$ be the part of paraboloid $z = 9 - x^2 - y^2$ with $z \geq 0$. Verify Stokes' theorem for vector field $\vec{\mathbf{F}}(x, y, z) = 3z\,\hat{\mathbf{i}} + 4x\,\hat{\mathbf{j}} + 2y\,\hat{\mathbf{k}}$.

36. [T] Use a CAS and Stokes' theorem to evaluate $\oint \vec{\mathbf{F}} \cdot dS$, if $\vec{\mathbf{F}}(x, y, z) = (3z - \sin x)\,\hat{\mathbf{i}} + (x^2 + e^y)\,\hat{\mathbf{j}} + (y^3 - \cos z)\,\hat{\mathbf{k}}$, where $C$ is the curve given by $x = \cos t,\ y = \sin t,\ z = 1;\ 0 \leq t \leq 2\pi$.

**Answer**

$$\oint_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = 0$$

37. [T] Use a CAS and Stokes' theorem to evaluate $\vec{\mathbf{F}}(x, y, z) = 2y\,\hat{\mathbf{i}} + e^z\,\hat{\mathbf{j}} - \arctan x\,\hat{\mathbf{k}}$ with $S$ as a portion of paraboloid $z = 4 - x^2 - y^2$ cut off by the $xy$-plane oriented counterclockwise.

38. [T] Use a CAS to evaluate $\iint_S curl(F) \cdot dS$, where $\vec{\mathbf{F}}(x, y, z) = 2z\,\hat{\mathbf{i}} + 3x\,\hat{\mathbf{j}} + 5y\,\hat{\mathbf{k}}$ and $S$ is the surface parametrically by $\vec{\mathbf{r}}(r, \theta) = r\cos\theta\,\hat{\mathbf{i}} + r\sin\theta\,\hat{\mathbf{j}} + (4 - r^2)\,\hat{\mathbf{k}}\ (0 \leq \theta \leq 2\pi,\ 0 \leq r \leq 3)$.

**Answer**

$$\iint_S curl(F) \cdot dS = 84.8230$$

39. Let $S$ be paraboloid $z = a(1 - x^2 - y^2)$, for $z \geq 0$, where $a > 0$ is a real number. Let $\vec{\mathbf{F}}(x, y, z) = \langle x - y,\ y + z,\ z - x \rangle$. For what value(s) of $a$ (if any) does $\iint_S (\vec{\nabla} \times \vec{\mathbf{F}}) \cdot \vec{\mathbf{n}}\, dS$ have its maximum value?

**For application exercises 40 - 41, the goal is to evaluate $A = \iint_S (\vec{\nabla} \times \vec{\mathbf{F}}) \cdot \vec{\mathbf{n}}\, dS$, where $\vec{\mathbf{F}} = \langle xz,\ -xz,\ xy \rangle$ and $S$ is the upper half of ellipsoid $x^2 + y^2 + 8z^2 = 1$, where $z \geq 0$.**

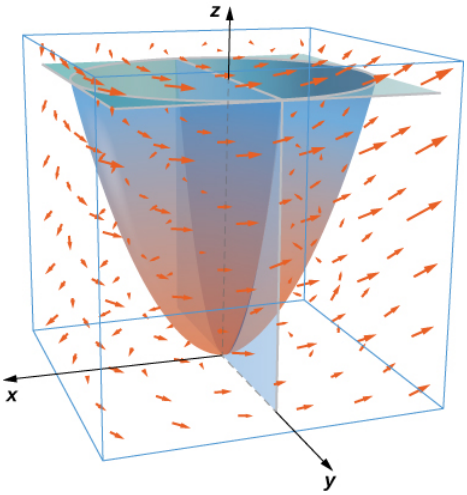
40. Evaluate a surface integral over a more convenient surface to find the value of $A$.

**Answer**

$$A = \iint_S (\vec{\nabla} \times \vec{\mathbf{F}}) \cdot \vec{\mathbf{n}}\, dS = 0$$

41. Evaluate $A$ using a line integral.

42. Take paraboloid $z = x^2 + y^2$, for $0 \leq z \leq 4$, and slice it with plane $y = 0$. Let $S$ be the surface that remains for $y \geq 0$, including the planar surface in the $xz$-plane. Let $C$ be the semicircle and line segment that bounded the cap of $S$ in plane $z = 4$ with counterclockwise orientation. Let $\vec{\mathbf{F}} = \langle 2z + y,\ 2x + z,\ 2y + x \rangle$. Evaluate $\iint_S (\vec{\nabla} \times \vec{\mathbf{F}}) \cdot \vec{\mathbf{n}}\, dS$.



**Answer**

$$\iint_S (\vec{\nabla} \times \vec{\mathbf{F}}) \cdot \vec{\mathbf{n}}\, dS = 2\pi$$

**For exercises 43 - 45, let $S$ be the disk enclosed by curve $C$ : $\vec{\mathbf{r}}(t) = \langle \cos\varphi \cos t,\ \sin t,\ \sin\varphi \cos t \rangle$, for $0 \leq t \leq 2\pi$, where $0 \leq \varphi \leq \frac{\pi}{2}$ is a fixed angle.**

43. What is the length of $C$ in terms of $\varphi$?

44. What is the circulation of $C$ of vector field $\vec{\mathbf{F}} = \langle -y,\ -z,\ x \rangle$ as a function of $\varphi$?

**Answer**

$$C = \pi(\cos\varphi - \sin\varphi)$$

45. For what value of $\varphi$ is the circulation a maximum?

46. Circle $C$ in plane $x + y + z = 8$ has radius $4$ and center $(2, 3, 3)$. Evaluate $\oint_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}$ for $\vec{\mathbf{F}} = \langle 0,\ -z,\ 2y \rangle$, where $C$ has a counterclockwise orientation when viewed from above.

**Answer**

$$\oint_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}} = 48\pi$$

47. Velocity field $v = \langle 0, 1 - x^2, 0 \rangle$, for $|x| \leq 1$ and $|z| \leq 1$, represents a horizontal flow in the $y$-direction. Compute the curl of $\vec{\mathbf{v}}$ in a clockwise rotation.

48. Evaluate integral $\iint_S (\vec{\nabla} \times \vec{\mathbf{F}}) \cdot \vec{\mathbf{n}}\, dS$, where $\vec{\mathbf{F}} = -xz\hat{\mathbf{i}} + yz\hat{\mathbf{j}} + xye^z\hat{\mathbf{k}}$ and $S$ is the cap of paraboloid $z = 5 - x^2 - y^2$ above plane $z = 3$, and $\vec{\mathbf{n}}$ points in the positive $z$-direction on $S$.

**Answer**

$$\iint_S (\vec{\nabla} \times \vec{\mathbf{F}}) \cdot \vec{\mathbf{n}} = 0$$

**In exercises 49 - 50, use Stokes' theorem to find the circulation of the following vector fields around any smooth, simple closed curve $C$.**

49. $\vec{\mathbf{F}} = \vec{\nabla}(x \sin ye^z)$

50. $\vec{\mathbf{F}} = \langle y^2z^3,\ z2xyz^3, 3xy^2z^2 \rangle$

**Answer**

**0**

# 16.9: The Divergence Theorem

**Learning Objectives**

- Explain the meaning of the divergence theorem.
- Use the divergence theorem to calculate the flux of a vector field.
- Apply the divergence theorem to an electrostatic field.

We have examined several versions of the Fundamental Theorem of Calculus in higher dimensions that relate the integral around an oriented boundary of a domain to a "derivative" of that entity on the oriented domain. In this section, we state the divergence theorem, which is the final theorem of this type that we will study. The divergence theorem has many uses in physics; in particular, the divergence theorem is used in the field of partial differential equations to derive equations modeling heat flow and conservation of mass. We use the theorem to calculate flux integrals and apply it to electrostatic fields.

**Overview of Theorems**

Before examining the divergence theorem, it is helpful to begin with an overview of the versions of the Fundamental Theorem of Calculus we have discussed:

1. The Fundamental Theorem of Calculus:

$$\int_a^b f'(x)\,dx = f(b) - f(a).$$

This theorem relates the integral of derivative $f'$ over line segment $[a, b]$ along the $x$-axis to a difference of $f$ evaluated on the boundary.

2. The Fundamental Theorem for Line Integrals:

$$\int_C \vec{\nabla} f \cdot d\vec{\mathbf{r}} = f(P_1) - f(P_0),$$

where $P_0$ is the initial point of $C$ and $P_1$ is the terminal point of $C$. The Fundamental Theorem for Line Integrals allows path $C$ to be a path in a plane or in space, not just a line segment on the $x$-axis. If we think of the gradient as a derivative, then this theorem relates an integral of derivative $\vec{\nabla} f$ over path $C$ to a difference of $f$ evaluated on the boundary of $C$.

3. Green's theorem, circulation form:

$$\iint_D (Q_x - P_y)\,dA = \int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}.$$

Since $Q_x - P_y = \text{curl } \vec{\mathbf{F}} \cdot \hat{\mathbf{k}}$ and curl is a derivative of sorts, Green's theorem relates the integral of derivative curl $\vec{\mathbf{F}}$ over planar region $D$ to an integral of $\vec{\mathbf{F}}$ over the boundary of $D$.

4. Green's theorem, flux form:

$$\iint_D (P_x + Q_y)\,dA = \int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\,dS.$$

Since $P_x + Q_y = \text{div } \vec{\mathbf{F}}$ and divergence is a derivative of sorts, the flux form of Green's theorem relates the integral of derivative div $\vec{\mathbf{F}}$ over planar region $D$ to an integral of $\vec{\mathbf{F}}$ over the boundary of $D$.

5. Stokes' theorem:

$$\iint_S curl\, \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}} = \int_C \vec{\mathbf{F}} \cdot d\vec{\mathbf{r}}.$$

If we think of the curl as a derivative of sorts, then Stokes' theorem relates the integral of derivative curl $\vec{\mathbf{F}}$ over surface $S$ (not necessarily planar) to an integral of $\vec{\mathbf{F}}$ over the boundary of $S$.

## Stating the Divergence Theorem

The divergence theorem follows the general pattern of these other theorems. If we think of divergence as a derivative of sorts, then the divergence theorem relates a triple integral of derivative div $\vec{\mathbf{F}}$ over a solid to a flux integral of $\vec{\mathbf{F}}$ over the boundary of the solid. More specifically, the divergence theorem relates a flux integral of vector field $\vec{\mathbf{F}}$ over a closed surface $S$ to a triple integral of the divergence of $\vec{\mathbf{F}}$ over the solid enclosed by $S$.

### The Divergence Theorem

Let $S$ be a piecewise, smooth closed surface that encloses solid $E$ in space. Assume that $S$ is oriented outward, and let $\vec{\mathbf{F}}$ be a vector field with continuous partial derivatives on an open region containing $E$ (Figure 16.9.1). Then

$$\iiint_E \operatorname{div} \vec{\mathbf{F}}\, dV = \iint_S \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}}. \tag{16.9.1}$$

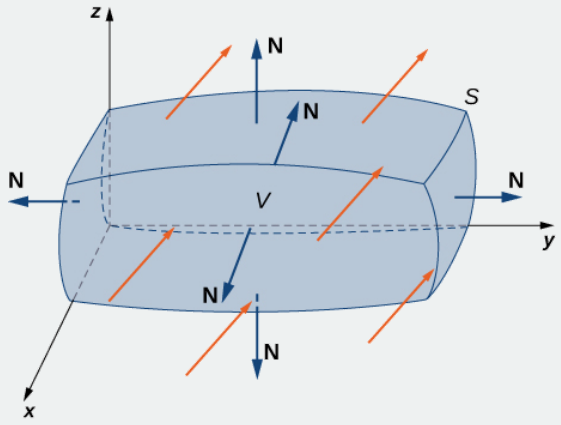

Figure 16.9.1: The divergence theorem relates a flux integral across a closed surface $S$ to a triple integral over solid $E$ enclosed by the surface.

Recall that the flux form of Green's theorem states that

$$\iint_D \operatorname{div} \vec{\mathbf{F}}\, dA = \int_C \vec{\mathbf{F}} \cdot \vec{\mathbf{N}}\, dS.$$

Therefore, the divergence theorem is a version of Green's theorem in one higher dimension.

The proof of the divergence theorem is beyond the scope of this text. However, we look at an informal proof that gives a general feel for why the theorem is true, but does not prove the theorem with full rigor. This explanation follows the informal explanation given for why Stokes' theorem is true.

### Proof

Let $B$ be a small box with sides parallel to the coordinate planes inside $E$ (Figure 16.9.2a). Let the center of $B$ have coordinates $(x, y, z)$ and suppose the edge lengths are $\Delta x$, $\Delta y$, and $\Delta z$. (Figure 16.9.1b). The normal vector out of the top of the box is $\hat{\mathbf{k}}$ and the normal vector out of the bottom of the box is $-\hat{\mathbf{k}}$. The dot product of $\vec{\mathbf{F}} = \langle P, Q, R \rangle$ with $\hat{\mathbf{k}}$ is $R$ and the dot product with $-\hat{\mathbf{k}}$ is $-R$. The area of the top of the box (and the bottom of the box) $\Delta S$ is $\Delta x \Delta y$.

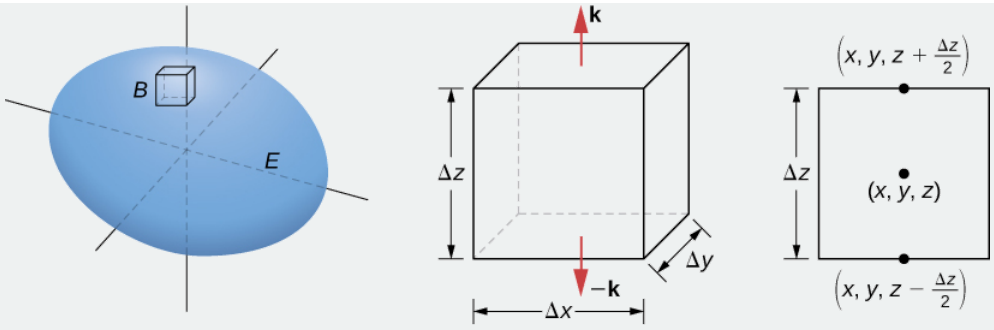

Figure 16.9.2: (a) A small box $B$ inside surface $E$ has sides parallel to the coordinate planes. (b) Box $B$ has side lengths $\Delta x$, $\Delta y$, and $\Delta z$ (c) If we look at the side view of $B$, we see that, since $(x, y, z)$ is the center of the box, to get to the top of the box we must travel a vertical distance of $\frac{\Delta z}{2}$ up from $(x, y, z)$. Similarly, to get to the bottom of the box we must travel a distance $\frac{\Delta z}{2}$ down from $(x, y, z)$.

The flux out of the top of the box can be approximated by $R\left(x, y, z+\frac{\Delta z}{2}\right)\,\Delta x\,\Delta y$ (Figure 16.9.2c) and the flux out of the bottom of the box is $-R\left(x, y, z-\frac{\Delta z}{2}\right)\,\Delta x\,\Delta y$. If we denote the difference between these values as $\Delta R$, then the net flux in the vertical direction can be approximated by $\Delta R\,\Delta x\,\Delta y$. However,

$$\Delta R\,\Delta x\,\Delta y = \left(\frac{\Delta R}{\Delta z}\right)\,\Delta x\,\Delta y\Delta z \approx \left(\frac{\partial R}{\partial z}\right)\,\Delta V.$$

Therefore, the net flux in the vertical direction can be approximated by $\left(\frac{\partial R}{\partial z}\right)\Delta V$. Similarly, the net flux in the $x$-direction can be approximated by $\left(\frac{\partial P}{\partial x}\right)\,\Delta V$ and the net flux in the $y$-direction can be approximated by $\left(\frac{\partial Q}{\partial y}\right)\,\Delta V$. Adding the fluxes in all three directions gives an approximation of the total flux out of the box:

$$\text{Total flux } \approx \left(\frac{\partial P}{\partial x}+\frac{\partial Q}{\partial y}+\frac{\partial R}{\partial z}\right)\Delta V = \text{div } \vec{\mathbf{F}}\,\Delta V.$$

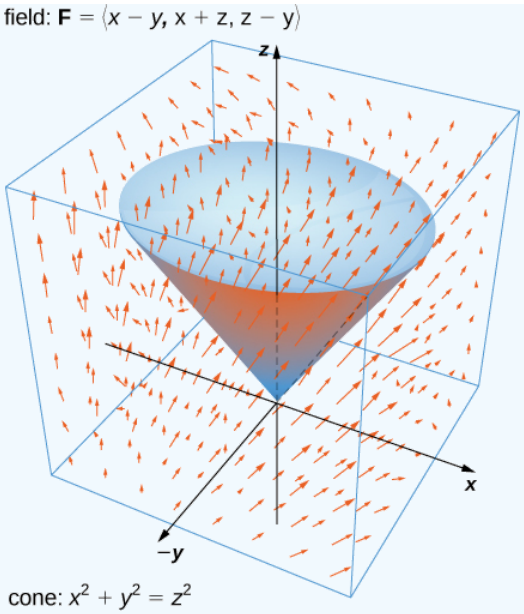
This approximation becomes arbitrarily close to the value of the total flux as the volume of the box shrinks to zero.

The sum of $\text{div } \vec{\mathbf{F}}\,\Delta V$ over all the small boxes approximating $E$ is approximately $\iiint_E \text{div } \vec{\mathbf{F}}\,dV$. On the other hand, the sum of $\text{div } \vec{\mathbf{F}}\,\Delta V$ over all the small boxes approximating $E$ is the sum of the fluxes over all these boxes. Just as in the informal proof of Stokes' theorem, adding these fluxes over all the boxes results in the cancelation of a lot of the terms. If an approximating box shares a face with another approximating box, then the flux over one face is the negative of the flux over the shared face of the adjacent box. These two integrals cancel out. When adding up all the fluxes, the only flux integrals that survive are the integrals over the faces approximating the boundary of $E$. As the volumes of the approximating boxes shrink to zero, this approximation becomes arbitrarily close to the flux over $S$.

□

## Example 16.9.1: Verifying the Divergence Theorem

Verify the divergence theorem for vector field $\vec{\mathbf{F}} = \langle x-y,\, x+z,\, z-y\rangle$ and surface $S$ that consists of cone $x^2+y^2=z^2$, $0 \le z \le 1$, and the circular top of the cone (see the following figure). Assume this surface is positively oriented.



**Solution**

Let $E$ be the solid cone enclosed by $S$. To verify the theorem for this example, we show that

$$\iiint_E \operatorname{div} \vec{\mathbf{F}}\, dV = \iint_S \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}}$$

by calculating each integral separately.

To compute the triple integral, note that $\operatorname{div} \vec{\mathbf{F}} = P_x + Q_y + R_z = 2$, and therefore the triple integral is

$$\begin{aligned}\iiint_E \operatorname{div} \vec{\mathbf{F}}\, dV &= 2 \iiint_E dV \\ &= 2\,(volume\ of\ E).\end{aligned}$$

The volume of a right circular cone is given by $\pi r^2 \frac{h}{3}$. In this case, $h = r = 1$. Therefore,

$$\iiint_E \operatorname{div} \vec{\mathbf{F}}\, dV = 2\,(volume\ of\ E) = \frac{2\pi}{3}.$$

To compute the flux integral, first note that $S$ is piecewise smooth; $S$ can be written as a union of smooth surfaces. Therefore, we break the flux integral into two pieces: one flux integral across the circular top of the cone and one flux integral across the remaining portion of the cone. Call the circular top $S_1$ and the portion under the top $S_2$. We start by calculating the flux across the circular top of the cone. Notice that $S_1$ has parameterization

$$\vec{\mathbf{r}}(u, v) = \langle u \cos v,\ u \sin v,\ 1\rangle,\ 0 \le u \le 1,\ 0 \le v \le 2\pi.$$

Then, the tangent vectors are $\vec{\mathbf{t}}_u = \langle \cos v,\ \sin v,\ 0\rangle$ and $\vec{\mathbf{t}}_v = \langle -u \sin v,\ u \cos v, 0\rangle$. Therefore, the flux across $S_1$ is

$$\begin{aligned}\iint_{S_1} \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}} &= \int_0^1 \int_0^{2\pi} \vec{\mathbf{F}}(\vec{\mathbf{r}}(u, v)) \cdot (\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v)\, dA \\ &= \int_0^1 \int_0^{2\pi} \langle u \cos v - u \sin v,\ u \cos v + 1,\ 1 - u \sin v\rangle \cdot \langle 0, 0, u\rangle\, dv\, du \\ &= \int_0^1 \int_0^{2\pi} u - u^2 \sin v\, dv du \\ &= \pi.\end{aligned}$$

We now calculate the flux over $S_2$. A parameterization of this surface is

$$\vec{\mathbf{r}}(u, v) = \langle u \cos v,\ u \sin v,\ u\rangle,\ 0 \le u \le 1,\ 0 \le v \le 2\pi.$$

The tangent vectors are $\vec{\mathbf{t}}_u = \langle \cos v,\ \sin v,\ 1\rangle$ and $\vec{\mathbf{t}}_v = \langle -u\sin v,\ u\cos v, 0\rangle$, so the cross product is

$$\vec{\mathbf{t}}_u \times \vec{\mathbf{t}}_v = \langle -u\cos v,\ -u\sin v,\ u\rangle.$$

Notice that the negative signs on the $x$ and $y$ components induce the negative (or inward) orientation of the cone. Since the surface is positively oriented, we use vector $\vec{\mathbf{t}}_v \times \vec{\mathbf{t}}_u = \langle u\cos v,\ u\sin v,\ -u\rangle$ in the flux integral. The flux across $S_2$ is then

$$\begin{aligned}\iint_{S_2} \vec{\mathbf{F}}\cdot d\vec{\mathbf{S}} &= \int_0^1\int_0^{2\pi} \vec{\mathbf{F}}(\vec{\mathbf{r}}(u,v))\cdot(\vec{\mathbf{t}}_u\times\vec{\mathbf{t}}_v)\,dA\\ &= \int_0^1\int_0^{2\pi} \langle u\cos v - u\sin v,\ u\cos v + u,\ u - u\sin v\rangle\cdot\langle u\cos v,\ u\sin v,\ -u\rangle\,dv\,du\\ &= \int_0^1\int_0^{2\pi} u^2\cos^2 v + 2u^2\sin v - u^2\,dv\,du\\ &= -\frac{\pi}{3}\end{aligned}$$

The total flux across $S$ is

$$\iint_S \vec{\mathbf{F}}\cdot d\vec{\mathbf{S}} = \iint_{S_1}\vec{\mathbf{F}}\cdot d\vec{\mathbf{S}} + \iint_{S_2}\vec{\mathbf{F}}\cdot d\vec{\mathbf{S}} = \frac{2\pi}{3} = \iiint_E \operatorname{div}\vec{\mathbf{F}}\,dV,$$

and we have verified the divergence theorem for this example.

**? Exercise 16.9.1**

Verify the divergence theorem for vector field $\vec{\mathbf{F}}(x,y,z) = \langle x+y+z,\ y,\ 2x-y\rangle$ and surface $S$ given by the cylinder $x^2+y^2=1$, $0\le z\le 3$ plus the circular top and bottom of the cylinder. Assume that $S$ is positively oriented.

**Hint**

Calculate both the flux integral and the triple integral with the divergence theorem and verify they are equal.

**Answer**

Both integrals equal $6\pi$.

Recall that the divergence of continuous field $\vec{\mathbf{F}}$ at point $P$ is a measure of the "outflowing-ness" of the field at $P$. If $\vec{\mathbf{F}}$ represents the velocity field of a fluid, then the divergence can be thought of as the rate per unit volume of the fluid flowing out less the rate per unit volume flowing in. The divergence theorem confirms this interpretation. To see this, let $P$ be a point and let $B_r$ be a ball of small radius $r$ centered at $P$ (Figure 16.9.3). Let $S_r$ be the boundary sphere of $B_r$. Since the radius is small and $\vec{\mathbf{F}}$ is continuous, $\operatorname{div}\vec{\mathbf{F}}(Q) \approx \operatorname{div}\vec{\mathbf{F}}(P)$ for all other points $Q$ in the ball. Therefore, the flux across $S_r$ can be approximated using the divergence theorem:

$$\iint_{S_r}\vec{\mathbf{F}}\cdot d\vec{\mathbf{S}} = \iiint_{B_r}\operatorname{div}\vec{\mathbf{F}}\,dV \approx \iiint_{B_r}\operatorname{div}\vec{\mathbf{F}}(P)\,dV.$$

Since $divF(P)$ is a constant,

$$\iiint_{B_r}\operatorname{div}\vec{\mathbf{F}}(P)\,dV = \operatorname{div}\vec{\mathbf{F}}(P)\,V(B_r).$$

Therefore, flux

$$\iint_{S_r}\vec{\mathbf{F}}\cdot d\vec{\mathbf{S}}$$

can be approximated by $\vec{\mathbf{F}}(P)\,V(B_r)$. This approximation gets better as the radius shrinks to zero, and therefore

$$\operatorname{div}\vec{\mathbf{F}}(P) = \lim_{r\to 0}\frac{1}{V(B_r)}\iint_{S_r}\vec{\mathbf{F}}\cdot d\vec{\mathbf{S}}.$$

This equation says that the divergence at $P$ is the net rate of outward flux of the fluid per unit volume.

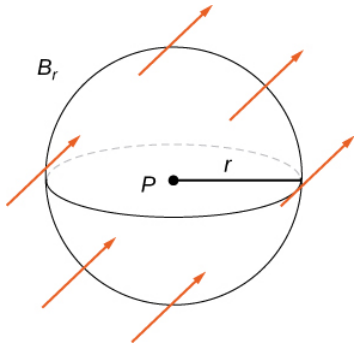


Figure 16.9.3: Ball $B_r$ of small radius $r$ centered at $P$.

## Using the Divergence Theorem

The divergence theorem translates between the flux integral of closed surface $S$ and a triple integral over the solid enclosed by $S$. Therefore, the theorem allows us to compute flux integrals or triple integrals that would ordinarily be difficult to compute by translating the flux integral into a triple integral and vice versa.

### Example 16.9.2: Applying the Divergence Theorem

Calculate the surface integral

$$\iint_S \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}},$$

where $S$ is cylinder $x^2 + y^2 = 1$, $0 \le z \le 2$, including the circular top and bottom, and $\vec{\mathbf{F}} = \left\langle \frac{x^3}{3} + yz,\ \frac{y^3}{3} - \sin(xz),\ z - x - y \right\rangle$.

**Solution**

We could calculate this integral without the divergence theorem, but the calculation is not straightforward because we would have to break the flux integral into three separate integrals: one for the top of the cylinder, one for the bottom, and one for the side. Furthermore, each integral would require parameterizing the corresponding surface, calculating tangent vectors and their cross product..

By contrast, the divergence theorem allows us to calculate the single triple integral

$$\iiint_E \operatorname{div} \vec{\mathbf{F}}\, dV,$$

where $E$ is the solid enclosed by the cylinder. Using the divergence theorem (Equation 16.9.1) and converting to cylindrical coordinates, we have

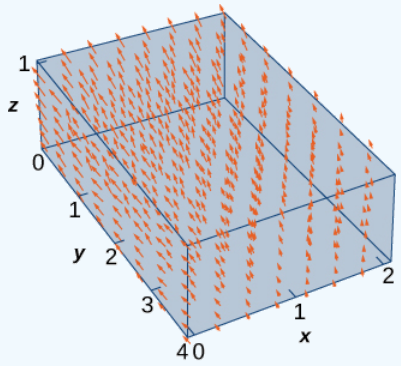
$$\begin{aligned}
\iint_S \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}} &= \iiint_E \operatorname{div} \vec{\mathbf{F}}\, dV, \\
&= \iiint_E (x^2 + y^2 + 1)\, dV \\
&= \int_0^{2\pi} \int_0^1 \int_0^2 (r^2 + 1)\, r\, dz\, dr\, d\theta \\
&= \frac{3}{2} \int_0^{2\pi} d\theta \\
&= 3\pi.
\end{aligned}$$

## Exercise 16.9.2

Use the divergence theorem to calculate flux integral

$$\iint_S \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}},$$

where $S$ is the boundary of the box given by $0 \le x \le 2,\ 0 \le y \le 4,\ 0 \le z \le 1$ and $\vec{\mathbf{F}} = \langle x^2 + yz,\ y - z,\ 2x + 2y + 2z \rangle$ (see the following figure).



**Hint**

Calculate the corresponding triple integral.

**Answer**

40

## Example 16.9.3: Applying the Divergence Theorem

Let $\vec{\mathbf{v}} = \langle -\frac{y}{z},\ \frac{x}{z},\ 0 \rangle$ be the velocity field of a fluid. Let $C$ be the solid cube given by $1 \le x \le 4,\ 2 \le y \le 5,\ 1 \le z \le 4$, and let $S$ be the boundary of this cube (see the following figure). Find the flow rate of the fluid across $S$.

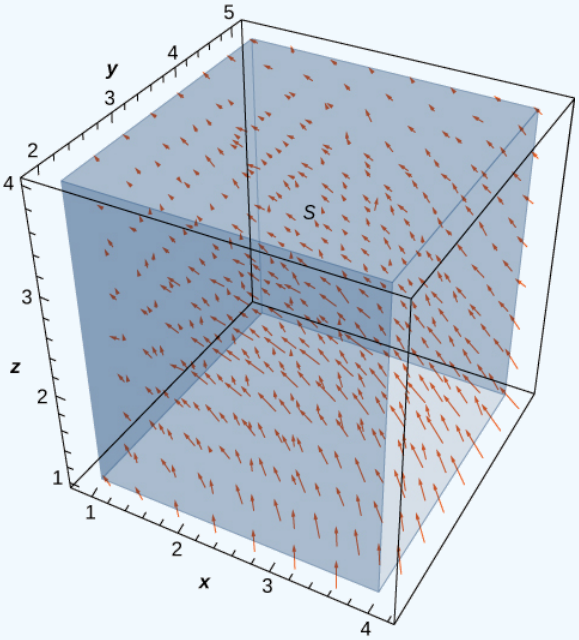


Figure 16.9.4: Vector field $\vec{\mathbf{v}} = \langle -\frac{y}{z},\ \frac{x}{z},\ 0 \rangle$.

**Solution**

The flow rate of the fluid across $S$ is $\iint_S \vec{\mathbf{v}} \cdot d\vec{\mathbf{S}}$. Before calculating this flux integral, let's discuss what the value of the integral should be. Based on Figure 16.9.4, we see that if we place this cube in the fluid (as long as the cube doesn't encompass the origin), then the rate of fluid entering the cube is the same as the rate of fluid exiting the cube. The field is rotational in nature and, for a given circle parallel to the $xy$-plane that has a center on the $z$-axis, the vectors along that circle are all the same magnitude. That is how we can see that the flow rate is the same entering and exiting the cube. The flow into the cube cancels with the flow out of the cube, and therefore the flow rate of the fluid across the cube should be zero.

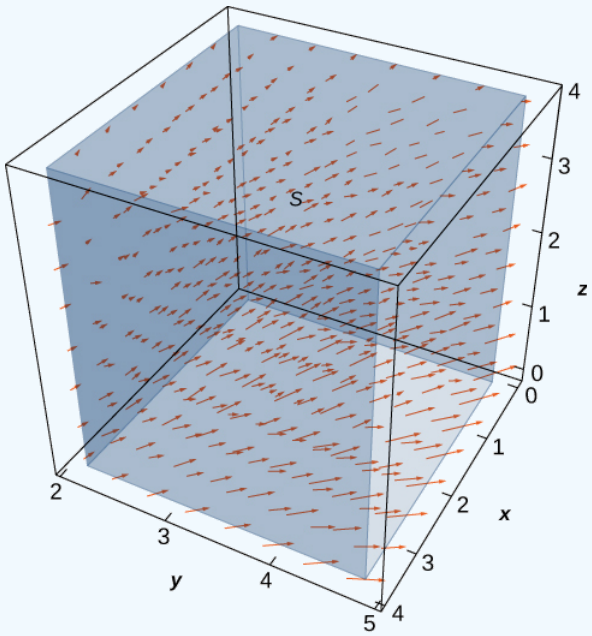
To verify this intuition, we need to calculate the flux integral. Calculating the flux integral directly requires breaking the flux integral into six separate flux integrals, one for each face of the cube. We also need to find tangent vectors, compute their cross product. However, using the divergence theorem makes this calculation go much more quickly:

$$\begin{aligned} \iint_S \vec{\mathbf{v}} \cdot d\vec{\mathbf{S}} &= \iiint_C \operatorname{div} \vec{\mathbf{v}}\, dV \\ &= \iiint_C 0\, dV = 0. \end{aligned}$$

Therefore the flux is zero, as expected.

**? Exercise 16.9.3**

Let $\vec{\mathbf{v}} = \langle \frac{x}{z}, \frac{y}{z}, 0 \rangle$ be the velocity field of a fluid. Let $C$ be the solid cube given by $1 \le x \le 4$, $2 \le y \le 5$, $1 \le z \le 4$, and let $S$ be the boundary of this cube (see the following figure). Find the flow rate of the fluid across $S$.



**Hint**

Use the divergence theorem and calculate a triple integral

**Answer**

$9 \ln(16)$

Example illustrates a remarkable consequence of the divergence theorem. Let $S$ be a piecewise, smooth closed surface and let $\vec{\mathbf{F}}$ be a vector field defined on an open region containing the surface enclosed by $S$. If $\vec{\mathbf{F}}$ has the form $F = \langle f(y,z), g(x,z), h(x,y) \rangle$, then the divergence of $\vec{\mathbf{F}}$ is zero. By the divergence theorem, the flux of $\vec{\mathbf{F}}$ across $S$ is also zero. This makes certain flux integrals incredibly easy to calculate. For example, suppose we wanted to calculate the flux integral $\iint_S \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}}$ where $S$ is a cube and

$$\vec{\mathbf{F}} = \langle \sin(y)\, e^{yz},\ x^2 z^2,\ \cos(xy)\, e^{\sin x} \rangle.$$

Calculating the flux integral directly would be difficult, if not impossible, using techniques we studied previously. At the very least, we would have to break the flux integral into six integrals, one for each face of the cube. But, because the divergence of this field is zero, the divergence theorem immediately shows that the flux integral is zero.

We can now use the divergence theorem to justify the physical interpretation of divergence that we discussed earlier. Recall that if $\vec{\mathbf{F}}$ is a continuous three-dimensional vector field and $P$ is a point in the domain of $\vec{\mathbf{F}}$, then the divergence of $\vec{\mathbf{F}}$ at $P$ is a measure of the "outflowing-ness" of $\vec{\mathbf{F}}$ at $P$. If $\vec{\mathbf{F}}$ represents the velocity field of a fluid, then the divergence of $\vec{\mathbf{F}}$ at $P$ is a measure of the net flow rate out of point $P$ (the flow of fluid out of $P$ less the flow of fluid in to $P$). To see how the divergence theorem justifies this interpretation, let $B_r$ be a ball of very small radius $r$ with center $P$, and assume that $B_r$ is in the domain of $\vec{\mathbf{F}}$. Furthermore, assume that $B_r$ has a positive, outward orientation. Since the radius of $B_r$ is small and $\vec{\mathbf{F}}$ is continuous, the divergence of $\vec{\mathbf{F}}$ is approximately constant on $B_r$. That is, ifv $P'$ is any point in $B_r$, then $\text{div}\ \vec{\mathbf{F}}(P) \approx \text{div}\ \vec{\mathbf{F}}(P')$. Let $S_r$ denote the boundary sphere of $B_r$. We can approximate the flux across $S_r$ using the divergence theorem as follows:

$$\begin{aligned} \iint_{S_r} \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}} &= \iiint_{B_r} \text{div}\ \vec{\mathbf{F}}\, dV \\ &\approx \iiint_{B_r} \text{div}\ \vec{\mathbf{F}}(P)\, dV \\ &= \text{div}\ \vec{\mathbf{F}}(P)\, V(B_r). \end{aligned}$$

As we shrink the radius $r$ to zero via a limit, the quantity $\text{div}\ \vec{\mathbf{F}}(P)\, V(B_r)$ gets arbitrarily close to the flux. Therefore,

$$\text{div}\ \vec{\mathbf{F}}(P) = \lim_{r \to 0} \frac{1}{V(B_r)} \iint_{S_r} \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}}$$

and we can consider the divergence at $P$ as measuring the net rate of outward flux per unit volume at $P$. Since "outflowing-ness" is an informal term for the net rate of outward flux per unit volume, we have justified the physical interpretation of divergence we discussed earlier, and we have used the divergence theorem to give this justification.

## Application to Electrostatic Fields

The divergence theorem has many applications in physics and engineering. It allows us to write many physical laws in both an integral form and a differential form (in much the same way that Stokes' theorem allowed us to translate between an integral and differential form of Faraday's law). Areas of study such as fluid dynamics, electromagnetism, and quantum mechanics have equations that describe the conservation of mass, momentum, or energy, and the divergence theorem allows us to give these equations in both integral and differential forms.

One of the most common applications of the divergence theorem is to **electrostatic fields**. An important result in this subject is **Gauss' law**. This law states that if $S$ is a closed surface in electrostatic field $\vec{\mathbf{E}}$, then the flux of $\vec{\mathbf{E}}$ across $S$ is the total charge enclosed by $S$ (divided by an electric constant). We now use the divergence theorem to justify the special case of this law in which the electrostatic field is generated by a stationary point charge at the origin.

If $(x, y, z)$ is a point in space, then the distance from the point to the origin is $r = \sqrt{x^2 + y^2 + z^2}$. Let $\vec{\mathbf{F}}_r$ denote radial vector field $\vec{\mathbf{F}}_r = \frac{1}{r^2} \left\langle \frac{x}{r}, \frac{y}{r}, \frac{z}{r} \right\rangle$.The vector at a given position in space points in the direction of unit radial vector $\left\langle \frac{x}{r}, \frac{y}{r}, \frac{z}{r} \right\rangle$ and is scaled by the quantity $1/r^2$. Therefore, the magnitude of a vector at a given point is inversely proportional to the square of the vector's distance from the origin. Suppose we have a stationary charge of $q$ Coulombs at the origin, existing in a vacuum. The charge generates electrostatic field $\vec{\mathbf{E}}$ given by

$$\vec{\mathbf{E}} = \frac{q}{4\pi\epsilon_0} \vec{\mathbf{F}}_r,$$

where the approximation $\epsilon_0 = 8.854 \times 10^{-12}$ farad (F)/m is an electric constant. (The constant $\epsilon_0$ is a measure of the resistance encountered when forming an electric field in a vacuum.) Notice that $\vec{\mathbf{E}}$ is a radial vector field similar to the gravitational field described in [link]. The difference is that this field points outward whereas the gravitational field points inward. Because

$$\vec{\mathbf{E}} = \frac{q}{4\pi\epsilon_0}\vec{\mathbf{F}}_r = \frac{q}{4\pi\epsilon_0}\left(\frac{1}{r^2}\left\langle \frac{x}{r}, \frac{y}{r}, \frac{z}{r}\right\rangle\right),$$

we say that electrostatic fields obey an inverse-square law. That is, the electrostatic force at a given point is inversely proportional to the square of the distance from the source of the charge (which in this case is at the origin). Given this vector field, we show that the flux across closed surface $S$ is zero if the charge is outside of $S$, and that the flux is $q/epsilon_0$ if the charge is inside of $S$. In other words, the flux across $S$ is the charge inside the surface divided by constant $\epsilon_0$. This is a special case of Gauss' law, and here we use the divergence theorem to justify this special case.

To show that the flux across $S$ is the charge inside the surface divided by constant $\epsilon_0$, we need two intermediate steps. First we show that the divergence of $\vec{\mathbf{F}}_r$ is zero and then we show that the flux of $\vec{\mathbf{F}}_r$ across any smooth surface $S$ is either zero or $4\pi$. We can then justify this special case of Gauss' law.

### Example 16.9.4: The Divergence of $F_r$ is Zero

Verify that the divergence of $\vec{\mathbf{F}}_r$ is zero where $\vec{\mathbf{F}}_r$ is defined (away from the origin).

**Solution**

Since $r = \sqrt{x^2+y^2+z^2}$, the quotient rule gives us

$$\begin{aligned}\frac{\partial}{\partial x}\left(\frac{x}{r^3}\right) &= \frac{\partial}{\partial x}\left(\frac{x}{(x^2+y^2+z^2)^{3/2}}\right)\\ &= \frac{(x^2+y^2+z^2)^{3/2} - x\left[\frac{3}{2}(x^2+y^2+z^2)^{1/2}2x\right]}{(x^2+y^2+z^2)^3}\\ &= \frac{r^3-3x^2r}{r^6} = \frac{r^2-3x^2}{r^5}.\end{aligned}$$

Similarly,

$$\frac{\partial}{\partial y}\left(\frac{y}{r^3}\right) = \frac{r^2-3y^2}{r^5} \text{ and } \frac{\partial}{\partial z}\left(\frac{z}{r^3}\right) = \frac{r^2-3z^2}{r^5}.$$

Therefore,

$$\begin{aligned}\text{div}\,\vec{\mathbf{F}}_r &= \frac{r^2-3x^2}{r^5} + \frac{r^2-3y^2}{r^5} + \frac{r^2-3z^2}{r^5}\\ &= \frac{3r^2-3(x^2+y^2+z^2)}{r^5}\\ &= \frac{3r^2-3r^2}{r^5} = 0.\end{aligned}$$

Notice that since the divergence of $\vec{\mathbf{F}}_r$ is zero and $\vec{\mathbf{E}}$ is $\vec{\mathbf{F}}_r$ scaled by a constant, the divergence of electrostatic field $\vec{\mathbf{E}}$ is also zero (except at the origin).

