This text is disseminated via the Open Education Resource (OER) LibreTexts Project (https://LibreTexts.org) and like the thousands of other texts available within this powerful platform, it is freely available for reading, printing, and "consuming."

The LibreTexts mission is to bring together students, faculty, and scholars in a collaborative effort to provide an accessible, and comprehensive platform that empowers our community to develop, curate, adapt, and adopt openly licensed resources and technologies; through these efforts we can reduce the financial burden born from traditional educational resource costs, ensuring education is more accessible for students and communities worldwide.

Most, but not all, pages in the library have licenses that may allow individuals to make changes, save, and print this book. Carefully consult the applicable license(s) before pursuing such effects. Instructors can adopt existing LibreTexts texts or Remix them to quickly build course-specific resources to meet the needs of their students. Unlike traditional textbooks, LibreTexts' web based origins allow powerful integration of advanced features and new technologies to support learning.

LibreTexts is the adaptable, user-friendly non-profit open education resource platform that educators trust for creating, customizing, and sharing accessible, interactive textbooks, adaptive homework, and ancillary materials. We collaborate with individuals and organizations to champion open education initiatives, support institutional publishing programs, drive curriculum development projects, and more.

The LibreTexts libraries are Powered by NICE CXone Expert and was supported by the Department of Education Open Textbook Pilot Project, the California Education Learning Lab, the UC Davis Office of the Provost, the UC Davis Library, the California State University Affordable Learning Solutions Program, and Merlot. This material is based upon work supported by the National Science Foundation under Grant No. 1246120, 1525057, and 1413739.

Welcome to the Mathematics Library. This Living Library is a principal hub of the LibreTexts project, which is a multi-institutional collaborative venture to develop the next generation of open-access texts to improve postsecondary education at all levels of higher learning. The LibreTexts approach is highly collaborative where an Open Access textbook environment is under constant revision by students, faculty, and outside experts to supplant conventional paper-based books.

# CHAPTER OVERVIEW

## 1: Critical Concepts for Calculus

> This page is a draft and is under active development.

Calculus is the mathematics that describes changes in functions. In this chapter, we review all the functions necessary to study calculus. We define polynomial, rational, trigonometric, exponential, and logarithmic functions. We review how to evaluate these functions, and we show the properties of their graphs. We provide examples of equations with terms involving these functions and illustrate the algebraic techniques necessary to solve them. In short, this chapter provides the foundation for the material to come. It is essential to be familiar and comfortable with these ideas before proceeding to the formal introduction of calculus in the next chapter.

**Caution**

Due to time constraints, many professors skip most of the material in this chapter and leave it to you to review on your own. This is not done because your professor is lazy. The reality is that you are expected to have mastery of all topics in elementary algebra (Algebra 1), intermediate algebra (Algebra 2), college algebra, and trigonometry prior to enrolling in a calculus course.

If you have not had a full course in trigonometry, it is highly recommended that you enroll in one at your college and save calculus for next semester. I cannot emphasize this enough.

This page titled 1: Critical Concepts for Calculus is shared under a CC BY-NC-SA 4.0 license and was authored, remixed, and/or curated by Gilbert Strang & Edwin “Jed” Herman (OpenStax) via source content that was edited to the style and standards of the LibreTexts platform.

# 1.1: Functions

**Learning Objectives**

- Use functional notation to evaluate a function.
- Determine the domain and range of a function.
- Draw the graph of a function.
- Find the zeros of a function.
- Recognize a function from a table of values.
- Make new functions from two or more given functions.
- Describe the symmetry properties of a function.

In this section, we provide a formal definition of a function and examine several ways in which functions are represented - namely, through tables, formulas, and graphs. We study formal notation and terms related to functions. We also define composition of functions and symmetry properties. Most of this material will be a review for you, but it serves as a handy reference to remind you of some of the algebraic techniques useful for working with functions.

## Functions

Given two sets $A$ and $B$ a set with elements that are ordered pairs $(x, y)$ where $x$ is an element of $A$ and $y$ is an element of $B$, is a relation from $A$ to $B$. A relation from $A$ to $B$ defines a relationship between those two sets. A function is a special type of relation in which each element of the first set is related to exactly one element of the second set. The element of the first set is called the **input**; the element of the second set is called the **output**. Functions are used all the time in mathematics to describe relationships between two sets. For any function, when we know the input, the output is determined, so we say that the output is a function of the input. For example, the area of a square is determined by its side length, so we say that the area (the output) is a function of its side length (the input). The velocity of a ball thrown in the air can be described as a function of the amount of time the ball is in the air. The cost of mailing a package is a function of the weight of the package. Since functions have so many uses, it is important to have precise definitions and terminology to study them.

Figure 1.1.1: A function can be visualized as an input/output device

**Definition: Functions**

A **function** $f$ consists of a set of inputs, a set of outputs, and a rule for assigning each input to exactly one output. The set of inputs is called the **domain** of the function. The set of outputs is called the **range** of the function.

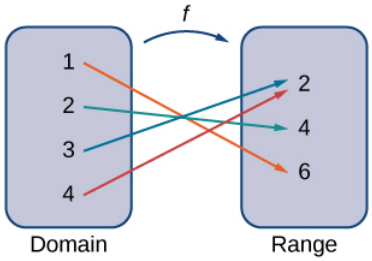

Figure 1.1.2: A function maps every element in the domain to exactly one element in the range. Although each input can be sent to only one output, two different inputs can be sent to the same output.

For example, consider the function $f$, where the domain is the set of all real numbers and the rule is to square the input. Then, the input $x = 3$ is assigned to the output $3^2 = 9$.

Since every nonnegative real number has a real-value square root, every nonnegative number is an element of the range of this function. Since there is no real number with a square that is negative, the negative real numbers are not elements of the range. We conclude that the range is the set of nonnegative real numbers.

For a general function $f$ with domain $D$, we often use $x$ to denote the input and $y$ to denote the output associated with $x$. When doing so, we refer to $x$ as the **independent variable** and $y$ as the **dependent variable**, because it depends on $x$. Using function notation, we write $y = f(x)$, and we read this equation as "$y$ equals $f$ of $x$." For the squaring function described earlier, we write $f(x) = x^2$.

The concept of a function can be visualized using Figures **1.1.1 - 1.1.3**.

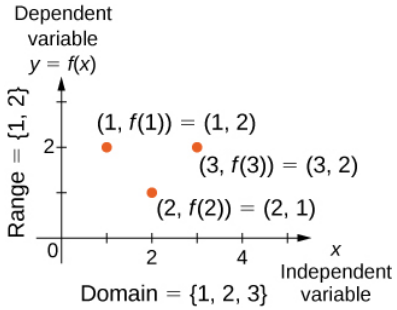

Figure **1.1.3**: In this case, a graph of a function $f$ has a domain of $\{1,2,3\}$ and a range of $\{1,2\}$. The independent variable is $x$ and the dependent variable is $y$.

We can also visualize a function by plotting points $(x, y)$ in the coordinate plane where $y = f(x)$. The graph of a function is the set of all these points. For example, consider the function $f$, where the domain is the set $D = \{1, 2, 3\}$ and the rule is $f(x) = 3 - x$. In Figure **1.1.4**, we plot a graph of this function.

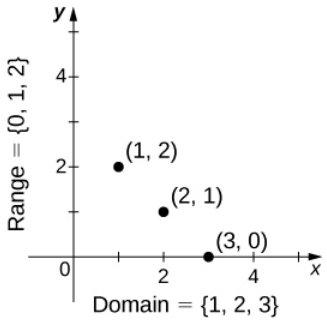

Figure **1.1.4**: Here we see a graph of the function $f$ with domain $\{1,2,3\}$ and rule $f(x) = 3 - x$. The graph consists of the points $(x, f(x))$ for all $x$ in the domain.

Every function has a domain. However, sometimes a function is described by an equation, as in $f(x) = x^2$, with no specific domain given. In this case, the domain is taken to be the set of all real numbers $x$ for which $f(x)$ is a real number. For example, since any real number can be squared, if no other domain is specified, we consider the domain of $f(x) = x^2$ to be the set of all real numbers. On the other hand, the square root function $f(x) = \sqrt{x}$ only gives a real output if $x$ is nonnegative. Therefore, the domain of the function $f(x) = \sqrt{x}$ is the set of nonnegative real numbers, sometimes called the natural domain.

For the functions $f(x) = x^2$ and $f(x) = \sqrt{x}$, the domains are sets with an infinite number of elements. Clearly we cannot list all these elements. When describing a set with an infinite number of elements, it is often helpful to use **set-builder** or **interval notation**. When using set-builder notation to describe a subset of all real numbers, denoted $R$, we write

$$\{x \mid x \text{ has some property}\}.$$

We read this as the set of real numbers $x$ such that $x$ has some property. For example, if we were interested in the set of real numbers that are greater than one but less than five, we could denote this set using set-builder notation by writing

$$\{x \mid 1 < x < 5\}.$$

A set such as this, which contains all numbers greater than $a$ and less than $b$, can also be denoted using the interval notation $(a, b)$. Therefore,

$$(1,5) = \{x \mid 1 < x < 5\}.$$

The numbers $1$ and $5$ are called the **endpoints** of this set. If we want to consider the set that includes the endpoints, we would denote this set by writing

$$[1,5] = \{x \mid 1 \leq x \leq 5\}.$$

We can use similar notation if we want to include one of the endpoints, but not the other. To denote the set of nonnegative real numbers, we would use the set-builder notation

$$\{x \mid x \geq 0\}.$$

The smallest number in this set is zero, but this set does not have a largest number. Using interval notation, we would use the symbol $\infty$, which refers to positive infinity, and we would write the set as

$$[0,\infty) = \{x \mid x \geq 0\}.$$

**Note**

It is important to note that $\infty$ is not a real number.