### Flux across a Smooth Surface

Let $S$ be a connected, piecewise smooth closed surface and let $\vec{\mathbf{F}}_r = \frac{1}{r^2}\left\langle \frac{x}{r}, \frac{y}{r}, \frac{z}{r}\right\rangle$. Then,

$$\iint_S \vec{\mathbf{F}}_r \cdot d\vec{\mathbf{S}} = \begin{cases} 0, & \text{if } S \text{ does not encompass the origin} \\ 4\pi, & \text{if } S \text{ encompasses the origin.}\end{cases}$$

In other words, this theorem says that the flux of $\vec{\mathbf{F}}_r$ across any piecewise smooth closed surface $S$ depends only on whether the origin is inside of $S$.

**Proof**

The logic of this proof follows the logic of [link], only we use the divergence theorem rather than Green's theorem.

First, suppose that $S$ does not encompass the origin. In this case, the solid enclosed by $S$ is in the domain of $\vec{\mathbf{F}}_\tau$, and since the divergence of $\vec{\mathbf{F}}_\tau$ is zero, we can immediately apply the divergence theorem and find that

$$\iint_S \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}}$$

is zero.

Now suppose that $S$ does encompass the origin. We cannot just use the divergence theorem to calculate the flux, because the field is not defined at the origin. Let $S_a$ be a sphere of radius $a$ inside of $S$ centered at the origin. The outward normal vector field on the sphere, in spherical coordinates, is

$$\vec{\mathbf{t}}_\phi \times \vec{\mathbf{t}}_\theta = \langle a^2 \cos\theta \sin^2\phi,\, a^2 \sin\theta \sin^2\phi,\, a^2 \sin\phi \cos\phi \rangle$$

(see [link]). Therefore, on the surface of the sphere, the dot product $\vec{\mathbf{F}}_\tau \cdot \vec{\mathbf{N}}$ (in spherical coordinates) is

$$\begin{aligned} \vec{\mathbf{F}}_\tau \cdot \vec{\mathbf{N}} &= \left\langle \frac{\sin\phi\cos\theta}{a^2}, \frac{\sin\phi\sin\theta}{a^2}, \frac{\cos\phi}{a^2} \right\rangle \cdot \langle a^2\cos\theta\sin^2\phi, a^2\sin\theta\sin^2\phi,\, a^2\sin\phi\cos\phi\rangle \\ &= \sin\phi(\langle \sin\phi\cos\theta,\, \sin\phi\sin\theta,\, \cos\phi\rangle \cdot \langle \sin\phi\cos\theta, \sin\phi\sin\theta,\, \cos\phi\rangle) \\ &= \sin\phi. \end{aligned}$$

The flux of $\vec{\mathbf{F}}_\tau$ across $S_a$ is

$$\iint_{S_a} \vec{\mathbf{F}}_\tau \cdot \vec{\mathbf{N}} dS = \int_0^{2\pi} \int_0^{\pi} \sin\phi \, d\phi \, d\theta = 4\pi.$$

Now, remember that we are interested in the flux across $S$, not necessarily the flux across $S_a$. To calculate the flux across $S$, let $E$ be the solid between surfaces $S_a$ and $S$. Then, the boundary of $E$ consists of $S_a$ and $S$. Denote this boundary by $S - S_a$ to indicate that $S$ is oriented outward but now $S_a$ is oriented inward. We would like to apply the divergence theorem to solid $E$. Notice that the divergence theorem, as stated, can't handle a solid such as $E$ because $E$ has a hole. However, the divergence theorem can be extended to handle solids with holes, just as Green's theorem can be extended to handle regions with holes. This allows us to use the divergence theorem in the following way. By the divergence theorem,

$$\begin{aligned} \iint_{S-S_a} \vec{\mathbf{F}}_\tau \cdot d\vec{\mathbf{S}} &= \iint_S \vec{\mathbf{F}}_\tau \cdot d\vec{\mathbf{S}} - \iint_{S_a} \vec{\mathbf{F}}_\tau \cdot d\vec{\mathbf{S}} \\ &= \iiint_E \operatorname{div} \vec{\mathbf{F}}_\tau \, dV \\ &= \iiint_E 0 \, dV = 0. \end{aligned}$$

Therefore,

$$\iint_S \vec{\mathbf{F}}_\tau \cdot d\vec{\mathbf{S}} = \iint_{S_a} \vec{\mathbf{F}}_\tau \cdot d\vec{\mathbf{S}} = 4\pi,$$

and we have our desired result.

□

Now we return to calculating the flux across a smooth surface in the context of electrostatic field $\vec{\mathbf{E}} = \frac{q}{4\pi\epsilon_0}\vec{\mathbf{F}}_\tau$ of a point charge at the origin. Let $S$ be a piecewise smooth closed surface that encompasses the origin. Then

$$\begin{aligned}\iint_S \vec{\mathbf{E}} \cdot d\vec{\mathbf{S}} &= \iint_S \frac{q}{4\pi\epsilon_0}\vec{\mathbf{F}}_r \cdot d\vec{\mathbf{S}} \\ &= \frac{q}{4\pi\epsilon_0}\iint_S \vec{\mathbf{F}}_r \cdot d\vec{\mathbf{S}} \\ &= \frac{q}{\epsilon_0}.\end{aligned}$$

If $S$ does not encompass the origin, then

$$\iint_S \vec{\mathbf{E}} \cdot d\vec{\mathbf{S}} = \frac{q}{4\pi\epsilon_0}\iint_S \vec{\mathbf{F}}_r \cdot d\vec{\mathbf{S}} = 0.$$

Therefore, we have justified the claim that we set out to justify: the flux across closed surface $S$ is zero if the charge is outside of $S$, and the flux is $q/\epsilon_0$ if the charge is inside of $S$.

This analysis works only if there is a single point charge at the origin. In this case, Gauss' law says that the flux of $\vec{\mathbf{E}}$ across $S$ is the total charge enclosed by $S$. Gauss' law can be extended to handle multiple charged solids in space, not just a single point charge at the origin. The logic is similar to the previous analysis, but beyond the scope of this text. In full generality, Gauss' law states that if $S$ is a piecewise smooth closed surface and $Q$ is the total amount of charge inside of $S$, then the flux of $\vec{\mathbf{E}}$ across $S$ is $Q/\epsilon_0$.

### Example 16.9.5: Using Gauss' law

Suppose we have four stationary point charges in space, all with a charge of 0.002 Coulombs (C). The charges are located at $(0,0,1)$, $(1,1,4)$, $(-1,0,0)$, and $(-2,-2,2)$. Let $\vec{\mathbf{E}}$ denote the electrostatic field generated by these point charges. If $S$ is the sphere of radius $2$ oriented outward and centered at the origin, then find

$$\iint_S \vec{\mathbf{E}} \cdot d\vec{\mathbf{S}}.$$

**Solution**

According to Gauss' law, the flux of $\vec{\mathbf{E}}$ across $S$ is the total charge inside of $S$ divided by the electric constant. Since $S$ has radius $2$, notice that only two of the charges are inside of $S$: the charge at $(0,1,1)$ and the charge at $(-1,0,0)$. Therefore, the total charge encompassed by $S$ is $0.004$ and, by Gauss' law,

$$\iint_S \vec{\mathbf{E}} \cdot d\vec{\mathbf{S}} = \frac{0.004}{8.854 \times 10^{-12}} \approx 4.418 \times 10^9\, V - m.$$

### Exercise 16.9.4

Work the previous example for surface $S$ that is a sphere of radius 4 centered at the origin, oriented outward.

**Hint**

Use Gauss' law.

**Answer**

$\approx 6.777 \times 10^9$

## Key Concepts

- The divergence theorem relates a surface integral across closed surface $S$ to a triple integral over the solid enclosed by $S$. The divergence theorem is a higher dimensional version of the flux form of Green's theorem, and is therefore a higher dimensional version of the Fundamental Theorem of Calculus.
- The divergence theorem can be used to transform a difficult flux integral into an easier triple integral and vice versa.
- The divergence theorem can be used to derive Gauss' law, a fundamental law in electrostatics.

## Key Equations

- **Divergence theorem**

$$\iiint_E \operatorname{div} \vec{\mathbf{F}}\, dV = \iint_S \vec{\mathbf{F}} \cdot d\vec{\mathbf{S}}$$

## Glossary

**divergence theorem**
a theorem used to transform a difficult flux integral into an easier triple integral and vice versa

**Gauss' law**
if $S$ is a piecewise, smooth closed surface in a vacuum and $Q$ is the total stationary charge inside of $S$, then the flux of electrostatic field $\vec{\mathbf{E}}$ across $S$ is $Q/\epsilon_0$

**inverse-square law**
the electrostatic force at a given point is inversely proportional to the square of the distance from the source of the charge

# 16.9E: Exercises for Section 16.8

**For exercises 1 - 9, use a computer algebraic system (CAS) and the divergence theorem to evaluate surface integral $\int_S \vec{\mathbf{F}} \cdot \vec{\mathbf{n}}\, ds$ for the given choice of $\vec{\mathbf{F}}$ and the boundary surface $S$. For each closed surface, assume $\vec{\mathbf{N}}$ is the outward unit normal vector.**

1. [T] $\vec{\mathbf{F}}(x,y,z) = x\,\hat{\mathbf{i}} + y\,\hat{\mathbf{j}} + z\,\hat{\mathbf{k}}$; $S$ is the surface of cube $0 \le x \le 1$, $0 \le y \le 1$, $0 < z \le 1$.

2. [T] $\vec{\mathbf{F}}(x,y,z) = (\cos yz)\,\hat{\mathbf{i}} + e^{xz}\,\hat{\mathbf{j}} + 3z^2\,\hat{\mathbf{k}}$; $S$ is the surface of hemisphere $z = \sqrt{4 - x^2 - y^2}$ together with disk $x^2 + y^2 \le 4$ in the $xy$-plane.

**Answer**

$$\int_S \vec{\mathbf{F}} \cdot \vec{\mathbf{n}}\, ds = 75.3982$$

3. [T] $\vec{\mathbf{F}}(x,y,z) = (x^2 + y^2 - x^2)\,\hat{\mathbf{i}} + x^2 y\,\hat{\mathbf{j}} + 3z\,\hat{\mathbf{k}}$; $S$ is the surface of the five faces of unit cube $0 \le x \le 1$, $0 \le y \le 1$, $0 < z \le 1$.

4. [T] $\vec{\mathbf{F}}(x,y,z) = x\,\hat{\mathbf{i}} + y\,\hat{\mathbf{j}} + z\,\hat{\mathbf{k}}$; $S$ is the surface of paraboloid $z = x^2 + y^2$ for $0 \le z \le 9$.

**Answer**

$$\int_S \vec{\mathbf{F}} \cdot \vec{\mathbf{n}}\, ds = 127.2345$$

5. [T] $\vec{\mathbf{F}}(x,y,z) = x^2\,\hat{\mathbf{i}} + y^2\,\hat{\mathbf{j}} + z^2\,\hat{\mathbf{k}}$; $S$ is the surface of sphere $x^2 + y^2 + z^2 = 4$.

6. [T] $\vec{\mathbf{F}}(x,y,z) = x\,\hat{\mathbf{i}} + y\,\hat{\mathbf{j}} + (z^2 - 1)\,\hat{\mathbf{k}}$; $S$ is the surface of the solid bounded by cylinder $x^2 + y^2 = 4$ and planes $z = 0$ and $z = 1$.

**Answer**

$$\int_S \vec{\mathbf{F}} \cdot \vec{\mathbf{n}}\, ds = 37.699$$

7. [T] $\vec{\mathbf{F}}(x,y,z) = x^2\,\hat{\mathbf{i}} + y^2\,\hat{\mathbf{j}} + z^2\,\hat{\mathbf{k}}$; $S$ is the surface bounded above by sphere $\rho = 2$ and below by cone $\varphi = \frac{\pi}{4}$ in spherical coordinates. (Think of $S$ as the surface of an "ice cream cone.")

8. [T] $\vec{\mathbf{F}}(x,y,z) = x^3\,\hat{\mathbf{i}} + y^3\,\hat{\mathbf{j}} + 3a^2 z\,\hat{\mathbf{k}}$ ($constant\ a > 0$); $S$ is the surface bounded by cylinder $x^2 + y^2 = a^2$ and planes $z = 0$ and $z = 1$.

**Answer**

$$\int_S \vec{\mathbf{F}} \cdot \vec{\mathbf{n}}\, ds = \frac{9\pi a^4}{2}$$

9. [T] Surface integral $\iint_S \vec{\mathbf{F}} \cdot dS$, where $S$ is the solid bounded by paraboloid $z = x^2 + y^2$ and plane $z = 4$, and $\vec{\mathbf{F}}(x,y,z) = (x + y^2 z^2)\,\hat{\mathbf{i}} + (y + z^2 x^2)\,\hat{\mathbf{j}} + (z + x^2 y^2)\,\hat{\mathbf{k}}$

10. Use the divergence theorem to calculate surface integral $\iint_S \vec{\mathbf{F}} \cdot dS$, where $\vec{\mathbf{F}}(x,y,z) = (e^{y^2}\,\hat{\mathbf{i}} + (y + \sin(z^2))\,\hat{\mathbf{j}} + (z - 1)\,\hat{\mathbf{k}}$ and $S$ is upper hemisphere $x^2 + y^2 + z^2 = 1$, $z \ge 0$, oriented upward.

**Answer**

$$\iint_S \vec{\mathbf{F}} \cdot dS = \frac{\pi}{3}$$

11. Use the divergence theorem to calculate surface integral $\iint_S \vec{\mathbf{F}} \cdot dS$, where $\vec{\mathbf{F}}(x,y,z) = x^4\,\hat{\mathbf{i}} - x^3 z^2\,\hat{\mathbf{j}} + 4xy^2 z\,\hat{\mathbf{k}}$ and $S$ is the surface bounded by cylinder $x^2 + y^2 = 1$ and planes $z = x + 2$ and $z = 0$.

12. Use the divergence theorem to calculate surface integral $\iint_S \vec{\mathbf{F}} \cdot dS$, when $\vec{\mathbf{F}}(x,y,z) = x^2 z^3\,\hat{\mathbf{i}} + 2xyz^3\,\hat{\mathbf{j}} + xz^4\,\hat{\mathbf{k}}$ and $S$ is the surface of the box with vertices $(\pm 1, \pm 2, \pm 3)$.

**Answer**

$$\iint_S \vec{\mathbf{F}} \cdot dS = 0$$

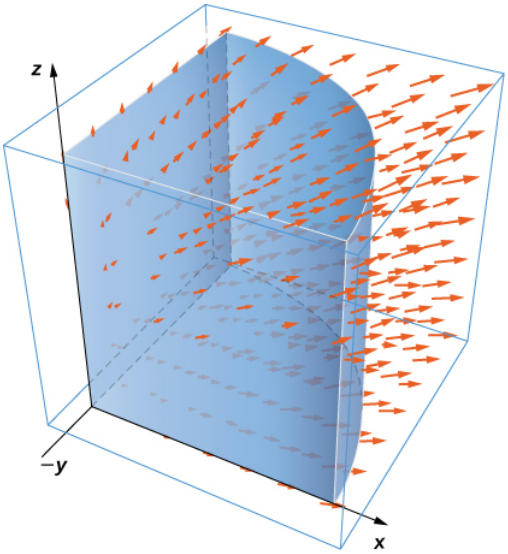
13. Use the divergence theorem to calculate surface integral $\iint_S \vec{\mathbf{F}} \cdot dS$, when $\vec{\mathbf{F}}(x, y, z) = z \tan^{-1}(y^2)\,\hat{\mathbf{i}} + z^3 \ln(x^2 + 1)\,\hat{\mathbf{j}} + z\,\hat{\mathbf{k}}$ and $S$ is a part of paraboloid $x^2 + y^2 + z = 2$ that lies above plane $z = 1$ and is oriented upward.

14. [T] Use a CAS and the divergence theorem to calculate flux $\iint_S \vec{\mathbf{F}} \cdot dS$, where $\vec{\mathbf{F}}(x, y, z) = (x^3 + y^3)\,\hat{\mathbf{i}} + (y^3 + z^3)\,\hat{\mathbf{j}} + (z^3 + x^3)\,\hat{\mathbf{k}}$ and $S$ is a sphere with center $(0, 0)$ and radius $2$.

**Answer**

$$\iint_S \vec{\mathbf{F}} \cdot dS = 241.2743$$

15. Use the divergence theorem to compute the value of flux integral $\iint_S \vec{\mathbf{F}} \cdot dS$, where $\vec{\mathbf{F}}(x, y, z) = (y^3 + 3x)\,\hat{\mathbf{i}} + (xz + y)\,\hat{\mathbf{j}} + (z + x^4 \cos(x^2 y))\,\hat{\mathbf{k}}$ and $S$ is the area of the region bounded by $x^2 + y^2 = 1$, $x \geq 0$, $y \geq 0$, and $0 \leq z \leq 1$.



16. Use the divergence theorem to compute flux integral $\iint_S \vec{\mathbf{F}} \cdot dS$, where $\vec{\mathbf{F}}(x, y, z) = y\,\hat{\mathbf{j}} - z\,\hat{\mathbf{k}}$ and $S$ consists of the union of paraboloid $y = x^2 + z^2$, $0 \leq y \leq 1$, and disk $x^2 + z^2 \leq 1$, $y = 1$, oriented outward. What is the flux through just the paraboloid?

**Answer**

$$\iint_S \vec{\mathbf{F}} \cdot dS = -\pi$$

17. Use the divergence theorem to compute flux integral $\iint_S \vec{\mathbf{F}} \cdot dS$, where $\vec{\mathbf{F}}(x, y, z) = x\,\hat{\mathbf{i}} + y\,\hat{\mathbf{j}} + z^4\,\hat{\mathbf{k}}$ and $S$ is a part of cone $z = \sqrt{x^2 + y^2}$ beneath top plane $z = 1$ oriented downward.

18. Use the divergence theorem to calculate surface integral $\iint_S \vec{\mathbf{F}} \cdot dS$ for $\vec{\mathbf{F}}(x, y, z) = x^4\,\hat{\mathbf{i}} - x^3 z^2\,\hat{\mathbf{j}} + 4xy^2 z\,\hat{\mathbf{k}}$, where $S$ is the surface bounded by cylinder $x^2 + y^2 = 1$ and planes $z = x + 2$ and $z = 0$.

**Answer**

$$\iint_S \vec{\mathbf{F}} \cdot dS = \frac{2\pi}{3}$$

19. Consider $\vec{\mathbf{F}}(x, y, z) = x^2\,\hat{\mathbf{i}} + xy\,\hat{\mathbf{j}} + (z + 1)\,\hat{\mathbf{k}}$. Let $E$ be the solid enclosed by paraboloid $z = 4 - x^2 - y^2$ and plane $z = 0$ with normal vectors pointing outside $E$. Compute flux $\vec{\mathbf{F}}$ across the boundary of $E$ using the divergence theorem.

**In exercises 20 - 23, use a CAS along with the divergence theorem to compute the net outward flux for the fields across the given surfaces $S$.**

20. [T] $\vec{\mathbf{F}} = \langle x, -2y, 3z\rangle$; $S$ is sphere $\{(x, y, z) : x^2 + y^2 + z^2 = 6\}$.

**Answer**

$15\sqrt{6}\pi$

21. [T] $\vec{\mathbf{F}} = \langle x, 2y, z\rangle$; $S$ is the boundary of the tetrahedron in the first octant formed by plane $x + y + z = 1$.

22. [T] $\vec{\mathbf{F}} = \langle y - 2x, x^3 - y, y^2 - z\rangle$; $S$ is sphere $\{(x, y, z) : x^2 + y^2 + z^2 = 4\}$.

**Answer**

$-\frac{128}{3}\pi$

23. [T] $\vec{\mathbf{F}} = \langle x, y, z\rangle$; $S$ is the surface of paraboloid $z = 4 - x^2 - y^2$, for $z \geq 0$, plus its base in the $xy$-plane.

**For exercises 24 - 26, use a CAS and the divergence theorem to compute the net outward flux for the vector fields across the boundary of the given regions $D$.**

24. [T] $\vec{\mathbf{F}} = \langle z - x, x - y, 2y - z\rangle$; $D$ is the region between spheres of radius 2 and 4 centered at the origin.

**Answer**

$-703.7168$

25. [T] $\vec{\mathbf{F}} = \dfrac{\vec{\mathbf{r}}}{\|\vec{\mathbf{r}}\|} = \dfrac{\langle x, y, z\rangle}{\sqrt{x^2 + y^2 + z^2}}$; $D$ is the region between spheres of radius 1 and 2 centered at the origin.

26. [T] $\vec{\mathbf{F}} = \langle x^2, -y^2, z^2\rangle$; $D$ is the region in the first octant between planes $z = 4 - x - y$ and $z = 2 - x - y$.

**Answer**

20

27. Let $\vec{\mathbf{F}}(x, y, z) = 2x\,\hat{\mathbf{i}} - 3xy\,\hat{\mathbf{j}} + xz^2\,\hat{\mathbf{k}}$. Use the divergence theorem to calculate $\iint_S \vec{\mathbf{F}} \cdot d\vec{S}$, where $S$ is the surface of the cube with corners at $(0, 0, 0)$, $(1, 0, 0)$, $(0, 1, 0)$, $(1, 1, 0)$, $(0, 0, 1)$, $(1, 0, 1)$, $(0, 1, 1)$, and $(1, 1, 1)$, oriented outward.

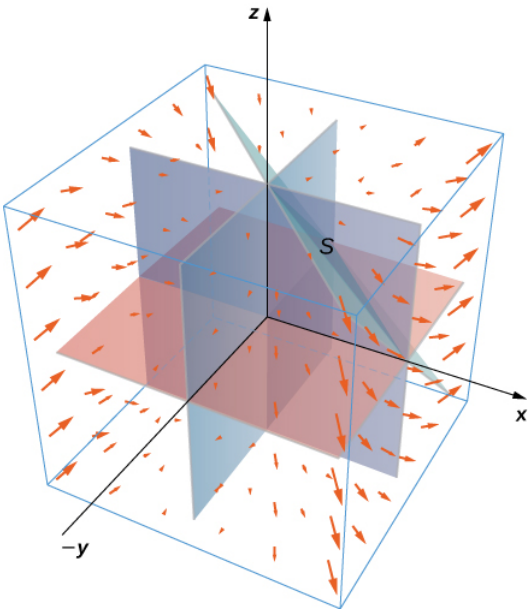
28. Use the divergence theorem to find the outward flux of field $\vec{\mathbf{F}}(x, y, z) = (x^3 - 3y)\,\hat{\mathbf{i}} + (2yz + 1)\,\hat{\mathbf{j}} + xyz\,\hat{\mathbf{k}}$ through the cube bounded by planes $x = \pm 1$, $y = \pm 1$, and $z = \pm 1$.

**Answer**

$\iint_S \vec{\mathbf{F}} \cdot d\vec{S} = 8$

29. Let $\vec{\mathbf{F}}(x, y, z) = 2x\,\hat{\mathbf{i}} - 3y\,\hat{\mathbf{j}} + 5z\,\hat{\mathbf{k}}$ and let $S$ be hemisphere $z = \sqrt{9 - x^2 - y^2}$ together with disk $x^2 + y^2 \leq 9$ in the $xy$-plane. Use the divergence theorem.

30. Evaluate $\iint_S \vec{\mathbf{F}} \cdot \vec{\mathbf{n}}\, dS$, where $\vec{\mathbf{F}}(x, y, z) = x^2\,\hat{\mathbf{i}} + xy\,\hat{\mathbf{j}} + x^3y^3\,\hat{\mathbf{k}}$ and $S$ is the surface consisting of all faces except the tetrahedron bounded by plane $x + y + z = 1$ and the coordinate planes, with outward unit normal vector $\vec{\mathbf{N}}$.



**Answer**

$$\iint_S \vec{\mathbf{F}} \cdot \vec{\mathbf{n}}\, dS = \frac{1}{8}$$

31. Find the net outward flux of field $\vec{\mathbf{F}} = \langle bz - cy,\ cx - az,\ ay - bx \rangle$ across any smooth closed surface in $R^3$ where $a$, $b$, and $c$ are constants.

32. Use the divergence theorem to evaluate $\iint_S ||\vec{\mathbf{R}}||\vec{\mathbf{R}} \cdot \vec{\mathbf{n}}\, ds$, where $\vec{\mathbf{R}}(x, y, z) = x\,\hat{\mathbf{i}} + y\,\hat{\mathbf{j}} + z\,\hat{\mathbf{k}}$ and $S$ is sphere $x^2 + y^2 + z^2 = a^2$, with constant $a > 0$.

**Answer**

$$\iint_S ||\vec{\mathbf{R}}||\vec{\mathbf{R}} \cdot \vec{\mathbf{n}}\, ds = 4\pi a^4$$

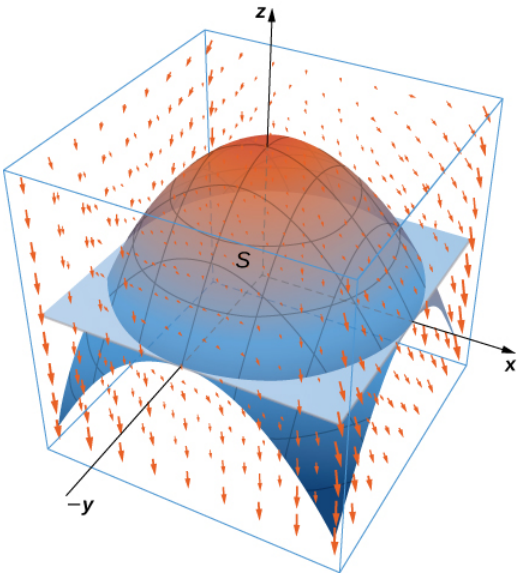
33. Use the divergence theorem to evaluate $\iint_S \vec{\mathbf{F}} \cdot dS$, where $\vec{\mathbf{F}}(x, y, z) = y^2 z\,\hat{\mathbf{i}} + y^3\,\hat{\mathbf{j}} + xz\,\hat{\mathbf{k}}$ and $S$ is the boundary of the cube defined by $-1 \le x \le 1$, $-1 \le y \le 1$, and $0 \le z \le 2$.

34. Let $R$ be the region defined by $x^2 + y^2 + z^2 \le 1$. Use the divergence theorem to find $\iiint_R z^2\, dV$.

**Answer**

$$\iiint_R z^2 dV = \frac{4\pi}{15}$$

35. Let $E$ be the solid bounded by the $xy$-plane and paraboloid $z = 4 - x^2 - y^2$ so that $S$ is the surface of the paraboloid piece together with the disk in the $xy$-plane that forms its bottom. If $\vec{\mathbf{F}}(x, y, z) = (xz \sin(yz) + x^3)\,\hat{\mathbf{i}} + \cos(yz)\,\hat{\mathbf{j}} + (3zy^2 - e^{x^2+y^2})\,\hat{\mathbf{k}}$, find $\iint_S \vec{\mathbf{F}} \cdot dS$ using the divergence theorem.



36. Let $E$ be the solid unit cube with diagonally opposite corners at the origin and $(1,1,1)$, and faces parallel to the coordinate planes. Let $S$ be the surface of $E$, oriented with the outward-pointing normal. Use a CAS to find $\iint_S \vec{\mathbf{F}} \cdot dS$ using the divergence theorem if $\vec{\mathbf{F}}(x,y,z) = 2xy\,\hat{\mathbf{i}} + 3ye^z\,\hat{\mathbf{j}} + x\sin z\,\hat{\mathbf{k}}$.

**Answer**

$$\iint_S \vec{\mathbf{F}} \cdot dS = 6.5759$$

37. Use the divergence theorem to calculate the flux of $\vec{\mathbf{F}}(x,y,z) = x^3\,\hat{\mathbf{i}} + y^3\,\hat{\mathbf{j}} + z^3\,\hat{\mathbf{k}}$ through sphere $x^2 + y^2 + z^2 = 1$.

38. Find $\iint_S \vec{\mathbf{F}} \cdot dS$, where $\vec{\mathbf{F}}(x,y,z) = x\,\hat{\mathbf{i}} + y\,\hat{\mathbf{j}} + z\,\hat{\mathbf{k}}$ and $S$ is the outwardly oriented surface obtained by removing cube $[1,2] \times [1,2] \times [1,2]$ from cube $[0,2] \times [0,2] \times [0,2]$.

**Answer**

$$\iint_S \vec{\mathbf{F}} \cdot dS = 21$$

39. Consider radial vector field $\vec{\mathbf{F}} = \dfrac{\vec{\mathbf{r}}}{\|\vec{\mathbf{r}}\|} = \dfrac{\langle x,y,z\rangle}{(x^2+y^2+z^2)^{1/2}}$. Compute the surface integral, where $S$ is the surface of a sphere of radius $a$ centered at the origin.

40. Compute the flux of water through parabolic cylinder $S : y = x^2$, from $0 \le x \le 2$, $0 \le z \le 3$, if the velocity vector is $\vec{\mathbf{F}}(x,y,z) = 3z^2\,\hat{\mathbf{i}} + 6\,\hat{\mathbf{j}} + 6xz\,\hat{\mathbf{k}}$.

**Answer**

$$\iint_S \vec{\mathbf{F}} \cdot dS = 72$$

41. [T] Use a CAS to find the flux of vector field $\vec{\mathbf{F}}(x,y,z) = z\,\hat{\mathbf{i}} + z\,\hat{\mathbf{j}} + \sqrt{x^2+y^2}\,\hat{\mathbf{k}}$ across the portion of hyperboloid $x^2 + y^2 = z^2 + 1$ between planes $z = 0$ and $z = \dfrac{\sqrt{3}}{3}$, oriented so the unit normal vector points away from the $z$-axis.

42. Use a CAS to find the flux of vector field $\vec{\mathbf{F}}(x,y,z) = (e^y + x)\,\hat{\mathbf{i}} + (3\cos(xz) - y)\,\hat{\mathbf{j}} + z\,\hat{\mathbf{k}}$ through surface $S$, where $S$ is given by $z^2 = 4x^2 + 4y^2$ from $0 \le z \le 4$, oriented so the unit normal vector points downward.

**Answer**

$$\iint_S \vec{\mathbf{F}} \cdot dS = -33.5103$$

43. [T] Use a CAS to compute $\iint_S \vec{\mathbf{F}} \cdot d\vec{S}$, where $\vec{\mathbf{F}}(x,y,z) = x\,\hat{\mathbf{i}} + y\,\hat{\mathbf{j}} + 2z\,\hat{\mathbf{k}}$ and $S$ is a part of sphere $x^2 + y^2 + z^2 = 2$ with $0 \le z \le 1$.

44. Evaluate $\iint_S \vec{\mathbf{F}} \cdot d\vec{S}$, where $\vec{\mathbf{F}}(x,y,z) = bxy^2\,\hat{\mathbf{i}} + bx^2y\,\hat{\mathbf{j}} + (x^2+y^2)z^2\,\hat{\mathbf{k}}$ and $S$ is a closed surface bounding the region and consisting of solid cylinder $x^2 + y^2 \le a^2$ and $0 \le z \le b$.

**Answer**

$$\iint_S \vec{\mathbf{F}} \cdot d\vec{S} = \pi a^4 b^2$$

45. [T] Use a CAS to calculate the flux of $\vec{\mathbf{F}}(x,y,z) = (x^3 + y\,\sin z)\,\hat{\mathbf{i}} + (y^3 + z\,\sin x)\,\hat{\mathbf{j}} + 3z\,\hat{\mathbf{k}}$ across surface $S$, where $S$ is the boundary of the solid bounded by hemispheres $z = \sqrt{4 - x^2 - y^2}$ and $z = \sqrt{1 - x^2 - y^2}$, and plane $z = 0$.

46. Use the divergence theorem to evaluate $\iint_S \vec{\mathbf{F}} \cdot d\vec{S}$, where $\vec{\mathbf{F}}(x,y,z) = xy\,\hat{\mathbf{i}} - \frac{1}{2}y^2\,\hat{\mathbf{j}} + z\,\hat{\mathbf{k}}$ and $S$ is the surface consisting of three pieces: $z = 4 - 3x^2 - 3y^2$, $1 \le z \le 4$ on the top; $x^2 + y^2 = 1$, $0 \le z \le 1$ on the sides; and $z = 0$ on the bottom.

**Answer**

$$\iint_S \vec{\mathbf{F}} \cdot d\vec{S} = \frac{5}{2}\pi$$

47. [T] Use a CAS and the divergence theorem to evaluate $\iint_S \vec{\mathbf{F}} \cdot d\vec{S}$, where $\vec{\mathbf{F}}(x,y,z) = (2x + y\,\cos z)\,\hat{\mathbf{i}} + (x^2 - y)\,\hat{\mathbf{j}} + y^2 z\,\hat{\mathbf{k}}$ and $S$ is sphere $x^2 + y^2 + z^2 = 4$ orientated outward.

48. Use the divergence theorem to evaluate $\iint_S \vec{\mathbf{F}} \cdot d\vec{S}$, where $\vec{\mathbf{F}}(x,y,z) = x\,\hat{\mathbf{i}} + y\,\hat{\mathbf{j}} + z\,\hat{\mathbf{k}}$ and $S$ is the boundary of the solid enclosed by paraboloid $y = x^2 + z^2 - 2$, cylinder $x^2 + z^2 = 1$, and plane $x + y = 2$, and $S$ is oriented outward.

**Answer**

$$\iint_S \vec{\mathbf{F}} \cdot d\vec{S} = \frac{21\pi}{2}$$

For the following exercises, **Fourier's law of heat transfer** states that the heat flow vector $\vec{\mathbf{F}}$ at a point is proportional to the negative gradient of the temperature; that is, $\vec{\mathbf{F}} = -k\vec{\nabla}T$, which means that heat energy flows hot regions to cold regions. The constant $k > 0$ is called the *conductivity*, which has metric units of joules per meter per second-kelvin or watts per meter-kelvin. A temperature function for region $D$ s given. Use the divergence theorem to find net outward heat flux $\iint_S \vec{\mathbf{F}} \cdot \vec{\mathbf{n}}\, dS = -k \iint_S \vec{\nabla}T \cdot N\, dS$ across the boundary $S$ of $D$, where $k = 1$.

49. $T(x,y,z) = 100 + x + 2y + z$;

$D = \{(x,y,z) : 0 \le x \le 1,\ 0 \le y \le 1,\ 0 \le z \le 1\}$

50. $T(x,y,z) = 100 + e^{-z}$;

$D = \{(x,y,z) : 0 \le x \le 1,\ 0 \le y \le 1,\ 0 \le z \le 1\}$

**Answer**

$-(1 - e^{-1})$

51. $T(x,y,z) = 100e^{-x^2-y^2-z^2}$; $D$ is the sphere of radius $a$ centered at the origin.

# 16.R: Chapter 16 Review Exercises

***True or False?* Justify your answer with a proof or a counterexample.**

1. The vector field $\vec{\mathbf{F}}(x,y) = x^2y\,\hat{\mathbf{i}} + y^2x\,\hat{\mathbf{j}}$ is conservative.

**Answer**

False

2. For vector field $\vec{\mathbf{F}}(x,y) = P(x,y)\,\hat{\mathbf{i}} + Q(x,y)\,\hat{\mathbf{j}}$, if $P_y(x,y) = Q_x(x,y)$ in open region $D$, then $\int_{\partial D} P\,dx + Q\,dy = 0$.

3. The divergence of a vector field is a vector field.

**Answer**

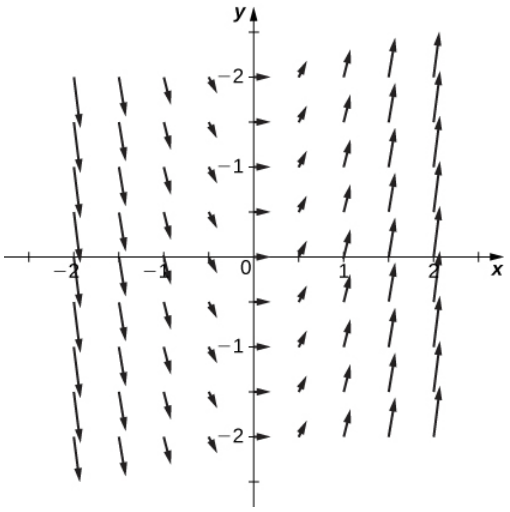
False

4. If $curl\,\vec{\mathbf{F}} = \vec{\mathbf{0}}$, then $\vec{\mathbf{F}}$ is a conservative vector field.

**Draw the following vector fields.**

5. $\vec{\mathbf{F}}(x,y) = \frac{1}{2}\,\hat{\mathbf{i}} + 2x\,\hat{\mathbf{j}}$

**Answer**



6. $\vec{\mathbf{F}}(x,y) = \sqrt{\dfrac{y\,\hat{\mathbf{i}} + 3x\,\hat{\mathbf{j}}}{x^2+y^2}}$

**Are the following the vector fields conservative? If so, find the potential function $\vec{\mathbf{F}}$ such that $\vec{\mathbf{F}} = \vec{\nabla} f$.**

7. $\vec{\mathbf{F}}(x,y) = y\,\hat{\mathbf{i}} + (x - 2e^y)\,\hat{\mathbf{j}}$

**Answer**

Conservative, $f(x,y) = xy - 2e^y$

8. $\vec{\mathbf{F}}(x,y) = (6xy)\,\hat{\mathbf{i}} + (3x^2 - ye^y)\,\hat{\mathbf{j}}$

9. $\vec{\mathbf{F}}(x,y) = (2xy + z^2)\,\hat{\mathbf{i}} + (x^2 + 2yz)\,\hat{\mathbf{j}} + (2xz + y^2)\,\hat{\mathbf{k}}$

**Answer**

Conservative, $f(x,y,z) = x^2y + y^2z + z^2x$

10. $\vec{\mathbf{F}}(x,y,z) = (e^x y)\,\hat{\mathbf{i}} + (e^x + z)\,\hat{\mathbf{j}} + (e^x + y^2)\,\hat{\mathbf{k}}$

**Evaluate the following integrals.**

11. $\int_C x^2\,dy + (2x - 3xy)\,dx$, along $C : y = \frac{1}{2}x$ from $(0,0)$ to $(4,2)$

**Answer**

$-\frac{16}{3}$

12. $\int_C y\,dx + xy^2\,dy$, where $C : x = \sqrt{t},\ y = t - 1,\ 0 \le t \le 1$

13. $\iint_S xy^2\,dS$, where $S$ is the surface $z = x^2 - y,\ 0 \le x \le 1,\ 0 \le y \le 4$

**Answer**

$\frac{32\sqrt{2}}{9}(3\sqrt{3} - 1)$

**Find the divergence and curl for the following vector fields.**

14. $\vec{\mathbf{F}}(x,y,z) = 3xyz\,\hat{\mathbf{i}} + xye^x\,\hat{\mathbf{j}} - 3xy\,\hat{\mathbf{k}}$

15. $\vec{\mathbf{F}}(x,y,z) = e^x\,\hat{\mathbf{i}} + e^{xy}\,\hat{\mathbf{j}} - e^{xyz}\,\hat{\mathbf{k}}$

**Answer**

Divergence: $e^x + x\,e^{xy} + xy\,e^{xyz}$
Curl: $xze^{xyz}\,\hat{\mathbf{i}} - yze^{xyz}\,\hat{\mathbf{j}} + ye^{xy}\,\hat{\mathbf{k}}$

**Use Green's theorem to evaluate the following integrals.**

16. $\int_C 3xy\,dx + 2xy^2\,dy$, where $C$ is a square with vertices $(0,0)$, $(0,2)$, $(2,2)$ and $(2,0)$.

17. $\oint_C 3y\,dx + (x + e^y)\,dy$, where $C$ is a circle centered at the origin with radius $3$.

**Answer**

$-2\pi$

**Use Stokes' theorem to evaluate $\iint_S curl\,\vec{\mathbf{F}} \cdot dS$.**

18. $\vec{\mathbf{F}}(x,y,z) = y\,\hat{\mathbf{i}} - x\,\hat{\mathbf{j}} + z\,\hat{\mathbf{k}}$, where $S$ is the upper half of the unit sphere

19. $\vec{\mathbf{F}}(x,y,z) = y\,\hat{\mathbf{i}} + xyz\,\hat{\mathbf{j}} - 2zx\,\hat{\mathbf{k}}$, where $S$ is the upward-facing paraboloid $z = x^2 + y^2$ lying in cylinder $x^2 + y^2 = 1$

**Answer**

$-\pi$

**Use the divergence theorem to evaluate $\iint_S \vec{\mathbf{F}} \cdot dS$.**

20. $\vec{\mathbf{F}}(x,y,z) = (x^3 y)\,\hat{\mathbf{i}} + (3y - e^x)\,\hat{\mathbf{j}} + (z + x)\,\hat{\mathbf{k}}$, over cube $S$ defined by $-1 \le x \le 1,\ 0 \le y \le 2,\ 0 \le z \le 2$

21. $\vec{\mathbf{F}}(x,y,z) = (2xy)\,\hat{\mathbf{i}} + (-y^2)\,\hat{\mathbf{j}} + (2z^3)\,\hat{\mathbf{k}}$, where $S$ is bounded by paraboloid $z = x^2 + y^2$ and plane $z = 2$

**Answer**

$31\pi/2$

22. Find the amount of work performed by a 50-kg woman ascending a helical staircase with radius 2 m and height 100 m. The woman completes five revolutions during the climb.

23. Find the total mass of a thin wire in the shape of a semicircle with radius $\sqrt{2}$, and a density function of $\rho(x,y) = y + x^2$.