$\infty$ is used symbolically here to indicate that this set includes all real numbers greater than or equal to zero. Similarly, if we wanted to describe the set of all nonpositive numbers, we could write

$$(-\infty, 0] = \{x \mid x \leq 0\}.$$

Here, the notation $-\infty$ refers to negative infinity, and it indicates that we are including all numbers less than or equal to zero, no matter how small. The set

$$(-\infty,\infty) = \{x \mid x \text{ is any real number}\}$$

refers to the set of all real numbers. Some functions are defined using different equations for different parts of their domain. These types of functions are known as **piecewise-defined functions**. For example, suppose we want to define a function $f$ with a domain that is the set of all real numbers such that $f(x) = 3x + 1$ for $x \geq 2$ and $f(x) = x^2$ for $x < 2$. We denote this function by writing

$$f(x) = \begin{cases} 3x+1, & \text{if } x \geq 2 \\ x^2, & \text{if } x < 2 \end{cases}$$

When evaluating this function for an input $x$, the equation to use depends on whether $x \geq 2$ or $x < 2$. For example, since $5 > 2$, we use the fact that $f(x) = 3x + 1$ for $x \geq 2$ and see that $f(5) = 3(5) + 1 = 16$. On the other hand, for $x = -1$, we use the fact that $f(x) = x^2$ for $x < 2$ and see that $f(-1) = 1$.

**Example 1.1.1: Evaluating Functions**

For the function $f(x) = 3x^2 + 2x - 1$, evaluate:

a. $f(-2)$
b. $f(\sqrt{2})$
c. $f(a+h)$

**Solutions**

a. $f(-2) = 3(-2)^2 + 2(-2) - 1 = 12 - 4 - 1 = 7$
b. $f(\sqrt{2}) = 3(\sqrt{2})^2 + 2\sqrt{2} - 1 = 6 + 2\sqrt{2} - 1 = 5 + 2\sqrt{2}$
c. $f(a+h) = 3(a+h)^2 + 2(a+h) - 1 = 3(a^2 + 2ah + h^2) + 2a + 2h - 1 = 3a^2 + 6ah + 3h^2 + 2a + 2h - 1$

## Exercise 1.1.1

For $f(x) = x^2 - 3x + 5$, evaluate $f(1)$ and $f(a+h)$.

**Hint**

Substitute 1 and $a+h$ for $x$ in the formula for $f(x)$.

**Answer**

$f(1) = 3$ and $f(a+h) = a^2 + 2ah + h^2 - 3a - 3h + 5$

## Example 1.1.2: Finding Domain and Range

For each of the following functions, determine the i. domain and ii. range.

a. $f(x) = (x-4)^2 + 5$
b. $f(x) = \sqrt{3x+2} - 1$
c. $f(x) = \dfrac{3}{x-2}$

**Solutions**

a. Consider $f(x) = (x-4)^2 + 5$.

i. Since $f(x) = (x-4)^2 + 5$ is a real number for any real number $x$, the domain of $f$ is the interval $(-\infty, \infty)$.

ii. Since $(x-4)^2 \geq 0$, we know $f(x) = (x-4)^2 + 5 \geq 5$. Therefore, the range must be a subset of $\{y \mid y \geq 5\}$. To show that every element in this set is in the range, we need to show that for a given $y$ in that set, there is a real number $x$ such that $f(x) = (x-4)^2 + 5 = y$. Solving this equation for $x$, we see that we need $x$ such that

$$(x-4)^2 = y - 5.$$

This equation is satisfied as long as there exists a real number $x$ such that

$$x - 4 = \pm\sqrt{y-5}$$

Since $y \geq 5$, the square root is well-defined. We conclude that for $x = 4 \pm \sqrt{y-5}$, $f(x) = y$, and therefore the range is $\{y \mid y \geq 5\}$.

b. Consider $f(x) = \sqrt{3x+2} - 1$.

i. To find the domain of $f$, we need the expression $3x + 2 \geq 0$. Solving this inequality, we conclude that the domain is $\{x \mid x \geq -2/3\}$.

ii. To find the range of $f$, we note that since $\sqrt{3x+2} \geq 0$, $f(x) = \sqrt{3x+2} - 1 \geq -1$. Therefore, the range of $f$ must be a subset of the set $\{y \mid y \geq -1\}$. To show that every element in this set is in the range of $f$, we need to show that for all $y$ in this set, there exists a real number $x$ in the domain such that $f(x) = y$. Let $y \geq -1$. Then, $f(x) = y$ if and only if

$$\sqrt{3x+2} - 1 = y.$$

Solving this equation for $x$, we see that $x$ must solve the equation

$$\sqrt{3x+2} = y + 1.$$

Since $y \geq -1$, such an $x$ could exist. Squaring both sides of this equation, we have $3x + 2 = (y+1)^2$. Therefore, we need

$$3x = (y+1)^2 - 2,$$

which implies

$$x = \frac{1}{3}(y+1)^2 - \frac{2}{3}.$$

We just need to verify that $x$ is in the domain of $f$. Since the domain of $f$ consists of all real numbers greater than or equal to $\frac{-2}{3}$, and

$$\frac{1}{3}(y+1)^2 - \frac{2}{3} \geq -\frac{2}{3},$$

there does exist an $x$ in the domain of $f$. We conclude that the range of $f$ is $\{y \mid y \geq -1\}$.

c. Consider $f(x) = \dfrac{3}{x-2}$.

i. Since $3/(x-2)$ is defined when the denominator is nonzero, the domain is $\{x \mid x \neq 2\}$.

ii. To find the range of $f$, we need to find the values of $y$ such that there exists a real number $x$ in the domain with the property that

$$\frac{3}{x-2} = y.$$

Solving this equation for $x$, we find that

$$x = \frac{3}{y} + 2.$$

Therefore, as long as $y \neq 0$, there exists a real number $x$ in the domain such that $f(x) = y$. Thus, the range is $\{y \mid y \neq 0\}$.

**? Exercise 1.1.2**

Find the domain and range for $f(x) = \sqrt{4-2x} + 5$.

**Hint**

Use $4 - 2x \geq 0$.

**Answer**

Domain = $\{x \mid x \leq 2\}$ and range = $\{y \mid y \geq 5\}$

## Representing Functions

Typically, a function is represented using one or more of the following tools:

- A table
- A graph
- A formula

We can identify a function in each form, but we can also use them together. For instance, we can plot on a graph the values from a table or create a table from a formula.

## Tables

Functions described using a **table of values** arise frequently in real-world applications. Consider the following simple example. We can describe temperature on a given day as a function of time of day. Suppose we record the temperature every hour for a 24-hour period starting at midnight. We let our input variable $x$ be the time after midnight, measured in hours, and the output variable $y$ be the temperature $x$ hours after midnight, measured in degrees Fahrenheit. We record our data in Table **1.1.1**.

Table **1.1.1**: Temperature as a Function of Time of Day

| Hour After Midnight | Temperature(°F) | Hour After Midnight | Temperature(°F) |
|---|---|---|---|
| 0 | 58 | 12 | 84 |
| 1 | 54 | 13 | 85 |
| 2 | 53 | 14 | 85 |
| 3 | 52 | 15 | 83 |
| 4 | 52 | 16 | 82 |
| 5 | 55 | 17 | 80 |
| 6 | 60 | 18 | 77 |
| 7 | 64 | 19 | 74 |
| 8 | 72 | 20 | 69 |
| 9 | 75 | 21 | 65 |
| 10 | 78 | 22 | 60 |
| 11 | 80 | 23 | 58 |

We can see from the table that temperature is a function of time, and the temperature decreases, then increases, and then decreases again. However, we cannot get a clear picture of the behavior of the function without graphing it.

## Graphs

Given a function $f$ described by a table, we can provide a visual picture of the function in the form of a graph. Graphing the temperatures listed in Table 1.1.1 can give us a better idea of their fluctuation throughout the day. Figure 1.1.5 shows the plot of the temperature function.

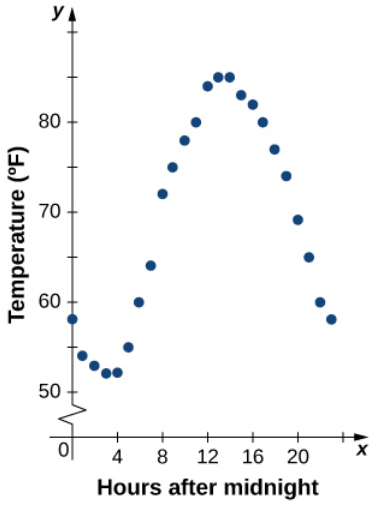

Figure 1.1.5: The graph of the data from Table 1.1.1 shows temperature as a function of time.

From the points plotted on the graph in Figure 1.1.5, we can visualize the general shape of the graph. It is often useful to connect the dots in the graph, which represent the data from the table. In this example, although we cannot make any definitive conclusion regarding what the temperature was at any time for which the temperature was not recorded, given the number of data points collected and the pattern in these points, it is reasonable to suspect that the temperatures at other times followed a similar pattern, as we can see in Figure 1.1.6.