**Answer**

$\sqrt{2}(2+\pi)$

24. Find the total mass of a thin sheet in the shape of a hemisphere with radius $2$ for $z \geq 0$ with a density function $\rho(x, y, z) = x + y + z$.

25. Use the divergence theorem to compute the value of the flux integral over the unit sphere with $\vec{\mathbf{F}}(x, y, z) = 3z\hat{\mathbf{i}} + 2y\hat{\mathbf{j}} + 2x\hat{\mathbf{k}}$.

**Answer**

$2\pi/3$

# CHAPTER OVERVIEW

## 17: Second-Order Differential Equations

We have already studied the basics of differential equations, including separable first-order equations. In this chapter, we go a little further and look at second-order equations, which are equations containing second derivatives of the dependent variable. The solution methods we examine are different from those discussed earlier, and the solutions tend to involve trigonometric functions as well as exponential functions. Here we concentrate primarily on second-order equations with constant coefficients.

17.1: Prelude to Second-Order Differential Equations

17.2: Second-Order Linear Equations

17.2E: Exercises for Section 17.1

17.3: Nonhomogeneous Linear Equations

17.3E: Exercises for Section 17.2

17.4: Applications of Second-Order Differential Equations

17.4E: Exercises for Section 17.3

17.5: Series Solutions of Differential Equations

17.5E: Exercises for Section 17.4

17.R: Chapter 17 Review Exercises

# 17.1: Prelude to Second-Order Differential Equations

We have already studied the basics of differential equations, including separable first-order equations. In this chapter, we go a little further and look at second-order equations, which are equations containing second derivatives of the dependent variable. The solution methods we examine are different from those discussed earlier, and the solutions tend to involve trigonometric functions as well as exponential functions. Here we concentrate primarily on second-order equations with constant coefficients.

Figure **17.1.1**: A motorcycle suspension system is an example of a damped spring-mass system. The spring absorbs bumps and keeps the tire in contact with the road. The shock absorber damps the motion so the motorcycle does not continue to bounce after going over each bump. (credit: nSeika, Flickr)

Such equations have many practical applications. The operation of certain electrical circuits, known as resistor–inductor–capacitor (*RLC* ) circuits, can be described by second-order differential equations with constant coefficients. These circuits are found in all kinds of modern electronic devices—from computers to smartphones to televisions. Such circuits can be used to select a range of frequencies from the entire radio wave spectrum, and are they commonly used for tuning AM/FM radios. We look at these circuits more closely in Applications.

Spring-mass systems, such as motorcycle shock absorbers, are a second common application of second-order differential equations. For motocross riders, the suspension systems on their motorcycles are very important. The off-road courses on which they ride often include jumps, and losing control of the motorcycle when landing could cost them the race. The movement of the shock absorber depends on the amount of damping in the system. In this chapter, we model forced and unforced spring-mass systems with varying amounts of damping.

# 17.2: Second-Order Linear Equations

**Learning Objectives**

- Recognize homogeneous and nonhomogeneous linear differential equations.
- Determine the characteristic equation of a homogeneous linear equation.
- Use the roots of the characteristic equation to find the solution to a homogeneous linear equation.
- Solve initial-value and boundary-value problems involving linear differential equations.

When working with differential equations, usually the goal is to find a solution. In other words, we want to find a function (or functions) that satisfies the differential equation. The technique we use to find these solutions varies, depending on the form of the differential equation with which we are working. Second-order differential equations have several important characteristics that can help us determine which solution method to use. In this section, we examine some of these characteristics and the associated terminology.

## Homogeneous Linear Equations

Consider the second-order differential equation

$$xy'' + 2x^2y' + 5x^3y = 0.$$

Notice that $y$ and its derivatives appear in a relatively simple form. They are multiplied by functions of $x$, but are not raised to any powers themselves, nor are they multiplied together. As discussed in previously, first-order equations with similar characteristics are said to be linear. The same is true of second-order equations. Also note that all the terms in this differential equation involve either $y$ or one of its derivatives. There are no terms involving only functions of $x$. Equations like this, in which every term contains $y$ or one of its derivatives, are called **homogeneous**.

Not all differential equations are homogeneous. Consider the differential equation

$$xy'' + 2x^2y' + 5x^3y = x^2.$$

The $x^2$ term on the right side of the equal sign does not contain $y$ or any of its derivatives. Therefore, this differential equation is *nonhomogeneous*.

**Definition: Homogeneous and Nonhomogeneous Linear Equations**

A second-order differential equation is linear if it can be written in the form

$$a_2(x)y'' + a)1(x)y' + a_0(x)y = r(x), \tag{17.2.1}$$

where $a_2(x), a_1(x), a_0(x)$, and $r(x)$ are real-valued functions and $a_2(x)$ is not identically zero. If $r(x) \equiv 0$—in other words, if $r(x) = 0$ for every value of $x$—the equation is said to be a *homogeneous linear equation*. If $r(x) \neq 0$ for some value of $x$, the equation is said to be a *nonhomogeneous linear equation*.

In linear differential equations, $y$ and its derivatives can be raised only to the first power and they may not be multiplied by one another. Terms involving $y^2$ or $\sqrt{y'}$ make the equation nonlinear. Functions of $y$ and its derivatives, such as $\sin y$ or $e^{y'}$, are similarly prohibited in linear differential equations.

Note that equations may not always be given in standard form (the form shown in the definition). It can be helpful to rewrite them in that form to decide whether they are linear, or whether a linear equation is homogeneous.

**Example 17.2.1: Classifying Second-Order Equations**

Classify each of the following equations as linear or nonlinear. If the equation is linear, determine further whether it is homogeneous or nonhomogeneous.

a. $y'' + 3x^4y' + x^2y^2 = x^3$

b. $(\sin x)y'' + (\cos x)y' + 3y = 0$
c. $4t^2x'' + 3tx x' + 4x = 0$
d. $5y'' + y = 4x^5$
e. $(\cos x)y'' - \sin y' + (\sin x)y - \cos x = 0$
f. $8ty'' - 6t^2y' + 4ty - 3t^2 = 0$
g. $\sin(x^2)y'' - (\cos x)y' + x^2y = y' - 3$
h. $y'' + 5xy' - 3y = \cos y$

**Solution**

a. This equation is nonlinear because of the $y^2$ term.
b. This equation is linear. There is no term involving a power or function of $y$, and the coefficients are all functions of $x$.The equation is already written in standard form, and $r(x)$ is identically zero, so the equation is homogeneous.
c. This equation is nonlinear. Note that, in this case, $x$ is the dependent variable and $t$is the independent variable. The second term involves the product of $x$ and $x'$, so the equation is nonlinear.
d. This equation is linear. Since $r(x) = 4x^5$, the equation is nonhomogeneous.
e. This equation is nonlinear, because of the $\sin y'$ term.
f. This equation is linear. Rewriting it in standard form gives

$$8t^2y'' - 6t^2y' + 4ty = 3t^2.$$

With the equation in standard form, we can see that $r(t) = 3t^2$,so the equation is nonhomogeneous.
g. This equation looks like it's linear, but we should rewrite it in standard form to be sure. We get

$$\sin(x^2)y'' - (\cos x + 1)y' + x^2y = -3.$$

This equation is, indeed, linear. With $r(x) = -3$, it is nonhomogeneous.
h. This equation is nonlinear because of the $\cos y$ term.

**? Exercise 17.2.1**

Classify each of the following equations as linear or nonlinear. If the equation is linear, determine further whether it is homogeneous or nonhomogeneous.

a. $(y'')2 - y' + 8x^3y = 0$
b. $(\sin t)y'' + \cos t - 3ty' = 0$

**Hint**

Write the equation in standard form (Equation 17.2.1) if necessary. Check for powers or functions of $y$ and its derivatives.

**Answer a**

Nonlinear Linear

**Answer b**

nonhomogeneous

Later in this section, we will see some techniques for solving specific types of differential equations. Before we get to that, however, let's get a feel for how solutions to linear differential equations behave. In many cases, solving differential equations depends on making educated guesses about what the solution might look like. Knowing how various types of solutions behave will be helpful.

**✓ Example 17.2.2: Verifying a Solution**

Consider the linear, homogeneous differential equation

$$x^2y'' - xy' - 3y = 0.$$

Looking at this equation, notice that the coefficient functions are polynomials, with higher powers of $x$ associated with higher-order derivatives of $y$. Show that $y = x^3$ is a solution to this differential equation.

### Solution

Let $y = x^3$. Then $y' = 3x^2$ and $y'' = 6x$. Substituting into the differential equation, we see that

$$\begin{aligned} x^2y'' - xy' - 3y &= x^2(6x) - x(3x^2) - 3(x^3) \\ &= 6x^3 - 3x^3 - 3x^3 \\ &= 0. \end{aligned}$$

**? Exercise 17.2.2**

Show that $y = 2x^2$ is a solution to the differential equation

$$\frac{1}{2}x^2y'' - xy' + y = 0. \tag{17.2.2}$$

**Hint**

Calculate the derivatives and substitute them into the differential equation.

**Answer**

This requires calculating $y'$ and $y''$.

$$y' = \frac{dy}{dx} = 4x$$

and

$$y'' = \frac{dy'}{dx} = 4$$

Inserting these derivatives along with $y = 2x^2$ into Equation 17.2.2.

$$\begin{aligned} \frac{1}{2}x^2y'' - xy' + y &\stackrel{?}{=} 0 \\ \frac{1}{2}x^2(4) - x(4x) + 2x^2 &\stackrel{?}{=} 0 \\ 2x^2 - 4x^2 + 2x^2 &\stackrel{\checkmark}{=} 0 \end{aligned}$$

Yes, this is a solution to the differential equation in Equation 17.2.2.

Although simply finding any solution to a differential equation is important, mathematicians and engineers often want to go beyond finding *one* solution to a differential equation to finding *all* solutions to a differential equation. In other words, we want to find a general solution**.** Just as with first-order differential equations, a general solution (or family of solutions) gives the entire set of solutions to a differential equation. An important difference between first-order and second-order equations is that, with second-order equations, we typically need to find two different solutions to the equation to find the general solution. If we find two solutions, then any linear combination of these solutions is also a solution. We state this fact as the following theorem.

**Theorem: SUPERPOSITION PRINCIPLE**

If $y_1(x)$ and $y_2(x)$ are solutions to a linear homogeneous differential equation, then the function

$$y(x) = c_1y_1(x) + c_2y_2(x), \tag{17.2.3}$$

where $c_1$ and $c_2$ are constants, is also a solution.

The proof of this superposition principle theorem is left as an exercise.

### Example 17.2.3: Verifying the Superposition Principle

Consider the differential equation

$$y'' - 4y' - 5y = 0.$$

Given that $e^{-x}$ and $e^{5x}$ are solutions to this differential equation, show that $4e^{-x} + e^{5x}$ is a solution.

#### Solution

Although this can be done through a simple application of the Superposition principle (Equation 17.2.3), but we can also confirm it is a solution via an approach like in Example 17.2.2. We have

$$\begin{aligned} y(x) &= 4e^{-x} + e^{5x} \\ y'(x) &= -4e^{-x} + 5e^{5x} \\ y''(x) &= 4e^{-x} + 25e^{5x}. \end{aligned}$$

Then

$$\begin{aligned} y'' - 4y' - 5y &\stackrel{?}{=} (4e^{-x} + 25e^{5x}) - 4(-4e^{-x} + 5e^{5x}) - 5(4e^{-x} + e^{5x}) \\ &\stackrel{?}{=} 4e^{-x} + 25e^{5x} + 16e^{-x} - 20e^{5x} - 20e^{-x} - 5e^{5x} \\ &\stackrel{\checkmark}{=} 0. \end{aligned}$$

Thus, $y(x) = 4e^{-x} + e^{5x}$ is a solution.

### Exercise 17.2.3

Consider the differential equation

$$y'' + 5y' + 6y = 0.$$

Given that $e^{-2x}$ and $e^{-3x}$ are solutions to this differential equation, show that $3e^{-2x} + 6e^{-3x}$ is a solution.

**Hint**

Differentiate the function and substitute into the differential equation.

**Answer**

Although this can be a simple application of the Superposition principle (Equation 17.2.3), we can also set through it like in Example 17.2.2. We have

$$\begin{aligned} y(x) &= 3e^{-2x} + 6e^{-3x} \\ y'(x) &= -6e^{-2x} - 18e^{-3x} \\ y''(x) &= 12e^{-2x} + 54e^{3x}. \end{aligned}$$

Then

$$\begin{aligned} y'' + 5y' + 6y &= (12e^{-2x} + 54e^{3x}) + 5(-6e^{-2x} - 18e^{-3x}) + 6(3e^{-2x} + 6e^{3x}) \\ &\stackrel{?}{=} \cancel{12e^{-2x}} + \cancel{54e^{3x}} - \cancel{30e^{-2x}} - \cancel{90e^{3x}} + \cancel{18e^{-2x}} + \cancel{36e^{3x}} \\ &\stackrel{\checkmark}{=} 0. \end{aligned}$$

Thus, $3e^{-2x} + 6e^{-3x}$ is a solution to the differential equation

Unfortunately, to find the general solution to a second-order differential equation, it is not enough to find any two solutions and then combine them. Consider the differential equation

$$x'' + 7x' + 12x = 0.$$

Both $e^{-3t}$ and $2e^{-3t}$ are solutions (you can check this). However,

$$x(t) = c_1 e^{-3t} + c_2(2e^{-3t})$$

is *not* the general solution. This expression does not account for all solutions to the differential equation. In particular, it fails to account for the function $e^{-4t}$, which is also a solution to the differential equation. It turns out that to find the general solution to a second-order differential equation, we must find two *linearly independent solutions*. We define that terminology here.

**Definition: Linearly Dependent functions**

A set of functions $f_1(x), f_2(x), \ldots, f_n(x)$ is said to be *linearly dependent* if there are constants $c_1, c_2, \ldots c_n,$, not all zero, such that

$$c_1 f_1(x) + c_2 f_2(x) + \cdots + c_n f_n(x) = 0$$

for all $x$ over the interval of interest. A set of functions that is not linearly dependent is said to be *linearly independent*.

In this chapter, we usually test sets of only two functions for linear independence, which allows us to simplify this definition. From a practical perspective, we see that two functions are linearly dependent if either one of them is identically zero or if they are constant multiples of each other.

First we show that if the functions meet the conditions given previously, then they are linearly dependent. If one of the functions is identically zero—say, $f_2(x) \equiv 0$—then choose $c_1 = 0$ and $c_2 = 1$, and the condition for linear dependence is satisfied. If, on the other hand, neither $f_1(x)$ nor $f_2(x)$ is identically zero, but $f_1(x) = Cf_2(x)$ for some constant $C$, then choose $c_1 = C$ and $c_2 = -1$, and again, the condition is satisfied.

Next, we show that if two functions are linearly dependent, then either one is identically zero or they are constant multiples of one another. Assume $f_1(x)$ and $f_2(x)$ are linearly independent. Then, there are constants, $c_1$ and $c_2$, not both zero, such that

$$c_1 f_1(x) + c_2 f_2(x) = 0$$

for all $x$ over the interval of interest. Then,

$$c_1 f_1(x) = -c_2 f_2(x).$$

Now, since we stated that $c_1$ and $c_2$ can't both be zero, assume $c_2 \neq 0$. Then, there are two cases: either $c_1 = 0$ or $c_1 \neq 0$. If $c_1 = 0$, then

$$0 = -c_2 f_2(x)$$
$$0 = f_2(x),$$

so one of the functions is identically zero. Now suppose $c_1 \neq 0$. Then,

$$f_1(x) = \left(-\frac{c_2}{c_1}\right) f_2(x)$$

and we see that the functions are constant multiples of one another.

**Theorem: Linear Dependence of Two Functions**

Two functions, $f_1(x)$ and $f_2(x)$, are said to be linearly dependent if either one of them is identically zero or if $f_1(x) = Cf_2(x)$ for some constant $C$ and for all $x$ over the interval of interest. Functions that are not linearly dependent are said to be *linearly independent*.

**Example 17.2.4: Testing for Linear Dependence**

Determine whether the following pairs of functions are linearly dependent or linearly independent.

a. $f_1(x) = x^2$ and $f_2(x) = 5x^2$
b. $f_1(x) = \sin x$ and $f_2(x) = \cos x$
c. $f_1(x) = e^{3x}$ and $f_2(x) = e^{-3x}$

d. $f_1(x) = 3x$ and $f_2(x) = 3x + 1$

**Solution**

a. $f_2(x) = 5f_1(x)$, so the functions are linearly dependent.
b. There is no constant $C$ such that $f_1(x) = Cf_2(x)$, so the functions are linearly independent.
c. There is no constant $C$ such that $f_1(x) = Cf_2(x)$, so the functions are linearly independent. Don't get confused by the fact that the exponents are constant multiples of each other. With two exponential functions, unless the exponents are equal, the functions are linearly independent.
d. There is no constant $C$ such that $f_1(x) = Cf_2(x)$, so the functions are linearly independent.

**? Exercise 17.2.4**

Determine whether the following pairs of functions are linearly dependent or linearly independent: $f_1(x) = e^x$ and $f_2(x) = 3e^{3x}$.

**Hint**

Are the functions constant multiples of one another?

**Answer**

Linearly independent

If we are able to find two linearly independent solutions to a second-order differential equation, then we can combine them to find the general solution. This result is formally stated in the following theorem.

**Theorem: General Solution to a Homogeneous Equation**

If $y_1(x)$ and $y_2(x)$ are linearly independent solutions to a second-order, linear, homogeneous differential equation, then the general solution is given by

$$y(x) = c_1y_1(x) + c_2y_2(x),$$

where $c_1$ and $c_2$ are constants.

When we say a family of functions is the general solution to a differential equation, we mean that

1. every expression of that form is a solution and
2. every solution to the differential equation can be written in that form, which makes this theorem extremely powerful.

If we can find two linearly independent solutions to a second order differential equation, we have, effectively, found *all* solutions to the second order differential equation—quite a remarkable statement. The proof of this theorem is beyond the scope of this text.

**✓ Example 17.2.5: Writing the General Solution**

If $y_1(t) = e^{3t}$ and $y_2(t) = e^{-3t}$ are solutions to $y'' - 9y = 0$, what is the general solution?

**Solution**

Note that $y_1$ and $y_2$ are not constant multiples of one another, so they are linearly independent. Then, the general solution to the differential equation is

$y(t) = c_1e^{3t} + c_2e^{-3t}$.

**? Exercise 17.2.5**

If $y_1(x) = e^{3x}$ and $y_2(x) = xe^{3x}$ are solutions to $y'' - 6y' + 9y = 0$, what is the general solution?

**Hint**

Check for linear independence first.

**Answer**

$y(x) = c_1 e^{3x} + c_2 x e^{3x}$

## Second-Order Equations with Constant Coefficients

Now that we have a better feel for linear differential equations, we are going to concentrate on solving second-order equations of the form

$$ay'' + by' + cy = 0, \tag{17.2}$$

where $a, b,$ and $c$ are constants.

Since all the coefficients are constants, the solutions are probably going to be functions with derivatives that are constant multiples of themselves. We need all the terms to cancel out, and if taking a derivative introduces a term that is not a constant multiple of the original function, it is difficult to see how that term cancels out. Exponential functions have derivatives that are constant multiples of the original function, so let's see what happens when we try a solution of the form $y(x) = e^{\lambda x}$, where $\lambda$ (the lowercase Greek letter lambda) is some constant.

If $y(x) = e^{\lambda x}$, then $y'(x) = \lambda e^{\lambda x}$ and $y'' = \lambda^2 e^{\lambda x}$. Substituting these expressions into Equation 17.2.1, we get

$$\begin{aligned} ay'' + by' + cy &= a(\lambda^2 e^{\lambda x}) + b(\lambda e^{\lambda x}) + ce^{\lambda x} \\ &= e^{\lambda x}(a\lambda^2 + b\lambda + c). \end{aligned}$$

Since $e^{\lambda x}$ is never zero, this expression can be equal to zero for all $x$ only if

$$a\lambda^2 + b\lambda + c = 0.$$

We call this the *characteristic equation* of the differential equation.

**Definition: characteristic equation**

The *characteristic equation* of the second order differential equation $ay'' + by' + cy = 0$ is

$$a\lambda^2 + b\lambda + c = 0.$$

The characteristic equation is very important in finding solutions to differential equations of this form. We can solve the characteristic equation either by factoring or by using the quadratic formula

$$\lambda = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}.$$

This gives three cases. The characteristic equation has

1. distinct real roots;
2. a single, repeated real root; or
3. complex conjugate roots.

We consider each of these cases separately.

### Case 1: Distinct Real Roots

If the characteristic equation has distinct real roots $\lambda_1$ and $\lambda_2$, then $e^{\lambda_1 x}$ and $e^{\lambda_2 x}$ are linearly independent solutions to Example 17.2.1, and the general solution is given by

$$y(x) = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x},$$

where $c_1$ and $c_2$ are constants.

For example, the differential equation $y'' + 9y' + 14y = 0$ has the associated characteristic equation $\lambda^2 + 9\lambda + 14 = 0$. This factors into $(\lambda + 2)(\lambda + 7) = 0$, which has roots $\lambda_1 = -2$ and $\lambda_2 = -7$. Therefore, the general solution to this differential equation is

$$y(x) = c_1 e^{-2x} + c_2 e^{-7x}.$$

### Case 2: Single Repeated Real Root

Things are a little more complicated if the characteristic equation has a repeated real root, $\lambda$. In this case, we know $e^{\lambda x}$ is a solution to Equation 17.2.1, but it is only one solution and we need two linearly independent solutions to determine the general solution. We might be tempted to try a function of the form $ke^{\lambda x}$, where $k$ is some constant, but it would not be linearly independent of $e^{\lambda x}$. Therefore, let's try $xe^{\lambda x}$ as the second solution. First, note that by the quadratic formula,

$$\lambda = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}.$$

But, $\lambda$ is a repeated root, so the discriminate $(b^2 - 4ac)$ is zero and $\lambda = \frac{-b}{2a}$. Thus, if $y = xe^{\lambda x}$, we have

$$\begin{aligned} y' &= e^{\lambda x} + \lambda x e^{\lambda x} \\ y'' &= 2\lambda e^{\lambda x} + \lambda^2 x e^{\lambda x}. \end{aligned}$$

Substituting both expressions into Equation 17.2.1, we see that

$$\begin{aligned} ay'' + by' + cy &= a(2\lambda e^{\lambda x} + \lambda^2 x e^{\lambda x}) + b(e^{\lambda x} + \lambda x e^{\lambda x}) + cxe^{\lambda x} \\ &= xe^{\lambda x}(a\lambda^2 + b\lambda + c) + e^{\lambda x}(2a\lambda + b) \\ &= xe^{\lambda x}(0) + e^{\lambda x}(2a(-b2a) + b) \\ &= 0 + e^{\lambda x}(0) \\ &\overset{\checkmark}{=} 0. \end{aligned}$$

This shows that $xe^{\lambda x}$ is a solution to Equation 17.2.1. Since $e^{\lambda x}$ and $xe^{\lambda x}$ are linearly independent, when the characteristic equation has a repeated root $\lambda$, the general solution to Equation 17.2.1 is given by

$$y(x) = c_1 e^{\lambda x} + c_2 x e^{\lambda x},$$

where $c_1$ and $c_2$ are constants.

For example, the differential equation $y'' + 12y' + 36y = 0$ has the associated characteristic equation

$$\lambda^2 + 12\lambda + 36 = 0.$$

This factors into $(\lambda + 6)^2 = 0$, which has a repeated root $\lambda = -6$. Therefore, the general solution to this differential equation is

$$y(x) = c_1 e^{-6x} + c_2 x e^{-6x}.$$

### Case 3: Complex Conjugate Roots

The third case we must consider is when $b^2 - 4ac < 0$. In this case, when we apply the quadratic formula, we are taking the square root of a negative number. We must use the imaginary number $i = \sqrt{-1}$ to find the roots, which take the form $\lambda_1 = \alpha + \beta i$ and $\lambda_2 = \alpha - \beta i$. The **complex number** $\alpha + \beta i$ is called the *conjugate* of $\alpha - \beta i$. Thus, we see that when the discriminate $b^2 - 4ac$ is negative, the roots of our characteristic equation are always **complex conjugates**.

This creates a little bit of a problem for us. If we follow the same process we used for distinct real roots—using the roots of the characteristic equation as the coefficients in the exponents of exponential functions—we get the functions $e^{(\alpha+\beta i)x}$ and $e^{(\alpha-\beta i)x}$ as our solutions. However, there are problems with this approach. First, these functions take on complex (imaginary) values, and a complete discussion of such functions is beyond the scope of this text. Second, even if we were comfortable with complex-value functions, in this course we do not address the idea of a derivative for such functions. So, if possible, we'd like to find two linearly independent *real-value* solutions to the differential equation. For purposes of this development, we are going to manipulate and differentiate the functions $e^{(\alpha+\beta i)x}$ and $e^{(\alpha-\beta i)x}$ as if they were real-value functions. For these particular functions, this approach is valid mathematically, but be aware that there are other instances when complex-value functions do not follow the same rules as real-value functions. Those of you interested in a more in-depth discussion of complex-value functions should consult a complex analysis text.

Based on the roots $\alpha \pm \beta i$ of the characteristic equation, the functions $e^{(\alpha+\beta i)x}$ and $e^{(\alpha-\beta i)x}$ are linearly independent solutions to the differential equation and the general solution is given by

$$y(x) = c_1 e^{(\alpha+\beta i)x} + c_2 e^{(\alpha-\beta i)x}.$$

Using some smart choices for $c_1$ and $c_2$, and a little bit of algebraic manipulation, we can find two linearly independent, real-value solutions to Equation 17.2.1 and express our general solution in those terms.

We encountered exponential functions with complex exponents earlier. One of the key tools we used to express these exponential functions in terms of sines and cosines was Euler's formula, which tells us that

$$\underbrace{e^{i\theta} = \cos\theta + i\sin\theta}_{\text{Euler's formula}} \tag{17.2.4}$$

for all real numbers $\theta$.

Going back to the general solution, we have

$$\begin{aligned} y(x) &= c_1 e^{(\alpha+\beta i)x} + c_2 e^{(\alpha-\beta i)x} \\ &= c_1 e^{\alpha x} e^{\beta i x} + c_2 e^{\alpha x} e^{-\beta i x} \\ &= e^{\alpha x}(c_1 e^{\beta i x} + c_2 e^{-\beta i x}). \end{aligned}$$

Applying Euler's formula (Equation 17.2.4) together with the identities $\cos(-x) = \cos x$ and $\sin(-x) = -\sin x$, we get

$$\begin{aligned} y(x) &= e^{\alpha x}[c_1(\cos\beta x + i\sin\beta x) + c_2(\cos(-\beta x) + i\sin(-\beta x))] \\ &= e^{\alpha x}[(c_1 + c_2)\cos\beta x + (c_1 - c_2)i\sin\beta x]. \end{aligned} \tag{17.2.5}$$

Now, if we choose $c_1 = c_2 = \frac{1}{2}$, the second term is zero and we get

$$y(x) = e^{\alpha x}\cos\beta x$$

as a real-value solution to Equation 17.2.1. Similarly, if we choose $c_1 = -\frac{i}{2}$ and $c_2 = \frac{i}{2}$, the first term of Equation 17.2.5 is zero and we get

$$y(x) = e^{\alpha x}\sin\beta x$$

as a second, linearly independent, real-value solution to Equation 17.2.1.

Based on this, we see that if the characteristic equation has complex conjugate roots $\alpha \pm \beta i$, then the general solution to Equation 17.2.1 is given by

$$\begin{aligned} y(x) &= c_1 e^{\alpha x}\cos\beta x + c_2 e^{\alpha x}\sin\beta x \\ &= e^{\alpha x}(c_1\cos\beta x + c_2\sin\beta x), \end{aligned}$$

where $c_1$ and $c_2$ are constants.

For example, the differential equation $y'' - 2y' + 5y = 0$ has the associated characteristic equation $\lambda^2 - 2\lambda + 5 = 0$. By the quadratic formula, the roots of the characteristic equation are $1 \pm 2i$. Therefore, the general solution to this differential equation is

$$y(x) = e^x(c_1\cos 2x + c_2\sin 2x).$$

## Summary of Results

We can solve second-order, linear, homogeneous differential equations with constant coefficients by finding the roots of the associated characteristic equation. The form of the general solution varies, depending on whether the characteristic equation has distinct, real roots; a single, repeated real root; or complex conjugate roots. The three cases are summarized in Table 17.2.1.

Table 17.2.1: Summary of Characteristic Equation Cases

| Characteristic Equation Roots | General Solution to the Differential Equation |
|---|---|
| Distinct real roots, $\lambda_1$ and $\lambda_2$ | $y(x) = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$ |
| A repeated real root, $\lambda$ | $y(x) = c_1 e^{\lambda x} + c_2 x e^{\lambda x}$ |
| Complex conjugate roots $\alpha \pm \beta i$ | $y(x) = e^{\alpha x}(c_1\cos\beta x + c_2\sin\beta x)$ |

### PROBLEM-SOLVING STRATEGY: USING THE CHARACTERISTIC EQUATION TO SOLVE SECOND-ORDER DIFFERENTIAL EQUATIONS WITH CONSTANT COEFFICIENTS

1. Write the differential equation in the form $ay'' + by' + cy = 0$.
2. Find the corresponding characteristic equation $a\lambda^2 + b\lambda + c = 0$.
3. Either factor the characteristic equation or use the quadratic formula to find the roots.
4. Determine the form of the general solution based on whether the characteristic equation has distinct, real roots; a single, repeated real root; or complex conjugate roots.

### Example 17.2.6: Solving Second-Order Equations with Constant Coefficients

Find the general solution to the following differential equations. Give your answers as functions of $x$.

a. $y'' + 3y' - 4y = 0$
b. $y'' + 6y' + 13y = 0$
c. $y'' + 2y' + y = 0$
d. $y'' - 5y' = 0$
e. $y'' - 16y = 0$
f. $y'' + 16y = 0$

**Solution**

Note that all these equations are already given in standard form (step 1).

1. The characteristic equation is $\lambda^2 + 3\lambda - 4 = 0$ (step 2). This factors into $(\lambda + 4)(\lambda - 1) = 0$, so the roots of the characteristic equation are $\lambda_1 = -4$ and $\lambda_2 = 1$ (step 3). Then the general solution to the differential equation is

$$y(x) = c_1 e^{-4x} + c_2 e^{x}. \qquad \text{(step 1)}$$

2. The characteristic equation is $\lambda^2 + 6\lambda + 13 = 0$ (step 2). Applying the quadratic formula, we see this equation has complex conjugate roots $-3 \pm 2i$ (step 3). Then the general solution to the differential equation is

$$y(t) = e^{-3t}(c_1 \cos 2t + c_2 \sin 2t). \qquad \text{(step 2)}$$

3. The characteristic equation is $\lambda^2 + 2\lambda + 1 = 0$ (step 2). This factors into $(\lambda + 1)2 = 0$, so the characteristic equation has a repeated real root $\lambda = -1$ (step 3). Then the general solution to the differential equation is

$$y(t) = c_1 e^{-t} + c_2 t e^{-t}. \qquad \text{(step 3)}$$

4. The characteristic equation is $\lambda^2 - 5\lambda$ (step 2). This factors into $\lambda(\lambda - 5) = 0$, so the roots of the characteristic equation are $\lambda_1 = 0$ and $\lambda_2 = 5$ (step 3). Note that $e^{0x} = e^0 = 1$, so our first solution is just a constant. Then the general solution to the differential equation is

$$y(x) = c_1 + c_2 e^{5x}. \qquad \text{(step 4)}$$

5. The characteristic equation is $\lambda^2 - 16 = 0$ (step 2). This factors into $(\lambda + 4)(\lambda - 4) = 0$, so the roots of the characteristic equation are $\lambda_1 = 4$ and $\lambda_2 = -4$ (step 3). Then the general solution to the differential equation is

$$y(x) = c_1 e^{4x} + c_2 e^{-4x}. \qquad \text{(step 5)}$$

6. The characteristic equation is $\lambda^2 + 16 = 0$ (step 2). This has complex conjugate roots $\pm 4i$ (step 3). Note that $e^{0x} = e^0 = 1$, so the exponential term in our solution is just a constant. Then the general solution to the differential equation is

$$y(t) = c_1 \cos 4t + c_2 \sin 4t. \qquad \text{(step 6)}$$

### Exercise 17.2.6

Find the general solution to the following differential equations:

a. $y'' - 2y' + 10y = 0$

b. $y'' + 14y' + 49y = 0$

**Hint**

Find the roots of the characteristic equation.

**Answer a**

$y(x) = e^x(c_1 \cos 3x + c_2 \sin 3x)$

**Answer b**

$y(x) = c_1 e^{-7x} + c_2 x e^{-7x}$

## Initial-Value Problems and Boundary-Value Problems

So far, we have been finding general solutions to differential equations. However, differential equations are often used to describe physical systems, and the person studying that physical system usually knows something about the state of that system at one or more points in time. For example, if a constant-coefficient differential equation is representing how far a motorcycle shock absorber is compressed, we might know that the rider is sitting still on his motorcycle at the start of a race, time $t = t_0$. This means the system is at equilibrium, so $y(t_0) = 0$, and the compression of the shock absorber is not changing, so $y'(t_0) = 0$. With these two initial conditions and the general solution to the differential equation, we can find the *specific* solution to the differential equation that satisfies both initial conditions. This process is known as *solving an initial-value problem*. (Recall that we discussed initial-value problems in Introduction to Differential Equations.) Note that second-order equations have two arbitrary constants in the general solution, and therefore we require two initial conditions to find the solution to the initial-value problem.

Sometimes we know the condition of the system at two different times. For example, we might know $y(t_0) = y_0$ and $y(t_1) = y_1$. These conditions are called boundary conditions, and finding the solution to the differential equation that satisfies the boundary conditions is called solving a boundary-value problem.

Mathematicians, scientists, and engineers are interested in understanding the conditions under which an initial-value problem or a boundary-value problem has a unique solution. Although a complete treatment of this topic is beyond the scope of this text, it is useful to know that, within the context of constant-coefficient, second-order equations, initial-value problems are guaranteed to have a unique solution as long as two initial conditions are provided. Boundary-value problems, however, are not as well behaved. Even when two boundary conditions are known, we may encounter boundary-value problems with unique solutions, many solutions, or no solution at all.

### Example 17.2.7: Solving an Initial-Value Problem

Solve the following initial-value problem: $y'' + 3y' - 4y = 0$, $y(0) = 1$, $y'(0) = -9$.

**Solution**

We already solved this differential equation in Example 17.6a. and found the general solution to be

$$y(x) = c_1 e^{-4x} + c_2 e^x.$$

Then

$$y'(x) = -4c_1 e^{-4x} + c_2 e^x.$$

When $x = 0$, we have $y(0) = c_1 + c_2$ and $y'(0) = -4c_1 + c_2$. Applying the initial conditions, we have

$$c_1 + c_2 = 1$$
$$-4c_1 + c_2 = -9.$$

Then $c_1 = 1 - c_2$. Substituting this expression into the second equation, we see that

$$-4(1-c_2)+c_2=-9$$
$$-4+4c_2+c_2=-9$$
$$5c_2=-5$$
$$c_2=-1.$$

So, $c_1=2$ and the solution to the initial-value problem is

$$y(x)=2e^{-4x}-e^{x}.$$

## Exercise 17.2.7

Solve the initial-value problem $y''-3y'-10y=0,\quad y(0)=0,\ y'(0)=7.$

**Hint**

Use the initial conditions to determine values for $c_1$ and $c_2$.

**Answer**

$$y(x)=-e^{-2x}+e^{5x}$$

## Example 17.2.8: Solving an Initial-Value Problem and Graphing the Solution

Solve the following initial-value problem and graph the solution:

$$y''+6y'+13y=0,\quad y(0)=0,\ y'(0)=2$$

**Solution**

We already solved this differential equation in Example 17.2.6*b*. and found the general solution to be

$$y(x)=e^{-3x}(c_1\cos 2x+c_2\sin 2x).$$

Then

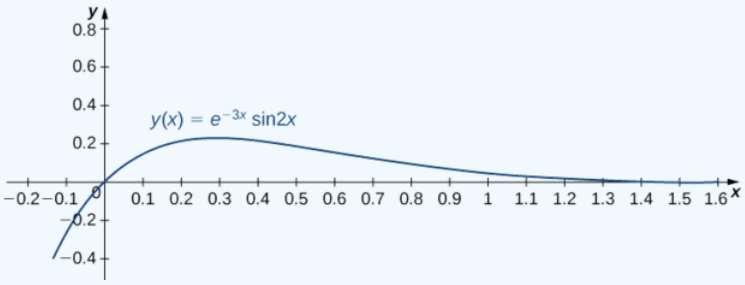
$$y'(x)=e^{-3x}(-2c_1\sin 2x+2c_2\cos 2x)-3e^{-3x}(c_1\cos 2x+c_2\sin 2x).$$

When $x=0$, we have $y(0)=c_1$ and $y'(0)=2c_2-3c_1$. Applying the initial conditions, we obtain

$$c_1=0$$
$$-3c_1+2c_2=2.$$

Therefore, $c_1=0$, $c_2=1$, and the solution to the initial value problem is shown in the following graph.

$$y=e^{-3x}\sin 2x.$$



## Exercise 17.2.8

Solve the following initial-value problem and graph the solution: $y''-2y'+10y=0,\quad y(0)=2,\ y'(0)=-1$

**Hint**

Use the initial conditions to determine values for $c_1$ and $c_2$.

**Answer**

$$y(x) = e^x(2\cos 3x - \sin 3x)$$

### Example 17.2.9: Initial-Value Problem Representing a Spring-Mass System

The following initial-value problem models the position of an object with mass attached to a spring. Spring-mass systems are examined in detail in Applications. The solution to the differential equation gives the position of the mass with respect to a neutral (equilibrium) position (in meters) at any given time. (Note that for spring-mass systems of this type, it is customary to define the downward direction as positive.)

$$y'' + 2y' + y = 0, \quad y(0) = 1,\ y'(0) = 0$$

Solve the initial-value problem and graph the solution. What is the position of the mass at time $t = 2$ sec? How fast is the mass moving at time $t = 1$ sec? In what direction?

**Solution**

In Example Example 17.2.6c. we found the general solution to this differential equation to be

$$y(t) = c_1e^{-t} + c_2te^{-t}.$$

Then

$$y'(t) = -c_1e^{-t} + c_2(-te^{-t} + e^{-t}).$$

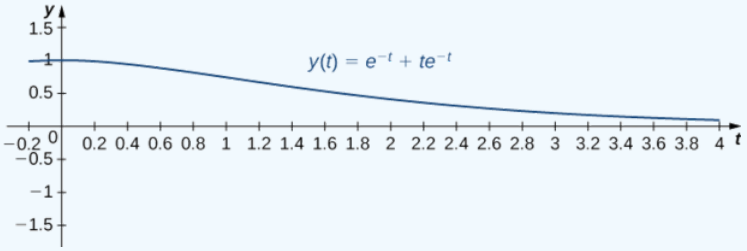
When $t = 0$, we have $y(0) = c_1$ and $y'(0) = c_1 + c_2$. Applying the initial conditions, we obtain

$$\begin{aligned} c_1 &= 1 \\ -c_1 + c_2 &= 0. \end{aligned}$$

Thus, $c_1 = 1, c_2 = 1$, and the solution to the initial value problem is

$$y(t) = e^{-t} + te^{-t}.$$

This solution is represented in the following graph. At time $t = 2$, the mass is at position $y(2) = e^{-2} + 2e^{-2} = 3e^{-2} \approx 0.406$ m below equilibrium.



To calculate the velocity at time $t = 1$, we need to find the derivative. We have $y(t) = e^{-t} + te^{-t}$, so

$$y'(t) = -e^{-t} + e^{-t} - te^{-t} = -te^{-t}.$$

Then $y'(1) = -e^{-1} \approx -0.3679$. At time $t = 1$, the mass is moving upward at $0.3679$ m/sec.

### Exercise 17.2.9

Suppose the following initial-value problem models the position (in feet) of a mass in a spring-mass system at any given time. Solve the initial-value problem and graph the solution. What is the position of the mass at time $t = 0.3$ sec? How fast is it moving at time $t = 0.1$ sec? In what direction?

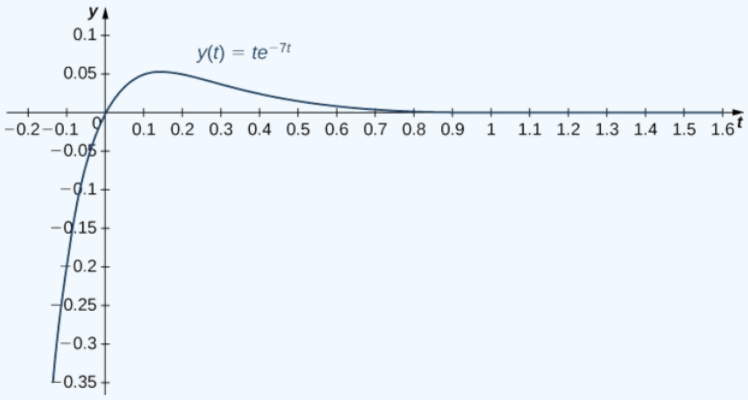
$$y'' + 14y' + 49y = 0, \quad y(0) = 0,\ y'(0) = 1$$

**Hint**

Use the initial conditions to determine values for $c_1$ and $c_2$.

**Answer**

$$y(t) = te^{-7t}$$



At time $t = 0.3,\ y(0.3) = 0.3e^{(-7*0.3)} = 0.3e^{-2.1} \approx 0.0367$. The mass is $0.0367$ft below equilibrium. At time $t = 0.1,\ y'(0.1) = 0.3e^{-0.7} \approx 0.1490$. The mass is moving downward at a speed of $0.1490$ ft/sec.

### Example 17.2.10: Solving a Boundary-Value Problem

In Example 17.6f. we solved the differential equation $y'' + 16y = 0$ and found the general solution to be $y(t) = c_1 \cos 4t + c_2 \sin 4t$. If possible, solve the boundary-value problem if the boundary conditions are the following:

a. $y(0) = 0, y(\frac{\pi}{4}) = 0$
b. $y(0) = 1, y(0) = 1, y(\frac{\pi}{8}) = 0$
c. $y(\frac{\pi}{8}) = 0, y(\frac{3\pi}{8}) = 2$

**Solution**

We have

$$y(x) = c_1 \cos 4t + c_2 \sin 4t.$$

1. Applying the first boundary condition given here, we get $y(0) = c_1 = 0$. So the solution is of the form $y(t) = c_2 \sin 4t$. When we apply the second boundary condition, though, we get $y(\frac{\pi}{4}) = c_2 \sin(4(\frac{\pi}{4})) = c_2 \sin \pi = 0$ for all values of $c_2$. The boundary conditions are not sufficient to determine a value for $c_2$, so this boundary-value problem has infinitely many solutions. Thus, $y(t) = c_2 \sin 4t$ is a solution for any value of $c_2$.
2. Applying the first boundary condition given here, we get $y(0) = c_1 = 1$. Applying the second boundary condition gives $y(\frac{\pi}{8}) = c_2 = 0$, so $c_2 = 0$. In this case, we have a unique solution: $y(t) = \cos 4t$.
3. Applying the first boundary condition given here, we get $y(\frac{\pi}{8}) = c_2 = 0$. However, applying the second boundary condition gives $y(\frac{3\pi}{8}) = -c_2 = 2$, so $c_2 = -2$. We cannot have $c_2 = 0 = -2$, so this boundary value problem has no solution.

## Key Concepts

- Second-order differential equations can be classified as linear or nonlinear, homogeneous or nonhomogeneous.
- To find a general solution for a homogeneous second-order differential equation, we must find two linearly independent solutions. If $y_1(x)$ and $y_2(x)$ are linearly independent solutions to a second-order, linear, homogeneous differential equation, then the general solution is given by

$$y(x) = c_1 y_1(x) + c_2 y_2(x).$$

- To solve homogeneous second-order differential equations with constant coefficients, find the roots of the characteristic equation. The form of the general solution varies depending on whether the characteristic equation has distinct, real roots; a

single, repeated real root; or complex conjugate roots.
- Initial conditions or boundary conditions can then be used to find the specific solution to a differential equation that satisfies those conditions, except when there is no solution or infinitely many solutions.

## Key Equations

- **Linear second-order differential equation**

$$a_2(x)y'' + a_1(x)y' + a_0(x)y = r(x)$$

- **Second-order equation with constant coefficients**

$$ay'' + by' + cy = 0$$

## Glossary

**boundary conditions**
the conditions that give the state of a system at different times, such as the position of a spring-mass system at two different times

**boundary-value problem**
a differential equation with associated boundary conditions

**characteristic equation**
the equation $a\lambda^2 + b\lambda + c = 0$ for the differential equation $ay''+by'+cy = 0$

**homogeneous linear equation**
a second-order differential equation that can be written in the form $a_2(x)y''+a_1(x)y'+a_0(x)y = r(x)$, but $r(x) = 0$ for every value of $x$

**nonhomogeneous linear equation**
a second-order differential equation that can be written in the form $a_2(x)y''+a_1(x)y'+a_0(x)y = r(x)$, but $r(x) \neq 0$ for some value of $x$

**linearly dependent**
a set of functions $f_1(x), f_2(x), \ldots, f_n(x)$ for whichthere are constants $c_1, c_2, \ldots, c_n$, not all zero, such that $c_1f_1(x) + c_2f_2(x) + \cdots + c_nf_n(x) = 0$ for all $x$ in the interval of interest

**linearly independent**
a set of functions $f_1(x), f_2(x), \ldots, f_n(x)$ for which there are no constants $c_1, c_2, \ldots, c_n$, such that $c_1f_1(x) + c_2f_2(x) + \cdots + c_nf_n(x) = 0$ for all $x$ in the interval of interest

# 17.2E: Exercises for Section 17.1

**In exercises 1 - 6, classify each of the following equations as linear or nonlinear. If the equation is linear, determine whether it is homogeneous or nonhomogeneous.**

1. $x^3y'' + (x-1)y' - 8y = 0$

**Answer**

linear, homogenous

2. $(1+y^2)y'' + xy' - 3y = \cos x$

3. $xy'' + e^y y' = x$

**Answer**

nonlinear

4. $y'' + \dfrac{4}{x}y' - 8xy = 5x^2 + 1$

5. $y'' + (\sin x)y' - xy = 4y$

**Answer**

linear, homogenous

6. $y'' + \left(\dfrac{x+3}{y}\right)y' = 0$

**In exercises 7 - 10, verify that the given function is a solution to the differential equation. Use a graphing utility to graph the particular solutions for several values of $c_1$ and $c_2$. What do the solutions have in common?**

7. **[T]** $y'' + 2y' - 3y = 0; \quad y(x) = c_1e^x + c_2e^{-3x}$

8. **[T]** $x^2y'' - 2y - 3x^2 + 1 = 0; \quad y(x) = c_1x^2 + c_2x^{-1} + x^2\ln(x) + \frac{1}{2}$

9. **[T]** $y'' + 14y + 49y = 0; \quad y(x) = c_1e^{-7x} + c_2xe^{-7x}$

10. **[T]** $6y'' - 49y' + 8y = 0; \quad y(x) = c_1e^{x/6} + c_2e^{8x}$

**In exercises 11 - 30, find the general solution to the linear differential equation.**

11. $y'' - 3y' - 10y = 0$

**Answer**

$y = c_1e^{5x} + c_2e^{-2x}$

12. $y'' - 7y' + 12y = 0$

13. $y'' + 4y' + 4y = 0$

**Answer**

$y = c_1e^{-2x} + c_2xe^{-2x}$

14. $4y'' - 12y' + 9y = 0$

15. $2y'' - 3y' - 5y = 0$

**Answer**

$y = c_1e^{5x/2} + c_2e^{-x}$

16. $3y'' - 14y' + 8y = 0$

17. $y'' + y' + y = 0$

**Answer**

$y = e^{-x/2}\left(c_1 \cos \frac{\sqrt{3}x}{2} + c_2 \sin \frac{\sqrt{3}x}{2}\right)$

18. $5y'' + 2y' + 4y = 0$

19. $y'' - 121y = 0$

**Answer**

$y = c_1 e^{-11x} + c_2 e^{11x}$

20. $8y'' + 14y' - 15y = 0$

21. $y'' + 81y = 0$

**Answer**

$y = c_1 \cos 9x + c_2 \sin 9x$

22. $y'' - y' + 11y = 0$

23. $2y'' = 0$

**Answer**

$y = c_1 + c_2 x$

24. $y'' - 6y' + 9y = 0$

25. $3y'' - 2y' - 7y = 0$

**Answer**

$y = c_1 e^{\left((1+\sqrt{22})/3\right)x} + c_2 e^{\left((1-\sqrt{22})/3\right)x}$

26. $4y'' - 10y' = 0$

27. $36\frac{d^2y}{dx^2} + 12\frac{dy}{dx} + y = 0$

**Answer**

$y = c_1 e^{-x/6} + c_2 x e^{-x/6}$

28. $25\frac{d^2y}{dx^2} - 80\frac{dy}{dx} + 64y = 0$

29. $\frac{d^2y}{dx^2} - 9\frac{dy}{dx} = 0$

**Answer**

$y = c_1 + c_2 e^{9x}$

30. $4\frac{d^2y}{dx^2} + 8y = 0$

**In exercises 31 - 38, solve the initial-value problem.**

31. $y'' + 5y' + 6y = 0, \quad y(0) = 0,\ y'(0) = -2$

**Answer**

$y = -2e^{-2x} + 2e^{-3x}$

32. $y'' + 2y' - 8y = 0, \quad y(0) = 5,\ y'(0) = 4$

33. $y'' + 4y = 0, \quad y(0) = 3,\ y'(0) = 10$

**Answer**

$y = 3\cos(2x) + 5\sin(2x)$

34. $y'' - 18y' + 81y = 0, \quad y(0) = 1,\ y'(0) = 5$

35. $y'' - y' - 30y = 0, \quad y(0) = 1,\ y'(0) = -16$

**Answer**

$y = -e^{6x} + 2e^{-5x}$

36. $4y'' + 4y' - 8y = 0, \quad y(0) = 2,\ y'(0) = 1$

37. $25y'' + 10y' + y = 0, \quad y(0) = 2,\ y'(0) = 1$

**Answer**

$y = 2e^{-x/5} + \frac{7}{5}xe^{-x/5}$

38. $y'' + y = 0, \quad y(\pi) = 1,\ y'(\pi) = -5$

**In exercises 39 - 46, solve the boundary-value problem, if possible.**

39. $y'' + y' - 42y = 0, \quad y(0) = 0,\ y(1) = 2$

**Answer**

$y = \left(\frac{2}{e^6 - e^{-7}}\right)e^{6x} - \left(\frac{2}{e^6 - e^{-7}}\right)e^{-7x}$

40. $9y'' + y = 0, \quad y(3\pi^2) = 6,\ y(0) = -8$

41. $y'' + 10y' + 34y = 0, \quad y(0) = 6,\ y(\pi) = 2$

**Answer**

No solutions exist.

42. $y'' + 7y' - 60y = 0, \quad y(0) = 4,\ y(2) = 0$

43. $y'' - 4y' + 4y = 0, \quad y(0) = 2,\ y(1) = -1$

**Answer**

$y = 2e^{2x} - \left(\frac{2e^2 + 1}{e^2}\right)xe^{2x}$

44. $y'' - 5y' = 0, \quad y(0) = 3,\ y(-1) = 2$

45. $y'' + 9y = 0, \quad y(0) = 4,\ y(\pi^3) = -4$

**Answer**

$y = 4\cos 3x + c_2 \sin 3x$, infinitely many solutions

46. $4y'' + 25y = 0, \quad y(0) = 2,\ y(2\pi) = -2$

47. Find a differential equation with a general solution that is $y = c_1e^{x/5} + c_2e^{-4x}$.

**Answer**

$5y'' + 19y' - 4y = 0$

48. Find a differential equation with a general solution that is $y = c_1e^{x} + c_2e^{-4x/3}$.

**For each differential equation in exercises 49 - 51:**

a. **Solve the initial value problem.**

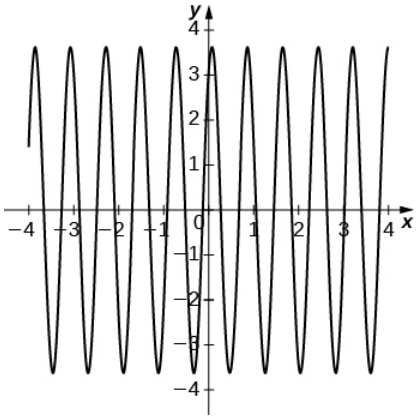
b. **[T] Use a graphing utility to graph the particular solution.**

49. $y'' + 64y = 0; \quad y(0) = 3,\ y'(0) = 16$

**Answer**

a. $y = 3\cos 8x + 2\sin 8x$

b.



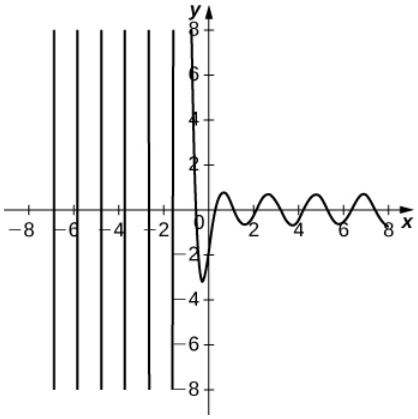
50. $y'' - 2y' + 10y = 0; \quad y(0) = 1,\ y'(0) = 13$

51. $y'' + 5y' + 15y = 0; \quad y(0) = -2,\ y'(0) = 7$

**Answer**

a. $y = e^{-5/2}\left[-2\cos\left(\frac{\sqrt{35}}{2}x\right) + \frac{4\sqrt{35}}{35}\sin\left(\frac{\sqrt{35}}{2}x\right)\right]$

b.



52. (Principle of superposition) Prove that if $y_1(x)$ and $y_2(x)$ are solutions to a linear homogeneous differential equation, $y'' + p(x)y' + q(x)y = 0$, then the function $y(x) = c_1y_1(x) + c_2y_2(x)$, where $c_1$ and $c_2$ are constants, is also a solution.

53. Prove that if $a$, $b$ and $c$ are positive constants, then all solutions to the second-order linear differential equation $ay'' + by' + cy = 0$ approach zero as $x \to \infty$. (*Hint:* Consider three cases: two distinct roots, repeated real roots, and complex conjugate roots.)

# 17.3: Nonhomogeneous Linear Equations

**Learning Objectives**

- Write the general solution to a nonhomogeneous differential equation.
- Solve a nonhomogeneous differential equation by the method of undetermined coefficients.
- Solve a nonhomogeneous differential equation by the method of variation of parameters.

In this section, we examine how to solve nonhomogeneous differential equations. The terminology and methods are different from those we used for homogeneous equations, so let's start by defining some new terms.

## General Solution to a Nonhomogeneous Linear Equation

Consider the nonhomogeneous linear differential equation

$$a_2(x)y''+a_1(x)y'+a_0(x)y = r(x).$$

The associated homogeneous equation

$$a_2(x)y''+a_1(x)y'+a_0(x)y = 0$$

is called the *complementary equation*. We will see that solving the complementary equation is an important step in solving a nonhomogeneous differential equation.

**Definition: Particular Solution**

A solution $y_p(x)$ of a differential equation that contains no arbitrary constants is called a *particular solution* to the equation.

**GENERAL Solution TO A NONHOMOGENEOUS EQUATION**

Let $y_p(x)$ be any particular solution to the nonhomogeneous linear differential equation

$$a_2(x)y''+a_1(x)y'+a_0(x)y = r(x).$$

Also, let $c_1y_1(x) + c_2y_2(x)$ denote the general solution to the complementary equation. Then, the *general solution* to the nonhomogeneous equation is given by

$$y(x) = c_1y_1(x) + c_2y_2(x) + y_p(x).$$

**Proof**

To prove $y(x)$ is the general solution, we must first show that it solves the differential equation and, second, that any solution to the differential equation can be written in that form. Substituting $y(x)$ into the differential equation, we have

$$\begin{aligned} a_2(x)y''+a_1(x)y'+a_0(x)y &= a_2(x)(c_1y_1 + c_2y_2 + y_p)''+a_1(x)(c_1y_1 + c_2y_2 + y_p)' \\ &\quad +a_0(x)(c_1y_1 + c_2y_2 + y_p) \\ &= [a_2(x)(c_1y_1 + c_2y_2)''+a_1(x)(c_1y_1 + c_2y_2)'+a_0(x)(c_1y_1 + c_2y_2)] \\ &\quad +a_2(x)y_p''+a_1(x)y_p'+a_0(x)y_p \\ &= 0 + r(x) \\ &= r(x). \end{aligned}$$

So $y(x)$ is a solution.

Now, let $z(x)$ be any solution to $a_2(x)y'' + a_1(x)y'+a_0(x)y = r(x)$. Then

$$\begin{aligned} a_2(x)(z-y_p)''+a_1(x)(z-y_p)'+a_0(x)(z-y_p) &= (a_2(x)z''+a_1(x)z'+a_0(x)z) \\ &\quad -(a_2(x)y_p''+a_1(x)y_p'+a_0(x)y_p) \\ &= r(x)-r(x) \\ &= 0, \end{aligned}$$

so $z(x)-y_p(x)$ is a solution to the complementary equation. But, $c_1y_1(x)+c_2y_2(x)$ is the general solution to the complementary equation, so there are constants $c_1$ and $c_2$ such that

$$z(x)-y_p(x)=c_1y_1(x)+c_2y_2(x).$$

Hence, we see that

$$z(x)=c_1y_1(x)+c_2y_2(x)+y_p(x).$$

### Example 17.3.1: Verifying the General Solution

Given that $y_p(x)=x$ is a particular solution to the differential equation $y''+y=x$, write the general solution and check by verifying that the solution satisfies the equation.

#### Solution

The complementary equation is $y''+y=0$, which has the general solution $c_1\cos x+c_2\sin x$. So, the general solution to the nonhomogeneous equation is

$$y(x)=c_1\cos x+c_2\sin x+x.$$

To verify that this is a solution, substitute it into the differential equation. We have

$$y'(x)=-c_1\sin x+c_2\cos x+1$$

and

$$y''(x)=-c_1\cos x-c_2\sin x.$$

Then

$$\begin{aligned} y''(x)+y(x) &= -c_1\cos x-c_2\sin x+c_1\cos x+c_2\sin x+x \\ &= x. \end{aligned}$$

So, $y(x)$ is a solution to $y''+y=x$.

### Exercise 17.3.1

Given that $y_p(x)=-2$ is a particular solution to $y''-3y'-4y=8$, write the general solution and verify that the general solution satisfies the equation.

**Hint**

Find the general solution to the complementary equation.

**Answer**

$y(x)=c_1e^{-x}+c_2e^{4x}-2$

In the preceding section, we learned how to solve homogeneous equations with constant coefficients. Therefore, for nonhomogeneous equations of the form $ay''+by'+cy=r(x)$, we already know how to solve the complementary equation, and the problem boils down to finding a particular solution for the nonhomogeneous equation. We now examine two techniques for this: the method of undetermined coefficients and the method of variation of parameters.

## Undetermined Coefficients

The method of *undetermined coefficients* involves making educated guesses about the form of the particular solution based on the form of $r(x)$. When we take derivatives of polynomials, exponential functions, sines, and cosines, we get polynomials, exponential functions, sines, and cosines. So when $r(x)$ has one of these forms, it is possible that the solution to the nonhomogeneous differential equation might take that same form. Let's look at some examples to see how this works.

### Example 17.3.2: Undetermined Coefficients When $r(x)$ Is a Polynomial

Find the general solution to $y''+4y'+3y=3x$.

**Solution**

The complementary equation is $y''+4y'+3y=0$, with general solution $c_1e^{-x}+c_2e^{-3x}$. Since $r(x)=3x$, the particular solution might have the form $y_p(x)=Ax+B$. If this is the case, then we have $y_p'(x)=A$ and $y_p''(x)=0$. For $y_p$ to be a solution to the differential equation, we must find values for $A$ and $B$ such that

$$\begin{aligned} y''+4y'+3y &= 3x \\ 0+4(A)+3(Ax+B) &= 3x \\ 3Ax+(4A+3B) &= 3x. \end{aligned}$$

Setting coefficients of like terms equal, we have

$$\begin{aligned} 3A &= 3 \\ 4A+3B &= 0. \end{aligned}$$

Then, $A=1$ and $B=-\frac{4}{3}$, so $y_p(x)=x-\frac{4}{3}$ and the general solution is

$$y(x)=c_1e^{-x}+c_2e^{-3x}+x-\frac{4}{3}.$$

In Example 17.3.2, notice that even though $r(x)$ did not include a constant term, it was necessary for us to include the constant term in our guess. If we had assumed a solution of the form $y_p=Ax$ (with no constant term), we would not have been able to find a solution. (Verify this!) If the function $r(x)$ is a polynomial, our guess for the particular solution should be a polynomial of the same degree, and it must include all lower-order terms, regardless of whether they are present in $r(x)$.

### Example 17.3.3: Undetermined Coefficients When $r(x)$ Is an Exponential

Find the general solution to $y''-y'-2y=2e^{3x}$.

**Solution**

The complementary equation is $y''-y'-2y=0$, with the general solution $c_1e^{-x}+c_2e^{2x}$. Since $r(x)=2e^{3x}$, the particular solution might have the form $y_p(x)=Ae^{3x}$. Then, we have $yp'(x)=3Ae^{3x}$ and $y_p''(x)=9Ae^{3x}$. For $y_p$ to be a solution to the differential equation, we must find a value for $A$ such that

$$\begin{aligned} y''-y'-2y &= 2e^{3x} \\ 9Ae^{3x}-3Ae^{3x}-2Ae^{3x} &= 2e^{3x} \\ 4Ae^{3x} &= 2e^{3x}. \end{aligned}$$

So, $4A=2$ and $A=1/2$. Then, $y_p(x)=(\frac{1}{2})e^{3x}$, and the general solution is

$$y(x)=c_1e^{-x}+c_2e^{2x}+\frac{1}{2}e^{3x}.$$

### Exercise 17.3.2

Find the general solution to $y''-4y'+4y=7\sin t-\cos t$.

**Hint**

Use $y_p(t) = A\sin t + B\cos t$ as a guess for the particular solution.

**Answer**

$y(t) = c_1e^{2t} + c_2te^{2t} + \sin t + \cos t$

In the previous checkpoint, $r(x)$ included both sine and cosine terms. However, even if $r(x)$ included a sine term only or a cosine term only, both terms must be present in the guess. The method of undetermined coefficients also works with products of polynomials, exponentials, sines, and cosines. Some of the key forms of $r(x)$ and the associated guesses for $y_p(x)$ are summarized in Table **17.3.1**.

Table **17.3.1**: Key Forms for the Method of Undetermined Coefficients

| $r(x)$ | **Initial guess for $y_p(x)$** |
|---|---|
| $k$ (a constant) | $A$ (a constant) |
| $ax + b$ | $Ax + B$ (*Note*: The guess must include both terms even if $b = 0$.) |
| $ax^2 + bx + c$ | $Ax^2 + Bx + C$ (*Note*: The guess must include all three terms even if $b$ or $c$ are zero.) |
| Higher-order polynomials | Polynomial of the same order as $r(x)$ |
| $ae^{\lambda x}$ | $Ae^{\lambda x}$ |
| $a\cos\beta x + b\sin\beta x$ | $A\cos\beta x + B\sin\beta x$ (*Note*: The guess must include both terms even if either $a = 0$ or $b = 0$.) |
| $ae^{\alpha x}\cos\beta x + be^{\alpha x}\sin\beta x$ | $Ae^{\alpha x}\cos\beta x + Be^{\alpha x}\sin\beta x$ |
| $(ax^2 + bx + c)e^{\lambda x}$ | $(Ax^2 + Bx + C)e^{\lambda x}$ |
| $(a_2x^2 + a_1x + a0)\cos\beta x$ $+ (b_2x^2 + b_1x + b_0)\sin\beta x$ | $(A_2x^2 + A_1x + A_0)\cos\beta x$ $+ (B_2x^2 + B_1x + B_0)\sin\beta x$ |
| $(a_2x^2 + a_1x + a_0)e^{\alpha x}\cos\beta x$ $+ (b_2x^2 + b_1x + b_0)e^{\alpha x}\sin\beta x$ | $(A_2x^2 + A_1x + A_0)e^{\alpha x}\cos\beta x$ $+ (B_2x^2 + B_1x + B_0)e^{\alpha x}\sin\beta x$ |

Keep in mind that there is a key pitfall to this method. Consider the differential equation $y'' + 5y' + 6y = 3e^{-2x}$. Based on the form of $r(x)$, we guess a particular solution of the form $y_p(x) = Ae^{-2x}$. But when we substitute this expression into the differential equation to find a value for $A$,we run into a problem. We have

$$y_p'(x) = -2Ae^{-2x}$$

and

$$y_p'' = 4Ae^{-2x},$$

so we want

$$\begin{aligned} y'' + 5y' + 6y &= 3e^{-2x} \\ 4Ae^{-2x} + 5(-2Ae^{-2x}) + 6Ae^{-2x} &= 3e^{-2x} \\ 4Ae^{-2x} - 10Ae^{-2x} + 6Ae^{-2x} &= 3e^{-2x} \\ 0 &= 3e^{-2x}, \end{aligned}$$

which is not possible.

Looking closely, we see that, in this case, the general solution to the complementary equation is $c_1e^{-2x} + c_2e^{-3x}$. The exponential function in $r(x)$ is actually a solution to the complementary equation, so, as we just saw, all the terms on the left side of the equation cancel out. We can still use the method of undetermined coefficients in this case, but we have to alter our guess by multiplying it by $x$. Using the new guess, $y_p(x) = Axe^{-2x}$, we have

$$y_p'(x) = A(e^{-2x} - 2xe^{-2x}$$

and

$$y_p''(x) = -4Ae^{-2x} + 4Axe^{-2x}.$$

Substitution gives

$$\begin{aligned} y''+5y'+6y &= 3e^{-2x} \\ (-4Ae^{-2x} + 4Axe^{-2x}) + 5(Ae^{-2x} - 2Axe^{-2x}) + 6Axe^{-2x} &= 3e^{-2x} \\ -4Ae^{-2x} + 4Axe^{-2x} + 5Ae^{-2x} - 10Axe^{-2x} + 6Axe^{-2x} &= 3e^{-2x} \\ Ae^{-2x} &= 3e^{-2x}. \end{aligned}$$

So, $A = 3$ and $y_p(x) = 3xe^{-2x}$. This gives us the following general solution

$$y(x) = c_1e^{-2x} + c_2e^{-3x} + 3xe^{-2x}.$$

Note that if $xe^{-2x}$ were also a solution to the complementary equation, we would have to multiply by $x$ again, and we would try $y_p(x) = Ax^2e^{-2x}$.

### PROBLEM-SOLVING STRATEGY: METHOD OF UNDETERMINED COEFFICIENTS

1. Solve the complementary equation and write down the general solution.
2. Based on the form of $r(x)$, make an initial guess for $y_p(x)$.
3. Check whether any term in the guess for$y_p(x)$ is a solution to the complementary equation. If so, multiply the guess by $x$. Repeat this step until there are no terms in $y_p(x)$ that solve the complementary equation.
4. Substitute $y_p(x)$ into the differential equation and equate like terms to find values for the unknown coefficients in $y_p(x)$.
5. Add the general solution to the complementary equation and the particular solution you just found to obtain the general solution to the nonhomogeneous equation.

### Example 17.3.4: Solving Nonhomogeneous Equations

Find the general solutions to the following differential equations.

a. $y'' - 9y = -6\cos 3x$
b. $x''+2x'+x = 4e^{-t}$
c. $y''-2y'+5y = 10x^2 - 3x - 3$
d. $y'' - 3y' = -12t$

**Solution**

a. The complementary equation is $y''-9y = 0$, which has the general solution $c_1e^{3x} + c_2e^{-3x}$(step 1). Based on the form of $r(x) = -6\cos 3x$, our initial guess for the particular solution is $y_p(x) = A\cos 3x + B\sin 3x$ (step 2). None of the terms in $y_p(x)$ solve the complementary equation, so this is a valid guess (step 3).
Now we want to find values for $A$ and $B$, so substitute $y_p$ into the differential equation. We have

$$y_p'(x) = -3A\sin 3x + 3B\cos 3x \text{ and } y_p''(x) = -9A\cos 3x - 9B\sin 3x,$$

so we want to find values of $A$ and $B$ such that

$$\begin{aligned} y''-9y &= -6\cos 3x \\ -9A\cos 3x - 9B\sin 3x - 9(A\cos 3x + B\sin 3x) &= -6\cos 3x \\ -18A\cos 3x - 18B\sin 3x &= -6\cos 3x. \end{aligned}$$

Therefore,

$$\begin{aligned} -18A &= -6 \\ -18B &= 0. \end{aligned}$$

This gives $A = \frac{1}{3}$ and $B = 0$, so $y_p(x) = (\frac{1}{3})\cos 3x$ (step 4).
Putting everything together, we have the general solution

$$y(x) = c_1 e^{3x} + c_2 e^{-3x} + \frac{1}{3}\cos 3x.$$

b. The complementary equation is $x'' + 2x' + x = 0$, which has the general solution $c_1 e^{-t} + c_2 te^{-t}$ (step 1). Based on the form $r(t) = 4e^{-t}$, our initial guess for the particular solution is $x_p(t) = Ae^{-t}$ (step 2). However, we see that this guess solves the complementary equation, so we must multiply by $t$, which gives a new guess: $x_p(t) = Ate^{-t}$ (step 3). Checking this new guess, we see that it, too, solves the complementary equation, so we must multiply by $t$ again, which gives $x_p(t) = At^2 e^{-t}$ (step 3 again). Now, checking this guess, we see that $x_p(t)$ does not solve the complementary equation, so this is a valid guess (step 3 yet again).
We now want to find a value for $A$, so we substitute $x_p$ into the differential equation. We have

$$x_p(t) = At^2 e^{-t}, \text{ so}$$
$$x_p'(t) = 2Ate^{-t} - At^2 e^{-t}$$

and

$$x_p''(t) = 2Ae^{-t} - 2Ate^{-t} - (2Ate^{-t} - At^2 e^{-t}) = 2Ae^{-t} - 4Ate^{-t} + At^2 e^{-t}.$$

Substituting into the differential equation, we want to find a value of $A$ so that

$$\begin{aligned} x''+2x'+x &= 4e^{-t} \\ 2Ae^{-t} - 4Ate^{-t} + At^2 e^{-t} + 2(2Ate^{-t} - At^2 e^{-t}) + At^2 e^{-t} &= 4e^{-t} \\ 2Ae^{-t} &= 4e^{-t}. \end{aligned}$$

This gives $A = 2$, so $x_p(t) = 2t^2 e^{-t}$ (step 4). Putting everything together, we have the general solution

$$x(t) = c_1 e^{-t} + c_2 te^{-t} + 2t^2 e^{-t}.$$

c. The complementary equation is $y''-2y'+5y = 0$, which has the general solution $c_1 e^x \cos 2x + c_2 e^x \sin 2x$ (step 1). Based on the form $r(x) = 10x^2 - 3x - 3$, our initial guess for the particular solution is $y_p(x) = Ax^2 + Bx + C$ (step 2). None of the terms in $y_p(x)$ solve the complementary equation, so this is a valid guess (step 3). We now want to find values for $A$, $B$, and $C$, so we substitute $y_p$ into the differential equation. We have $y_p'(x) = 2Ax + B$ and $y_p''(x) = 2A$, so we want to find values of $A$, $B$, and $C$ such that

$$\begin{aligned} y''-2y'+5y &= 10x^2 - 3x - 3 \\ 2A - 2(2Ax + B) + 5(Ax^2 + Bx + C) &= 10x^2 - 3x - 3 \\ 5Ax^2 + (5B - 4A)x + (5C - 2B + 2A) &= 10x^2 - 3x - 3. \end{aligned}$$

Therefore,

$$\begin{aligned} 5A &= 10 \\ 5B - 4A &= -3 \\ 5C - 2B + 2A &= -3. \end{aligned}$$

This gives $A = 2$, $B = 1$, and $C = -1$, so $y_p(x) = 2x^2 + x - 1$ (step 4). Putting everything together, we have the general solution

$$y(x) = c_1 e^x \cos 2x + c_2 e^x \sin 2x + 2x^2 + x - 1.$$

d. The complementary equation is $y''-3y' = 0$, which has the general solution $c_1 e^{3t} + c_2$ (step 1). Based on the form r(t)=−12t,r(t)=−12t, our initial guess for the particular solution is $y_p(t) = At + B$ (step 2). However, we see that the constant term in this guess solves the complementary equation, so we must multiply by $t$, which gives a new guess: $y_p(t) = At^2 + Bt$ (step 3). Checking this new guess, we see that none of the terms in $y_p(t)$ solve the complementary equation, so this is a

valid guess (step 3 again). We now want to find values for $A$ and $B$, so we substitute $y_p$ into the differential equation. We have $y_p'(t) = 2At + B$ and $y_p''(t) = 2A$, so we want to find values of AA and BB such that

$$\begin{aligned} y''-3y' &= -12t \\ 2A - 3(2At + B) &= -12t \\ -6At + (2A - 3B) &= -12t. \end{aligned}$$

Therefore,

$$\begin{aligned} -6A &= -12 \\ 2A - 3B &= 0. \end{aligned}$$

This gives $A = 2$ and $B = 4/3$, so $y_p(t) = 2t^2 + (4/3)t$ (step 4). Putting everything together, we have the general solution

$$y(t) = c_1e^{3t} + c_2 + 2t^2 + \frac{4}{3}t.$$

**? Exercise 17.3.3**

Find the general solution to the following differential equations.

a. $y''-5y'+4y = 3e^x$
b. $y''+y'-6y = 52\cos 2t$

**Hint**

Use the problem-solving strategy.

**Answer a**

$y(x) = c_1e^{4x} + c_2e^x - xe^x$

**Answer b**

$y(t) = c_1e^{-3t} + c_2e^{2t} - 5\cos 2t + \sin 2t$

## Variation of Parameters

Sometimes, $r(x)$ is not a combination of polynomials, exponentials, or sines and cosines. When this is the case, the method of undetermined coefficients does not work, and we have to use another approach to find a particular solution to the differential equation. We use an approach called the *method of variation of parameters*.

To simplify our calculations a little, we are going to divide the differential equation through by $a$, so we have a leading coefficient of 1. Then the differential equation has the form

$$y''+py'+qy = r(x),$$

where $p$ and $q$ are constants.

If the general solution to the complementary equation is given by $c_1y_1(x) + c_2y_2(x)$, we are going to look for a particular solution of the form

$$y_p(x) = u(x)y_1(x) + v(x)y_2(x).$$

In this case, we use the two linearly independent solutions to the complementary equation to form our particular solution. However, we are assuming the coefficients are functions of $x$, rather than constants. We want to find functions $u(x)$ and $v(x)$ such that $y_p(x)$ satisfies the differential equation. We have

$$\begin{aligned} y_p &= uy_1 + vy_2 \\ y_p' &= u'y_1 + uy_1'+v'y_2 + vy_2' \\ y_p'' &= (u'y_1 + v'y_2)'+u'y_1'+uy_1''+v'y_2'+vy_2''. \end{aligned}$$

Substituting into the differential equation, we obtain

$$\begin{aligned} y_p''+py_p'+qy_p &= [(u'y_1+v'y_2)'+u'y_1'+uy_1''+v'y_2'+vy_2''] \\ &\quad +p[u'y_1+uy_1'+v'y_2+vy_2'] + q[uy_1+vy_2] \\ &= u[y_1''+py_1'+qy_1] + v[y_2''+py_2'+qy_2] \\ &\quad +(u'y_1+v'y_2)'+p(u'y_1+v'y_2) + (u'y_1'+v'y_2'). \end{aligned}$$

Note that $y_1$ and $y_2$ are solutions to the complementary equation, so the first two terms are zero. Thus, we have

$$(u'y_1+v'y_2)'+p(u'y_1+v'y_2)+(u'y_1'+v'y_2') = r(x).$$

If we simplify this equation by imposing the additional condition $u'y_1+v'y_2=0$, the first two terms are zero, and this reduces to $u'y_1'+v'y_2'=r(x)$. So, with this additional condition, we have a system of two equations in two unknowns:

$$\begin{aligned} u'y_1+v'y_2 &= 0 \\ u'y_1'+v'y_2' &= r(x). \end{aligned}$$

Solving this system gives us $u'$ and $v'$, which we can integrate to find $u$ and $v$.

Then, $y_p(x) = u(x)y_1(x) + v(x)y_2(x)$ is a particular solution to the differential equation. Solving this system of equations is sometimes challenging, so let's take this opportunity to review Cramer's rule, which allows us to solve the system of equations using determinants.

**RULE: CRAMER'S RULE**

The system of equations

$$\begin{aligned} a_1z_1+b_1z_2 &= r_1 \\ a_2z_1+b_2z_2 &= r_2 \end{aligned}$$

has a unique solution if and only if the determinant of the coefficients is not zero. In this case, the solution is given by

$$z_1 = \frac{\begin{vmatrix} r_1 & b_1 \\ r_2 & b_2 \end{vmatrix}}{\begin{vmatrix} a_1 & b_1 \\ a_2 & b_2 \end{vmatrix}} \quad \text{and} \quad z_2 = \frac{\begin{vmatrix} a_1 & r_1 \\ a_2 & r_2 \end{vmatrix}}{\begin{vmatrix} a_1 & b_1 \\ a_2 & b_2 \end{vmatrix}}. \tag{17.3.1}$$

**Example 17.3.5: Using Cramer's Rule**

Use Cramer's rule to solve the following system of equations.

$$\begin{aligned} x^2z_1+2xz_2 &= 0 \\ z_1-3x^2z_2 &= 2x \end{aligned}$$

**Solution**

We have

$$\begin{aligned} a_1(x) &= x^2 \\ a_2(x) &= 1 \\ b_1(x) &= 2x \\ b_2(x) &= -3x^2 \\ r_1(x) &= 0 \\ r_2(x) &= 2x. \end{aligned}$$

Then,

$$\begin{vmatrix} a_1 & b_1 \\ a_2 & b_2 \end{vmatrix} = \begin{vmatrix} x^2 & 2x \\ 1 & -3x^2 \end{vmatrix} = -3x^4-2x$$

and

$$\begin{vmatrix} r_1b_1 \\ r_2b_2 \end{vmatrix} = \begin{vmatrix} 02x \\ 2x-3x^2 \end{vmatrix} = 0-4x^2 = -4x^2.$$

Thus,

$$z1 = \frac{\begin{vmatrix} r_1b_1 \\ r_2b_2 \end{vmatrix}}{\begin{vmatrix} a_1b_1 \\ a_2b_2 \end{vmatrix}} = \frac{-4x^2}{-3x^4-2x} = \frac{4x}{3x^3+2}.$$

In addition,

$$\begin{vmatrix} a_1r_1 \\ a_2r_2 \end{vmatrix} = \begin{vmatrix} x^20 \\ 12x \end{vmatrix} = 2x^3 - 0 = 2x^3.$$

Thus,

$$z2 = \frac{\begin{vmatrix} a_1r_1 \\ a_2r_2 \end{vmatrix}}{\begin{vmatrix} a_1b_1 \\ a_2b_2 \end{vmatrix}} = \frac{2x^3}{-3x^4-2x} = \frac{-2x^2}{3x^3+2}.$$

## Exercise 17.3.4

Use Cramer's rule to solve the following system of equations.

$$2xz_1 - 3z_2 = 0$$
$$x^2z_1 + 4xz_2 = x+1$$

**Hint**

Use the process from the previous example.

**Answer**

$z_1 = \frac{3x+3}{11x^2}, z_2 = \frac{2x+2}{11x}$

## PROBLEM-SOLVING STRATEGY: METHOD OF VARIATION OF PARAMETERS

1. Solve the complementary equation and write down the general solution
$$c_1y_1(x) + c_2y_2(x).$$
2. Use Cramer's rule or another suitable technique to find functions $u'(x)$ and $v'(x)$ satisfying
$$u'y_1 + v'y_2 = 0$$
$$u'y_1' + v'y_2' = r(x).$$
3. Integrate $u'$ and $v'$ to find $u(x)$ and $v(x)$. Then, $y_p(x) = u(x)y_1(x) + v(x)y_2(x)$ is a particular solution to the equation.
4. Add the general solution to the complementary equation and the particular solution found in step 3 to obtain the general solution to the nonhomogeneous equation.

## Example 17.3.6: Using the Method of Variation of Parameters

Find the general solution to the following differential equations.

a. $y''-2y'+y = \frac{e^t}{t^2}$
b. $y''+y = 3\sin^2 x$

**Solution**

a. The complementary equation is $y''-2y'+y=0$ with associated general solution $c_1e^t+c_2te^t$. Therefore, $y_1(t)=e^t$ and $y_2(t)=te^t$. Calculating the derivatives, we get $y_1'(t)=e^t$ and $y_2'(t)=e^t+te^t$ (step 1). Then, we want to find functions $u'(t)$ and $v'(t)$ so that

$$\begin{aligned} u'e^t+v'te^t&=0\\ u'e^t+v'(e^t+te^t)&=\frac{e^t}{t^2}. \end{aligned}$$

Applying Cramer's rule (Equation 17.3.1), we have

$$u'=\frac{\begin{vmatrix} 0 & te^t\\ \frac{e^t}{t^2} & e^t+te^t\end{vmatrix}}{\begin{vmatrix} te^t & te^t\\ e^t & e^t+te^t\end{vmatrix}}=\frac{0-te^t\left(\frac{e^t}{t^2}\right)}{e^t(e^t+te^t)-e^tte^t}=\frac{-\frac{e^{2t}}{t}}{e^{2t}}=-\frac{1}{t}$$

and

$$v'=\frac{\begin{vmatrix} e^t & 0\\ e^t & \frac{e^t}{t^2}\end{vmatrix}}{\begin{vmatrix} te^t & te^t\\ e^t & e^t+te^t\end{vmatrix}}=\frac{e^t\left(\frac{e^t}{t^2}\right)}{e^{2t}}=\frac{1}{t^2}\quad\text{(step 2)}.$$

Integrating, we get

$$\begin{aligned} u&=-\int\frac{1}{t}dt=-\ln|t|\\ v&=\int\frac{1}{t^2}dt=-\frac{1}{t}\qquad\text{(step 3)} \end{aligned}$$

Then we have

$$\begin{aligned} y_p&=-e^t\ln|t|-\frac{1}{t}te^t\\ &=-e^t\ln|t|-e^t.\qquad\text{(step 4)} \end{aligned}$$

The $e^t$ term is a solution to the complementary equation, so we don't need to carry that term into our general solution explicitly. The general solution is

$$y(t)=c_1e^t+c_2te^t-e^t\ln|t|\qquad\text{(step 5)}$$

b. The complementary equation is $y''+y=0$ with associated general solution $c_1\cos x+c_2\sin x$. So, $y_1(x)=\cos x$ and $y_2(x)=\sin x$ (step 1). Then, we want to find functions $u'(x)$ and $v'(x)$ such that

$$\begin{aligned} u'\cos x+v'\sin x&=0\\ -u'\sin x+v'\cos x&=3\sin_2 x. \end{aligned}$$

Applying Cramer's rule, we have

$$u'=\frac{\begin{vmatrix} 0 & \sin x\\ 3\sin^2x\cos x & \cos x\sin x\end{vmatrix}}{\begin{vmatrix} \cos x\sin x & \sin x\\ -\sin x\cos x & \cos x\end{vmatrix}}=\frac{0-3\sin^3x}{\cos^2x+\sin^2x}=-3\sin^3x$$

and

$$v' = \frac{\begin{vmatrix} \cos x & 0 \\ -\sin x & 3\sin^2 x \end{vmatrix}}{\begin{vmatrix} \cos x & \sin x \\ -\sin x & \cos x \end{vmatrix}} = \frac{3\sin^2 x \cos x}{1} = 3\sin^2 x \cos x \text{(step 2)}.$$

Integrating first to find $u$, we get

$$u = \int -3\sin^3 x dx = -3\left[-\frac{1}{3}\sin^2 x \cos x + \frac{2}{3}\int \sin x dx\right] = \sin^2 x \cos x + 2\cos x.$$

Now, we integrate to find $v$. Using substitution (with $w = \sin x$), we get

$$v = \int 3\sin^2 x \cos x dx = \int 3w^2 dw = w^3 = sin^3 x.$$

Then,

$$\begin{aligned} y_p &= (\sin^2 x \cos x + 2\cos x)\cos x + (\sin^3 x)\sin x \\ &= \sin_2 x \cos_2 x + 2\cos_2 x + \sin_4 x \\ &= 2\cos_2 x + \sin_2 x(\cos^2 x + \sin^2 x) \qquad \text{(step 4)}. \\ &= 2\cos_2 x + \sin_2 x \\ &= \cos_2 x + 1 \end{aligned}$$

The general solution is

$$y(x) = c_1 \cos x + c_2 \sin x + 1 + \cos^2 x \text{(step 5)}.$$

## ? Exercise 17.3.5

Find the general solution to the following differential equations.

a. $y'' + y = \sec x$

b. $x'' - 2x' + x = \dfrac{e^t}{t}$

**Hint**

Follow the problem-solving strategy.