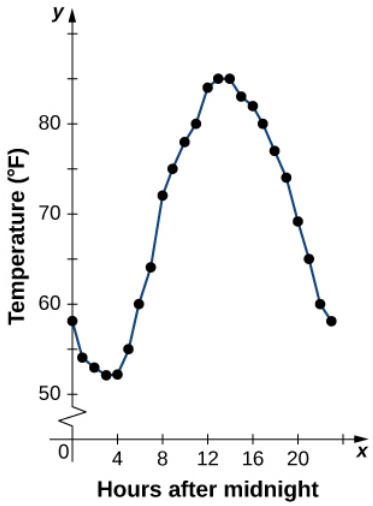

Figure **1.1.6**: Connecting the dots in Figure **1.1.5** shows the general pattern of the data.

## Algebraic Formulas

Sometimes we are not given the values of a function in table form, rather we are given the values in an explicit formula. Formulas arise in many applications. For example, the area of a circle of radius $r$ is given by the formula $A(r) = \pi r^2$. When an object is thrown upward from the ground with an initial velocity $v_0$ ft/s, its height above the ground from the time it is thrown until it hits the ground is given by the formula $s(t) = -16t^2 + v_0 t$. When $P$ dollars are invested in an account at an annual interest rate $r$ compounded continuously, the amount of money after $t$ years is given by the formula $A(t) = Pe^{rt}$. Algebraic formulas are important tools to calculate function values. Often we also represent these functions visually in graph form.

Given an algebraic formula for a function $f$, the graph of $f$ is the set of points $(x, f(x))$, where $x$ is in the domain of $f$ and $f(x)$ is in the range. To graph a function given by a formula, it is helpful to begin by using the formula to create a table of inputs and outputs. If the domain of $f$ consists of an infinite number of values, we cannot list all of them, but because listing some of the inputs and outputs can be very useful, it is often a good way to begin.

When creating a table of inputs and outputs, we typically check to determine whether zero is an output. Those values of $x$ where $f(x) = 0$ are called the **zeros** of the function. For example, the zeros of $f(x) = x^2 - 4$ are $x = \pm 2$. The zeros determine where the graph of $f$ intersects the $x$-axis, which gives us more information about the shape of the graph of the function. The graph of a function may never intersect the $x$-axis, or it may intersect multiple (or even infinitely many) times.

Another point of interest is the $y$ -intercept, if it exists. The $y$-intercept is given by $(0, f(0))$.

Since a function has exactly one output for each input, the graph of a function can have, at most, one $y$-intercept. If $x = 0$ is in the domain of a function $f$, then $f$ has exactly one $y$-intercept. If $x = 0$ is not in the domain of $f$, then $f$ has no $y$-intercept. Similarly, for any real number $c$, if $c$ is in the domain of $f$, there is exactly one output $f(c)$, and the line $x = c$ intersects the graph of $f$ exactly once. On the other hand, if $c$ is not in the domain of $f$, $f(c)$ is not defined and the line $x = c$ does not intersect the graph of $f$. This property is summarized in the Vertical Line Test.

**Theorem 1.1.1: Vertical Line Test**

Given a function $f$, every vertical line that may be drawn intersects the graph of $f$ no more than once. If any vertical line intersects a set of points more than once, the set of points does not represent a function.

We can use this test to determine whether a set of plotted points represents the graph of a function (Figure **1.1.7**).

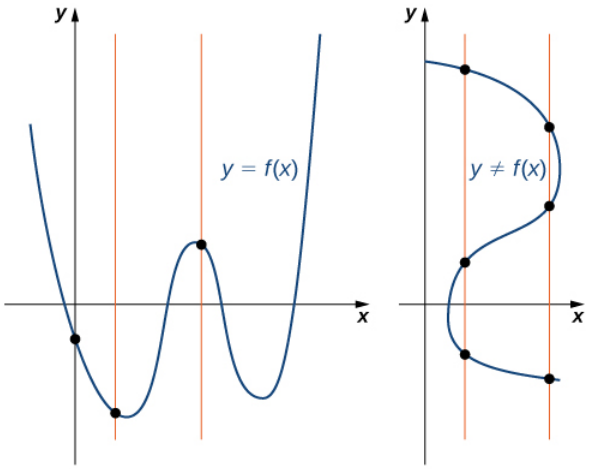

Figure 1.1.7: (a) The set of plotted points represents the graph of a function because every vertical line intersects the set of points, at most, once. (b) The set of plotted points does not represent the graph of a function because some vertical lines intersect the set of points more than once.

### Example 1.1.3: Finding Zeros and $y$-Intercepts of a Function

Consider the function $f(x) = -4x + 2$.

a. Find all zeros of $f$.
b. Find the $y$-intercept (if any).
c. Sketch a graph of $f$.

**Solutions**

a. To find the zeros, solve $f(x) = -4x + 2 = 0$. We discover that $f$ has one zero at $x = 1/2$.
b. The $y$-intercept is given by $(0, f(0)) = (0, 2)$.
c. Given that $f$ is a linear function of the form $f(x) = mx + b$ that passes through the points $(1/2, 0)$ and $(0, 2)$, we can sketch the graph of $f$ (Figure 1.1.8).

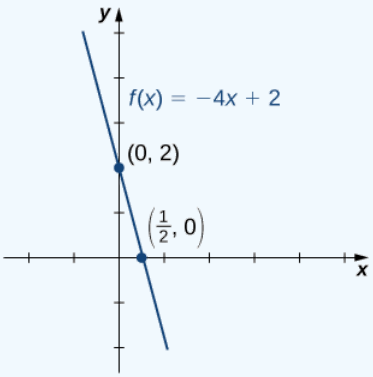

Figure 1.1.8: The function $f(x) = -4x + 2$ is a line with $x$-intercept $(1/2, 0)$ and $y$-intercept $(0, 2)$.

### Example 1.1.4: Using Zeros and $y$-Intercepts to Sketch a Graph

Consider the function $f(x) = \sqrt{x + 3} + 1$.

a. Find all zeros of $f$.
b. Find the $y$-intercept (if any).
c. Sketch a graph of $f$.

**Solutions**

a. To find the zeros, solve $\sqrt{x+3}+1=0$. This equation implies $\sqrt{x+3}=-1$. Since $\sqrt{x+3}\geq 0$ for all $x$, this equation has no solutions, and therefore $f$ has no zeros.

b. The $y$-intercept is given by $(0, f(0)) = (0, \sqrt{3}+1)$.

c. To graph this function, we make a table of values. Since we need $x+3\geq 0$, we need to choose values of $x\geq -3$. We choose values that make the square-root function easy to evaluate.

| $x$ | -3 | -2 | 1 |
|---|---|---|---|
| $f(x)$ | 1 | 2 | 3 |

Making use of the table and knowing that, since the function is a square root, the graph of $f$ should be similar to the graph of $y=\sqrt{x}$, we sketch the graph (Figure 1.1.9).

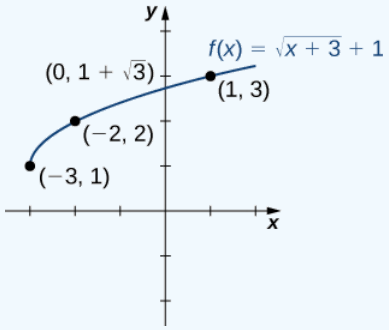

Figure 1.1.9: The graph of $f(x)=\sqrt{x+3}+1$ has a $y$-intercept but no $x$-intercepts.

## Exercise 1.1.4

Find the zeros of $f(x)=x^3-5x^2+6x$.

**Hint**

Factor the polynomial.

**Answer**

$x=0, 2, 3$

## Example 1.1.5: Finding the Height of a Free-Falling Object

If a ball is dropped from a height of 100 ft, its height s at time $t$ is given by the function $s(t)=-16t^2+100$, where s is measured in feet and $t$ is measured in seconds. The domain is restricted to the interval $[0, c]$, where $t=0$ is the time when the ball is dropped and $t=c$ is the time when the ball hits the ground.

a. Create a table showing the height s(t) when $t=0,\ 0.5,\ 1,\ 1.5,\ 2,$ and $2.5$. Using the data from the table, determine the domain for this function. That is, find the time $c$ when the ball hits the ground.

b. Sketch a graph of $s$.

**Solutions**

a.

| $t$ | 0 | 0.5 | 1 | 1.5 | 2 | 2.5 |
|---|---|---|---|---|---|---|
| $s(t)$ | 100 | 96 | 84 | 64 | 36 | 0 |

Since the ball hits the ground when $t = 2.5$, the domain of this function is the interval $[0, 2.5]$.

b.

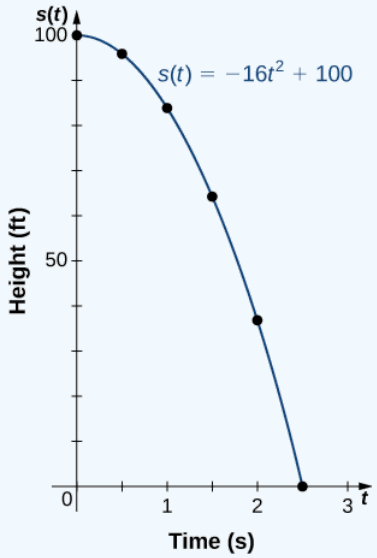

Figure 1.1.8, the values of $f(x)$ are getting smaller as $x$ is getting larger. A function with this property is said to be decreasing. On the other hand, for the function $f(x) = \sqrt{x+3} + 1$ graphed in Figure 1.1.9, the values of $f(x)$ are getting larger as the values of $x$ are getting larger. A function with this property is said to be increasing. It is important to note, however, that a function can be increasing on some interval or intervals and decreasing over a different interval or intervals. For example, using our temperature function plotted above, we can see that the function is decreasing on the interval $(0, 4)$, increasing on the interval $(4, 14)$, and then decreasing on the interval $(14, 23)$. We make the idea of a function increasing or decreasing over a particular interval more precise in the next definition.