**Answer a**

$y(x) = c_1 \cos x + c_2 \sin x + \cos x \ln|\cos x| + x \sin x$

**Answer b**

$x(t) = c_1 e^t + c_2 t e^t + t e^t \ln|t|$

## Key Concepts

- To solve a nonhomogeneous linear second-order differential equation, first find the general solution to the complementary equation, then find a particular solution to the nonhomogeneous equation.
- Let $y_p(x)$ be any particular solution to the nonhomogeneous linear differential equation

  $$a_2(x)y'' + a_1(x)y' + a_0(x)y = r(x),$$

  and let $c_1 y_1(x) + c_2 y_2(x)$ denote the general solution to the complementary equation. Then, the general solution to the nonhomogeneous equation is given by

  $$y(x) = c_1 y_1(x) + c_2 y_2(x) + y_p(x).$$

- When $r(x)$ is a combination of polynomials, exponential functions, sines, and cosines, use the method of undetermined coefficients to find the particular solution. To use this method, assume a solution in the same form as $r(x)$, multiplying by $x$ as

necessary until the assumed solution is linearly independent of the general solution to the complementary equation. Then, substitute the assumed solution into the differential equation to find values for the coefficients.

- When $r(x)$ is *not* a combination of polynomials, exponential functions, or sines and cosines, use the method of variation of parameters to find the particular solution. This method involves using Cramer's rule or another suitable technique to find functions and $v'(x)$ satisfying

$$u'y_1 + v'y_2 = 0$$
$$u'y_1' + v'y_2' = r(x).$$

Then, $y_p(x) = u(x)y_1(x) + v(x)y_2(x)$ is a particular solution to the differential equation.

### Key Equations

- **Complementary equation**
  $a_2(x)y'' + a_1(x)y' + a_0(x)y = 0$
- **General solution to a nonhomogeneous linear differential equation**
  $y(x) = c_1y_1(x) + c_2y_2(x) + y_p(x)$

## Glossary

**complementary equation**

for the nonhomogeneous linear differential equation $a + 2(x)y'' + a_1(x)y' + a_0(x)y = r(x)$, the associated homogeneous equation, called the *complementary equation*, is $a_2(x)y'' + a_1(x)y' + a_0(x)y = 0$

**method of undetermined coefficients**

a method that involves making a guess about the form of the particular solution, then solving for the coefficients in the guess

**method of variation of parameters**

a method that involves looking for particular solutions in the form $y_p(x) = u(x)y_1(x) + v(x)y_2(x)$, where $y_1$ and $y_2$ are linearly independent solutions to the complementary equations, and then solving a system of equations to find $u(x)$ and $v(x)$

**particular solution**

a solution $y_p(x)$ of a differential equation that contains no arbitrary constants

# 17.3E: Exercises for Section 17.2

**Solve the following equations using the method of undetermined coefficients.**

1. $2y'' - 5y' - 12y = 6$

2. $3y'' + y' - 4y = 8$

**Answer**

$y = c_1 e^{-4x/3} + c_2 e^{x} - 2$

3. $y'' - 6y' + 5y = e^{-x}$

4. $y'' + 16y = e^{-2x}$

**Answer**

$y = c_1 \cos 4x + c_2 \sin 4x + \frac{1}{20} e^{-2x}$

5. $y'' - 4y = x^2 + 1$

6. $y'' - 4y' + 4y = 8x^2 + 4x$

**Answer**

$y = c_1 e^{2x} + c_2 x e^{2x} + 2x^2 + 5x$

7. $y'' - 2y' - 3y = \sin 2x$

8. $y'' + 2y' + y = \sin x + \cos x$

**Answer**

$y = c_1 e^{-x} + c_2 x e^{-x} + \frac{1}{2} \sin x - \frac{1}{2} \cos x$

9. $y'' + 9y = e^{x} \cos x$

10. $y'' + y = 3 \sin 2x + x \cos 2x$

**Answer**

$y = c_1 \cos x + c_2 \sin x - \frac{1}{3} x \cos 2x - \frac{5}{9} \sin 2x$

11. $y'' + 3y' - 28y = 10e^{4x}$

12. $y'' + 10y' + 25y = xe^{-5x} + 4$

**Answer**

$y = c_1 e^{-5x} + c_2 x e^{-5x} + \frac{1}{6} x^3 e^{-5x} + \frac{4}{25}$

**In exercises 13 - 18,**

a. **Write the form for the particular solution $y_p(x)$ for the method of undetermined coefficients.**
b. **[T]** Use a computer algebra system to find a particular solution to the given equation.

13. $y'' - y' - y = x + e^{-x}$

14. $y'' - 3y = x^2 - 4x + 11$

**Answer**

a. $y_p(x) = Ax^2 + Bx + C$

b. $y_p(x) = -\frac{1}{3} x^2 + \frac{4}{3} x - \frac{35}{9}$

15. $y'' - y' - 4y = e^x \cos 3x$

16. $2y'' - y' + y = (x^2 - 5x)e^{-x}$

**Answer**

a. $y_p(x) = (Ax^2 + Bx + C)e^{-x}$

b. $y_p(x) = (\frac{1}{4}x^2 - \frac{5}{8}x - \frac{33}{32})e^{-x}$

17. $4y'' + 5y' - 2y = e^{2x} + x \sin x$

18. $y'' - y' - 2y = x^2 e^x \sin x$

**Answer**

a. $y_p(x) = (Ax^2 + Bx + C)e^x \cos x + (Dx^2 + Ex + F)e^x \sin x$

b. $y_p(x) = (-\frac{1}{10}x^2 - \frac{11}{25}x - \frac{27}{250})e^x \cos x + (-\frac{3}{10}x^2 + \frac{2}{25}x + \frac{39}{250})e^x \sin x$

**Solve the differential equation using either the method of undetermined coefficients or the variation of parameters.**

19. $y'' + 3y' - 4y = 2e^x$

20. $y'' + 2y' = e^{3x}$

**Answer**

$y = c_1 + c_2 e^{-2x} + \frac{1}{15}e^{3x}$

21. $y'' + 6y' + 9y = e^{-x}$

22. $y'' + 2y' - 8y = 6e^{2x}$

**Answer**

$y = c_1 e^{2x} + c_2 e^{-4x} + xe^{2x}$

**Solve the differential equation using the method of variation of parameters.**

23. $4y'' + y = 2 \sin x$

24. $y'' - 9y = 8x$

**Answer**

$y = c_1 e^{3x} + c_2 e^{-3x} - \frac{8x}{9}$

25. $y'' + y = \sec x, \quad 0 < x < \pi/2$

26. $y'' + 4y = 3 \csc 2x, \quad 0 < x < \pi/2$

**Answer**

$y = c_1 \cos 2x + c_2 \sin 2x - \frac{3}{2}x \cos 2x + \frac{3}{4} \sin 2x \ln(\sin 2x)$

**Find the unique solution satisfying the differential equation and the initial conditions given, where $y_p(x)$ is the particular solution.**

27. $y'' - 2y' + y = 12e^x, \quad y_p(x) = 6x^2 e^x, \; y(0) = 6, \; y'(0) = 0$

28. $y'' - 7y' = 4xe^{7x}, \quad y_p(x) = \frac{2}{7}x^2 e^{7x} - \frac{4}{49}xe^{7x}, \; y(0) = -1, \; y'(0) = 0$

**Answer**

$y = -\frac{347}{343} + \frac{4}{343}e^{7x} + \frac{2}{7}x^2 e^{7x} - \frac{4}{49}xe^{7x}$

29. $y'' + y = \cos x - 4 \sin x, \quad y_p(x) = 2x \cos x + \frac{1}{2}x \sin x, \; y(0) = 8, \; y'(0) = -4$

30. $y''-5y'=e^{5x}+8e^{-5x}, \quad y_p(x)=\frac{1}{5}xe^{5x}+\frac{4}{25}e^{-5x},\ y(0)=-2,\ y'(0)=0$

**Answer**

$y=-\frac{57}{25}+\frac{3}{25}e^{5x}+\frac{1}{5}xe^{5x}+\frac{4}{25}e^{-5x}$

**In problems 31 - 32, two linearly independent solutions—$y_1$ and $y_2$—are given that satisfy the corresponding homogeneous equation. Use the method of variation of parameters to find a particular solution to the given nonhomogeneous equation. Assume $x>0$ in each exercise.**

31. $x^2y''+2xy'-2y=3x, \quad y_1(x)=x,\ y2(x)=x^{-2}$

32. $x^2y''-2y=10x^2-1, \quad y_1(x)=x^2,\ y_2(x)=x^{-1}$

**Answer**

$y_p=\frac{1}{2}+\frac{10}{3}x^2\ln x$

# 17.4: Applications of Second-Order Differential Equations

**Learning Objectives**

- Solve a second-order differential equation representing simple harmonic motion.
- Solve a second-order differential equation representing damped simple harmonic motion.
- Solve a second-order differential equation representing forced simple harmonic motion.
- Solve a second-order differential equation representing charge and current in an RLC series circuit.

We saw in the chapter introduction that second-order linear differential equations are used to model many situations in physics and engineering. In this section, we look at how this works for systems of an object with mass attached to a vertical spring and an electric circuit containing a resistor, an inductor, and a capacitor connected in series. Models such as these can be used to approximate other more complicated situations; for example, bonds between atoms or molecules are often modeled as springs that vibrate, as described by these same differential equations.

## Simple Harmonic Motion

Consider a mass suspended from a spring attached to a rigid support. (This is commonly called a **spring-mass system**.) Gravity is pulling the mass downward and the restoring force of the spring is pulling the mass upward. As shown in Figure **17.4.1**, when these two forces are equal, the mass is said to be at the equilibrium position. If the mass is displaced from equilibrium, it oscillates up and down. This behavior can be modeled by a second-order constant-coefficient differential equation.

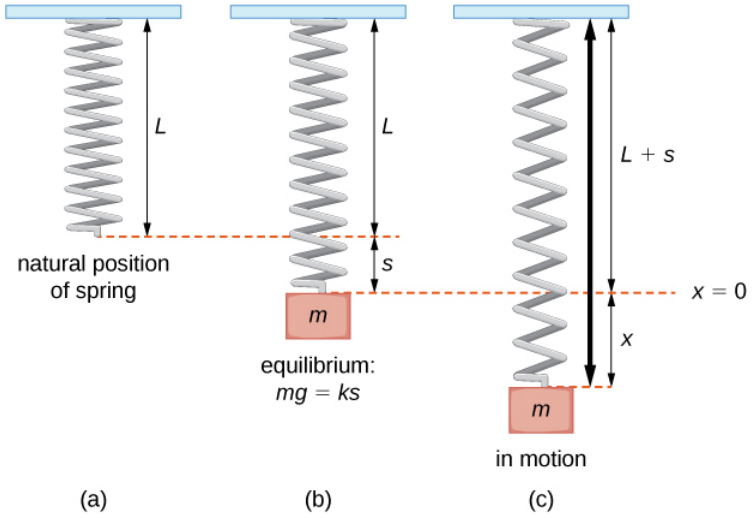

Figure **17.4.1**: A spring in its natural position (a), at equilibrium with a mass *m* attached (b), and in oscillatory motion (c).

Let $x(t)$ denote the displacement of the mass from equilibrium. Note that for spring-mass systems of this type, it is customary to adopt the convention that down is positive. Thus, a positive displacement indicates the mass is *below* the equilibrium point, whereas a negative displacement indicates the mass is *above* equilibrium. Displacement is usually given in feet in the English system or meters in the metric system.

Consider the forces acting on the mass. The force of gravity is given by mg.mg. In the English system, mass is in slugs and the acceleration resulting from gravity is in feet per second squared. The acceleration resulting from gravity is constant, so in the English system, $g = 32\ ft/sec^2$. Recall that 1 slug-foot/sec$^2$ is a pound, so the expression *mg* can be expressed in pounds. Metric system units are kilograms for mass and m/sec$^2$ for gravitational acceleration. In the metric system, we have $g = 9.8$ m/sec$^2$.

According to **Hooke's law**, the restoring force of the spring is proportional to the displacement and acts in the opposite direction from the displacement, so the restoring force is given by $-k(s + x)$. The spring constant is given in pounds per foot in the English system and in newtons per meter in the metric system.

Now, by Newton's second law, the sum of the forces on the system (gravity plus the restoring force) is equal to mass times acceleration, so we have

$$\begin{aligned} mx'' &= -k(s+x) + mg \\ &= -ks - kx + mg. \end{aligned}$$

However, by the way we have defined our equilibrium position, $mg = ks$, the differential equation becomes

$$mx'' + kx = 0.$$

It is convenient to rearrange this equation and introduce a new variable, called the **angular frequency**, $\omega$. Letting $\omega = \sqrt{k/m}$, we can write the equation as

$$x'' + \omega^2 x = 0.$$

This differential equation has the general solution

$$x(t) = c_1 \cos \omega t + c_2 \sin \omega t, \tag{17.4.1}$$

which gives the position of the mass at any point in time. The motion of the mass is called simple **harmonic motion**. The period of this motion (the time it takes to complete one oscillation) is $T = \dfrac{2\pi}{\omega}$ and the frequency is $f = \dfrac{1}{T} = \dfrac{\omega}{2\pi}$ (Figure 17.4.2).

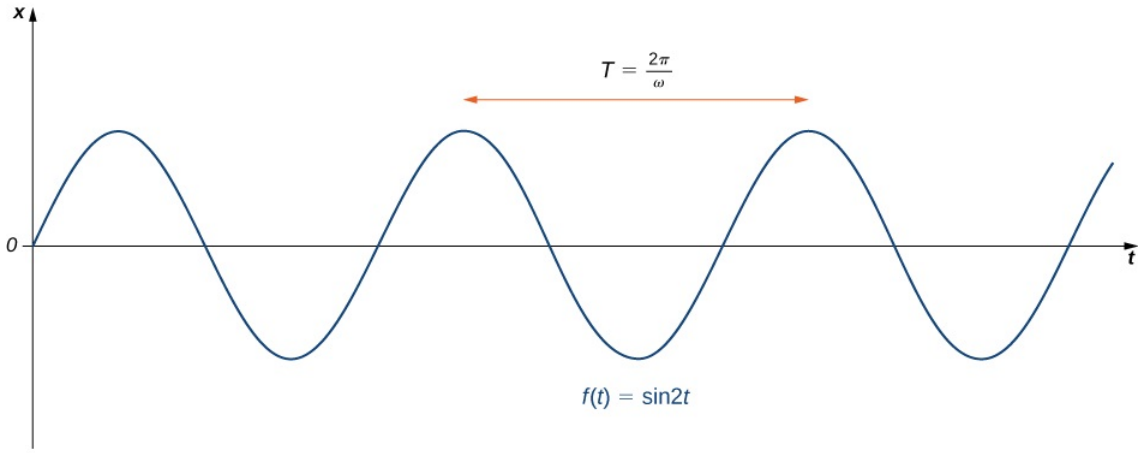

Figure 17.4.2: A graph of vertical displacement versus time for simple harmonic motion.

### Example 17.4.1: Simple Harmonic Motion

Assume an object weighing 2 lb stretches a spring 6 in. Find the equation of motion if the spring is released from the equilibrium position with an upward velocity of 16 ft/sec. What is the period of the motion?

**Solution**

We first need to find the spring constant. We have

$$\begin{aligned} mg &= ks \\ 2 &= k\left(\frac{1}{2}\right) \\ k &= 4. \end{aligned}$$

We also know that weight $W$ equals the product of mass $m$ and the acceleration due to gravity $g$. In English units, the acceleration due to gravity is 32 ft/sec$^2$.

$$\begin{aligned} W &= mg \\ 2 &= m(32) \\ m &= \frac{1}{16} \end{aligned}$$

Thus, the differential equation representing this system is

$$\frac{1}{16}x''+4x=0.$$

Multiplying through by 16, we get $x''+64x=0$, which can also be written in the form $x''+(8^2)x=0$. This equation has the general solution

$$x(t)=c_1\cos(8t)+c_2\sin(8t).$$

The mass was released from the equilibrium position, so $x(0)=0$, and it had an initial upward velocity of 16 ft/sec, so $x'(0)=-16$. Applying these initial conditions to solve for $c_1$ and $c_2$. gives

$$x(t)=-2\sin 8t.$$

The period of this motion is $\frac{2\pi}{8}=\frac{\pi}{4}$ sec.

**? Exercise 17.4.1**

A 200-g mass stretches a spring 5 cm. Find the equation of motion of the mass if it is released from rest from a position 10 cm below the equilibrium position. What is the frequency of this motion?

**Hint**

First find the spring constant.

**Answer**

$x(t)=0.1\cos(14t)$ (in meters); frequency is $\frac{14}{2\pi}$ Hz.

Writing the general solution in the form $x(t)=c_1\cos(\omega t)+c_2\sin(\omega t)$ (Equation 17.4.1) has some advantages. It is easy to see the link between the differential equation and the solution, and the period and frequency of motion are evident. This form of the function tells us very little about the amplitude of the motion, however. In some situations, we may prefer to write the solution in the form

$$x(t)=A\sin(\omega t+\phi).$$

Although the link to the differential equation is not as explicit in this case, the period and frequency of motion are still evident. Furthermore, the amplitude of the motion, $A$, is obvious in this form of the function. The constant $\phi$ is called a **phase shift** and has the effect of shifting the graph of the function to the left or right.

To convert the solution to this form, we want to find the values of $A$ and $\phi$ such that

$$c_1\cos(\omega t)+c_2\sin(\omega t)=A\sin(\omega t+\phi).$$

We first apply the trigonometric identity

$$\sin(\alpha+\beta)=\sin\alpha\cos\beta+\cos\alpha\sin\beta$$

to get

$$\begin{aligned}c_1\cos(\omega t)+c_2\sin(\omega t)&=A(\sin(\omega t)\cos\phi+\cos(\omega t)\sin\phi)\\&=A\sin\phi(\cos(\omega t))+A\cos\phi(\sin(\omega t)).\end{aligned}$$

Thus,

$$c_1=A\sin\phi \text{ and } c_2=A\cos\phi.$$

If we square both of these equations and add them together, we get

$$\begin{aligned}c_1^2+c_2^2&=A^2\sin_2\phi+A^2\cos_2\phi\\&=A^2(\sin^2\phi+\cos^2\phi)\\&=A^2.\end{aligned}$$

Thus,

$$A = \sqrt{c_1^2 + c_2^2}.$$

Now, to find $\phi$, go back to the equations for $c_1$ and $c_2$, but this time, divide the first equation by the second equation to get

$$\begin{aligned} \frac{c_1}{c_2} &= \frac{A\sin\phi}{A\cos\phi} \\ &= \tan\phi. \end{aligned}$$

Then,

$$\tan\phi = \frac{c_1}{c_2}.$$

We summarize this finding in the following theorem.

**SOLUTION TO THE EQUATION FOR SIMPLE HARMONIC MOTION**

The function $x(t) = c_1\cos(\omega t) + c_2\sin(\omega t)$ can be written in the form $x(t) = A\sin(\omega t + \phi)$, where $A = \sqrt{c_1^2 + c_2^2}$ and $\tan\phi = \frac{c_1}{c_2}$.

Note that when using the formula $\tan\phi = \frac{c_1}{c_2}$ to find $\phi$, we must take care to ensure $\phi$ is in the right quadrant (Figure 17.4.3).

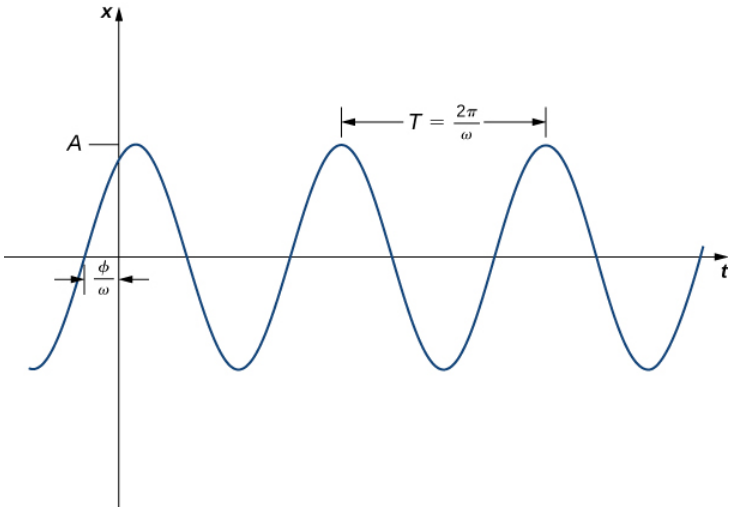

Figure 17.4.3: A graph of vertical displacement versus time for simple harmonic motion with a phase change.

**Example 17.4.2: Expressing the Solution with a Phase Shift**

Express the following functions in the form $A\sin(\omega t + \phi)$. What is the frequency of motion? The amplitude?

a. $x(t) = 2\cos(3t) + \sin(3t)$
b. $x(t) = 3\cos(2t) - 2\sin(2t)$

**Solution**

We have

$$A = \sqrt{c_1^2 + c_2^2} = \sqrt{2^2 + 1^2} = \sqrt{5}$$

and

$$\tan\phi = \frac{c_1}{c_2} = \frac{2}{1} = 2.$$

Note that both $c_1$ and $c_2$ are positive, so $\phi$ is in the first quadrant. Thus,

$$\phi \approx 1.107 \text{ rad},$$

so we have

$$x(t) = 2\cos(3t) + \sin(3t) = 5\sin(3t + 1.107).$$

The frequency is $\frac{\omega}{2\pi} = \frac{3}{2\pi} \approx 0.477$. The amplitude is $\sqrt{5}$.

1. We have

$$A = \sqrt{c_1^2 + c_2^2} = \sqrt{3^2 + 2^2} = \sqrt{13}$$

and

$$\tan\phi = \frac{c_1}{c_2} = \frac{3}{-2} = -\frac{3}{2}.$$

Note that $c_1$ is positive but $c_2$ is negative, so $\phi$ is in the fourth quadrant. Thus,

$$\phi \approx -0.983 \text{ rad},$$

so we have

$$\begin{aligned} x(t) &= 3\cos(2t) - 2\sin(2t) \\ &= \sqrt{13}\sin(2t - 0.983). \end{aligned}$$

The frequency is $\frac{\omega}{2\pi} = \frac{2}{2\pi} \approx 0.318$. The amplitude is $\sqrt{13}$.

**? Exercise 17.4.2**

Express the function $x(t) = \cos(4t) + 4\sin(4t)$ in the form $A\sin(\omega t + \phi)$. What is the frequency of motion? The amplitude?

**Hint**

Use the process from the Example 17.4.2.

**Answer**

$x(t) = \sqrt{17}\sin(4t + 0.245)$, frequency $= \frac{4}{2\pi} \approx 0.637$, $A = \sqrt{17}$

## Damped Vibrations

With the model just described, the motion of the mass continues indefinitely. Clearly, this doesn't happen in the real world. In the real world, there is almost always some friction in the system, which causes the oscillations to die off slowly—an effect called *damping*. So now let's look at how to incorporate that damping force into our differential equation.

Physical spring-mass systems almost always have some damping as a result of friction, air resistance, or a physical damper, called a *dashpot* (a pneumatic cylinder; Figure 17.4.4).

Figure 17.4.4: A dashpot is a pneumatic cylinder that dampens the motion of an oscillating system.

Because damping is primarily a friction force, we assume it is proportional to the velocity of the mass and acts in the opposite direction. So the damping force is given by $-bx'$ for some constant $b > 0$. Again applying Newton's second law, the differential equation becomes

$$mx''+bx'+kx = 0.$$

Then the associated characteristic equation is

$$m\lambda^2 + b\lambda + k = 0.$$

Applying the quadratic formula, we have

$$\lambda = \frac{-b \pm \sqrt{b^2 - 4mk}}{2m}.$$

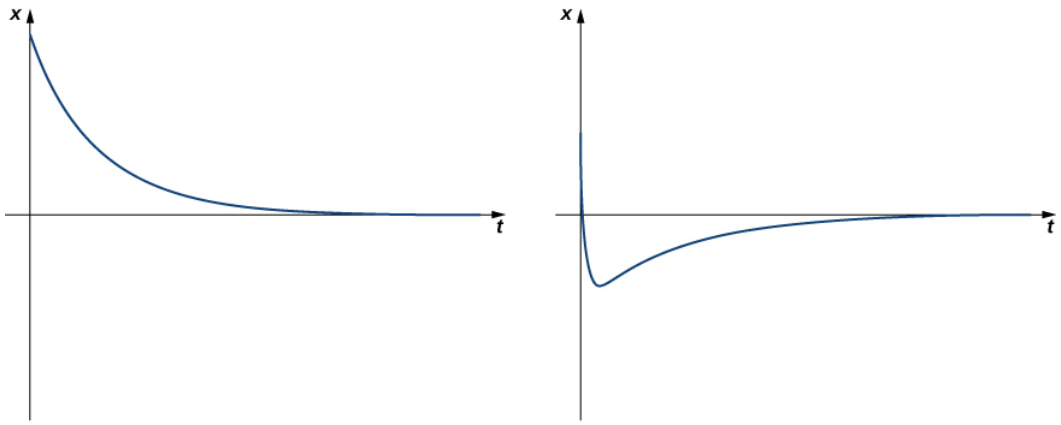
Just as in Second-Order Linear Equations we consider three cases, based on whether the characteristic equation has distinct real roots, a repeated real root, or complex conjugate roots.

### Case 1: Overdamped Vibrations

When $b^2 > 4mk$, we say the system is ***overdamped***. The general solution has the form

$$x(t) = c_1 e^{\lambda_1 t} + c_2 e^{\lambda_2 t},$$

where both $\lambda_1$ and $\lambda_2$ are less than zero. Because the exponents are negative, the displacement decays to zero over time, usually quite quickly. Overdamped systems do not oscillate (no more than one change of direction), but simply move back toward the equilibrium position. Figure 17.4.5 shows what typical critically damped behavior looks like.



(a) (b)

Figure **17.4.5**: Behavior of an overdamped spring-mass system, with no change in direction (a) and only one change in direction (b).

### Example 17.4.3: Overdamped Spring-Mass System

A 16-lb mass is attached to a 10-ft spring. When the mass comes to rest in the equilibrium position, the spring measures 15 ft 4 in. The system is immersed in a medium that imparts a damping force equal to 5252 times the instantaneous velocity of the mass. Find the equation of motion if the mass is pushed upward from the equilibrium position with an initial upward velocity of 5 ft/sec. What is the position of the mass after 10 sec? Its velocity?

**Solution**

The mass stretches the spring 5 ft 4 in., or $\frac{16}{3}$ ft. Thus, $16 = \left(\frac{16}{3}\right)k$, so $k = 3$. We also have $m = \frac{16}{32} = \frac{1}{2}$, so the differential equation is

$$\frac{5}{2}x' + 3x = 0.$$

Multiplying through by 2 gives $x'' + 5x' + 6x = 0$, which has the general solution

$$x(t) = c_1 e^{-2t} + c_2 e^{-3t}.$$

Applying the initial conditions, $x(0) = 0$ and $x'(0) = -5$, we get

$$x(t) = -5e^{-2t} + 5e^{-3t}.$$

After 10 sec the mass is at position

$$x(10) = -5e^{-20} + 5e^{-30} \approx -1.0305 \times 10^{-8} \approx 0,$$

so it is, effectively, at the equilibrium position. We have $x'(t) = 10e^{-2t} - 15e^{-3t}$, so after 10 sec the mass is moving at a velocity of

$$x'(10) = 10e^{-20} - 15e^{-30} \approx 2.061 \times 10^{-8} \approx 0.$$

After only 10 sec, the mass is barely moving.

### Exercise 17.4.3

A 2-kg mass is attached to a spring with spring constant 24 N/m. The system is then immersed in a medium imparting a damping force equal to 16 times the instantaneous velocity of the mass. Find the equation of motion if it is released from rest at a point 40 cm below equilibrium.

**Hint**

Follow the process from the previous example.

**Answer**

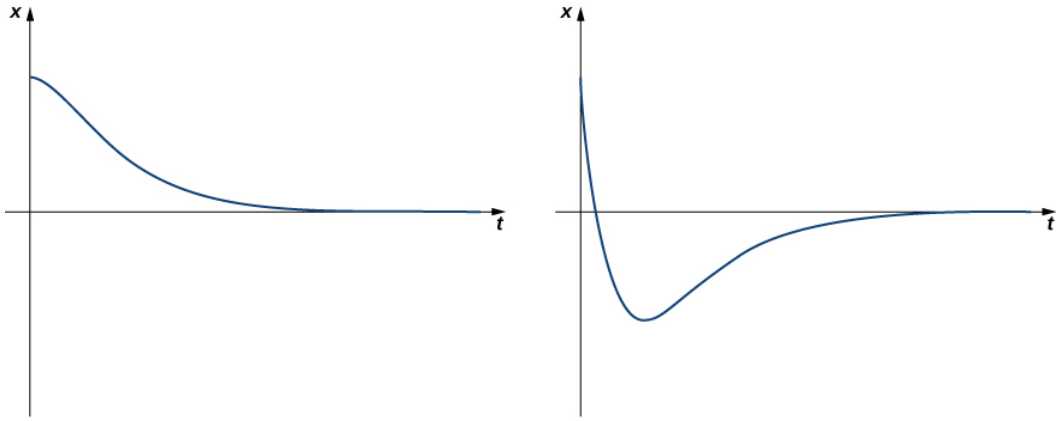
$x(t) = 0.6e^{-2t} - 0.2e^{-6t}$

### Case 2: Critically Damped Vibrations

When $b^2 = 4mk$, we say the system is *critically damped*. The general solution has the form

$$x(t) = c_1 e^{\lambda_1 t} + c_2 t e^{\lambda_1 t},$$

where $\lambda_1$ is less than zero. The motion of a critically damped system is very similar to that of an overdamped system. It does not oscillate. However, with a critically damped system, if the damping is reduced even a little, oscillatory behavior results. From a practical perspective, physical systems are almost always either overdamped or underdamped (case 3, which we consider next). It is impossible to fine-tune the characteristics of a physical system so that $b^2$ and $4mk$ are exactly equal. Figure 17.4.6 shows what typical critically damped behavior looks like.



(a) (b)

Figure 17.4.6: Behavior of a critically damped spring-mass system. The system graphed in part (a) has more damping than the system graphed in part (b).

**Example 17.4.4: Critically Damped Spring-Mass System**

A 1-kg mass stretches a spring 20 cm. The system is attached to a dashpot that imparts a damping force equal to 14 times the instantaneous velocity of the mass. Find the equation of motion if the mass is released from equilibrium with an upward velocity of 3 m/sec.

**Solution**

We have $mg = 1(9.8) = 0.2k$, so $k = 49$. Then, the differential equation is

$$x'' + 14x' + 49x = 0,$$

which has general solution

$$x(t) = c_1 e^{-7t} + c_2 t e^{-7t}.$$

Applying the initial conditions $x(0) = 0$ and $x'(0) = -3$ gives

$$x(t) = -3te^{-7t}.$$

**Exercise 17.4.4**

A 1-lb weight stretches a spring 6 in., and the system is attached to a dashpot that imparts a damping force equal to half the instantaneous velocity of the mass. Find the equation of motion if the mass is released from rest at a point 6 in. below equilibrium.

**Hint**

First find the spring constant.

**Answer**

$x(t) = \frac{1}{2}e^{-8t} + 4te^{-8t}$

### Case 3: Undamped Vibrations

When $b^2 < 4mk$, we say the system is *underdamped*. The general solution has the form

$$x(t) = e^{\alpha t}(c_1 \cos(\beta t) + c_2 \sin(\beta t)),$$

where $\alpha$ is less than zero. Underdamped systems do oscillate because of the sine and cosine terms in the solution. However, the exponential term dominates eventually, so the amplitude of the oscillations decreases over time. Figure **17.4.7** shows what typical underdamped behavior looks like.

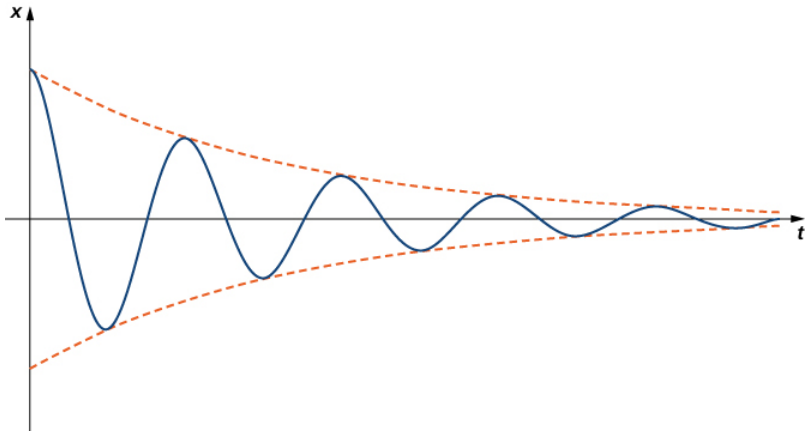


Figure **17.4.7**: Behavior of an underdamped spring-mass system.

Note that for all damped systems, $\lim_{t\to\infty} x(t) = 0$. The system always approaches the equilibrium position over time.

**Example 17.4.5**: Underdamped Spring-Mass System

A 16-lb weight stretches a spring 3.2 ft. Assume the damping force on the system is equal to the instantaneous velocity of the mass. Find the equation of motion if the mass is released from rest at a point 9 in. below equilibrium.

**Solution**

We have $k = \frac{16}{3.2} = 5$ and $m = \frac{16}{32} = \frac{1}{2}$, so the differential equation is

$$\frac{1}{2}x'' + x' + 5x = 0, \text{ or } x'' + 2x' + 10x = 0.$$

This equation has the general solution

$$x(t) = e^{-t}(c_1 \cos(3t) + c_2 \sin(3t)).$$

Applying the initial conditions, $x(0) = \frac{3}{4}$ and $x'(0) = 0$, we get

$$x(t) = e^{-t}\left(\frac{3}{4}\cos(3t) + \frac{1}{4}\sin(3t)\right).$$

**Exercise 17.4.5**

A 1-kg mass stretches a spring 49 cm. The system is immersed in a medium that imparts a damping force equal to four times the instantaneous velocity of the mass. Find the equation of motion if the mass is released from rest at a point 24 cm above equilibrium.

**Hint**

First find the spring constant.

**Answer**

$x(t) = -0.24e^{-2t}\cos(4t) - 0.12e^{-2t}\sin(4t)$

### Example 17.4.6: Chapter Opener: Modeling a Motorcycle Suspension System

For motocross riders, the suspension systems on their motorcycles are very important. The off-road courses on which they ride often include jumps, and losing control of the motorcycle when they land could cost them the race.

Figure 17.4.8: (credit: modification of work by nSeika, Flickr)

This suspension system can be modeled as a damped spring-mass system. We define our frame of reference with respect to the frame of the motorcycle. Assume the end of the shock absorber attached to the motorcycle frame is fixed. Then, the "mass" in our spring-mass system is the motorcycle wheel. We measure the position of the wheel with respect to the motorcycle frame. This may seem counterintuitive, since, in many cases, it is actually the motorcycle frame that moves, but this frame of reference preserves the development of the differential equation that was done earlier. As with earlier development, we define the downward direction to be positive.

When the motorcycle is lifted by its frame, the wheel hangs freely and the spring is uncompressed. This is the spring's natural position. When the motorcycle is placed on the ground and the rider mounts the motorcycle, the spring compresses and the system is in the equilibrium position (Figure 17.4.9).

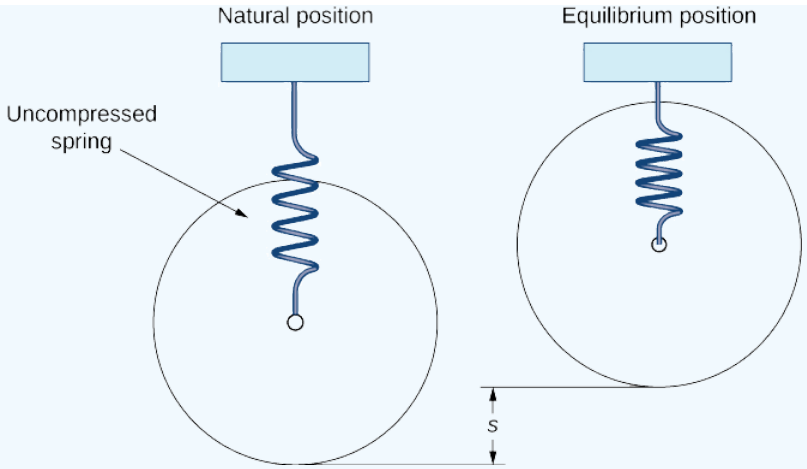

Figure 17.4.9: We can use a spring-mass system to model a motorcycle suspension.

This system can be modeled using the same differential equation we used before:

$$mx''+bx'+kx=0.$$

A motocross motorcycle weighs 204 lb, and we assume a rider weight of 180 lb. When the rider mounts the motorcycle, the suspension compresses 4 in., then comes to rest at equilibrium. The suspension system provides damping equal to 240 times the instantaneous vertical velocity of the motorcycle (and rider).

1. Set up the differential equation that models the behavior of the motorcycle suspension system.
2. We are interested in what happens when the motorcycle lands after taking a jump. Let time

   $$t=0$$

   denote the time when the motorcycle first contacts the ground. If the motorcycle hits the ground with a velocity of 10 ft/sec downward, find the equation of motion of the motorcycle after the jump.
3. Graph the equation of motion over the first second after the motorcycle hits the ground.

**Solution**

1. We have defined equilibrium to be the point where $mg=ks$, so we have

   $$\begin{aligned} mg &= ks \\ 384 &= k\left(\frac{1}{3}\right) \\ k &= 1152. \end{aligned}$$

   We also have

   $$\begin{aligned} W &= mg \\ 384 &= m(32) \\ m &= 12. \end{aligned}$$

   Therefore, the differential equation that models the behavior of the motorcycle suspension is

   $$12x''+240x'+1152x=0.$$

   Dividing through by 12, we get

   $$x''+20x'+96x=0.$$

2. The differential equation found in part a. has the general solution

   $$x(t)=c_1e^{-8t}+c_2e^{-12t}.$$

   Now, to determine our initial conditions, we consider the position and velocity of the motorcycle wheel when the wheel first contacts the ground. Since the motorcycle was in the air prior to contacting the ground, the wheel was hanging freely

and the spring was uncompressed. Therefore the wheel is 4 in. $\left(\frac{1}{3}\text{ ft}\right)$ below the equilibrium position (with respect to the motorcycle frame), and we have $x(0)=\frac{1}{3}$. According to the problem statement, the motorcycle has a velocity of 10 ft/sec downward when the motorcycle contacts the ground, so the spring will be given an equal and opposite velocity of 10 ft/sec upward, giving us $x'(0)=-10$. Applying these initial conditions, we get $c_1=-\frac{3}{2}$ and $c_2=\frac{11}{6}$, so the equation of motion is

$$x(t)=-\frac{3}{2}e^{-8t}+\frac{11}{6}e^{-12t}.$$

3. The graph is shown in Figure 17.4.10.

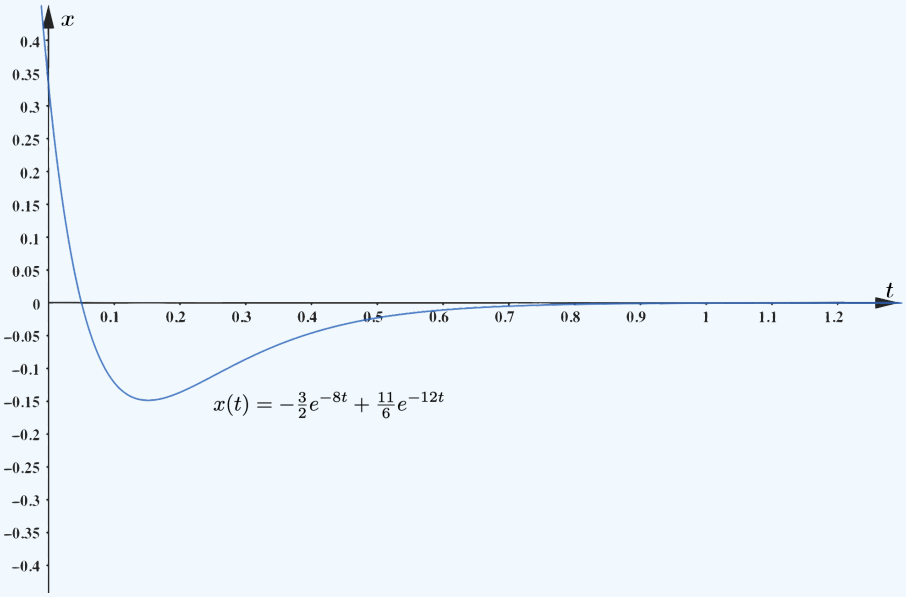

Figure 17.4.10: Graph of the equation of motion over a time of one second.

## LANDING VEHICLE

NASA is planning a mission to Mars. To save money, engineers have decided to adapt one of the moon landing vehicles for the new mission. However, they are concerned about how the different gravitational forces will affect the suspension system that cushions the craft when it touches down. The acceleration resulting from gravity on the moon is 1.6 m/sec$^2$, whereas on Mars it is 3.7 m/sec$^2$.

The suspension system on the craft can be modeled as a damped spring-mass system. In this case, the spring is below the moon lander, so the spring is slightly compressed at equilibrium, as shown in Figure 17.4.11.

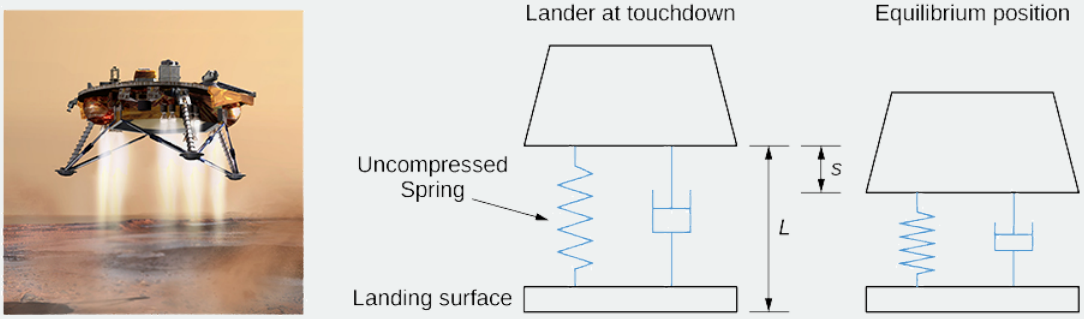

Figure 17.4.11: The landing craft suspension can be represented as a damped spring-mass system. (credit “lander”: NASA)

We retain the convention that down is positive. Despite the new orientation, an examination of the forces affecting the lander shows that the same differential equation can be used to model the position of the landing craft relative to equilibrium:

$$mx''+bx'+kx=0,$$

where $m$ is the mass of the lander, $b$ is the damping coefficient, and $k$ is the spring constant.

1. The lander has a mass of 15,000 kg and the spring is 2 m long when uncompressed. The lander is designed to compress the spring 0.5 m to reach the equilibrium position under lunar gravity. The dashpot imparts a damping force equal to 48,000 times the instantaneous velocity of the lander. Set up the differential equation that models the motion of the lander when the craft lands on the moon.
2. Let time $t = 0$ denote the instant the lander touches down. The rate of descent of the lander can be controlled by the crew, so that it is descending at a rate of 2 m/sec when it touches down. Find the equation of motion of the lander on the moon.
3. If the lander is traveling too fast when it touches down, it could fully compress the spring and "bottom out." Bottoming out could damage the landing craft and must be avoided at all costs. Graph the equation of motion found in part 2. If the spring is 0.5 m long when fully compressed, will the lander be in danger of bottoming out?
4. Assuming NASA engineers make no adjustments to the spring or the damper, how far does the lander compress the spring to reach the equilibrium position under Martian gravity?
5. If the lander crew uses the same procedures on Mars as on the moon, and keeps the rate of descent to 2 m/sec, will the lander bottom out when it lands on Mars?
6. What adjustments, if any, should the NASA engineers make to use the lander safely on Mars?

## Forced Vibrations

The last case we consider is when an external force acts on the system. In the case of the motorcycle suspension system, for example, the bumps in the road act as an external force acting on the system. Another example is a spring hanging from a support; if the support is set in motion, that motion would be considered an external force on the system. We model these forced systems with the nonhomogeneous differential equation

$$mx'' + bx' + kx = f(t),$$

where the external force is represented by the $f(t)$ term. As we saw in Nonhomogenous Linear Equations, differential equations such as this have solutions of the form

$$x(t) = c_1x_1(t) + c_2x_2(t) + x_p(t),$$

where $c_1x_1(t) + c_2x_2(t)$ is the general solution to the complementary equation and $x_p(t)$ is a particular solution to the nonhomogeneous equation. If the system is damped, $\lim_{t\to\infty} c_1x_1(t) + c_2x_2(t) = 0$. Since these terms do not affect the long-term behavior of the system, we call this part of the solution the ***transient solution.*** The long-term behavior of the system is determined by $x_p(t)$, so we call this part of the solution the **steady-state solution**.

### Example 17.4.7: Forced Vibrations

A mass of 1 slug stretches a spring 2 ft and comes to rest at equilibrium. The system is attached to a dashpot that imparts a damping force equal to eight times the instantaneous velocity of the mass. Find the equation of motion if an external force equal to $f(t) = 8\sin(4t)$ is applied to the system beginning at time $t = 0$. What is the transient solution? What is the steady-state solution?

#### Solution

We have $mg = 1(32) = 2k$, so $k = 16$ and the differential equation is

$$x'' + 8x' + 16x = 8\sin(4t).$$

The general solution to the complementary equation is

$$c_1e^{-4t} + c_2te^{-4t}.$$

Assuming a particular solution of the form $x_p(t) = A\cos(4t) + B\sin(4t)$ and using the method of undetermined coefficients, we find $x_p(t) = -\frac{1}{4}\cos(4t)$, so

$$x(t) = c_1e^{-4t} + c_2te^{-4t} - \frac{1}{4}\cos(4t).$$

At $t = 0$, the mass is at rest in the equilibrium position, so $x(0) = x'(0) = 0$. Applying these initial conditions to solve for $c_1$ and $c_2$, we get

$$x(t) = \frac{1}{4}e^{-4t} + te^{-4t} - \frac{1}{4}\cos(4t).$$

The transient solution is $\frac{1}{4}e^{-4t} + te^{-4t}$. The steady-state solution is $-\frac{1}{4}\cos(4t)$.

## Exercise 17.4.6

A mass of 2 kg is attached to a spring with constant 32 N/m and comes to rest in the equilibrium position. Beginning at time $t = 0$, an external force equal to $f(t) = 68e^{-2t}\cos(4t)$ is applied to the system. Find the equation of motion if there is no damping. What is the transient solution? What is the steady-state solution?

**Hint**

Find the particular solution *before* applying the initial conditions.

**Answer**

$x(t) = -\frac{1}{2}\cos(4t) + \frac{9}{4}\sin(4t) + \frac{1}{2}e^{-2t}\cos(4t) - 2e^{-2t}\sin(4t)$

Transient solution: $\frac{1}{2}e^{-2t}\cos(4t) - 2e^{-2t}\sin(4t)$

Steady-state solution: $-\frac{1}{2}\cos(4t) + \frac{9}{4}\sin(4t)$

## RESONANCE

Consider an undamped system exhibiting simple harmonic motion. In the real world, we never truly have an undamped system; –some damping always occurs. For theoretical purposes, however, we could imagine a spring-mass system contained in a vacuum chamber. With no air resistance, the mass would continue to move up and down indefinitely.

The frequency of the resulting motion, given by $f = \frac{1}{T} = \frac{\omega}{2\pi}$, is called the *natural frequency of the system*. If an external force acting on the system has a frequency close to the natural frequency of the system, a phenomenon called ***resonance*** results. The external force reinforces and amplifies the natural motion of the system.

1. Consider the differential equation $x'' + x = 0$. Find the general solution. What is the natural frequency of the system?
2. Now suppose this system is subjected to an external force given by $f(t) = 5\cos t$. Solve the initial-value problem $x'' + x = 5\cos t$, $x(0) = 0$, $x'(0) = 1$.
3. Graph the solution. What happens to the behavior of the system over time?
4. In the real world, there is always some damping. However, if the damping force is weak, and the external force is strong enough, real-world systems can still exhibit resonance. One of the most famous examples of resonance is the collapse of the **Tacoma Narrows Bridge** on November 7, 1940. The bridge had exhibited strange behavior ever since it was built. The roadway had a strange "bounce" to it. On the day it collapsed, a strong windstorm caused the roadway to twist and ripple violently. The bridge was unable to withstand these forces and it ultimately collapsed. Experts believe the windstorm exerted forces on the bridge that were very close to its natural frequency, and the resulting resonance ultimately shook the bridge apart.

   This website contains more information about the collapse of the Tacoma Narrows Bridge.

   During the short time the Tacoma Narrows Bridge stood, it became quite a tourist attraction. Several people were on site the day the bridge collapsed, and one of them caught the collapse on film.

Watch the video to see the collapse of the Tacoma Narrows Bridge "Gallopin' Gertie". https://www.youtube.com/watch?v=j-zczJXSxnw

1. Another real-world example of resonance is a singer shattering a crystal wineglass when she sings just the right note. When someone taps a crystal wineglass or wets a finger and runs it around the rim, a tone can be heard. That note is created by the wineglass vibrating at its natural frequency. If a singer then sings that same note at a high enough volume, the glass shatters as a result of resonance.

   The TV show *Mythbusters* aired an episode on this phenomenon. Visit this website to learn more about it. Adam Savage also described the experience. Watch this video for his account.

## The *RLC* Series Circuit

Consider an electrical circuit containing a resistor, an inductor, and a capacitor, as shown in Figure **17.4.12**. Such a circuit is called an ***RLC* series circuit**. *RLC* circuits are used in many electronic systems, most notably as tuners in AM/FM radios. The tuning knob varies the capacitance of the capacitor, which in turn tunes the radio. Such circuits can be modeled by second-order, constant-coefficient differential equations.

Let $I(t)$ denote the current in the *RLC* circuit and $q(t)$ denote the charge on the capacitor. Furthermore, let $L$ denote inductance in henrys (H), $R$ denote resistance in ohms ($\Omega$), and $C$ denote capacitance in farads (F). Last, let $E(t)$ denote electric potential in volts (V).

Kirchhoff's voltage rule states that the sum of the voltage drops around any closed loop must be zero. So, we need to consider the voltage drops across the inductor (denoted $E_L$), the resistor (denoted $E_R$), and the capacitor (denoted $E_C$). Because the *RLC* circuit shown in Figure **17.4.12** includes a voltage source, $E(t)$, which adds voltage to the circuit, we have $E_L + E_R + E_C = E(t)$.

We present the formulas below without further development and those of you interested in the derivation of these formulas can review the links. Using Faraday's law and Lenz's law, the voltage drop across an inductor can be shown to be proportional to the instantaneous rate of change of current, with proportionality constant $L$. Thus,

$$E_L = L\frac{dI}{dt}.$$

Next, according to Ohm's law, the voltage drop across a resistor is proportional to the current passing through the resistor, with proportionality constant $R$. Therefore,

$$E_R = RI.$$

Last, the voltage drop across a capacitor is proportional to the charge, $q$, on the capacitor, with proportionality constant $1/C$. Thus,

$$E_C = \frac{1}{C}q.$$

Adding these terms together, we get

$$L\frac{dI}{dt} + RI + \frac{1}{C}q = E(t).$$

Noting that $I = (dq)/(dt)$, this becomes

$$L\frac{d^2q}{dt^2} + R\frac{dq}{dt} + \frac{1}{C}q = E(t).$$

Mathematically, this system is analogous to the spring-mass systems we have been examining in this section.

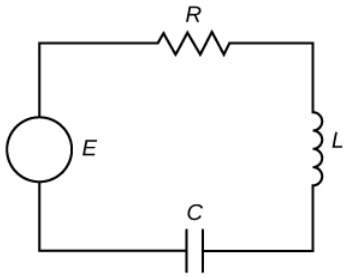

Figure **17.4.12**: An *RLC* series circuit can be modeled by the same differential equation as a mass-spring system.

### Series Circuit

Find the charge on the capacitor in an *RLC* series circuit where $L = 5/3$ H, $R = 10\Omega$, $C = 1/30$ F, and $E(t) = 300$ V. Assume the initial charge on the capacitor is 0 C and the initial current is 9 A. What happens to the charge on the capacitor over time?

**Solution**

We have

$$L\frac{d^2q}{dt^2} + R\frac{dq}{dt} + \frac{1}{C}q = E(t)$$
$$\frac{5}{3}\frac{d^2q}{dt^2} + 10\frac{dq}{dt} + 30q = 300$$
$$\frac{d^2q}{dt^2} + 6\frac{dq}{dt} + 18q = 180.$$

The general solution to the complementary equation is

$$e^{-3t}(c_1\cos(3t) + c_2\sin(3t)).$$

Assume a particular solution of the form $q_p = A$, where $A$ is a constant. Using the method of undetermined coefficients, we find $A = 10$. So,

$$q(t) = e^{-3t}(c_1\cos(3t) + c_2\sin(3t)) + 10.$$

Applying the initial conditions $q(0) = 0$ and $i(0) = ((dq)/(dt))(0) = 9$, we find $c_1 = -10$ and $c_2 = -7$. So the charge on the capacitor is

$$q(t) = -10e^{-3t}\cos(3t) - 7e^{-3t}\sin(3t) + 10.$$

Looking closely at this function, we see the first two terms will decay over time (as a result of the negative exponent in the exponential function). Therefore, the capacitor eventually approaches a steady-state charge of 10 C.

**? Exercise 17.4.7**

Find the charge on the capacitor in an *RLC* series circuit where $L = 1/5$ H, $R = 2/5\Omega$, $C = 1/2$ F, and $E(t) = 50$ V. Assume the initial charge on the capacitor is 0 C and the initial current is 4 A.

**Hint**

Remember, $E_L = L((dI)/(dt))$.

**Answer**

$$q(t) = -25e^{-t}\cos(3t) - 7e^{-t}\sin(3t) + 25$$

## Key Concepts

- Second-order constant-coefficient differential equations can be used to model spring-mass systems.
- An examination of the forces on a spring-mass system results in a differential equation of the form

  $$mx'' + bx' + kx = f(t),$$

  where $m$ represents the mass, $b$ is the coefficient of the damping force, $k$ is the spring constant, and $f(t)$ represents any net external forces on the system.
- If $b = 0$, there is no damping force acting on the system, and simple harmonic motion results.
- If $b \neq 0$,the behavior of the system depends on whether $b^2 - 4mk > 0, b^2 - 4mk = 0$, or $b^2 - 4mk < 0$.
  - If $b^2 - 4mk > 0$, the system is overdamped and does not exhibit oscillatory behavior.
  - If $b^2 - 4mk = 0$, the system is critically damped. It does not exhibit oscillatory behavior, but any slight reduction in the damping would result in oscillatory behavior.
  - If $b^2 - 4mk < 0$, the system is underdamped. It exhibits oscillatory behavior, but the amplitude of the oscillations decreases over time.
- If $f(t) \neq 0$, the solution to the differential equation is the sum of a transient solution and a steady-state solution. The steady-state solution governs the long-term behavior of the system.
- The charge on the capacitor in an *RLC* series circuit can also be modeled with a second-order constant-coefficient differential equation of the form

  $$L\frac{d^2q}{dt^2} + R\frac{dq}{dt} + \frac{1}{C}q = E(t),$$

  where $L$ is the inductance, $R$ is the resistance, $C$ is the capacitance, and $E(t)$ is the voltage source.

## Key Equations

- Equation of simple harmonic motion

  $$x'' + \omega^2 x = 0$$

- Solution for simple harmonic motion

  $$x(t) = c_1\cos(\omega t) + c_2\sin(\omega t)$$

- Alternative form of solution for SHM

  $$x(t) = A\sin(\omega t + \phi)$$

- Forced harmonic motion

  $$mx'' + bx' + kx = f(t)$$

- Charge in a RLC series circuit

  $$L\frac{d^2q}{dt^2} + R\frac{dq}{dt} + \frac{1}{C}q = E(t),$$

## Glossary

***RLC* series circuit**
: a complete electrical path consisting of a resistor, an inductor, and a capacitor; a second-order, constant-coefficient differential equation can be used to model the charge on the capacitor in an *RLC* series circuit

**simple harmonic motion**
: motion described by the equation $x(t) = c_1 \cos(\omega t) + c_2 \sin(\omega t)$, as exhibited by an undamped spring-mass system in which the mass continues to oscillate indefinitely

**steady-state solution**
: a solution to a nonhomogeneous differential equation related to the forcing function; in the long term, the solution approaches the steady-state solution

# 17.4E: Exercises for Section 17.3

1. A mass weighing 4 lb stretches a spring 8 in. Find the equation of motion if the spring is released from the equilibrium position with a downward velocity of 12 ft/sec. What is the period and frequency of the motion?

2. A mass weighing 2 lb stretches a spring 2 ft. Find the equation of motion if the spring is released from 2 in. below the equilibrium position with an upward velocity of 8 ft/sec. What is the period and frequency of the motion?

**Answer**

differential equation: $x''+16x=0$,
equation of motion: $x(t)=\frac{1}{6}\cos(4t)-2\sin(4t)$,
period $=\frac{\pi}{2}$ sec,
frequency $=\frac{2}{\pi}$ Hz

3. A 100-g mass stretches a spring 0.1 m. Find the equation of motion of the mass if it is released from rest from a position 20 cm below the equilibrium position. What is the frequency of this motion?

4. A 400-g mass stretches a spring 5 cm. Find the equation of motion of the mass if it is released from rest from a position 15 cm below the equilibrium position. What is the frequency of this motion?

**Answer**

differential equation: $x''+196x=0$,
equation of motion: $x(t)=0.15\cos(14t)$,
period $=\frac{\pi}{7}$ sec,
frequency $=\frac{7}{\pi}$ Hz

5. A block has a mass of 9 kg and is attached to a vertical spring with a spring constant of 0.25 N/m. The block is stretched 0.75 m below its equilibrium position and released.

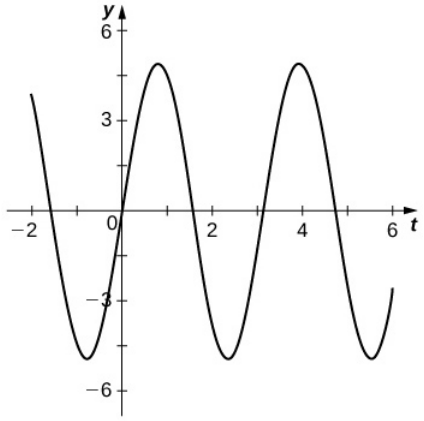
a. Find the position function $x(t)$ of the block.
b. Find the period and frequency of the vibration.
c. Sketch a graph of $x(t)$.
d. At what time does the block first pass through the equilibrium position?

6. A block has a mass of 5 kg and is attached to a vertical spring with a spring constant of 20 N/m. The block is released from the equilibrium position with a downward velocity of 10 m/sec.

a. Find the position function $x(t)$ of the block.
b. Find the period and frequency of the vibration.
c. Sketch a graph of $x(t)$.
d. At what time does the block first pass through the equilibrium position?

**Answer**

a. $x(t)=5\sin(2t)$
b. period $=\pi$ sec,
frequency $=\frac{1}{\pi}$ Hz
c.



d. $t = \frac{\pi}{2}$ sec

7. A 1-kg mass is attached to a vertical spring with a spring constant of 21 N/m. The resistance in the spring-mass system is equal to 10 times the instantaneous velocity of the mass.

a. Find the equation of motion if the mass is released from a position 2 m below its equilibrium position with a downward velocity of 2 m/sec.
b. Graph the solution and determine whether the motion is overdamped, critically damped, or underdamped.

8. An 800-lb weight (25 slugs) is attached to a vertical spring with a spring constant of 226 lb/ft. The system is immersed in a medium that imparts a damping force equal to 10 times the instantaneous velocity of the mass.

a. Find the equation of motion if it is released from a position 20 ft below its equilibrium position with a downward velocity of 41 ft/sec.
b. Graph the solution and determine whether the motion is overdamped, critically damped, or underdamped.

**Answer**

a. $x(t) = e^{-t/5}(20\cos(3t) + 15\sin(3t))$

b. underdamped

9. A 9-kg mass is attached to a vertical spring with a spring constant of 16 N/m. The system is immersed in a medium that imparts a damping force equal to 24 times the instantaneous velocity of the mass.

a. Find the equation of motion if it is released from its equilibrium position with an upward velocity of 4 m/sec.
b. Graph the solution and determine whether the motion is overdamped, critically damped, or underdamped.

10. A 1-kg mass stretches a spring 6.25 cm. The resistance in the spring-mass system is equal to eight times the instantaneous velocity of the mass.

a. Find the equation of motion if the mass is released from a position 5 m below its equilibrium position with an upward velocity of 10 m/sec.
b. Determine whether the motion is overdamped, critically damped, or underdamped.

**Answer**

a. $x(t) = 5e^{-4t} + 10te^{-4t}$

b. critically damped

11. A 32-lb weight (1 slug) stretches a vertical spring 4 in. The resistance in the spring-mass system is equal to four times the instantaneous velocity of the mass.

a. Find the equation of motion if it is released from its equilibrium position with a downward velocity of 12 ft/sec.
b. Determine whether the motion is overdamped, critically damped, or underdamped.

12. A 64-lb weight is attached to a vertical spring with a spring constant of 4.625 lb/ft. The resistance in the spring-mass system is equal to the instantaneous velocity. The weight is set in motion from a position 1 ft below its equilibrium position with an upward velocity of 2 ft/sec. Is the mass above or below the equation position at the end of $\pi$ sec? By what distance?

**Answer**

$x(\pi) = \frac{7e^{-\pi/4}}{6}$ ft below

13. A mass that weighs 8 lb stretches a spring 6 inches. The system is acted on by an external force of $8\sin 8t$lb. If the mass is pulled down 3 inches and then released, determine the position of the mass at any time.

14. A mass that weighs 6 lb stretches a spring 3 in. The system is acted on by an external force of $8\sin(4t)$ lb. If the mass is pulled down 1 inch and then released, determine the position of the mass at any time.

**Answer**

$x(t) = \frac{32}{9}\sin(4t) + \cos(\sqrt{128}t) - \frac{16}{9\sqrt{2}}\sin(\sqrt{128}t)$

15. Find the charge on the capacitor in an *RLC* series circuit where $L = 40$ H, $R = 30\,\Omega$, $C = 1/200$ F, and $E(t) = 200$ V. Assume the initial charge on the capacitor is 7 C and the initial current is 0 A.

16. Find the charge on the capacitor in an *RLC* series circuit where $L = 2$ H, $R = 24\,\Omega$, $C = 0.005$ F, and $E(t) = 12\sin 10t$ V. Assume the initial charge on the capacitor is 0.001 C and the initial current is 0 A.

**Answer**

$q(t) = e^{-6t}(0.051\cos(8t) + 0.03825\sin(8t)) - \frac{1}{20}\cos(10t)$

17. A series circuit consists of a device where$L = 1$ H, $R = 20\,\Omega$, $C = 0.002$ F, and $E(t) = 12$ V. If the initial charge and current are both zero, find the charge and current at time $t$.

18. A series circuit consists of a device where $L = 12$ H, $R = 10\,\Omega$, $C = \frac{1}{50}$ F, and $E(t) = 250$ V. If the initial charge on the capacitor is 0 C and the initial current is 18 A, find the charge and current at time $t$.

**Answer**

$q(t) = e^{-10t}(-32t - 5) + 5, I(t) = 2e^{-10t}(160t + 9)$

# 17.5: Series Solutions of Differential Equations

**Learning Objectives**

- Use power series to solve first-order and second-order differential equations.

Previously, we studied how functions can be represented as power series, $y(x) = \sum_{n=0}^{\infty} a_n x^n$. We also saw that we can find series representations of the derivatives of such functions by differentiating the power series term by term. This gives

$$y'(x) = \sum_{n=1}^{\infty} n a_n x^{n-1}$$

and

$$y''(x) = \sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}.$$

In some cases, these power series representations can be used to find solutions to differential equations.

The examples and exercises in this section were chosen for which power solutions exist. However, it is not always the case that power solutions exist. Those of you interested in a more rigorous treatment of this topic should review the differential equations section of the LibreTexts.

**Problem-Solving Strategy: Finding Power Series Solutions to Differential Equations**

1. Assume the differential equation has a solution of the form

$$y(x) = \sum_{n=0}^{\infty} a_n x^n.$$

2. Differentiate the power series term by term to get

$$y'(x) = \sum_{n=1}^{\infty} n a_n x^{n-1}$$

and

$$y''(x) = \sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}.$$

3. Substitute the power series expressions into the differential equation.
4. Re-index sums as necessary to combine terms and simplify the expression.
5. Equate coefficients of like powers of $x$ to determine values for the coefficients $a_n$ in the power series.
6. Substitute the coefficients back into the power series and write the solution.

**Example 17.5.1: Series Solutions to Differential Equations**

Find a power series solution for the following differential equations.

a. $y'' - y = 0$

b. $(x^2 - 1)y'' + 6xy' + 4y = -4$

**Solution**

**Part a**

Assume

$$y(x) = \sum_{n=0}^{\infty} a_n x^n \qquad \text{(step 1)}$$

Then,

$$y'(x) = \sum_{n=1}^{\infty} n a_n x^{n-1} \qquad \text{(step 2A)}$$

and

$$y''(x) = \sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} \qquad \text{(step 2B)}$$

We want to find values for the coefficients $a_n$ such that

$$y'' - y = 0$$

$$\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} - \sum_{n=0}^{\infty} a_n x^n = 0. \qquad \text{(step 3)}$$

We want the indices on our sums to match so that we can express them using a single summation. That is, we want to rewrite the first summation so that it starts with $n = 0$.

To re-index the first term, replace $n$ with $n + 2$ inside the sum, and change the lower summation limit to $n = 0$. We get

$$\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)(n+1) a_{n+2} x^n.$$

This gives

$$\sum_{n=0}^{\infty} (n+2)(n+1) a_{n+2} x^n - \sum_{n=0}^{\infty} a_n x_n = 0$$

$$\sum_{n=0}^{\infty} [(n+2)(n+1) a_{n+2} - a_n] x^n = 0. \qquad \text{(step 4)}$$

Because power series expansions of functions are unique, this equation can be true only if the coefficients of each power of $x$ are zero. So we have

$$(n+2)(n+1) a_{n+2} - a_n = 0 \text{ for } n = 0, 1, 2, \ldots.$$

This recurrence relationship allows us to express each coefficient $a_n$ in terms of the coefficient two terms earlier. This yields one expression for even values of $n$ and another expression for odd values of $n$. Looking first at the equations involving even values of $n$, we see that

$$a_2 = \frac{a_0}{2}$$

$$a_4 = \frac{a_2}{4 \cdot 3} = \frac{a_0}{4!}$$

$$a_6 = \frac{a_4}{6 \cdot 5} = \frac{a_0}{6!}$$

$$\vdots$$

Thus, in general, when $n$ is even,

$$a_n = \frac{a_0}{n!}. \qquad \text{(step 5)}$$

For the equations involving odd values of $n$, we see that

$$a_3 = \frac{a_1}{3 \cdot 2} = \frac{a_1}{3!}$$
$$a_5 = \frac{a_3}{5 \cdot 4} = \frac{a_1}{5!}$$
$$a_7 = \frac{a_5}{7 \cdot 6} = \frac{a_1}{7!}$$
$$\vdots$$

Therefore, in general, when $n$ is odd,

$$a_n = \frac{a_1}{n!}. \qquad \text{(step 5)}$$

Putting this together, we have

$$\begin{aligned} y(x) &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_0 + a_1 x + \frac{a_0}{2} x^2 + \frac{a_1}{3!} x^3 + \frac{a_0}{4!} x^4 + \frac{a_1}{5!} x^5 + \cdots. \end{aligned}$$

Re-indexing the sums to account for the even and odd values of $n$ separately, we obtain

$$y(x) = a_0 \sum_{k=0}^{\infty} \frac{1}{(2k)!} x^{2k} + a_1 \sum_{k=0}^{\infty} \frac{1}{(2k+1)!} x^{2k+1}. \qquad \text{(step 6)}$$

**Analysis for part a.**

As expected for a second-order differential equation, this solution depends on two arbitrary constants. However, note that our differential equation is a constant-coefficient differential equation, yet the power series solution does not appear to have the familiar form (containing exponential functions) that we are used to seeing. Furthermore, since $y(x) = c_1 e^x + c_2 e^{-x}$ is the general solution to this equation, we must be able to write any solution in this form, and it is not clear whether the power series solution we just found can, in fact, be written in that form.

Fortunately, after writing the power series representations of $e^x$ and $e^{-x}$, and doing some algebra, we find that if we choose

$$c_0 = \frac{(a_0 + a_1)}{2}, c_1 = \frac{(a_0 - a_1)}{2},$$

we then have $a_0 = c_0 + c_1$ and $a_1 = c_0 - c_1$, and

$$\begin{aligned} y(x) &= a_0 + a_1 x + \frac{a_0}{2} x^2 + \frac{a_1}{3!} x^3 + \frac{a_0}{4!} x^4 + \frac{a_1}{5!} x^5 + \cdots \\ &= (c_0 + c_1) + (c_0 - c_1)x + \frac{(c_0 + c_1)}{2} x^2 + \frac{(c_0 - c_1)}{3!} x^3 + \frac{(c_0 + c_1)}{4!} x^4 + \frac{(c_0 - c_1)}{5!} x^5 + \cdots \\ &= c_0 \sum_{n=0}^{\infty} \frac{x^n}{n!} + c_1 \sum_{n=0}^{\infty} \frac{(-x)^n}{n!} \\ &= c_0 e^x + c_1 e^{-x}. \end{aligned}$$

So we have, in fact, found the same general solution. Note that this choice of $c_1$ and $c_2$ is not obvious. This is a case when we know what the answer should be, and have essentially "reverse-engineered" our choice of coefficients.

**Part b**

Assume

$$y(x) = \sum_{n=0}^{\infty} a_n x^n \qquad \text{(step 1)}$$

Then,

$$y'(x) = \sum_{n=1}^{\infty} n a_n x^{n-1} \qquad \text{(step 2)}$$

and

$$y''(x) = \sum_{n=2}^{\infty} n(n-1)a_n x^{n-2} \qquad \text{(step 2)}$$

We want to find values for the coefficients $a_n$ such that

$$\begin{aligned}(x^2-1)y''+6xy'+4y &= -4\\ (x^2-1)\sum_{n=2}^{\infty} n(n-1)a_n x^{n-2} + 6x\sum_{n=1}^{\infty} n a_n x^{n-1} + 4\sum_{n=0}^{\infty} a_n x^n &= -4\\ x^2\sum_{n=2}^{\infty} n(n-1)a_n x^{n-2} - \sum_{n=2}^{\infty} n(n-1)a_n x^{n-2} + 6x\sum_{n=1}^{\infty} n a_n x^{n-1} + 4\sum_{n=0}^{\infty} a_n x^n &= -4.\end{aligned}$$

Taking the external factors inside the summations, we get

$$\sum_{n=2}^{\infty} n(n-1)a_n x^n - \sum_{n=2}^{\infty} n(n-1)a_n x^{n-2} + \sum_{n=1}^{\infty} 6n a_n x^n + \sum_{n=0}^{\infty} 4a_n x^n = -4. \qquad \text{(step 3)}$$

Now, in the first summation, we see that when $n = 0$ or $n = 1$, the term evaluates to zero, so we can add these terms back into our sum to get

$$\sum_{n=2}^{\infty} n(n-1)a_n x^n = \sum_{n=0}^{\infty} n(n-1)a_n x^n.$$

Similarly, in the third term, we see that when $n = 0$, the expression evaluates to zero, so we can add that term back in as well. We have

$$\sum_{n=1}^{\infty} 6n a_n x^n = \sum_{n=0}^{\infty} 6n a_n x^n.$$

Then, we need only shift the indices in our second term. We get

$$\sum_{n=2}^{\infty} n(n-1)a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)(n+1)a_{n+2} x^n.$$

Thus, we have

$$\begin{aligned}\sum_{n=0}^{\infty} n(n-1)a_n x^n - \sum_{n=0}^{\infty} (n+2)(n+1)a_{n+2} x^n + \sum_{n=0}^{\infty} 6n a_n x^n + \sum_{n=0}^{\infty} 4a_n x^n &= -4 \qquad \text{(step 4)}\\ \sum_{n=0}^{\infty} [n(n-1)a_n - (n+2)(n+1)a_{n+2} + 6n a_n + 4a_n] x^n &= -4\\ \sum_{n=0}^{\infty} [(n^2-n)a_n + 6n a_n + 4a_n - (n+2)(n+1)a_{n+2}] x^n &= -4\\ \sum_{n=0}^{\infty} [n^2 a_n + 5n a_n + 4a_n - (n+2)(n+1)a_{n+2}] x^n &= -4\\ \sum_{n=0}^{\infty} [(n^2+5n+4)a_n - (n+2)(n+1)a_{n+2}] x^n &= -4\\ \sum_{n=0}^{\infty} [(n+4)(n+1)a_n - (n+2)(n+1)a_{n+2}] x^n &= -4\end{aligned}$$

Looking at the coefficients of each power of $x$, we see that the constant term must be equal to $-4$, and the coefficients of all other powers of $x$ must be zero. Then, looking first at the constant term,

$$\begin{aligned}4a_0 - 2a_2 &= -4\\ a_2 &= 2a_0 + 2\end{aligned} \qquad \text{(step 3)}$$

For $n \geq 1$, we have

$$(n+4)(n+1)a_n-(n+2)(n+1)a_{n+2}=0$$
$$(n+1)[(n+4)a_n-(n+2)a_{n+2}]=0.$$

Since $n\geq 1,\ n+1\neq 0$, we see that

$$(n+4)a_n-(n+2)a_{n+2}=0$$

and thus

$$a_{n+2}=\frac{n+4}{n+2}a_n.$$

For even values of $n$, we have

$$a_4=\frac{6}{4}(2a_0+2)=3a_0+3$$
$$a_6=\frac{8}{6}(3a_0+3)=4a_0+4$$
$$\vdots$$

In general,

$$a_{2k}=(k+1)(a_0+1). \qquad \text{(step 5)}$$

For odd values of $n$, we have

$$a_3=\frac{5}{3}a_1$$
$$a_5=\frac{7}{5}a_3=\frac{7}{3}a_1$$
$$a_7=\frac{9}{7}a_5=\frac{9}{3}a_1=3a_1$$
$$\vdots$$

In general,

$$a_{2k+1}=\frac{2k+3}{3}a_1. \qquad \text{(step 5 continued)}$$

Putting this together, we have

$$y(x)=\sum_{k=0}^{\infty}(k+1)(a_0+1)x^{2k}+\sum_{k=0}^{\infty}(\frac{2k+3}{3})a_1x^{2k+1}. \qquad \text{(step 6)}$$

## ? Exercise 17.5.1

Find a power series solution for the following differential equations.

a. $y'+2xy=0$
b. $(x+1)y'=3y$

**Hint**

Follow the problem-solving strategy.

**Answer a**

$$y(x)=a_0\sum_{n=0}^{\infty}\frac{(-1)^n}{n!}x^{2n}=a_0e^{-x^2}$$

**Answer b**

$$y(x)=a_0(x+1)^3$$

## Bessel functions

We close this section with a brief introduction to *Bessel functions*. Complete treatment of Bessel functions is well beyond the scope of this course, but we get a little taste of the topic here so we can see how series solutions to differential equations are used in real-world applications. The Bessel equation of order $n$ is given by

$$x^2y''+xy'+(x^2-n^2)y=0.$$

This equation arises in many physical applications, particularly those involving cylindrical coordinates, such as the vibration of a circular drum head and transient heating or cooling of a cylinder. In the next example, we find a power series solution to the Bessel equation of order 0.

### Example 17.5.2: Power Series Solution to the Bessel Equation

Find a power series solution to the Bessel equation of order 0 and graph the solution.

**Solution**

The Bessel equation of order 0 is given by

$$x^2y''+xy'+x^2y=0.$$

We assume a solution of the form $y=\sum_{n=0}^{\infty}a_nx^n$. Then $y'(x)=\sum_{n=1}^{\infty}na_nx^{n-1}$ and $y''(x)=\sum_{n=2}^{\infty}n(n-1)a_nx^{n-2}$.Substituting this into the differential equation, we get

$$\begin{aligned}
&x^2\sum_{n=2}^{\infty}n(n-1)a_nx^{n-2}+x\sum_{n=1}^{\infty}na_nx^{n-1}\\
&\qquad+x^2\sum_{n=0}^{\infty}a_nx^n=0 && \text{Substitution.}\\
&\sum_{n=2}^{\infty}n(n-1)a_nx^n+\sum_{n=1}^{\infty}na_nx^n+\sum_{n=0}^{\infty}a_nx^{n+2}=0 && \text{Bring external factors within sums.}\\
&\sum_{n=2}^{\infty}n(n-1)a_nx^n+\sum_{n=1}^{\infty}na_nx^n+\sum_{n=2}^{\infty}a_{n-2}x^n=0 && \text{Re-index third sum.}\\
&\qquad\sum_{n=2}^{\infty}n(n-1)a_nx^n+a_1x\\
&\qquad+\sum_{n=2}^{\infty}na_nx^n+\sum_{n=2}^{\infty}a_{n-2}x^n=0 && \text{Separate } n=1 \text{ term from second sum.}\\
&a_1x+\sum_{n=2}^{\infty}[n(n-1)a_n+na_n+a_{n-2}]x^n=0 && \text{Collect summation terms.}\\
&a_1x+\sum_{n=2}^{\infty}[(n^2-n)a_n+na_n+a_{n-2}]x^n=0 && \text{Multiply through in first term.}\\
&\qquad a_1x+\sum_{n=2}^{\infty}[n^2a_n+a_{n-2}]x^n=0. && \text{Simplify.}
\end{aligned}$$

Then, $a_1=0$, and for $n\geq 2$,

$$\begin{aligned}
n^2a_n+a_{n-2}&=0\\
a_n&=-\frac{1}{n^2}a_{n-2}.
\end{aligned}$$

Because $a_1=0$, all odd terms are zero. Then, for even values of $n$, we have

$$a_2 = -\frac{1}{2^2}a_0$$
$$a_4 = -\frac{1}{4^2}a_2 = \frac{1}{4^2 \cdot 2^2}a_0.$$
$$a_6 = -\frac{1}{6^2}a_4 = -\frac{1}{6^2 \cdot 4^2 \cdot 2^2}a_0$$

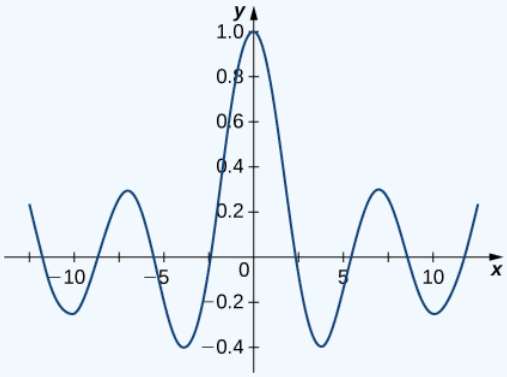
In general,

$$a_{2k} = \frac{(-1)^k}{(2)^{2k}(k!)^2}a_0.$$

Thus, we have

$$y(x) = a_0 \sum_{k=0}^{\infty} \frac{(-1)^k}{(2)^{2k}(k!)^2}x^{2k}.$$

The graph appears below.



## ? Exercise 17.5.2

Verify that the expression found in Example **17.5.2** is a solution to the Bessel equation of order 0.

**Hint**

Differentiate the power series term by term and substitute it into the differential equation.

## Key Concepts

- Power series representations of functions can sometimes be used to find solutions to differential equations.
- Differentiate the power series term by term and substitute into the differential equation to find relationships between the power series coefficients.