### Definition: Increasing and Decreasing on an Interval

We say that a function $f$ is **increasing** on the interval $I$ if for all $x_1, x_2 \in I$,

$$f(x_1) \leq f(x_2) \text{ when } x_1 < x_2.$$

We say $f$ is **strictly increasing** on the interval $I$ if for all $x_1, x_2 \in I$,

$$f(x_1) < f(x_2) \text{ when } x_1 < x_2.$$

We say that a function $f$ is **decreasing** on the interval $I$ if for all $x_1, x_2 \in I$,

$$f(x_1) \geq f(x_2) \text{ if } x_1 < x_2.$$

We say that a function $f$ is **strictly decreasing** on the interval $I$ if for all $x_1, x_2 \in I$,

$$f(x_1) > f(x_2) \text{ if } x_1 < x_2.$$

For example, the function $f(x) = 3x$ is increasing on the interval $(-\infty, \infty)$ because $3x_1 < 3x_2$ whenever $x_1 < x_2$. On the other hand, the function $f(x) = -x^3$ is decreasing on the interval $(-\infty, \infty)$ because $-x_1^3 > -x_2^3$ whenever $x_1 < x_2$ (Figure 1.1.10).

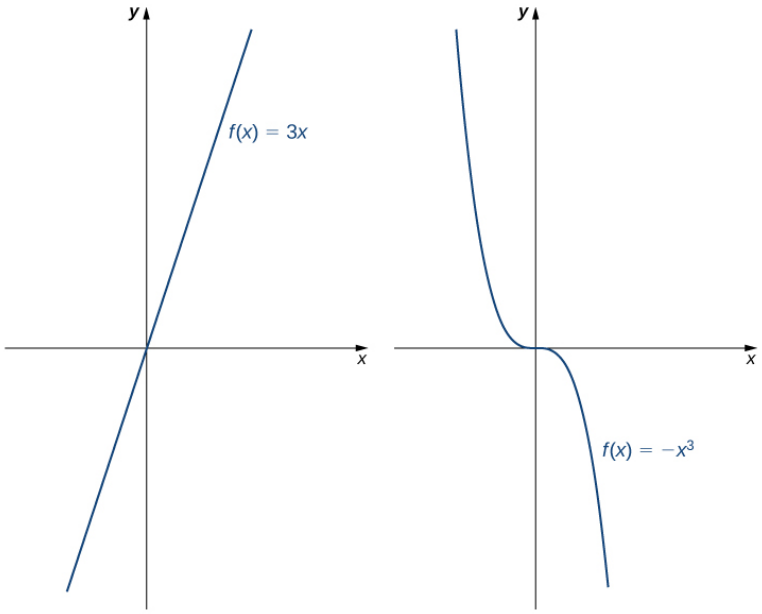

Figure **1.1.10**: (a) The function $f(x) = 3x$ is increasing on the interval $(-\infty, \infty)$. (b) The function $f(x) = -x^3$ is decreasing on the interval $(-\infty, \infty)$.

## Combining Functions

Now that we have reviewed the basic characteristics of functions, we can see what happens to these properties when we combine functions in different ways, using basic mathematical operations to create new functions. For example, if the cost for a company to manufacture $x$ items is described by the function $C(x)$ and the revenue created by the sale of $x$ items is described by the function $R(x)$, then the profit on the manufacture and sale of $x$ items is defined as $P(x) = R(x) - C(x)$. Using the difference between two functions, we created a new function.

Alternatively, we can create a new function by **composing** two functions. For example, given the functions $f(x) = x^2$ and $g(x) = 3x + 1$, the **composite function** $f \circ g$ is defined such that

$$(f \circ g)(x) = f(g(x)) = (g(x))^2 = (3x + 1)^2.$$

The composite function $g \circ f$ is defined such that

$$(g \circ f)(x) = g(f(x)) = 3f(x) + 1 = 3x^2 + 1.$$

Note that these two new functions are different from each other.

## Combining Functions with Mathematical Operators

To combine functions using mathematical operators, we simply write the functions with the operator and simplify. Given two functions $f$ and $g$, we can define four new functions:

| | |
|---|---|
| $(f + g)(x) = f(x) + g(x)$ | Sum |
| $(f - g)(x) = f(x) - g(x)$ | Difference |
| $(f \cdot g)(x) = f(x)g(x)$ | Product |
| $(\frac{f}{g})(x) = \frac{f(x)}{g(x)}$ for $g(x) \neq 0$ | Quotient |

### Example 1.1.6: Combining Functions Using Mathematical Operations

Given the functions $f(x) = 2x - 3$ and $g(x) = x^2 - 1$, find each of the following functions and state its domain.

a. $(f + g)(x)$
b. $(f - g)(x)$
c. $(f \cdot g)(x)$
d. $\left(\frac{f}{g}\right)(x)$

**Solutions**

a. $(f + g)(x) = (2x - 3) + (x^2 - 1) = x^2 + 2x - 4$. The domain of this function is the interval $(-\infty, \infty)$.
b. $(f - g)(x) = (2x - 3) - (x^2 - 1) = -x^2 + 2x - 2$. The domain of this function is the interval $(-\infty, \infty)$.
c. $(f \cdot g)(x) = (2x - 3)(x^2 - 1) = 2x^3 - 3x^2 - 2x + 3$. The domain of this function is the interval $(-\infty, \infty)$.
d. $\left(\frac{f}{g}\right)(x) = \frac{2x - 3}{x^2 - 1}$. The domain of this function is $\{x \mid x \neq \pm 1\}$.

### Exercise 1.1.6

For $f(x) = x^2 + 3$ and $g(x) = 2x - 5$, find $(f/g)(x)$ and state its domain.

**Hint**

The new function $(f/g)(x)$ is a quotient of two functions. For what values of $x$ is the denominator zero?

**Answer**

$\left(\frac{f}{g}\right)(x) = \frac{x^2+3}{2x-5}$. The domain is $\{x \mid x \neq \frac{5}{2}\}$.

## Function Composition

When we compose functions, we take a function of a function. For example, suppose the temperature $T$ on a given day is described as a function of time $t$ (measured in hours after midnight) as in Table 1.1.1. Suppose the cost $C$, to heat or cool a building for 1 hour, can be described as a function of the temperature $T$. Combining these two functions, we can describe the cost of heating or cooling a building as a function of time by evaluating $C(T(t))$. We have defined a new function, denoted $C \circ T$, which is defined such that $(C \circ T)(t) = C(T(t))$ for all $t$ in the domain of $T$. This new function is called a composite function. We note that since cost is a function of temperature and temperature is a function of time, it makes sense to define this new function $(C \circ T)(t)$. It does not make sense to consider $(T \circ C)(t)$, because temperature is not a function of cost.

### Definition: Composite Functions

Consider the function $f$ with domain $A$ and range $B$, and the function $g$ with domain $D$ and range $E$. If $B$ is a subset of $D$, then the **composite function** $(g \circ f)(x)$ is the function with domain $A$ such that

$$(g \circ f)(x) = g(f(x))$$

A composite function $g \circ f$ can be viewed in two steps. First, the function $f$ maps each input $x$ in the domain of $f$ to its output $f(x)$ in the range of $f$. Second, since the range of $f$ is a subset of the domain of $g$, the output $f(x)$ is an element in the domain of $g$, and therefore it is mapped to an output $g(f(x))$ in the range of $g$. In Figure 1.1.11, we see a visual image of a composite function.

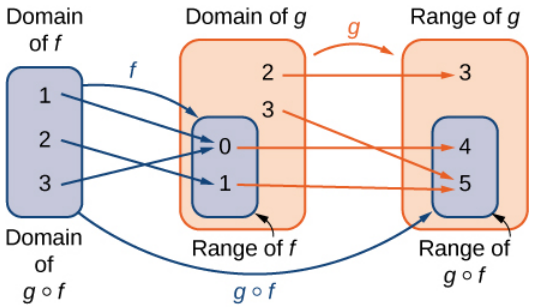

Figure 1.1.11: For the composite function $g \circ f$, we have $(g \circ f)(1) = 4$, $(g \circ f)(2) = 5$, and $(g \circ f)(3) = 4$.

### Example 1.1.7: Compositions of Functions Defined by Formulas

Consider the functions $f(x) = x^2 + 1$ and $g(x) = 1/x$.

a. Find $(g \circ f)(x)$ and state its domain and range.
b. Evaluate $(g \circ f)(4)$, $(g \circ f)(-1/2)$.
c. Find $(f \circ g)(x)$ and state its domain and range.
d. Evaluate $(f \circ g)(4)$, $(f \circ g)(-1/2)$.