# 17.5E: Exercises for Section 17.4

**Find a power series solution for each of the following differential equations.**

1. $y''+6y'=0$

2. $5y''+y'=0$

**Answer**

$$y=c_0+5c_1\sum_{n=1}^{\infty}\frac{(-x/5)^n}{n!}=c_0+5c_1e^{-x/5}$$

3. $y''+25y=0$

4. $y''-y=0$

**Answer**

$$y=c_0\sum_{n=0}^{\infty}\frac{(x)^{2n}}{(2n)!}+c_1\sum_{n=0}^{\infty}\frac{(x)^{2n+1}}{(2n+1)!}$$

5. $2y'+y=0$

6. $y'-2xy=0$

**Answer**

$$y=c_0\sum_{n=0}^{\infty}\frac{x^{2n}}{n!}=c_0e^{x^2}$$

7. $(x-7)y'+2y=0$

8. $y''-xy'-y=0$

**Answer**

$$y=c_0\sum_{n=0}^{\infty}\frac{x^{2n}}{2^n n!}+c_1\sum_{n=0}^{\infty}\frac{x^{2n+1}}{1\cdot 3\cdot 5\cdot 7\cdots(2n+1)}$$

9. $(1+x^2)y''-4xy'+6y=0$

10. $x^2y''-xy'-3y=0$

**Answer**

$$y=c_1x^3+\frac{c_2}{x}$$

11. $y''-8y'=0,\quad y(0)=-2,\ y'(0)=10$

12. $y''-2xy=0,\quad y(0)=1,\ y'(0)=-3$

**Answer**

$$y=1-3x+\frac{2x^3}{3!}-\frac{12x^4}{4!}+\frac{16x^6}{6!}-\frac{120x^7}{7!}+\cdots$$

13. The differential equation $x^2y''+xy'+(x^2-1)y=0$ is a Bessel equation of order $1$. Use a power series of the form $y=\sum_{n=0}^{\infty}a_nx^n$ to find the solution.

# 17.R: Chapter 17 Review Exercises

***True or False*? Justify your answer with a proof or a counterexample.**

1. If $y$ and $z$ are both solutions to $y''+2y'+y=0$, then $y+z$ is also a solution.

**Answer**

True

2. The following system of algebraic equations has a unique solution:

$6z_1+3z_2=8$
$4z_1+2z_2=4.$

3. $y=e^x\cos(3x)+e^x\sin(2x)$ is a solution to the second-order differential equation $y''+2y'+10=0.$

**Answer**

False

4. To find the particular solution to a second-order differential equation, you need one initial condition.

**In problems 5 - 8, classify the differential equations. Determine the order, whether it is linear and, if linear, whether the differential equation is homogeneous or nonhomogeneous. If the equation is second-order homogeneous and linear, find the characteristic equation.**

5. $y''-2y=0$

**Answer**

second order, linear, homogeneous, $\lambda^2-2=0$

6. $y''-3y+2y=\cos(t)$

7. $\left(\frac{dy}{dt}\right)^2+yy'=1$

**Answer**

first order, nonlinear, nonhomogeneous

8. $\frac{d^2y}{dt^2}+t\frac{dy}{dt}+\sin^2(t)y=e^t$

**In problems 9 - 16, find the general solution.**

9. $y''+9y=0$

**Answer**

$y=c_1\sin(3x)+c_2\cos(3x)$

10. $y''+2y'+y=0$

11. $y''-2y'+10y=4x$

**Answer**

$y=c_1e^x\sin(3x)+c_2e^x\cos(3x)+\frac{2}{5}x+\frac{2}{25}$

12. $y''=\cos(x)+2y'+y$

13. $y''+5y+y=x+e^{2x}$

**Answer**

$y=c_1e^{-x}+c_2e^{-4x}+\frac{x}{4}+\frac{e^{2x}}{18}-\frac{5}{16}$

14. $y'' = 3y' + xe^{-x}$

15. $y'' - x^2 = -3y' - \frac{9}{4}y + 3x$

**Answer**

$y = c_1 e^{(-3/2)x} + c_2 x e^{(-3/2)x} + \frac{4}{9}x^2 + \frac{4}{27}x - \frac{16}{27}$

16. $y'' = 2\cos x + y' - y$

**In problems 17 - 18, find the solution to the initial-value problem, if possible.**

17. $y'' + 4y' + 6y = 0,\ y(0) = 0,\ y'(0) = \sqrt{2}$

**Answer**

$y = e^{-2x}\sin(\sqrt{2}x)$

18. $y'' = 3y - \cos(x),\ y(0) = \frac{9}{4},\ y'(0) = 0$

**In problems 19 - 20, find the solution to the boundary-value problem.**

19. $4y' = -6y + 2y'',\ y(0) = 0,\ y(1) = 1$

**Answer**

$y = \dfrac{e^{1-x}}{e^4 - 1}(e^{4x} - 1)$

20. $y'' = 3x - y - y',\ y(0) = -3,\ y(1) = 0$

**For the following problem, set up and solve the differential equation.**

21. The motion of a swinging pendulum for small angles $\theta$ can be approximated by $\dfrac{d^2\theta}{dt^2} + \dfrac{g}{L}\theta = 0$, where $\theta$ is the angle the pendulum makes with respect to a vertical line, $g$ is the acceleration resulting from gravity, and $L$ is the length of the pendulum. Find the equation describing the angle of the pendulum at time $t$, assuming an initial displacement of $\theta_0$ and an initial velocity of zero.

**Answer**

$\theta(t) = \theta_0 \cos\left(\sqrt{\frac{g}{l}}t\right)$

**In problems 22 - 23, consider the "beats" that occur when the forcing term of a differential equation causes "slow" and "fast" amplitudes. Consider the general differential equation $ay'' + by = \cos(\omega t)$ that governs undamped motion. Assume that $\sqrt{\frac{b}{a}} \neq \omega$.**

22. Find the general solution to this equation (*Hint:* call $\omega_0 = \sqrt{b/a}$).

23. Assuming the system starts from rest, show that the particular solution can be written as $y = \dfrac{2}{a(\omega_0^2 - \omega^2)}\sin\left(\dfrac{\omega_0 - \omega t}{2}\right)\sin\left(\dfrac{\omega_0 + \omega t}{2}\right)$.

**24. [T]** Using your solutions derived earlier, plot the solution to the system $2y'' + 9y = \cos(2t)$ over the interval $t = [-50, 50]$. Find, analytically, the period of the fast and slow amplitudes.

**For the following problem, set up and solve the differential equations.**

25. An opera singer is attempting to shatter a glass by singing a particular note. The vibrations of the glass can be modeled by $y'' + ay = \cos(bt)$, where $y'' + ay = 0$ represents the natural frequency of the glass and the singer is forcing the vibrations at $\cos(bt)$. For what value $b$ would the singer be able to break that glass? (*Note*: in order for the glass to break, the oscillations would need to get higher and higher.)

**Answer**

$b = \sqrt{a}$

# 18.1: Table of Derivatives

## General Formulas

1. $\frac{d}{dx}(c) = 0$
2. $\frac{d}{dx}(f(x) + g(x)) = f'(x) + g'(x)$
3. $\frac{d}{dx}(f(x)g(x)) = f'(x)g(x) + f(x)g'(x)$
4. $\frac{d}{dx}(x^n) = nx^{n-1}, \quad \text{for real numbers } n$
5. $\frac{d}{dx}(cf(x)) = cf'(x)$
6. $\frac{d}{dx}(f(x) - g(x)) = f'(x) - g'(x)$
7. $\frac{d}{dx}\left(\frac{f(x)}{g(x)}\right) = \frac{g(x)f'(x) - f(x)g'(x)}{(g(x))^2}$
8. $\frac{d}{dx}[f(g(x))] = f'(g(x)) \cdot g'(x)$

## Trigonometric Functions

9. $\frac{d}{dx}(\sin x) = \cos x$
10. $\frac{d}{dx}(\tan x) = \sec^2 x$
11. $\frac{d}{dx}(\sec x) = \sec x \tan x$
12. $\frac{d}{dx}(\cos x) = -\sin x$
13. $\frac{d}{dx}(\cot x) = -\csc^2 x$
14. $\frac{d}{dx}(\csc x) = -\csc x \cot x$

## Inverse Trigonometric Functions

15. $\frac{d}{dx}(\sin^{-1} x) = \frac{1}{\sqrt{1-x^2}}$
16. $\frac{d}{dx}(\tan^{-1} x) = \frac{1}{1+x^2}$
17. $\frac{d}{dx}(\sec^{-1} x) = \frac{1}{|x|\sqrt{x^2-1}}$
18. $\frac{d}{dx}(\cos^{-1} x) = \frac{-1}{\sqrt{1-x^2}}$
19. $\frac{d}{dx}(\cot^{-1} x) = \frac{-1}{1+x^2}$
20. $\frac{d}{dx}(\csc^{-1} x) = \frac{-1}{|x|\sqrt{x^2-1}}$

## Exponential and Logarithmic Functions

21. $\frac{d}{dx}(e^x) = e^x$
22. $\frac{d}{dx}(\ln|x|) = \frac{1}{x}$
23. $\frac{d}{dx}(b^x) = b^x \ln b$
24. $\frac{d}{dx}(\log_b x) = \frac{1}{x \ln b}$

## Hyperbolic Functions

25. $\frac{d}{dx}(\sinh x) = \cosh x$
26. $\frac{d}{dx}(\tanh x) = \operatorname{sech}^2 x$
27. $\frac{d}{dx}(\operatorname{sech} x) = -\operatorname{sech} x \tanh x$
28. $\frac{d}{dx}(\cosh x) = \sinh x$
29. $\frac{d}{dx}(\coth x) = -\operatorname{csch}^2 x$
30. $\frac{d}{dx}(\operatorname{csch} x) = -\operatorname{csch} x \coth x$

## Inverse Hyperbolic Functions

31. $\frac{d}{dx}\left(\sinh^{-1} x\right) = \frac{1}{\sqrt{x^2+1}}$
32. $\frac{d}{dx}\left(\tanh^{-1} x\right) = \frac{1}{1-x^2} \quad (|x| < 1)$
33. $\frac{d}{dx}\left(\operatorname{sech}^{-1} x\right) = \frac{-1}{x\sqrt{1-x^2}} \quad (0 < x < 1)$
34. $\frac{d}{dx}\left(\cosh^{-1} x\right) = \frac{1}{\sqrt{x^2-1}} \quad (x > 1)$
35. $\frac{d}{dx}\left(\coth^{-1} x\right) = \frac{1}{1-x^2} \quad (|x| > 1)$
36. $\frac{d}{dx}\left(\operatorname{csch}^{-1} x\right) = \frac{-1}{|x|\sqrt{1+x^2}} \quad (x \neq 0)$

# 18.2: Table of Integrals

## Basic Integrals

1. $\int u^n\,du = \frac{u^{n+1}}{n+1} + C, \quad n \neq -1$
2. $\int \frac{du}{u} = \ln|u| + C$
3. $\int e^u\,du = e^u + C$
4. $\int a^u\,du = \frac{a^u}{\ln a} + C$
5. $\int \sin u\,du = -\cos u + C$
6. $\int \cos u\,du = \sin u + C$
7. $\int \sec^2 u\,du = \tan u + C$
8. $\int \csc^2 u\,du = -\cot u + C$
9. $\int \sec u \tan u\,du = \sec u + C$
10. $\int \csc u \cot u\,du = -\csc u + C$
11. $\int \tan u\,du = \ln|\sec u| + C$
12. $\int \cot u\,du = \ln|\sin u| + C$
13. $\int \sec u\,du = \ln|\sec u + \tan u| + C$
14. $\int \csc u\,du = \ln|\csc u - \cot u| + C$
15. $\int \frac{du}{\sqrt{a^2 - u^2}} = \sin^{-1}\left(\frac{u}{a}\right) + C$
16. $\int \frac{du}{a^2 + u^2} = \frac{1}{a}\tan^{-1}\left(\frac{u}{a}\right) + C$
17. $\int \frac{du}{u\sqrt{u^2 - a^2}} = \frac{1}{a}\sec^{-1}\frac{|u|}{a} + C$

## Trigonometric Integrals

18. $\int \sin^2 u\,du = \frac{1}{2}u - \frac{1}{4}\sin 2u + C$
19. $\int \cos^2 u\,du = \frac{1}{2}u + \frac{1}{4}\sin 2u + C$
20. $\int \tan^2 u\,du = \tan u - u + C$
21. $\int \cot^2 u\,du = -\cot u - u + C$
22. $\int \sin^3 u\,du = -\frac{1}{3}(2 + \sin^2 u)\cos u + C$
23. $\int \cos^3 u\,du = \frac{1}{3}(2 + \cos^2 u)\sin u + C$
24. $\int \tan^3 u\,du = \frac{1}{2}\tan^2 u + \ln|\cos u| + C$
25. $\int \cot^3 u\,du = -\frac{1}{2}\cot^2 u - \ln|\sin u| + C$

26. $\int \sec^3 u\,du = \frac{1}{2}\sec u \tan u + \frac{1}{2}\ln|\sec u + \tan u| + C$

27. $\int \csc^3 u\,du = -\frac{1}{2}\csc u \cot u + \frac{1}{2}\ln|\csc u - \cot u| + C$

28. $\int \sin^n u\,du = \frac{-1}{n}\sin^{n-1} u \cos u + \frac{n-1}{n}\int \sin^{n-2} u\,du$

29. $\int \cos^n u\,du = \frac{1}{n}\cos^{n-1} u \sin u + \frac{n-1}{n}\int \cos^{n-2} u\,du$

30. $\int \tan^n u\,du = \frac{1}{n-1}\tan^{n-1} u - \int \tan^{n-2} u\,du$

31. $\int \cot^n u\,du = \frac{-1}{n-1}\cot^{n-1} u - \int \cot^{n-2} u\,du$

32. $\int \sec^n u\,du = \frac{1}{n-1}\tan u \sec^{n-2} u + \frac{n-2}{n-1}\int \sec^{n-2} u\,du$

33. $\int \csc^n u\,du = \frac{-1}{n-1}\cot u \csc^{n-2} u + \frac{n-2}{n-1}\int \csc^{n-2} u\,du$

34. $\int \sin au \sin bu\,du = \frac{\sin(a-b)u}{2(a-b)} - \frac{\sin(a+b)u}{2(a+b)} + C$

35. $\int \cos au \cos bu\,du = \frac{\sin(a-b)u}{2(a-b)} + \frac{\sin(a+b)u}{2(a+b)} + C$

36. $\int \sin au \cos bu\,du = -\frac{\cos(a-b)u}{2(a-b)} - \frac{\cos(a+b)u}{2(a+b)} + C$

37. $\int u \sin u\,du = \sin u - u\cos u + C$

38. $\int u \cos u\,du = \cos u + u\sin u + C$

39. $\int u^n \sin u\,du = -u^n \cos u + n\int u^{n-1}\cos u\,du$

40. $\int u^n \cos u\,du = u^n \sin u - n\int u^{n-1}\sin u\,du$

41. Erroneous nesting of equation structures

## Exponential and Logarithmic Integrals

42. $\int ue^{au}\,du = \frac{1}{a^2}(au-1)e^{au} + C$

43. $\int u^n e^{au}\,du = \frac{1}{a}u^n e^{au} - \frac{n}{a}\int u^{n-1}e^{au}\,du$

44. $\int e^{au}\sin bu\,du = \frac{e^{au}}{a^2+b^2}(a\sin bu - b\cos bu) + C$

45. $\int e^{au}\cos bu\,du = \frac{e^{au}}{a^2+b^2}(a\cos bu + b\sin bu) + C$

46. $\int \ln u\,du = u\ln u - u + C$

47. $\int u^n \ln u\,du = \frac{u^{n+1}}{(n+1)^2}[(n+1)\ln u - 1] + C$

48. $\int \frac{1}{u\ln u}\,du = \ln|\ln u| + C$

## Hyperbolic Integrals

49. $\int \sinh u\,du = \cosh u + C$

50. $\int \cosh u\,du = \sinh u + C$

51. $\int \tanh u\,du = \ln\cosh u + C$

52. $\int \coth u\,du = \ln|\sinh u| + C$

53. $\int \operatorname{sech} u\,du = \tan^{-1}|\sinh u| + C$

54. $\int \operatorname{csch} u\,du = \ln|\tanh \frac{1}{2}u| + C$

55. $\int \operatorname{sech}^2 u\,du = \tanh u + C$

56. $\int \operatorname{csch}^2 u\,du = -\coth u + C$

57. $\int \operatorname{sech} u \tanh u\,du = -\operatorname{sech} u + C$

58. $\int \operatorname{csch} u \coth u\,du = -\operatorname{csch} u + C$

## Inverse Trigonometric Integrals

59. $\int \sin^{-1} u\,du = u\sin^{-1} u + \sqrt{1-u^2} + C$

60. $\int \cos^{-1} u\,du = u\cos^{-1} u - \sqrt{1-u^2} + C$

61. $\int \tan^{-1} u\,du = u\tan^{-1} u - \frac{1}{2}\ln(1+u^2) + C$

62. $\int u\sin^{-1} u\,du = \frac{2u^2-1}{4}\sin^{-1} u + \frac{u\sqrt{1-u^2}}{4} + C$

63. $\int u\cos^{-1} u\,du = \frac{2u^2-1}{4}\cos^{-1} u - \frac{u\sqrt{1-u^2}}{4} + C$

64. $\int u\tan^{-1} u\,du = \frac{u^2+1}{2}\tan^{-1} u - \frac{u}{2} + C$

65. $\int u^n \sin^{-1} u\,du = \frac{1}{n+1}\left[u^{n+1}\sin^{-1} u - \int \frac{u^{n+1}\,du}{\sqrt{1-u^2}}\right], \quad n \neq -1$

66. $\int u^n \cos^{-1} u\,du = \frac{1}{n+1}\left[u^{n+1}\cos^{-1} u + \int \frac{u^{n+1}\,du}{\sqrt{1-u^2}}\right], \quad n \neq -1$

67. $\int u^n \tan^{-1} u\,du = \frac{1}{n+1}\left[u^{n+1}\tan^{-1} u - \int \frac{u^{n+1}\,du}{1+u^2}\right], \quad n \neq -1$

## Integrals Involving $a^2 + u^2$, $a > 0$

68. $\int \sqrt{a^2+u^2}\,du = \frac{u}{2}\sqrt{a^2+u^2} + \frac{a^2}{2}\ln\left(u + \sqrt{a^2+u^2}\right) + C$

69. $\int u^2\sqrt{a^2+u^2}\,du = \frac{u}{8}(a^2+2u^2)\sqrt{a^2+u^2} - \frac{a^4}{8}\ln\left(u + \sqrt{a^2+u^2}\right) + C$

70. $\int \frac{\sqrt{a^2+u^2}}{u}\,du = \sqrt{a^2+u^2} - a\ln\left|\frac{a+\sqrt{a^2+u^2}}{u}\right| + C$

71. $\int \frac{\sqrt{a^2+u^2}}{u^2}\,du = -\frac{\sqrt{a^2+u^2}}{u} + \ln\left(u + \sqrt{a^2+u^2}\right) + C$

72. $\int \frac{du}{\sqrt{a^2+u^2}} = \ln\left(u + \sqrt{a^2+u^2}\right) + C$

73. $\int \frac{u^2}{\sqrt{a^2+u^2}}\,du = \frac{u}{2}\left(\sqrt{a^2+u^2}\right) - \frac{a^2}{2}\ln\left(u + \sqrt{a^2+u^2}\right) + C$

74. $\int \frac{du}{u\sqrt{a^2+u^2}} = \frac{-1}{a}\ln\left|\frac{\sqrt{a^2+u^2}+a}{u}\right| + C$

75. $\int \frac{du}{u^2\sqrt{a^2+u^2}} = -\frac{\sqrt{a^2+u^2}}{a^2u} + C$

76. $\int \frac{du}{(a^2+u^2)^{3/2}} = \frac{u}{a^2\sqrt{a^2+u^2}} + C$

## Integrals Involving $u^2 - a^2$, $a > 0$

77. $\int \sqrt{u^2-a^2}\,du = \frac{u}{2}\sqrt{u^2-a^2} - \frac{a^2}{2}\ln\left|u+\sqrt{u^2-a^2}\right| + C$

78. $\int u^2\sqrt{u^2-a^2}\,du = \frac{u}{8}(2u^2-a^2)\sqrt{u^2-a^2} - \frac{a^4}{8}\ln\left|u+\sqrt{u^2-a^2}\right| + C$

79. $\int \frac{\sqrt{u^2-a^2}}{u}\,du = \sqrt{u^2-a^2} - a\cos^{-1}\frac{a}{|u|} + C$

80. $\int \frac{\sqrt{u^2-a^2}}{u^2}\,du = -\frac{\sqrt{u^2-a^2}}{u} + \ln\left|u+\sqrt{u^2-a^2}\right| + C$

81. $\int \frac{du}{\sqrt{u^2-a^2}} = \ln\left|u+\sqrt{u^2-a^2}\right| + C$

82. $\int \frac{u^2}{\sqrt{u^2-a^2}}\,du = \frac{u}{2}\sqrt{u^2-a^2} + \frac{a^2}{2}\ln\left|u+\sqrt{u^2-a^2}\right| + C$

83. $\int \frac{du}{u^2\sqrt{u^2-a^2}} = \frac{\sqrt{u^2-a^2}}{a^2u} + C$

84. $\int \frac{du}{(u^2-a^2)^{3/2}} = -\frac{u}{a^2\sqrt{u^2-a^2}} + C$

## Integrals Involving $a^2 - u^2$, $a > 0$

85. $\int \sqrt{a^2-u^2}\,du = \frac{u}{2}\sqrt{a^2-u^2} + \frac{a^2}{2}\sin^{-1}\frac{u}{a} + C$

86. $\int u^2\sqrt{a^2-u^2}\,du = \frac{u}{8}(2u^2-a^2)\sqrt{a^2-u^2} + \frac{a^4}{8}\sin^{-1}\frac{u}{a} + C$

87. $\int \frac{\sqrt{a^2-u^2}}{u}\,du = \sqrt{a^2-u^2} - a\ln\left|\frac{a+\sqrt{a^2-u^2}}{u}\right| + C$

88. $\int \frac{\sqrt{a^2-u^2}}{u^2}\,du = \frac{-1}{u}\sqrt{a^2-u^2} - \sin^{-1}\frac{u}{a} + C$

89. $\int \frac{u^2}{\sqrt{a^2-u^2}}\,du = \frac{1}{2}\left(-u\sqrt{a^2-u^2} + a^2\sin^{-1}\frac{u}{a}\right) + C$

90. $\int \frac{du}{u\sqrt{a^2-u^2}} = -\frac{1}{a}\ln\left|\frac{a+\sqrt{a^2-u^2}}{u}\right| + C$

91. $\int \frac{du}{u^2\sqrt{a^2-u^2}} = -\frac{1}{a^2u}\sqrt{a^2-u^2} + C$

92. $\int (a^2-u^2)^{3/2}\,du = -\frac{u}{8}\left(2u^2-5a^2\right)\sqrt{a^2-u^2} + \frac{3a^4}{8}\sin^{-1}\frac{u}{a} + C$

93. $\int \frac{du}{(a^2-u^2)^{3/2}} = -\frac{u}{a^2\sqrt{a^2-u^2}} + C$

## Integrals Involving $2au - u^2$, $a > 0$

94. $\int \sqrt{2au-u^2}\,du = \frac{u-a}{2}\sqrt{2au-u^2} + \frac{a^2}{2}\cos^{-1}\left(\frac{a-u}{a}\right) + C$

95. $\int \frac{du}{\sqrt{2au-u^2}} = \cos^{-1}\left(\frac{a-u}{a}\right) + C$

96. $\int u\sqrt{2au-u^2}\,du = \frac{2u^2-au-3a^2}{6}\sqrt{2au-u^2} + \frac{a^3}{2}\cos^{-1}\left(\frac{a-u}{a}\right) + C$

97. $\int \frac{du}{u\sqrt{2au-u^2}} = -\frac{\sqrt{2au-u^2}}{au} + C$

## Integrals Involving $a + bu$, $a \neq 0$

98. $\int \frac{u}{a+bu}\,du = \frac{1}{b^2}(a+bu-a\ln|a+bu|) + C$

99. $$\int \frac{u^2}{a+bu}\,du = \frac{1}{2b^3}\left[(a+bu)^2 - 4a(a+bu) + 2a^2\ln|a+bu|\right] + C$$

100. $$\int \frac{du}{u(a+bu)} = \frac{1}{a}\ln\left|\frac{u}{a+bu}\right| + C$$

101. $$\int \frac{du}{u^2(a+bu)} = -\frac{1}{au} + \frac{b}{a^2}\ln\left|\frac{a+bu}{u}\right| + C$$

102. $$\int \frac{u}{(a+bu)^2}\,du = \frac{a}{b^2(a+bu)} + \frac{1}{b^2}\ln|a+bu| + C$$

103. $$\int \frac{u}{u(a+bu)^2}\,du = \frac{1}{a(a+bu)} - \frac{1}{a^2}\ln\left|\frac{a+bu}{u}\right| + C$$

104. $$\int \frac{u^2}{(a+bu)^2}\,du = \frac{1}{b^3}\left(a+bu - \frac{a^2}{a+bu} - 2a\ln|a+bu|\right) + C$$

105. $$\int u\sqrt{a+bu}\,du = \frac{2}{15b^2}(3bu-2a)(a+bu)^{3/2} + C$$

106. $$\int \frac{u}{\sqrt{a+bu}}\,du = \frac{2}{3b^2}(bu-2a)\sqrt{a+bu} + C$$

107. $$\int \frac{u^2}{\sqrt{a+bu}}\,du = \frac{2}{15b^3}(8a^2+3b^2u^2-4abu)\sqrt{a+bu} + C$$

108. $$\int \frac{du}{u\sqrt{a+bu}} = \begin{cases} \frac{1}{\sqrt{a}}\ln\left|\frac{\sqrt{a+bu}-\sqrt{a}}{\sqrt{a+bu}+\sqrt{a}}\right| + C, & \text{if } a > 0 \\ \frac{\sqrt{2}}{\sqrt{-a}}\tan^{-1}\sqrt{\frac{a+bu}{-a}} + C, & \text{if } a < 0 \end{cases}$$

109. $$\int \frac{\sqrt{a+bu}}{u}\,du = 2\sqrt{a+bu} + a\int \frac{du}{u\sqrt{a+bu}}$$

110. $$\int \frac{\sqrt{a+bu}}{u^2}\,du = -\frac{\sqrt{a+bu}}{u} + \frac{b}{2}\int \frac{du}{u\sqrt{a+bu}}$$

111. $$\int u^n\sqrt{a+bu}\,du = \frac{2}{b(2n+3)}\left[u^n(a+bu)^{3/2} - na\int u^{n-1}\sqrt{a+bu}\,du\right]$$

112. $$\int \frac{u^n}{\sqrt{a+bu}}\,du = \frac{2u^n\sqrt{a+bu}}{b(2n+1)} - \frac{2na}{b(2n+1)}\int \frac{u^{n-1}}{\sqrt{a+bu}}\,du$$

113. $$\int \frac{du}{u^n\sqrt{a+bu}} = -\frac{\sqrt{a+bu}}{a(n-1)u^{n-1}} - \frac{b(2n-3)}{2a(n-1)}\int \frac{du}{u^{n-1}\sqrt{a+bu}}$$

# 18.3: Other Strategies for Integration

**Learning Objectives**

- Use a table of integrals to solve integration problems.
- Use a computer algebra system (CAS) to solve integration problems.

In addition to the techniques of integration we have already seen, several other tools are widely available to assist with the process of integration. Among these tools are **integration tables**, which are readily available in many books, including the appendices to this one. Also widely available are **computer algebra systems (CAS)**, which are found on calculators and in many campus computer labs, and are free online.

## Tables of Integrals

Integration tables, if used in the right manner, can be a handy way either to evaluate or check an integral quickly. The integration tables in this text are in Appendix B. Keep in mind that when using a table to check an answer, it is possible for two completely correct solutions to look very different. For example, in Trigonometric Substitution, we found that, by using the substitution $x = \tan\theta$, we can arrive at

$$\int \frac{dx}{\sqrt{1+x^2}} = \ln\left|x+\sqrt{x^2+1}\right| + C.$$

However, using $x = \sinh\theta$, we obtained a different solution - namely,

$$\int \frac{dx}{\sqrt{1+x^2}} = \sinh^{-1} x + C.$$

Luckily, in Differential Calculus (specifically, in Section 1.7 of the Differential Calculus textbook), we showed algebraically that the two solutions are equivalent. That is, we showed that $\sinh^{-1} x = \ln\left|x+\sqrt{x^2+1}\right|$. In this case, the two antiderivatives that we found were actually equal. This need not be the case. However, as long as the difference in the two antiderivatives is a constant, they are equivalent.

**Example 18.3.1: Using a Formula from a Table to Evaluate an Integral**

Use the table formula

$$\int \frac{\sqrt{a^2-u^2}}{u^2}\,du = -\frac{\sqrt{a^2-u^2}}{u} - \sin^{-1}\frac{u}{a} + C$$

from Appendix B to evaluate $\int \frac{\sqrt{16-e^{2x}}}{e^x}\,dx$.

### Solution

If we look at integration tables, we see that several formulas contain expressions of the form $\sqrt{a^2-u^2}$. This expression is actually similar to $\sqrt{16-e^{2x}}$, where $a = 4$ and $u = e^x$. Keep in mind that we must also have $du = e^x\,dx$. Multiplying the numerator and the denominator of the given integral by $e^x$ should help to put this integral in a useful form. Thus, we now have

$$\int \frac{\sqrt{16-e^{2x}}}{e^x}\,dx = \int \frac{\sqrt{16-e^{2x}}}{e^{2x}}e^x\,dx.$$

Substituting $u = e^x$ and $du = e^x\,dx$ produces $\int \frac{\sqrt{a^2-u^2}}{u^2}\,du$. From the integration table (#88 in Appendix B),

$$\int \frac{\sqrt{a^2-u^2}}{u^2}\,du = -\frac{\sqrt{a^2-u^2}}{u} - \sin^{-1}\frac{u}{a} + C.$$

Thus,

$$\begin{aligned}\int \frac{\sqrt{16-e^{2x}}}{e^x}\,dx &= \int \frac{\sqrt{16-e^{2x}}}{e^{2x}}e^x\,dx \\ &= \int \frac{\sqrt{4^2-u^2}}{u^2}\,du \\ &= \frac{\sqrt{4^2-u^2}}{u} - \sin^{-1}\frac{u}{4} + C \\ &= -\frac{\sqrt{16-e^{2x}}}{e^x} - \sin^{-1}\left(\frac{e^x}{4}\right) + C\end{aligned}$$

## Computer Algebra Systems

If available, a CAS is a faster alternative to a table for solving an integration problem. Many such systems are widely available and are, in general, quite easy to use.

### Example 18.3.2: Using a Computer Algebra System to Evaluate an Integral

Use a computer algebra system to evaluate $\int \frac{dx}{\sqrt{x^2-4}}$. Compare this result with $\ln\left|\frac{\sqrt{x^2-4}}{2}+\frac{x}{2}\right|+C$, a result we might have obtained if we had used Trigonometric Substitution.

**Solution**

Using Wolfram Alpha, we obtain

$$\int \frac{dx}{\sqrt{x^2-4}} = \ln\left|\sqrt{x^2-4}+x\right|+C.$$

Notice that

$$\ln\left|\frac{\sqrt{x^2-4}}{2}+\frac{x}{2}\right|+C = \ln\left|\frac{\sqrt{x^2-4}+x}{2}\right|+C = \ln\left|\sqrt{x^2-4}+x\right| - \ln 2 + C.$$

Since these two antiderivatives differ by only a constant, the solutions are equivalent. We could have also demonstrated that each of these antiderivatives is correct by differentiating them.

You can access an integral calculator for more examples.

### Example 18.3.3: Using a CAS to Evaluate an Integral

Evaluate $\int \sin^3 x\,dx$ using a CAS. Compare the result to $\frac{1}{3}\cos^3 x - \cos x + C$, the result we might have obtained using the technique for integrating odd powers of $\sin x$ discussed earlier in this chapter.

**Solution**

Using Wolfram Alpha, we obtain

$$\int \sin^3 x\,dx = \frac{1}{12}(\cos(3x) - 9\cos x) + C.$$

This looks quite different from $\frac{1}{3}\cos^3 x - \cos x + C$. To see that these antiderivatives are equivalent, we can make use of a few trigonometric identities:

$$\begin{aligned}\frac{1}{12}(\cos(3x)-9\cos x) &= \frac{1}{12}(\cos(x+2x)-9\cos x)\\ &= \frac{1}{12}(\cos(x)\cos(2x)-\sin(x)\sin(2x)-9\cos x)\\ &= \frac{1}{12}(\cos x(2\cos^2 x-1)-\sin x(2\sin x\cos x)-9\cos x)\\ &= \frac{1}{12}(2\cos^3 x-\cos x-2\cos x(1-\cos^2 x)-9\cos x)\\ &= \frac{1}{12}(4\cos^3 x-12\cos x)\\ &= \frac{1}{3}\cos^3 x-\cos x.\end{aligned}$$

Thus, the two antiderivatives are identical.

We may also use a CAS to compare the graphs of the two functions, as shown in the following figure.

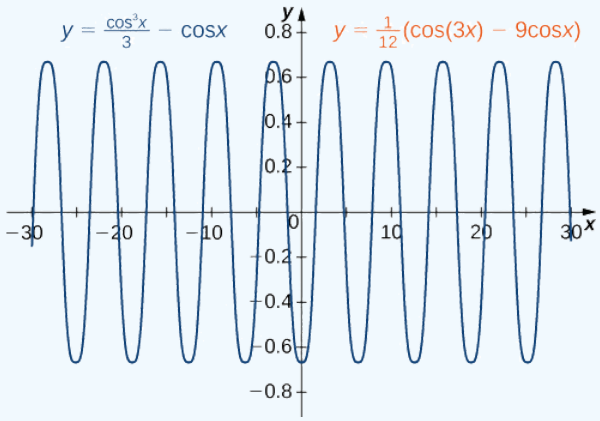

Figure 18.3.1: The graphs of $y=\frac{1}{3}\cos^3 x-\cos x$ and $y=\frac{1}{12}(\cos(3x)-9\cos x)$ are identical.

## ? Exercise 18.3.3

Use a CAS to evaluate $\int \frac{dx}{\sqrt{x^2+4}}$.

**Hint**

Answers may vary.

**Answer**

Possible solutions include $\sinh^{-1}\left(\frac{x}{2}\right)+C$ and $\ln\left|\sqrt{x^2+4}+x\right|+C$.

## Key Concepts

- An integration table may be used to evaluate indefinite integrals.
- A CAS (or computer algebra system) may be used to evaluate indefinite integrals.
- It may require some effort to reconcile equivalent solutions obtained using different methods.

## Glossary

**computer algebra system (CAS)**

technology used to perform many mathematical tasks, including integration

**integration table**

a table that lists integration formulas

## Review Topics

### Differential Calculus

- hyperbolic functions

## 18.3.1: Exercises

**Use a table of integrals to evaluate the following integrals.**

1) $\int_0^4 \frac{x}{\sqrt{1+2x}}\,dx$

2) $\int \frac{x+3}{x^2+2x+2}\,dx$

**Answer**

$$\int \frac{x+3}{x^2+2x+2}\,dx = \tfrac{1}{2}\ln|x^2+2x+2| + 2\arctan(x+1) + C$$

3) $\int x^3\sqrt{1+2x^2}\,dx$

4) $\int \frac{1}{\sqrt{x^2+6x}}\,dx$

**Answer**

$$\int \frac{1}{\sqrt{x^2+6x}}\,dx = \cosh^{-1}\left(\frac{x+3}{3}\right) + C$$

5) $\int \frac{x}{x+1}\,dx$

6) $\int x\cdot 2^{x^2}\,dx$

**Answer**

$$\int x\cdot 2^{x^2}\,dx = \frac{2^{x^2-1}}{\ln 2} + C$$

7) $\int \frac{1}{4x^2+25}\,dx$

8) $\int \frac{dy}{\sqrt{4-y^2}}$

**Answer**

$$\int \frac{dy}{\sqrt{4-y^2}} = \arcsin\left(\frac{y}{2}\right) + C$$

9) $\int \sin^3(2x)\cos(2x)\,dx$

10) $\int \csc(2w)\cot(2w)\,dw$

**Answer**

$$\int \csc(2w)\cot(2w)\,dw = -\tfrac{1}{2}\csc(2w) + C$$

11) $\int 2^y\,dy$

12) $\int_0^1 \frac{3x}{\sqrt{x^2+8}}\,dx$

**Answer**

$$\int_0^1 \frac{3x}{\sqrt{x^2+8}}\,dx = 9 - 6\sqrt{2}$$

13) $\int_{-1/4}^{1/4} \sec^2(\pi x)\tan(\pi x)\,dx$

14) $\int_0^{\pi/2} \tan^2\left(\frac{x}{2}\right)\,dx$

**Answer**

$$\int_0^{\pi/2} \tan^2\left(\frac{x}{2}\right)\,dx = 2 - \frac{\pi}{2}$$

15) $\int \cos^3 x\,dx$

16) $\int \tan^5(3x)\,dx$

**Answer**

$$\int \tan^5(3x)\,dx = \tfrac{1}{12}\tan^4(3x) - \tfrac{1}{6}\tan^2(3x) + \tfrac{1}{3}\ln|\sec 3x| + C$$

17) $\int \sin^2 y \cos^3 y\,dy$

**Use a CAS to evaluate the following integrals. Tables can also be used to verify the answers.**

18) [Technology Required] $\int \frac{dw}{1+\sec\left(\frac{w}{2}\right)}$

**Answer**

$$\int \frac{dw}{1+\sec\left(\frac{w}{2}\right)} = 2\cot\left(\tfrac{w}{2}\right) - 2\csc\left(\tfrac{w}{2}\right) + w + C$$

19) [Technology Required] $\int \frac{dw}{1-\cos(7w)}$

20) [Technology Required] $\int_0^t \frac{dt}{4\cos t + 3\sin t}$

**Answer**

$$\int_0^t \frac{dt}{4\cos t + 3\sin t} = \tfrac{1}{5}\ln\left|\frac{2(5+4\sin t - 3\cos t)}{4\cos t + 3\sin t}\right|$$

21) [Technology Required] $\int \frac{\sqrt{x^2-9}}{3x}\,dx$

22) [Technology Required] $\int \frac{dx}{x^{1/2}+x^{1/3}}$

**Answer**

$$\int \frac{dx}{x^{1/2}+x^{1/3}} = 6x^{1/6} - 3x^{1/3} + 2\sqrt{x} - 6\ln[1+x^{1/6}] + C$$

23) [Technology Required] $\int \frac{dx}{x\sqrt{x-1}}$

24) [Technology Required] $\int x^3 \sin x\,dx$

**Answer**

$$\int x^3 \sin x\,dx = -x^3\cos x + 3x^2\sin x + 6x\cos x - 6\sin x + C$$

25) [Technology Required] $\int x\sqrt{x^4-9}\,dx$

26) [Technology Required] $\int \frac{x}{1+e^{-x^2}}\,dx$

**Answer**

$$\int \frac{x}{1+e^{-x^2}}\,dx = \tfrac{1}{2}\left(x^2 + \ln|1+e^{-x^2}|\right) + C$$

27) [Technology Required] $\int \frac{\sqrt{3-5x}}{2x}\,dx$

28) [Technology Required] $\int \frac{dx}{x\sqrt{x-1}}$

**Answer**

$$\int \frac{dx}{x\sqrt{x-1}} = 2\arctan\left(\sqrt{x-1}\right) + C$$

29) [Technology Required] $\int e^x \cos^{-1}(e^x)\,dx$

**Use a calculator or CAS to evaluate the following integrals.**

30) [Technology Required] $\int_0^{\pi/4} \cos 2x\,dx$

**Answer**

$$\int_0^{\pi/4} \cos 2x\,dx = 0.5 = \frac{1}{2}$$

31) [Technology Required] $\int_0^1 x \cdot e^{-x^2}\,dx$

32) [Technology Required] $\int_0^8 \frac{2x}{\sqrt{x^2+36}}\,dx$

**Answer**

$$\int_0^8 \frac{2x}{\sqrt{x^2+36}}\,dx = 8.0$$

33) [Technology Required] $\int_0^{2/\sqrt{3}} \frac{1}{4+9x^2}\,dx$

34) [Technology Required] $\int \frac{dx}{x^2+4x+13}$

**Answer**

$$\int \frac{dx}{x^2+4x+13} = \tfrac{1}{3}\arctan\left(\tfrac{1}{3}(x+2)\right) + C$$

35) [Technology Required] $\int \frac{dx}{1+\sin x}$

**Use tables to evaluate the integrals. You may need to complete the square or change variables to put the integral into a form given in the table.**

36) $\int \frac{dx}{x^2+2x+10}$

**Answer**

$$\int \frac{dx}{x^2+2x+10} = \tfrac{1}{3}\arctan\left(\frac{x+1}{3}\right) + C$$

37) $\int \frac{dx}{\sqrt{x^2-6x}}$

38) $\int \frac{e^x}{\sqrt{e^{2x}-4}}\,dx$

**Answer**

$$\int \frac{e^x}{\sqrt{e^{2x}-4}}\,dx = \ln\left(e^x + \sqrt{4+e^{2x}}\right) + C$$

39) $\int \frac{\cos x}{\sin^2 x + 2\sin x}\,dx$

40) $\int \frac{\arctan(x^3)}{x^4}\,dx$

**Answer**

$$\int \frac{\arctan(x^3)}{x^4}\,dx = \ln x - \tfrac{1}{6}\ln(x^6+1) - \frac{\arctan(x^3)}{3x^3} + C$$

41) $\int \frac{\ln|x|\arcsin(\ln|x|)}{x}\,dx$

**Use tables to perform the integration.**

42) $\int \frac{dx}{\sqrt{x^2+16}}$

**Answer**

$$\int \frac{dx}{\sqrt{x^2+16}} = \ln|x| + \sqrt{16+x^2}\,| + C$$

43) $\int \frac{3x}{2x+7}\,dx$

44) $\int \frac{dx}{1-\cos 4x}$

**Answer**

$$\int \frac{dx}{1-\cos 4x} = -\frac{1}{4}\cot 2x + C$$

45) $\int \frac{dx}{\sqrt{4x+1}}$

46) Find the area bounded by $y(4+25x^2)=5,\ x=0,\ y=0,$ and $x=4.$ Use a table of integrals or a CAS.