**Solutions**

a. We can find the formula for $(g \circ f)(x)$ in two different ways. We could write

$$(g \circ f)(x) = g(f(x)) = g(x^2 + 1) = \frac{1}{x^2 + 1}.$$

Alternatively, we could write

$$(g \circ f)(x) = g(f(x)) = \frac{1}{f(x)} = \frac{1}{x^2 + 1}.$$

Since $x^2 + 1 \neq 0$ for all real numbers $x$, the domain of $(g \circ f)(x)$ is the set of all real numbers. Since $0 < 1/(x^2 + 1) \leq 1$, the range is, at most, the interval $(0, 1]$. To show that the range is this entire interval, we let $y = 1/(x^2 + 1)$ and solve this equation for $x$ to show that for all $y$ in the interval $(0, 1]$, there exists a real number $x$ such that $y = 1/(x^2 + 1)$. Solving this equation for $x$, we see that $x^2 + 1 = 1/y$, which implies that

$$x = \pm\sqrt{\frac{1}{y} - 1}.$$

If $y$ is in the interval $(0, 1]$, the expression under the radical is nonnegative, and therefore there exists a real number $x$ such that $1/(x^2 + 1) = y$. We conclude that the range of $g \circ f$ is the interval $(0, 1]$.

b.

$$(g \circ f)(4) = g(f(4)) = g(4^2 + 1) = g(17) = \frac{1}{17}$$

$$(g \circ f)(-\frac{1}{2}) = g(f(-\frac{1}{2})) = g((-\frac{1}{2})^2 + 1) = g(\frac{5}{4}) = \frac{4}{5}$$

c. We can find a formula for $(f \circ g)(x)$ in two ways. First, we could write

$$(f \circ g)(x) = f(g(x)) = f(\frac{1}{x}) = (\frac{1}{x})^2 + 1.$$

Alternatively, we could write

$$(f \circ g)(x) = f(g(x)) = (g(x))^2 + 1 = (\frac{1}{x})^2 + 1.$$

The domain of $f \circ g$ is the set of all real numbers $x$ such that $x \neq 0$. To find the range of $f$, we need to find all values $y$ for which there exists a real number $x \neq 0$ such that

$$\left(\frac{1}{x}\right)^2 + 1 = y.$$

Solving this equation for $x$, we see that we need $x$ to satisfy

$$\left(\frac{1}{x}\right)^2 = y - 1,$$

which simplifies to

$$\frac{1}{x} = \pm\sqrt{y-1}$$

Finally, we obtain

$$x = \pm\frac{1}{\sqrt{y-1}}.$$

Since $1/\sqrt{y-1}$ is a real number if and only if $y > 1$, the range of $f$ is the set $\{y \mid y \geq 1\}$.

d.
$$(f \circ g)(4) = f(g(4)) = f(\frac{1}{4}) = (\frac{1}{4})^2 + 1 = \frac{17}{16}$$

$$(f \circ g)(-\frac{1}{2}) = f(g(-\frac{1}{2})) = f(-2) = (-2)^2 + 1 = 5$$

In Example 1.1.7, we can see that $(f \circ g)(x) \neq (g \circ f)(x)$. This tells us, in general terms, that the order in which we compose functions matters.

## Exercise 1.1.7

Let $f(x) = 2 - 5x$. Let $g(x) = \sqrt{x}$. Find $(f \circ g)(x)$.

**Answer**

$(f \circ g)(x) = 2 - 5\sqrt{x}$.

## Example 1.1.8: Composition of Functions Defined by Tables

Consider the functions $f$ and $g$ described by

| $x$ | -3 | -2 | -1 | 0 | 1 | 2 | 3 | 4 |
|---|---|---|---|---|---|---|---|---|
| $f(x)$ | 0 | 4 | 2 | 4 | -2 | 0 | -2 | 4 |

| $x$ | -4 | -2 | 0 | 2 | 4 |
|---|---|---|---|---|---|
| $g(x)$ | 1 | 0 | 3 | 0 | 5 |

a. Evaluate $(g \circ f)(3), (g \circ f)(0)$.
b. State the domain and range of $(g \circ f)(x)$.
c. Evaluate $(f \circ f)(3), (f \circ f)(1)$.
d. State the domain and range of $(f \circ f)(x)$.

**Solutions**

a.
$$(g \circ f)(3) = g(f(3)) = g(-2) = 0$$

$$(g \circ f)(0) = g(4) = 5$$

b. The domain of $g \circ f$ is the set $\{-3, -2, -1, 0, 1, 2, 3, 4\}$. Since the range of $f$ is the set $\{-2, 0, 2, 4\}$, the range of $g \circ f$ is the set $\{0, 3, 5\}$.

c. $$(f \circ f)(3) = f(f(3)) = f(-2) = 4$$
$$(f \circ f)(1) = f(f(1)) = f(-2) = 4$$

d. The domain of $f \circ f$ is the set $\{-3, -2, -1, 0, 1, 2, 3, 4\}$. Since the range of $f$ is the set $\{-2, 0, 2, 4\}$, the range of $f \circ f$ is the set $\{0, 4\}$.

### Example 1.1.9: Application Involving a Composite Function

A store is advertising a sale of 20% off all merchandise. Caroline has a coupon that entitles her to an additional 15% off any item, including sale merchandise. If Caroline decides to purchase an item with an original price of $x$ dollars, how much will she end up paying if she applies her coupon to the sale price? Solve this problem by using a composite function.

**Solution**

Since the sale price is 20% off the original price, if an item is $x$ dollars, its sale price is given by $f(x) = 0.80x$. Since the coupon entitles an individual to 15% off the price of any item, if an item is $y$ dollars, the price, after applying the coupon, is given by g(y)=0.85y. Therefore, if the price is originally $x$ dollars, its sale price will be $f(x) = 0.80x$ and then its final price after the coupon will be $g(f(x)) = 0.85(0.80x) = 0.68x$.

### Exercise 1.1.9

If items are on sale for 10% off their original price, and a customer has a coupon for an additional 30% off, what will be the final price for an item that is originally $x$ dollars, after applying the coupon to the sale price?

**Hint**

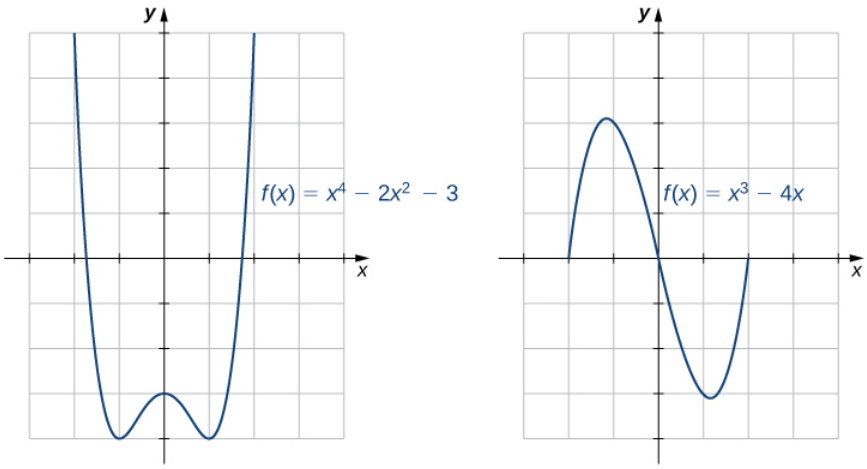
The sale price of an item with an original price of $x$ dollars is $f(x) = 0.90x$. The coupon price for an item that is $y$ dollars is $g(y) = 0.70y$.

**Answer**

$(g \circ f)(x) = 0.63x$

## Symmetry of Functions

The graphs of certain functions have symmetry properties that help us understand the function and the shape of its graph. For example, consider the function $f(x) = x^4 - 2x^2 - 3$ shown in Figure 1.1.12*a*. If we take the part of the curve that lies to the right of the $y$-axis and flip it over the $y$-axis, it lays exactly on top of the curve to the left of the $y$-axis. In this case, we say the function has **symmetry about the $y$-axis**. On the other hand, consider the function $f(x) = x^3 - 4x$ shown in Figure 1.1.12*b*. If we take the graph and rotate it $180°$ about the origin, the new graph will look exactly the same. In this case, we say the function has **symmetry about the origin**.



(a) Symmetry about the $y$-axis (b) Symmetry about the origin

Figure **1.1.12**: (a) A graph that is symmetric about the $y$-axis. (b) A graph that is symmetric about the origin.

If we are given the graph of a function, it is easy to see whether the graph has one of these symmetry properties. But without a graph, how can we determine algebraically whether a function $f$ has symmetry? Looking at Figure **1.1.12***a* again, we see that since $f$ is symmetric about the $y$-axis, if the point $(x, y)$ is on the graph, the point $(-x, y)$ is on the graph. In other words, $f(-x) = f(x)$. If a function $f$ has this property, we say $f$ is an **even function**, which has symmetry about the $y$-axis. For example, $f(x) = x^2$ is even because

$$f(-x) = (-x)^2 = x^2 = f(x).$$

In contrast, looking at Figure **1.1.12***b* again, if a function $f$ is symmetric about the origin, then whenever the point $(x, y)$ is on the graph, the point $(-x, -y)$ is also on the graph. In other words, $f(-x) = -f(x)$. If $f$ has this property, we say $f$ is an **odd function**, which has symmetry about the origin. For example, $f(x) = x^3$ is odd because

$$f(-x) = (-x)^3 = -x^3 = -f(x).$$

**Definition: Even and Odd Functions**

- If $f(x) = f(-x)$ for all $x$ in the domain of $f$, then $f$ is an **even function**. An even function is symmetric about the $y$-axis.
- If $f(-x) = -f(x)$ for all $x$ in the domain of $f$, then $f$ is an **odd function**. An odd function is symmetric about the origin.

**Example 1.1.10: Even and Odd Functions**

Determine whether each of the following functions is even, odd, or neither.

a. $f(x) = -5x^4 + 7x^2 - 2$
b. $f(x) = 2x^5 - 4x + 5$
c. $f(x) = \frac{3x}{x^2+1}$

**Solutions**

a. $f(-x) = -5(-x)^4 + 7(-x)^2 - 2 = -5x^4 + 7x^2 - 2 = f(x)$. Therefore, $f$ is even.
b. $f(-x) = 2(-x)^5 - 4(-x) + 5 = -2x^5 + 4x + 5$. Now, $f(-x) \neq f(x)$. Furthermore, noting that $-f(x) = -2x^5 + 4x - 5$, we see that $f(-x) \neq -f(x)$. Therefore, $f$ is neither even nor odd.
c. $f(-x) = 3(-x)/((-x)2 + 1) = -3x/(x^2 + 1) = -[3x/(x^2 + 1)] = -f(x)$. Therefore, $f$ is odd.

**Exercise 1.1.10**

Determine whether $f(x) = 4x^3 - 5x$ is even, odd, or neither.

**Hint**

Compare $f(-x)$ with $f(x)$ and $-f(x)$.

**Answer**

$f(x)$ is odd.

One symmetric function that arises frequently is the **absolute value function**, written as $|x|$. The absolute value function is defined as

$$|x| = \begin{cases} -x, & \text{if } x < 0 \\ x, & \text{if } x \geq 0 \end{cases}$$

Some students describe this function by stating that it "makes everything positive." By the definition of the absolute value function, we see that if $x < 0$, then $|x| = -x > 0$, and if $x > 0$, then $|x| = x > 0$. However, for $x = 0$, $|x| = 0$. Therefore, it is more accurate to say that for all nonzero inputs, the output is positive, but if $x = 0$, the output $|x| = 0$. We conclude that the range of the absolute value function is $\{y \mid y \geq 0\}$. In Figure 1.1.13, we see that the absolute value function is symmetric about the $y$-axis and is therefore an even function.

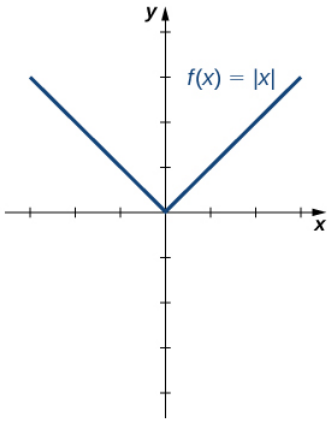


Figure 1.1.13: The graph of $f(x) = |x|$ is symmetric about the $y$-axis.

### Example 1.1.11: Working with the Absolute Value Function

Find the domain and range of the function $f(x) = 2|x - 3| + 4$.

**Solution**

Since the absolute value function is defined for all real numbers, the domain of this function is $(-\infty, \infty)$. Since $|x - 3| \geq 0$ for all $x$, the function $f(x) = 2|x - 3| + 4 \geq 4$. Therefore, the range is, at most, the set $\{y \mid y \geq 4\}$. To see that the range is, in fact, this whole set, we need to show that for $y \geq 4$ there exists a real number $x$ such that

$$2|x - 3| + 4 = y$$

A real number $x$ satisfies this equation as long as

$$|x - 3| = \frac{1}{2}(y - 4)$$

Since $y \geq 4$, we know $y - 4 \geq 0$, and thus the right-hand side of the equation is nonnegative, so it is possible that there is a solution. Furthermore,

$$|x - 3| = \begin{cases} -(x - 3), & \text{if } x < 3 \\ x - 3, & \text{if } x \geq 3 \end{cases}$$

Therefore, we see there are two solutions:

$$x = \pm\frac{1}{2}(y - 4) + 3.$$

The range of this function is $\{y \mid y \geq 4\}$.

**? Exercise 1.1.11: Domain and Range**

For the function $f(x) = |x + 2| - 4$, find the domain and range.

**Hint**

$|x + 2| \geq 0$ for all real numbers $x$.

**Answer**

Domain = $(-\infty, \infty)$, range = $\{y \mid y \geq -4\}$.

## Key Concepts

- A function is a mapping from a set of inputs to a set of outputs with exactly one output for each input.
- If no domain is stated for a function $y = f(x)$, the domain is considered to be the set of all real numbers $x$ for which the function is defined.
- When sketching the graph of a function $f$, each vertical line may intersect the graph, at most, once.
- A function may have any number of zeros, but it has, at most, one $y$-intercept.
- To define the composition $g \circ f$, the range of $f$ must be contained in the domain of $g$.
- Even functions are symmetric about the $y$-axis whereas odd functions are symmetric about the origin.

## Key Equations

- **Composition of two functions**

  $$(g \circ f)(x) = g\big(f(x)\big)$$

- **Absolute value function**

  $$|x| = \begin{cases} -x, & \text{if } x < 0 \\ x, & \text{if } x \geq 0 \end{cases}$$

## Glossary

**absolute value function**

$$|x| = \begin{cases} -x, & \text{if } x < 0 \\ x, & \text{if } x \geq 0 \end{cases}$$

**composite function**

given two functions $f$ and $g$, a new function, denoted $g \circ f$, such that $(g \circ f)(x) = g(f(x))$

**decreasing on the interval $I$**

a function decreasing on the interval $I$ if, for all $x_1, x_2 \in I$, $f(x_1) \geq f(x_2)$ if $x_1 < x_2$

**dependent variable**

the output variable for a function

**domain**

the set of inputs for a function

**even function**

a function is even if $f(-x) = f(x)$ for all $x$ in the domain of $f$

**function**

a set of inputs, a set of outputs, and a rule for mapping each input to exactly one output

**graph of a function**

the set of points $(x, y)$ such that $x$ is in the domain of $f$ and $y = f(x)$

**increasing on the interval $I$**

a function increasing on the interval $I$ if for all $x_1,\ x_2 \in I,\ f(x_1) \leq f(x_2)$ if $x_1 < x_2$

**independent variable**

the input variable for a function

**odd function**

a function is odd if $f(-x) = -f(x)$ for all $x$ in the domain of $f$

**range**

the set of outputs for a function

**symmetry about the origin**

the graph of a function $f$ is symmetric about the origin if $(-x, -y)$ is on the graph of $f$ whenever $(x, y)$ is on the graph

**symmetry about the $y$-axis**

the graph of a function $f$ is symmetric about the $y$-axis if $(-x, y)$ is on the graph of $f$ whenever $(x, y)$ is on the graph

**table of values**

a table containing a list of inputs and their corresponding outputs

**Vertical Line Test**

given the graph of a function, every vertical line intersects the graph, at most, once

**zeros of a function**

when a real number $x$ is a zero of a function $f,\ f(x) = 0$

# 1.1E: Exercises

**For exercises 1 - 6, (a) determine the domain and the range of each relation, and (b) state whether the relation is a function.**

1)

| $x$ | $y$ | $x$ | $y$ |
|---|---|---|---|
| -3 | 9 | 1 | 1 |
| -2 | 4 | 2 | 4 |
| -1 | 1 | 3 | 9 |
| 0 | 0 | | |

**Answer**

a. Domain = $\{-3, -2, -1, 0, 1, 2, 3\}$, Range = $\{0, 1, 4, 9\}$

b. Yes, a function

2)

| $x$ | $y$ | $x$ | $y$ |
|---|---|---|---|
| -3 | -2 | 1 | 1 |
| -2 | -8 | 2 | 8 |
| -1 | -1 | 3 | -2 |
| 0 | 0 | | |

3)

| $x$ | $y$ | $x$ | $y$ |
|---|---|---|---|
| 1 | -3 | 1 | 1 |
| 2 | -2 | 2 | 2 |
| 3 | -1 | 3 | 3 |
| 0 | 0 | | |

**Answer**

a. Domain = $\{0, 1, 2, 3\}$, Range = $\{-3, -2, -1, 0, 1, 2, 3\}$

b. No, not a function

4)

| $x$ | $y$ | $x$ | $y$ |
|---|---|---|---|
| 1 | 1 | 5 | 1 |
| 2 | 1 | 6 | 1 |
| 3 | 1 | 7 | 1 |
| 4 | 1 | | |

5)

| $x$ | $y$ | $x$ | $y$ |
|---|---|---|---|
| 3 | 3 | 15 | 1 |
| 5 | 2 | 21 | 2 |
| 8 | 1 | 33 | 3 |
| 10 | 0 | | |

**Answer**

a. Domain = $\{3, 5, 8, 10, 15, 21, 33\}$, Range = $\{0, 1, 2, 3\}$

b. Yes, a function

6)

| $x$ | $y$ | $x$ | $y$ |
|---|---|---|---|
| -7 | 11 | 1 | -2 |
| -2 | 5 | 3 | 4 |
| -2 | 1 | 6 | 11 |
| 0 | -1 | | |

**For exercises 7 - 13, find the values for each function, if they exist, then simplify.**

a. $f(0)$ b. $f(1)$ c. $f(3)$ d. $f(-x)$ e. $f(a)$ f. $f(a+h)$

7) $f(x) = 5x - 2$

**Answer**

a. $-2$ b. $3$ c. $13$ d. $-5x - 2$ e. $5a - 2$ f. $5a + 5h - 2$

8) $f(x) = 4x^2 - 3x + 1$

9) $f(x) = \frac{2}{x}$

**Answer**

a. Undefined b. $2$ c. $\frac{2}{3}$ d. $-\frac{2}{x}$ e. $\frac{2}{a}$ f. $\frac{2}{a+h}$

10) $f(x) = |x - 7| + 8$

11) $f(x) = \sqrt{6x + 5}$

**Answer**

a. $\sqrt{5}$ b. $\sqrt{11}$ c. $\sqrt{23}$ d. $\sqrt{-6x + 5}$ e. $\sqrt{6a + 5}$ f. $\sqrt{6a + 6h + 5}$