**Answer**

$\frac{1}{2}\arctan 10$ units$^2$

47) The region bounded between the curve $y=\frac{1}{\sqrt{1+\cos x}},\ 0.3\le x\le 1.1,$ and the $x$-axis is revolved about the $x$-axis to generate a solid. Use a table of integrals to find the volume of the solid generated. (Round the answer to two decimal places.)

48) Use substitution and a table of integrals to find the area of the surface generated by revolving the curve $y=e^x,\ 0\le x\le 3,$ about the $x$-axis. (Round the answer to two decimal places.)

**Answer**

1276.14 units$^2$

49) [Technology Required] Use an integral table and a calculator to find the area of the surface generated by revolving the curve $y=\frac{x^2}{2},\ 0\le x\le 1,$ about the $x$-axis. (Round the answer to two decimal places.)

50) [Technology Required] Use a CAS or tables to find the area of the surface generated by revolving the curve $y=\cos x,\ 0\le x\le \frac{\pi}{2},$ about the $x$-axis. (Round the answer to two decimal places.)

**Answer**

7.21 units$^2$

51) Find the length of the curve $y=\frac{x^2}{4}$ over $[0,8]$.

52) Find the length of the curve $y=e^x$ over $[0,\ln(2)]$.

**Answer**

$\left(\sqrt{5}-\sqrt{2}+\ln\left|\frac{2+2\sqrt{2}}{1+\sqrt{5}}\right|\right)$ units

53) Find the area of the surface formed by revolving the graph of $y = 2\sqrt{x}$ over the interval $[0, 9]$ about the $x$-axis.

54) Find the average value of the function $f(x) = \dfrac{1}{x^2 + 1}$ over the interval $[-3, 3]$.

**Answer**

$\frac{1}{3}\arctan(3) \approx 0.416$

55) Approximate the arc length of the curve $y = \tan \pi x$ over the interval $\left[0, \frac{1}{4}\right]$. (Round the answer to three decimal places.)

13.2: Vector-Valued Functions and Space Curves
heuristic
7.3: Integration by Parts
Hooke’s law
6.4: Work
17.4: Applications of Second-Order Differential Equations
horizontal asymptote
2.4: The Limit Laws - Limits at Infinity
4.4: An Interlude for Limits - L’Hospital’s Rule and Indeterminate Forms
horizontal line test
1.3: Inverse Functions
hydrostatic pressure
6.5: Hydrostatic Force and Pressure
hyperbolas
10.6: Conic Sections
hyperbolic cosecant
1.6: Hyperbolic Functions
hyperbolic cosine
1.6: Hyperbolic Functions
hyperbolic cosine function
1.6: Hyperbolic Functions
hyperbolic cotangent
1.6: Hyperbolic Functions
hyperbolic functions
1.6: Hyperbolic Functions
hyperbolic identity
1.6: Hyperbolic Functions
hyperbolic secant
1.6: Hyperbolic Functions
hyperbolic sine
1.6: Hyperbolic Functions
hyperbolic sine function
1.6: Hyperbolic Functions
hyperbolic tangent
1.6: Hyperbolic Functions
hyperboloid
12.7: Quadric Surfaces
Hyperboloid of one sheet
12.7: Quadric Surfaces
Hyperboloid of two sheets
12.7: Quadric Surfaces
hypocycloid
10.2: Parametric Equations

I

Imperial system
6.4: Work
implicit differentiation
3.6: Implicit Differentiation and the Derivatives of the Inverse Trigonometric and Hyperbolic Functions
improper double integral
15.3: Double Integrals over General Regions
improper integral
8.1: Improper Integrals
increasing on the interval I
1.1: Functions
increasing sequence
8.2: Sequences
indefinite integral
5.1: Antiderivatives and Indefinite Integrals
independent variable
1.1: Functions
indeterminate forms
4.5: Graphing Using Calculus - Putting it Altogether
index variable
8.2: Sequences
infinite discontinuity
2.7: Continuity
infinite limit
2.2: The Limit of a Function - A Numerical and Graphical Investigation
infinite limit at a finite number (intuitive definition)
2.2: The Limit of a Function - A Numerical and Graphical Investigation
infinite limit at infinity
2.4: The Limit Laws - Limits at Infinity
4.4: An Interlude for Limits - L’Hospital’s Rule and Indeterminate Forms
infinite sequence
8.2: Sequences
infinite series
8.3: Infinite Series
inflection point
4.3: Graphing Using Calculus - Shaping the Curve
initial point
12.2: Vectors in the Plane
initial population
11.5: The Logistic Equation
initial value
11.2: Basics of Differential Equations
initial value problem
5.1: Antiderivatives and Indefinite Integrals
initial velocity
11.2: Basics of Differential Equations
inner product
12.4: The Dot Product
instantaneous rate of change
2.1: Tangent Lines and Velocity
2.8: Defining the Derivative
instantaneous velocity
2.1: Tangent Lines and Velocity
2.8: Defining the Derivative
integrable function
5.3: The Definite Integral
Integral Test
8.4: The Divergence and Integral Tests
integral transform
8.1: Improper Integrals
integrand
5.3: The Definite Integral
integrating factor
11.6: First-order Linear Equations
integration by parts
7.3: Integration by Parts
integration by substitution
5.6: Integration by Substitution
integration table
18.3: Other Strategies for Integration
interior point
14.3: Limits and Continuity
Intermediate Value Theorem
2.7: Continuity
intermediate variable
14.6: The Chain Rule for Multivariable Functions
International System of Units
6.4: Work
Interpretation of Curl
16.8: Stokes’ Theorem
interval of convergence
9.1: Power Series and Functions
inverse function
1.3: Inverse Functions
inverse function theorem
3.7: Derivatives of Logarithms and Logarithmic Differentiation
inverse hyperbolic functions
1.6: Hyperbolic Functions
inverse trigonometric functions
1.3: Inverse Functions
1.5: Trigonometry
irreducible quadratic factors
7.5: Partial Fractions
iterated integral
15.2: Double Integrals over Rectangular Regions
iterative process
4.7: Newton’s Method

J

jacobian
15.8: Change of Variables in Multiple Integrals
joule
6.4: Work
jump discontinuity
2.7: Continuity

## K

Kepler’s laws of planetary motion
13.5: Motion in Space

## L

L’Hôpital’s rule
4.5: Graphing Using Calculus - Putting it Altogether
Lagrange multiplier
14.9: Lagrange Multipliers
lamina
6.6: Moments and Centers of Mass
Laplace transform
8.1: Improper Integrals
lateral surface area
6.3: Arc Length of a Curve and Surface Area
Laws of Exponents
1.4: Exponential and Logarithmic Functions
Laws of Logarithms
1.4: Exponential and Logarithmic Functions
level curve of a function of two variables
14.2: Functions of Several Variables
level surface of a function of three variables
14.2: Functions of Several Variables
LIATE
7.3: Integration by Parts
limacon
10.4: Polar Coordinates
limit
2.1: Tangent Lines and Velocity
limit (intuitive definition)
2.2: The Limit of a Function - A Numerical and Graphical Investigation
limit at infinity
2.4: The Limit Laws - Limits at Infinity
4.4: An Interlude for Limits - L’Hospital’s Rule and Indeterminate Forms
Limit Comparison Test
8.5: The Comparison Tests
limit laws
2.3: The Limit Laws - Limits at Finite Numbers
LIMIT LAWS FOR FUNCTIONS OF TWO VARIABLES
14.3: Limits and Continuity
limit of a constant
2.2: The Limit of a Function - A Numerical and Graphical Investigation
limit of a sequence
8.2: Sequences
limit of the identity function
2.2: The Limit of a Function - A Numerical and Graphical Investigation
line integrals
16.3: Line Integrals
linear
11.6: First-order Linear Equations
linear approximation
3.9: Linear Approximations and Differentials
14.5: Tangent Planes and Linear Approximations
linear density
6.6: Moments and Centers of Mass
linear density function
6.6: Moments and Centers of Mass
linear function
1.2: Basic Classes of Functions and Their Graphs
linearization
3.9: Linear Approximations and Differentials
linearly dependent
17.2: Second-Order Linear Equations
linearly independent
17.2: Second-Order Linear Equations
local extremum
4.1: Graphing Using Calculus - Maxima and Minima
local maximum
4.1: Graphing Using Calculus - Maxima and Minima
local minimum
4.1: Graphing Using Calculus - Maxima and Minima
Logarithmic Function
1.2: Basic Classes of Functions and Their Graphs
1.4: Exponential and Logarithmic Functions
logistic differential equation
11.5: The Logistic Equation
lower sum
5.2: Approximating Areas

## M

Möbius strip
16.7: Surface Integrals
Maclaurin polynomial
9.3: Taylor and Maclaurin Series
Maclaurin series
9.3: Taylor and Maclaurin Series
magnitude
12.2: Vectors in the Plane
major axis
10.6: Conic Sections
mass flux
16.7: Surface Integrals
mathematical model
1.2: Basic Classes of Functions and Their Graphs
Mean Value Theorem
4.2: A Theoretical Interlude - The Mean Value Theorem
Mean Value Theorem for Integrals
5.4: The Fundamental Theorem of Calculus
6.7: The Mean Value Theorem for Integrals
method of cylindrical shells
6.2: Volumes of Revolution - Cylindrical Shells
method of equating coefficients
7.5: Partial Fractions
method of exhaustion
5.2: Approximating Areas
method of Lagrange multipliers
14.9: Lagrange Multipliers
method of strategic substitution
7.5: Partial Fractions
method of undetermined coefficients
17.3: Nonhomogeneous Linear Equations
method of variation of parameters
17.3: Nonhomogeneous Linear Equations
metric system
6.4: Work
Midpoint Rule
7.6: Numerical Integration
minor axis
10.6: Conic Sections
mixed partial derivatives
14.4: Partial Derivatives
moment
6.6: Moments and Centers of Mass
moment of the system
6.6: Moments and Centers of Mass
moments
6.6: Moments and Centers of Mass
Moments of Inertia
6.6: Moments and Centers of Mass
15.7: Calculating Centers of Mass and Moments of Inertia
Monotone Convergence Theorem
8.2: Sequences
monotone sequence
8.2: Sequences
Multiple Integration
15: Multiple Integration

## N

nappe
10.6: Conic Sections
nappes
10.6: Conic Sections
natural exponential function
1.4: Exponential and Logarithmic Functions
natural logarithm
1.4: Exponential and Logarithmic Functions
neighborhood
2.5: The Precise Definition of a Finite Limit at a Finite Number
net change theorem
5.5: The Net Change Theorem, Distances, and Symmetry
net signed area
5.3: The Definite Integral
Newton
6.4: Work
Newton’s Law of Cooling
11.4: Separable Equations
Newton’s method
4.7: Newton’s Method
Newton's Second Law of Motion
6.4: Work
nonelementary integral
9.4: The Binomial Theorem and Applications of Taylor Series
nonhomogeneous linear equation
17.2: Second-Order Linear Equations
nonrepeated irreducible quadratic factors
7.5: Partial Fractions
nonrepeated linear factors
7.5: Partial Fractions
normal component of acceleration
13.5: Motion in Space
normal plane
13.4: Arc Length and Curvature
normal vector
12.6: Equations of Lines and Planes in Space
Normalization
12.2: Vectors in the Plane
number e
1.4: Exponential and Logarithmic Functions

numerical integration
7.6: Numerical Integration

## O

objective function
14.9: Lagrange Multipliers
oblique asymptote
2.4: The Limit Laws - Limits at Infinity
4.4: An Interlude for Limits - L'Hospital's Rule and Indeterminate Forms
octants
12.3: Vectors in Three Dimensions
odd function
1.1: Functions
open set
14.3: Limits and Continuity
optimization problem
14.9: Lagrange Multipliers
optimization problems
4.6: Optimization
order of a differential equation
11.2: Basics of Differential Equations
ordinary point
17.5: Series Solutions of Differential Equations
orientation
10.2: Parametric Equations
orientation of a surface
16.7: Surface Integrals
orthogonal vectors
12.4: The Dot Product
osculating circle
13.4: Arc Length and Curvature
osculating plane
13.4: Arc Length and Curvature

## P

parabola
10.6: Conic Sections
paraboloid
12.7: Quadric Surfaces
parallelepiped
12.5: The Cross Product
parallelogram method
12.2: Vectors in the Plane
parameter
10.2: Parametric Equations
parameter domain
16.7: Surface Integrals
parameter space
16.7: Surface Integrals
parameterization of a curve
10.2: Parametric Equations
parameterized surface
16.7: Surface Integrals
parametric curve
10.2: Parametric Equations
parametric equations
10.2: Parametric Equations
parametric equations of a line
12.6: Equations of Lines and Planes in Space
parametric surface
16.7: Surface Integrals
Parametric Surfaces
16.7: Surface Integrals
partial derivative
14.4: Partial Derivatives
partial differential equation
14.4: Partial Derivatives
Partial Differentiation
14.4: Partial Derivatives
partial fraction decomposition
7.5: Partial Fractions
partial sum
8.3: Infinite Series
particular solution
11.2: Basics of Differential Equations
17.3: Nonhomogeneous Linear Equations
partition
5.2: Approximating Areas
Pascal's Principle
6.5: Hydrostatic Force and Pressure
pascals
6.5: Hydrostatic Force and Pressure
percentage error
3.9: Linear Approximations and Differentials
periodic function
1.5: Trigonometry
phase line
11.5: The Logistic Equation
planar transformation
15.8: Change of Variables in Multiple Integrals
plane curve
13.2: Vector-Valued Functions and Space Curves
point mass
6.4: Work
6.6: Moments and Centers of Mass
point of tangency
2.1: Tangent Lines and Velocity
points of inflection
4.3: Graphing Using Calculus - Shaping the Curve
Polar Areas
15.4: Double Integrals in Polar Coordinates
polar axis
10.4: Polar Coordinates
polar coordinate system
10.4: Polar Coordinates
polar equation
10.4: Polar Coordinates
polar rectangle
15.4: Double Integrals in Polar Coordinates
Polar Volumes
15.4: Double Integrals in Polar Coordinates
pole
10.4: Polar Coordinates
polynomial function
1.2: Basic Classes of Functions and Their Graphs
power function
1.2: Basic Classes of Functions and Their Graphs
Power Reduction Formula
7.1: Expanding the Substitution Method
power rule
3.1: Derivatives of Polynomial Functions
3.2: Differentiation Techniques - The Product and Quotient Rules
Power rule with rational exponents
3.7: Derivatives of Logarithms and Logarithmic Differentiation
power series
9: Power Series
9.1: Power Series and Functions
Precise Definition of a Finite Limit at a Finite Number
2.5: The Precise Definition of a Finite Limit at a Finite Number
Precise Definition of a Finite Limit at Infinity
2.6: The Precise Definitions of Infinite Limits and Limits at Infinity
Precise Definition of a Limit
2.5: The Precise Definition of a Finite Limit at a Finite Number
Precise Definition of an Infinite Limit at a Finite Number
2.6: The Precise Definitions of Infinite Limits and Limits at Infinity
Precise Definition of an Infinite Limit at Infinity
2.6: The Precise Definitions of Infinite Limits and Limits at Infinity
pressure
6.5: Hydrostatic Force and Pressure
principal unit normal vector
13.4: Arc Length and Curvature
principal unit tangent vector
13.3: Calculus of Vector-Valued Functions
product law for limits
2.3: The Limit Laws - Limits at Finite Numbers
product rule
3.1: Derivatives of Polynomial Functions
3.2: Differentiation Techniques - The Product and Quotient Rules
projectile motion
13.5: Motion in Space
propagated error
3.9: Linear Approximations and Differentials
properties of convergent series
8.3: Infinite Series
psi
6.5: Hydrostatic Force and Pressure

## Q

quadratic function
1.2: Basic Classes of Functions and Their Graphs
Quadric Surfaces
12.7: Quadric Surfaces
quotient law for limits
2.3: The Limit Laws - Limits at Finite Numbers
quotient rule
3.1: Derivatives of Polynomial Functions
3.2: Differentiation Techniques - The Product and Quotient Rules

## R

radial coordinate
10.4: Polar Coordinates
radial density
6.6: Moments and Centers of Mass
radians
1.5: Trigonometry

radical substitution method
7.5: Partial Fractions
radius of convergence
9.1: Power Series and Functions
radius of curvature
13.4: Arc Length and Curvature
radius of gyration
15.7: Calculating Centers of Mass and Moments of Inertia
radius of rotation
6.1: Volumes of Revolution - The Disk and Washer Methods
6.10: Determining Volumes by Slicing
range
1.1: Functions
ratio test
8.7: The Ratio and Root Tests
rational function
1.2: Basic Classes of Functions and Their Graphs
rationalizing substitution method
7.5: Partial Fractions
recurrence relation
8.2: Sequences
recursion relation
8.2: Sequences
region
14.3: Limits and Continuity
regular parameterization
16.7: Surface Integrals
regular partition
5.2: Approximating Areas
related rates
3.8: Related Rates
relative error
3.9: Linear Approximations and Differentials
7.6: Numerical Integration
Remainder Estimate
8.4: The Divergence and Integral Tests
removable discontinuity
2.7: Continuity
reparameterization
13.2: Vector-Valued Functions and Space Curves
repeated irreducible quadratic factors
7.5: Partial Fractions
repeated linear factors
7.5: Partial Fractions
restricted domain
1.3: Inverse Functions
Riemann Rearrangement Theorem
8.6: The Alternating Series Test
Riemann sum
5.2: Approximating Areas
RLC series circuit
17.4: Applications of Second-Order Differential Equations
Rolle’s Theorem
4.2: A Theoretical Interlude - The Mean Value Theorem
root function
1.2: Basic Classes of Functions and Their Graphs
root law for limits
2.3: The Limit Laws - Limits at Finite Numbers
root test
8.7: The Ratio and Root Tests
rose
10.4: Polar Coordinates
rotational field
16.2: Vector Fields
rotational volume
6.1: Volumes of Revolution - The Disk and Washer Methods
6.10: Determining Volumes by Slicing
rulings
12.7: Quadric Surfaces

## S

saddle point
14.8: Maxima/Minima Problems
scalar
12.2: Vectors in the Plane
Scalar Equation of a Plane
12.6: Equations of Lines and Planes in Space
scalar line integral
16.3: Line Integrals
scalar multiplication
12.2: Vectors in the Plane
scalar product
12.4: The Dot Product
scalar projection
12.4: The Dot Product
Secant Function
1.5: Trigonometry
secant line
2.1: Tangent Lines and Velocity
second derivative test
4.3: Graphing Using Calculus - Shaping the Curve
separation of variables
11.4: Separable Equations
sequence
8.2: Sequences
sequences
8.2: Sequences
Series Comparison Test
8.5: The Comparison Tests
shell method
6.2: Volumes of Revolution - Cylindrical Shells
SI system
6.4: Work
sigma notation
5.2: Approximating Areas
simple harmonic motion
17.4: Applications of Second-Order Differential Equations
Simpson's rule
7.6: Numerical Integration
sine function
1.5: Trigonometry
singular point
17.5: Series Solutions of Differential Equations
skew lines
12.6: Equations of Lines and Planes in Space
slicing method
6.1: Volumes of Revolution - The Disk and Washer Methods
6.10: Determining Volumes by Slicing
slope
1.2: Basic Classes of Functions and Their Graphs
slope field
11.3: Direction Fields and Numerical Methods
smooth
13.4: Arc Length and Curvature
smooth curve
6.3: Arc Length of a Curve and Surface Area
smooth function
6.3: Arc Length of a Curve and Surface Area
solid of revolution
6.1: Volumes of Revolution - The Disk and Washer Methods
6.2: Volumes of Revolution - Cylindrical Shells
6.10: Determining Volumes by Slicing
solution curve
11.3: Direction Fields and Numerical Methods
solution to a differential equation
11.2: Basics of Differential Equations
space curve
13.2: Vector-Valued Functions and Space Curves
specific mass
6.4: Work
specific weight
6.4: Work
sphere
12.3: Vectors in Three Dimensions
spherical coordinate system
12.8: Cylindrical and Spherical Coordinates
spherical coordinates
12.8: Cylindrical and Spherical Coordinates
spring constant
6.4: Work
squeeze theorem
2.3: The Limit Laws - Limits at Finite Numbers
Squeeze Theorem for Sequences
8.2: Sequences
standard equation of a sphere
12.3: Vectors in Three Dimensions
standard form
10.6: Conic Sections
standard unit vectors
12.2: Vectors in the Plane
step size
11.3: Direction Fields and Numerical Methods
Stokes’ Theorem
16.8: Stokes’ Theorem
16.9: The Divergence Theorem
sum law for limits
2.3: The Limit Laws - Limits at Finite Numbers
Sum Rule
3.1: Derivatives of Polynomial Functions
3.2: Differentiation Techniques - The Product and Quotient Rules
summation notation
5.2: Approximating Areas
superposition principle
17.2: Second-Order Linear Equations
surface
14.2: Functions of Several Variables
surface area
6.3: Arc Length of a Curve and Surface Area
16.7: Surface Integrals
Surface area generated by a parametric curve
10.3: Calculus of Parametric Curves

surface area of a frustum
6.3: Arc Length of a Curve and Surface Area
surface independent
16.8: Stokes' Theorem
surface integral
16.7: Surface Integrals
surface integral of a vector field
16.7: Surface Integrals
surface integrals
16.7: Surface Integrals
surface of revolution
6.3: Arc Length of a Curve and Surface Area
Symmetric Equations of a Line
12.6: Equations of Lines and Planes in Space
symmetry about the origin
1.1: Functions
Symmetry Principle
6.6: Moments and Centers of Mass

T

table of values
1.1: Functions
tangent
2.1: Tangent Lines and Velocity
Tangent Function
1.5: Trigonometry
tangent line
2.1: Tangent Lines and Velocity
2.8: Defining the Derivative
tangent line approximation
3.9: Linear Approximations and Differentials
tangent plane
14.5: Tangent Planes and Linear Approximations
tangent vector
13.3: Calculus of Vector-Valued Functions
tangential component of acceleration
13.5: Motion in Space
Taylor polynomials
9.3: Taylor and Maclaurin Series
Taylor series
9.3: Taylor and Maclaurin Series
Taylor's theorem with remainder
9.3: Taylor and Maclaurin Series
telescoping series
8.3: Infinite Series
term
8.2: Sequences
terminal point
12.2: Vectors in the Plane
The Dot Product
12.4: The Dot Product
The Logistic Equation
11.5: The Logistic Equation
The power rule for functions
3.4: Differentiation Techniques - The Chain Rule
Theorem of Pappus
6.6: Moments and Centers of Mass
Theorem of Pappus for Volume
6.6: Moments and Centers of Mass
threshold population
11.5: The Logistic Equation
torque
12.5: The Cross Product
Torricelli's Trumpet
8.1: Improper Integrals
total area
5.3: The Definite Integral
total differential
14.5: Tangent Planes and Linear Approximations
trace
12.7: Quadric Surfaces
transcendental function
1.2: Basic Classes of Functions and Their Graphs
transformation
15.8: Change of Variables in Multiple Integrals
transformation of a function
1.2: Basic Classes of Functions and Their Graphs
trapezoidal rule
7.6: Numerical Integration
Triangle Inequality
12.2: Vectors in the Plane
triangle method
12.2: Vectors in the Plane
trigonometric functions
1.5: Trigonometry
trigonometric identities
1.5: Trigonometry
trigonometric identity
1.5: Trigonometry
trigonometric integral
7.1: Expanding the Substitution Method
trigonometric substitution
7.2: Expanding the Substitution Method - Trigonometric Substitution
triple integral
15.5: Triple Integrals
triple integral in cylindrical coordinates
15.6: Triple Integrals in Cylindrical and Spherical Coordinates
triple integral in spherical coordinates
15.6: Triple Integrals in Cylindrical and Spherical Coordinates
Triple Scalar Product
12.5: The Cross Product
Type I
15.3: Double Integrals over General Regions
Type II
15.3: Double Integrals over General Regions

U

U.S. customary measurement system
6.4: Work
unit circle
1.5: Trigonometry
unit hyperbola
1.6: Hyperbolic Functions
unit vector
12.2: Vectors in the Plane
upper sum
5.2: Approximating Areas

V

variable of integration
5.3: The Definite Integral
vector
12.2: Vectors in the Plane
vector addition
12.2: Vectors in the Plane
vector difference
12.2: Vectors in the Plane
vector equation of a line
12.6: Equations of Lines and Planes in Space
Vector Equation of a Plane
12.6: Equations of Lines and Planes in Space
vector fields
16.2: Vector Fields
VECTOR LINE INTEGRALS
16.3: Line Integrals
vector parameterization
13.2: Vector-Valued Functions and Space Curves
vector product
12.5: The Cross Product
vector projection
12.4: The Dot Product
vector sum
12.2: Vectors in the Plane
Vectors in R3
12.3: Vectors in Three Dimensions
velocity
2.1: Tangent Lines and Velocity
velocity vector
13.5: Motion in Space
vertex
10.6: Conic Sections
vertical asymptote (calculus definition)
2.2: The Limit of a Function - A Numerical and Graphical Investigation
vertical line test
1.1: Functions
vertical trace
14.2: Functions of Several Variables
Volume by Shells
12.8: Cylindrical and Spherical Coordinates
volumetric density
6.4: Work

W

washer method
6.1: Volumes of Revolution - The Disk and Washer Methods
6.10: Determining Volumes by Slicing
weight density
6.4: Work
Witch of Agnesi
10.2: Parametric Equations
work
6.4: Work
work done by a force
12.4: The Dot Product

Z

zero vector
12.2: Vectors in the Plane
zeros of a function
1.1: Functions

5: Investigating Integrals - *CC BY-NC-SA 4.0*
- 5.1: Antiderivatives and Indefinite Integrals - *CC BY-NC-SA 4.0*
  - 5.1E: Exercises - *Undeclared*
- 5.2: Approximating Areas - *CC BY-NC-SA 4.0*
  - 5.2E: Exercises - *Undeclared*
- 5.3: The Definite Integral - *CC BY-NC-SA 4.0*
  - 5.3E: Exercises - *Undeclared*
- 5.4: The Fundamental Theorem of Calculus - *CC BY-NC-SA 4.0*
  - 5.4E: Exercises - *Undeclared*
- 5.5: The Net Change Theorem, Distances, and Symmetry - *CC BY-NC-SA 4.0*
  - 5.5E: Exercises - *Undeclared*
- 5.6: Integration by Substitution - *CC BY-NC-SA 4.0*
  - 5.6E: Exercises - *Undeclared*
- 5.7: Chapter 5 Review Exercises - *Undeclared*

6: Applications of Integration - *CC BY-NC-SA 4.0*
- 6.1: Volumes of Revolution - The Disk and Washer Methods - *CC BY-NC 4.0*
  - 6.1E: Exercises - *CC BY-NC-SA 4.0*
- 6.2: Volumes of Revolution - Cylindrical Shells - *CC BY-NC 4.0*
  - 6.2E: Exercises - *CC BY-NC 4.0*
- 6.3: Arc Length of a Curve and Surface Area - *CC BY-NC 4.0*
  - 6.3E: Exercises - *CC BY-NC 4.0*
- 6.4: Work - *CC BY-NC 4.0*
  - 6.4E: Exercises - *CC BY-NC 4.0*
- 6.5: Hydrostatic Force and Pressure - *CC BY-NC-SA 4.0*
  - 6.5E: Exercises - *CC BY-NC-SA 4.0*
- 6.6: Moments and Centers of Mass - *CC BY-NC-SA 4.0*
  - 6.6E: Exercises - *CC BY-NC-SA 4.0*
- 6.7: The Mean Value Theorem for Integrals - *CC BY-NC-SA 4.0*
  - 6.7E: Exercises - *Undeclared*
- 6.8: Chapter 1 Review Exercises - *Undeclared*
- 6.9: Areas Between Curves - *CC BY-NC 4.0*
  - 6.9E: Exercises - *CC BY-NC 4.0*
- 6.10: Determining Volumes by Slicing - *CC BY-NC 4.0*
  - 6.10E: Exercises - *CC BY-NC 4.0*

7: Techniques of Integration - *CC BY-NC-SA 4.0*
- 7.1: Expanding the Substitution Method - *CC BY-NC-SA 4.0*

- 7.1E: Exercises - *CC BY-NC-SA 4.0*
- 7.2: Expanding the Substitution Method - Trigonometric Substitution - *CC BY-NC-SA 4.0*
  - 7.2E: Exercises - *CC BY-NC-SA 4.0*
- 7.3: Integration by Parts - *CC BY-NC-SA 4.0*
  - 7.3E: Exercises - *Undeclared*
- 7.4: Chapter 2 Review Exercises - *Undeclared*
- 7.5: Partial Fractions - *CC BY-NC-SA 4.0*
  - 7.5E: Exercises - *CC BY-NC-SA 4.0*
- 7.6: Numerical Integration - *CC BY-NC-SA 4.0*
  - 7.6E: Exercises - *CC BY-NC-SA 4.0*

8: Sequences and Series - *CC BY-NC-SA 4.0*
- 8.1: Improper Integrals - *CC BY-NC-SA 4.0*
  - 8.1.1: Exercises - *CC BY-NC-SA 4.0*
- 8.2: Sequences - *CC BY-NC-SA 4.0*
  - 8.2E: Exercises - *CC BY-NC-SA 4.0*
- 8.3: Infinite Series - *CC BY-NC-SA 4.0*
  - 8.3E: Exercises - *CC BY-NC-SA 4.0*
- 8.4: The Divergence and Integral Tests - *CC BY-NC-SA 4.0*
  - 8.4E: Exercises - *CC BY-NC-SA 4.0*
- 8.5: The Comparison Tests - *CC BY-NC-SA 4.0*
  - 8.5E: Exercises - *CC BY-NC-SA 4.0*
- 8.6: The Alternating Series Test - *CC BY-NC-SA 4.0*
  - 8.6E: Exercises - *CC BY-NC-SA 4.0*
- 8.7: The Ratio and Root Tests - *CC BY-NC-SA 4.0*
  - 8.7E: Exercises - *CC BY-NC-SA 4.0*
- 8.8: Chapter 3 Review Exercises - *CC BY-NC-SA 4.0*

9: Power Series - *CC BY-NC-SA 4.0*
- 9.1: Power Series and Functions - *CC BY-NC-SA 4.0*
  - 9.1E: Exercises - *CC BY-NC-SA 4.0*
- 9.2: Properties of Power Series - *CC BY-NC-SA 4.0*
  - 9.2E: Exercises - *CC BY-NC-SA 4.0*
- 9.3: Taylor and Maclaurin Series - *CC BY-NC-SA 4.0*
  - 9.3E: Exercises - *CC BY-NC-SA 4.0*
- 9.4: The Binomial Theorem and Applications of Taylor Series - *CC BY-NC-SA 4.0*
  - 9.4E: Exercises - *CC BY-NC-SA 4.0*
- 9.5: Chapter 4 Review Exercises - *CC BY-NC-SA 4.0*

10: Parametric Equations and Polar Coordinates - *CC BY-NC-SA 4.0*
- 10.1: Chapter 5 Review Exercises - *CC BY-NC-SA 4.0*
- 10.2: Parametric Equations - *CC BY-NC-SA 4.0*
  - 10.2E: Exercises - *Undeclared*
- 10.3: Calculus of Parametric Curves - *CC BY-NC-SA 4.0*
  - 10.3E: Exercises - *CC BY-NC-SA 4.0*
- 10.4: Polar Coordinates - *CC BY-NC-SA 4.0*
  - 10.4E: Exercises - *CC BY-NC-SA 4.0*
- 10.5: Area and Arc Length in Polar Coordinates - *CC BY-NC-SA 4.0*
  - 10.5E: Exercises - *CC BY-NC-SA 4.0*
- 10.6: Conic Sections - *CC BY-NC-SA 4.0*
  - 10.6E: Exercises - *CC BY-NC-SA 4.0*

11: Introduction to Differential Equations - *CC BY-NC-SA 4.0*
- 11.1: Chapter 6 Review Exercises - *CC BY-NC-SA 4.0*
- 11.2: Basics of Differential Equations - *CC BY-NC-SA 4.0*
  - 11.2E: Exercises for Section 8.1 - *CC BY-NC-SA 4.0*
- 11.3: Direction Fields and Numerical Methods - *CC BY-NC-SA 4.0*
  - 11.3E: Exercises for Section 8.2 - *CC BY-NC-SA 4.0*
- 11.4: Separable Equations - *CC BY-NC-SA 4.0*
  - 11.4E: Exercises for Section 8.3 - *CC BY-NC-SA 4.0*
- 11.5: The Logistic Equation - *CC BY-NC-SA 4.0*
  - 11.5E: Exercises for Section 8.4 - *CC BY-NC-SA 4.0*
- 11.6: First-order Linear Equations - *CC BY-NC-SA 4.0*
  - 11.6E: Exercises for Section 8.5 - *CC BY-NC-SA 4.0*

12: Vectors in Space - *CC BY-NC-SA 4.0*
- 12.1: Prelude to Vectors in Space - *CC BY-NC-SA 4.0*
- 12.2: Vectors in the Plane - *CC BY-NC-SA 4.0*
  - 12.2E: Exercises for Section 12.1 - *CC BY-NC-SA 4.0*
- 12.3: Vectors in Three Dimensions - *CC BY-NC-SA 4.0*
  - 12.3E: Exercises for Section 12.2 - *CC BY-NC-SA 4.0*
- 12.4: The Dot Product - *CC BY-NC-SA 4.0*
  - 12.4E: Exercises for Section 12.3 - *CC BY-NC-SA 4.0*
- 12.5: The Cross Product - *CC BY-NC-SA 4.0*

- 12.5E: Exercises for Section 12.4 - *CC BY-NC-SA 4.0*
- 12.6: Equations of Lines and Planes in Space - *CC BY-NC-SA 4.0*
  - 12.6E: Exercises for Section 12.5 - *CC BY-NC-SA 4.0*
- 12.7: Quadric Surfaces - *CC BY-NC-SA 4.0*
  - 12.7E: Exercises for Section 12.6 - *CC BY-NC-SA 4.0*
- 12.8: Cylindrical and Spherical Coordinates - *CC BY-NC-SA 4.0*
  - 12.8E: Exercises for Section 12.7 - *CC BY-NC-SA 4.0*
- 12.R: Chapter 12 Review Exercises - *CC BY-NC-SA 4.0*

13: Vector-Valued Functions - *CC BY-NC-SA 4.0*

- 13.1: Prelude to Vector-Valued Functions - *CC BY-NC-SA 4.0*
- 13.2: Vector-Valued Functions and Space Curves - *CC BY-NC-SA 4.0*
  - 13.2E: Exercises for Section 13.1 - *CC BY-NC-SA 4.0*
- 13.3: Calculus of Vector-Valued Functions - *CC BY-NC-SA 4.0*
  - 13.3E: Exercises for Section 13.2 - *CC BY-NC-SA 4.0*
- 13.4: Arc Length and Curvature - *CC BY-NC-SA 4.0*
  - 13.4E: Exercises for Section 13.3 - *CC BY-NC-SA 4.0*
- 13.5: Motion in Space - *CC BY-NC-SA 4.0*
  - 13.5E: Exercises for Section 13.4 - *CC BY-NC-SA 4.0*
- 13.R: Chapter 13 Review Exercises - *CC BY-NC-SA 4.0*

14: Differentiation of Functions of Several Variables - *CC BY-NC-SA 4.0*

- 14.1: Prelude to Differentiation of Functions of Several Variables - *CC BY-NC-SA 4.0*
- 14.2: Functions of Several Variables - *CC BY-NC-SA 4.0*
  - 14.2E: Exercises for Section 14.1 - *CC BY-NC-SA 4.0*
- 14.3: Limits and Continuity - *CC BY-NC-SA 4.0*
  - 14.3E: Exercises for Section 14.2 - *CC BY-NC-SA 4.0*
- 14.4: Partial Derivatives - *CC BY-NC-SA 4.0*
  - 14.4E: Exercises for Section 14.3 - *CC BY-NC-SA 4.0*
- 14.5: Tangent Planes and Linear Approximations - *CC BY-NC-SA 4.0*
  - 14.5E: Exercises for Section 14.4 - *CC BY-NC-SA 4.0*
- 14.6: The Chain Rule for Multivariable Functions - *CC BY-NC-SA 4.0*
  - 14.6E: Exercises for Section 14.5 - *CC BY-NC-SA 4.0*
- 14.7: Directional Derivatives and the Gradient - *CC BY-NC-SA 4.0*
  - 14.7E: Exercises for Section 14.6 - *CC BY-NC-SA 4.0*
- 14.8: Maxima/Minima Problems - *CC BY-NC-SA 4.0*
  - 14.8E: Exercises for Section 14.7 - *CC BY-NC-SA 4.0*
- 14.9: Lagrange Multipliers - *CC BY-NC-SA 4.0*
  - 14.9E: Exercises for Section 14.8 - *CC BY-NC-SA 4.0*
- 14.R: Chapter 14 Review Exercises - *CC BY-NC-SA 4.0*

15: Multiple Integration - *CC BY-NC-SA 4.0*

- 15.1: Prelude to Multiple Integration - *CC BY-NC-SA 4.0*
- 15.2: Double Integrals over Rectangular Regions - *CC BY-NC-SA 4.0*
  - 15.2E: Exercises for Section 15.1 - *CC BY-NC-SA 4.0*
- 15.3: Double Integrals over General Regions - *CC BY-NC-SA 4.0*
  - 15.3E: Exercises for Section 15.2 - *CC BY-NC-SA 4.0*
- 15.4: Double Integrals in Polar Coordinates - *CC BY-NC-SA 4.0*
  - 15.4E: Exercises for Section 15.3 - *CC BY-NC-SA 4.0*
- 15.5: Triple Integrals - *CC BY-NC-SA 4.0*
  - 15.5E: Exercises for Section 15.4 - *CC BY-NC-SA 4.0*
- 15.6: Triple Integrals in Cylindrical and Spherical Coordinates - *CC BY-NC-SA 4.0*
  - 15.6E: Exercises for Section 15.5 - *CC BY-NC-SA 4.0*
- 15.7: Calculating Centers of Mass and Moments of Inertia - *CC BY-NC-SA 4.0*

- 15.7E: Exercises for Section 15.6 - *CC BY-NC-SA 4.0*
- 15.8: Change of Variables in Multiple Integrals - *CC BY-NC-SA 4.0*
  - 15.8E: Exercises for Section 15.7 - *CC BY-NC-SA 4.0*
- 15.R: Chapter 15 Review Exercises - *CC BY-NC-SA 4.0*

16: Vector Calculus - *CC BY-NC-SA 4.0*
- 16.1: Prelude to Vector Calculus - *CC BY-NC-SA 4.0*
- 16.2: Vector Fields - *CC BY-NC-SA 4.0*
  - 16.2E: Exercises for Section 16.1 - *CC BY-NC-SA 4.0*
- 16.3: Line Integrals - *CC BY-NC-SA 4.0*
  - 16.3E: Exercises for Section 16.2 - *CC BY-NC-SA 4.0*
- 16.4: Conservative Vector Fields - *CC BY-NC-SA 4.0*
  - 16.4E: Exercises for Section 16.3 - *CC BY-NC-SA 4.0*
- 16.5: Green's Theorem - *CC BY-NC-SA 4.0*
  - 16.5E: Exercises for Section 16.4 - *CC BY-NC-SA 4.0*
- 16.6: Divergence and Curl - *CC BY-NC-SA 4.0*
  - 16.6E: Exercises for Section 16.5 - *CC BY-NC-SA 4.0*
- 16.7: Surface Integrals - *CC BY-NC-SA 4.0*
  - 16.7E: Exercises for Section 16.6 - *CC BY-NC-SA 4.0*
- 16.8: Stokes' Theorem - *CC BY-NC-SA 4.0*
  - 16.8E: Exercises for Section 16.7 - *CC BY-NC-SA 4.0*
- 16.9: The Divergence Theorem - *CC BY-NC-SA 4.0*
  - 16.9E: Exercises for Section 16.8 - *CC BY-NC-SA 4.0*
- 16.R: Chapter 16 Review Exercises - *CC BY-NC-SA 4.0*

17: Second-Order Differential Equations - *CC BY-NC-SA 4.0*
- 17.1: Prelude to Second-Order Differential Equations - *CC BY-NC-SA 4.0*
- 17.2: Second-Order Linear Equations - *CC BY-NC-SA 4.0*
  - 17.2E: Exercises for Section 17.1 - *CC BY-NC-SA 4.0*
- 17.3: Nonhomogeneous Linear Equations - *CC BY-NC-SA 4.0*
  - 17.3E: Exercises for Section 17.2 - *CC BY-NC-SA 4.0*
- 17.4: Applications of Second-Order Differential Equations - *CC BY-NC-SA 4.0*
  - 17.4E: Exercises for Section 17.3 - *CC BY-NC-SA 4.0*
- 17.5: Series Solutions of Differential Equations - *CC BY-NC-SA 4.0*
  - 17.5E: Exercises for Section 17.4 - *CC BY-NC-SA 4.0*
- 17.R: Chapter 17 Review Exercises - *CC BY-NC-SA 4.0*

18: Appendices - *CC BY-NC-SA 4.0*
- 18.1: Table of Derivatives - *CC BY-NC-SA 4.0*
- 18.2: Table of Integrals - *CC BY-NC-SA 4.0*
- 18.3: Other Strategies for Integration - *CC BY-NC-SA 4.0*
  - 18.3.1: Exercises - *CC BY-NC-SA 4.0*