12) $f(x) = \frac{x - 2}{3x + 7}$

13) $f(x) = 9$

**Answer**

a. 9 b. 9 c. 9 d. 9 e. 9 f. 9

**For exercises 14 - 21, find the domain, range, and all zeros/intercepts, if any, of the functions.**

14) $f(x) = \dfrac{x}{x^2 - 16}$

15) $g(x) = \sqrt{8x - 1}$

**Answer**

$x \geq \frac{1}{8}$; $y \geq 0$; $x = \frac{1}{8}$; no y-intercept

16) $h(x) = \dfrac{3}{x^2 + 4}$

17) $f(x) = -1 + \sqrt{x + 2}$

**Answer**

$x \geq -2$; $y \geq -1$; $x = -1$; $y = -1 + \sqrt{2}$

18) $f(x) = 1x - \sqrt{9}$

19) $g(x) = \dfrac{3}{x - 4}$

**Answer**

$x \neq 4$; $y \neq 0$; no x-intercept; $y = -\frac{3}{4}$

20) $f(x) = 4|x + 5|$

21) $g(x) = \sqrt{\dfrac{7}{x - 5}}$

**Answer**

$x > 5$; $y > 0$; no intercepts

**For exercises 22 - 27, set up a table to sketch the graph of each function using the following values: $x = -3, -2, -1, 0, 1, 2, 3$.**

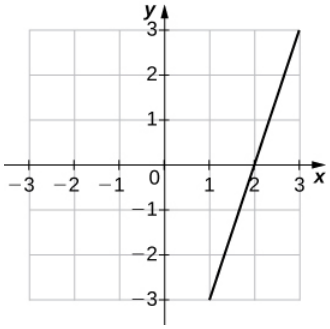
22) $f(x) = x^2 + 1$

| $x$ | $y$ | $x$ | $y$ |
|---|---|---|---|
| -3 | 10 | 1 | 2 |
| -2 | 5 | 2 | 5 |
| -1 | 2 | 3 | 10 |
| 0 | 1 | | |

23) $f(x) = 3x - 6$

| $x$ | $y$ | $x$ | $y$ |
|---|---|---|---|
| -3 | -15 | 1 | -3 |
| -2 | -12 | 2 | 0 |
| -1 | -9 | 3 | 3 |
| 0 | -6 | | |

**Answer**



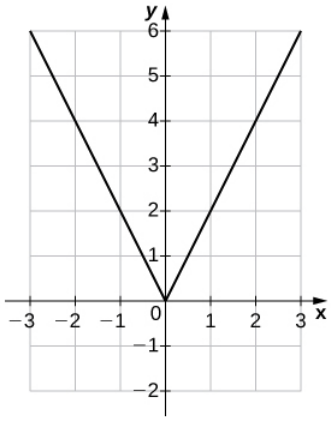
24) $f(x) = \frac{1}{2}x + 1$

| $x$ | $y$ | $x$ | $y$ |
|---|---|---|---|
| -3 | $-\frac{1}{2}$ | 1 | $\frac{3}{2}$ |
| -2 | 0 | 2 | 2 |
| -1 | $\frac{1}{2}$ | 3 | $\frac{5}{2}$ |
| 0 | 1 | | |

25) $f(x) = 2|x|$

| $x$ | $y$ | $x$ | $y$ |
|---|---|---|---|
| -3 | 6 | 1 | 2 |
| -2 | 4 | 2 | 4 |
| -1 | 2 | 3 | 6 |
| 0 | 0 | | |

**Answer**



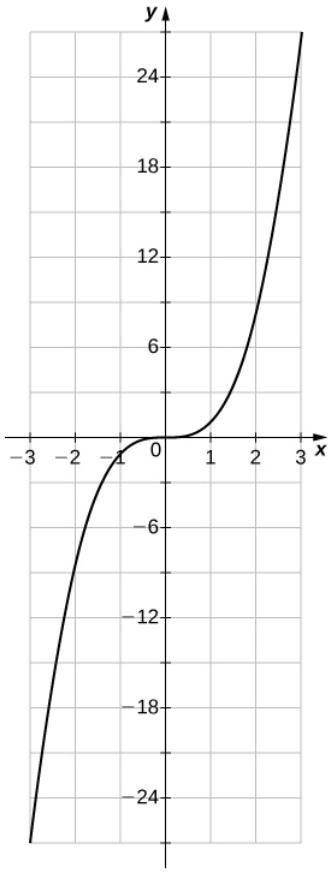
26) $f(x) = -x^2$

| $x$ | $y$ | $x$ | $y$ |
|---|---|---|---|
| -3 | -9 | 1 | -1 |
| -2 | -4 | 2 | -4 |
| -1 | -1 | 3 | -9 |
| 0 | 0 | | |

27) $f(x) = x^3$

| $x$ | $y$ | $x$ | $y$ |
|---|---|---|---|
| -3 | -27 | 1 | 1 |
| -2 | -8 | 2 | 8 |
| -1 | -1 | 3 | 27 |
| 0 | 0 | | |

**Answer**



**For exercises 28 - 35, use the vertical line test to determine whether each of the given graphs represents a function. Assume that a graph continues at both ends if it extends beyond the given grid. If the graph represents a function, then determine the following for each graph:**

a. Domain and range

b. $x$ -intercept, if any (estimate where necessary)

c. $y$-Intercept, if any (estimate where necessary)

d. The intervals for which the function is increasing

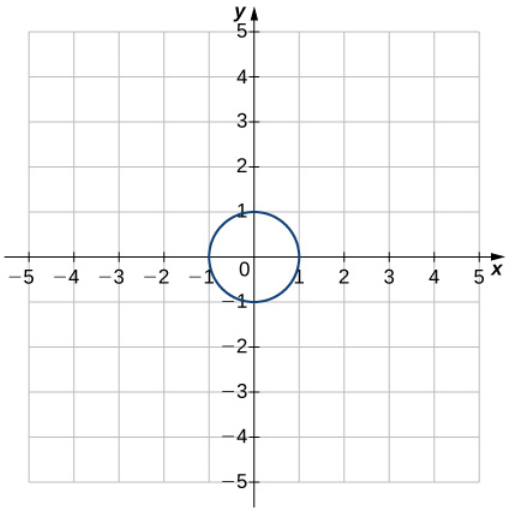
e. The intervals for which the function is decreasing

f. The intervals for which the function is constant

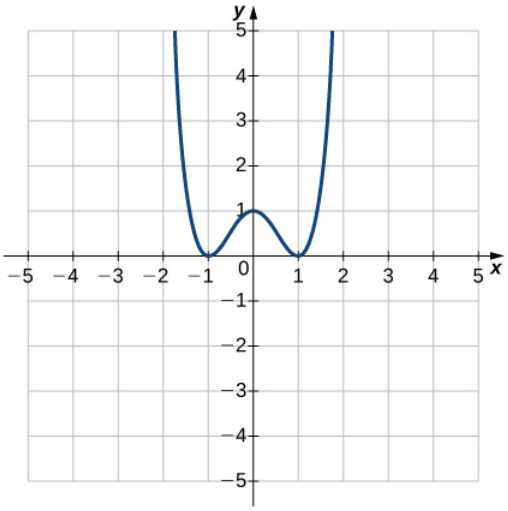
g. Symmetry about any axis and/or the origin

h. Whether the function is even, odd, or neither

28)



29)



**Answer**

Function;

a. Domain: all real numbers, range: $y \geq 0$

b. $x = \pm 1$

c. $y = 1$

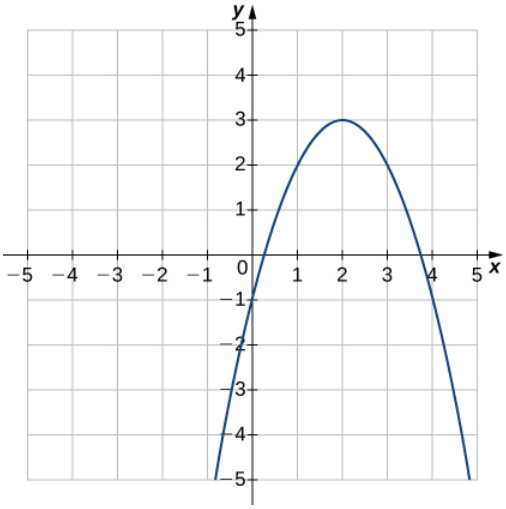
d. $-1 < x < 0$ and $1 < x < \infty$

e. $-\infty < x < -1$ and $0 < x < 1$

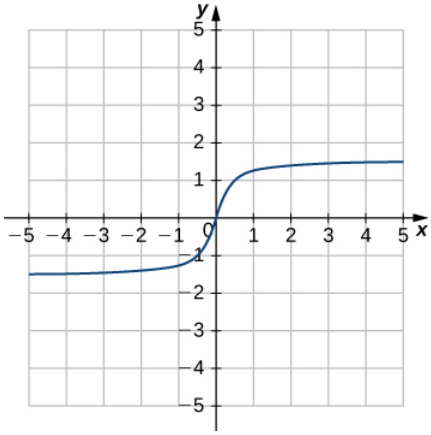
f. Not constant

g. $y$-axis
h. Even

30)



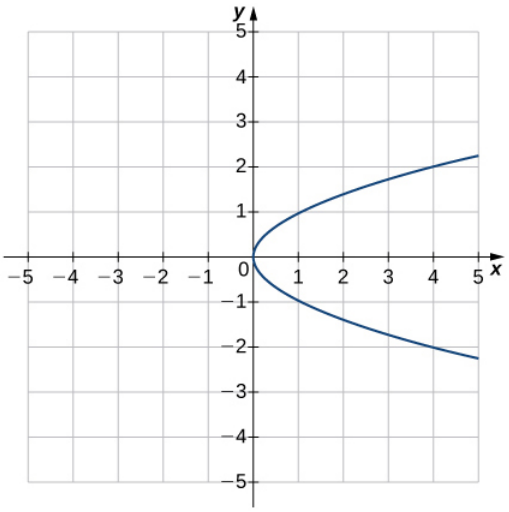
31)



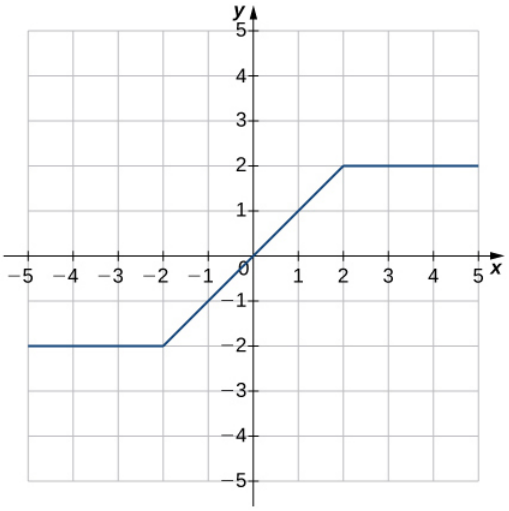
**Answer**

Function;
a. Domain: all real numbers, range: $-1.5 \leq y \leq 1.5$
b. $x = 0$
c. $y = 0$
d. all real numbers
e. None
f. Not constant
g. Origin
h. Odd

32)



33)



**Answer**

Function;

a. Domain: $-\infty < x < \infty$, range: $-2 \leq y \leq 2$

b. $x = 0$

c. $y = 0$

d. $-2 < x < 2$

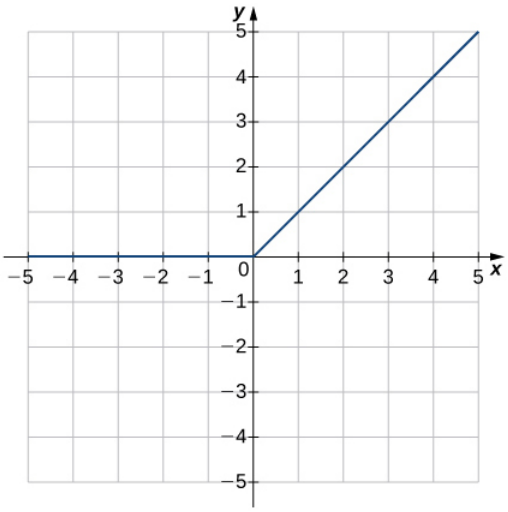
e. Not decreasing

f. $-\infty < x < -2$ and $2 < x < \infty$

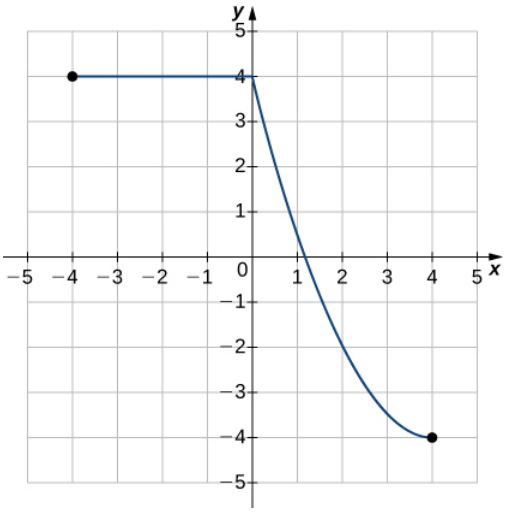
g. Origin

h. Odd

34)



35)



**Answer**

Function;

a. Domain: $-4 \le x \le 4$, range: $-4 \le y \le 4$

b. $x = 1.2$

c. $y = 4$

d. Not increasing

e. $0 < x < 4$

f. $-4 < x < 0$

g. No Symmetry

h. Neither

**For exercises 36 - 41, for each pair of functions, find a. $f+g$ b. $f-g$ c. $f \cdot g$ d. $f/g$. Determine the domain of each of these new functions.**

36) $f(x) = 3x + 4, \quad g(x) = x - 2$

37) $f(x) = x - 8, \quad g(x) = 5x^2$

**Answer**

a. $5x^2+x-8$; all real numbers

b. $-5x^2+x-8$; all real numbers

c. $5x^3-40x^2$; all real numbers

d. $\frac{x-8}{5x^2}$; $x\neq 0$

38) $f(x)=3x^2+4x+1, \quad g(x)=x+1$

39) $f(x)=9-x^2, \quad g(x)=x^2-2x-3$

**Answer**

a. $-2x+6$; all real numbers

b. $-2x^2+2x+12$; all real numbers

c. $-x^4+2x^3+12x^2-18x-27$; all real numbers

d. $-\frac{x+3}{x+1}$; $x\neq -1,3$

40) $f(x)=\sqrt{x}, \quad g(x)=x-2$

41) $f(x)=6+\frac{1}{x}, \quad g(x)=\frac{1}{x}$

**Answer**

a. $6+\frac{2}{x}$; $x\neq 0$

b. $6$; $x\neq 0$

c. $6x+\frac{1}{x^2}$; $x\neq 0$

d. $6x+1$; $x\neq 0$

**For exercises 42 - 48, for each pair of functions, find a. $(f\circ g)(x)$ and b. $(g\circ f)(x)$ Simplify the results. Find the domain of each of the results.**

42) $f(x)=3x, \quad g(x)=x+5$

43) $f(x)=x+4, \quad g(x)=4x-1$

**Answer**

a. $4x+3$; all real numbers

b. $4x+15$; all real numbers

44) $f(x)=2x+4, \quad g(x)=x^2-2$

45) $f(x)=x^2+7, \quad g(x)=x^2-3$

**Answer**

a. $x^4-6x^2+16$; all real numbers

b. $x^4+14x^2+46$; all real numbers

46) $f(x)=\sqrt{x}, \quad g(x)=x+9$

47) $f(x)=\frac{3}{2x+1}, \quad g(x)=\frac{2}{x}$

**Answer**

a. $\frac{3x}{4+x}$; $x\neq 0,-4$

b. $\frac{4x+2}{3}$; $x\neq -\frac{1}{2}$

48) $f(x) = |x + 1|, \quad g(x) = x^2 + x - 4$

49) The table below lists the NBA championship winners for the years 2001 to 2012.

| Year | Winner |
|---|---|
| 2001 | LA Lakers |
| 2002 | LA Lakers |
| 2003 | Sam Antonio Spurs |
| 2004 | Detroit Pistons |
| 2005 | Sam Antonio Spurs |
| 2006 | Miami Heat |
| 2007 | Sam Antonio Spurs |
| 2008 | Boston Celtics |
| 2009 | LA Lakers |
| 2010 | LA Lakers |
| 2011 | Dallas Mavericks |
| 2012 | Miami Heat |

a. Consider the relation in which the domain values are the years 2001 to 2012 and the range is the corresponding winner. Is this relation a function? Explain why or why not.

b. Consider the relation where the domain values are the winners and the range is the corresponding years. Is this relation a function? Explain why or why not.

**Answer**

a. Yes, because there is only one winner for each year.
b. No, because there are three teams that won more than once during the years 2001 to 2012.

50) [Technology Required] The area $A$ of a square depends on the length of the side s.

a. Write a function $A(s)$ for the area of a square.

b. Find and interpret $A(6.5)$.

c. Find the exact and the two-significant-digit approximation to the length of the sides of a square with area 56 square units.

51) [Technology Required] The volume of a cube depends on the length of the sides $s$.

a. Write a function $V(s)$ for the area of a square.

b. Find and interpret $V(11.8)$.

**Answer**

a. $V(s) = s^3$
b. $V(11.8) \approx 1643$; a cube of side length 11.8 each has a volume of approximately 1643 cubic units.

52) [Technology Required] A rental car company rents cars for a flat fee of $20 and an hourly charge of $10.25. Therefore, the total cost $C$ to rent a car is a function of the hours $t$ the car is rented plus the flat fee.

a. Write the formula for the function that models this situation.

b. Find the total cost to rent a car for 2 days and 7 hours.

c. Determine how long the car was rented if the bill is $432.73.

53) [Technology Required] A vehicle has a 20-gal tank and gets 15 mpg. The number of miles $N$ that can be driven depends on the amount of gas $x$ in the tank.

a. Write a formula that models this situation.

b. Determine the number of miles the vehicle can travel on (i) a full tank of gas and (ii) 3/4 of a tank of gas.

c. Determine the domain and range of the function.

d. Determine how many times the driver had to stop for gas if she has driven a total of 578 mi.

**Answer**

a. $N(x) = 15x$
b. i. $N(20) = 15(20) = 300$; therefore, the vehicle can travel 300 mi on a full tank of gas.
ii. $N(15) = 225$; therefore, the vehicle can travel 225 mi on 3/4 of a tank of gas.
c. Domain: $0 \le x \le 20$; range: $[0, 300]$
d. The driver had to stop at least once, given that it takes approximately 39 gal of gas to drive a total of 578 mi.

54) [Technology Required] The volume $V$ of a sphere depends on the length of its radius as $V = (4/3)\pi r^3$. Because Earth is not a perfect sphere, we can use the mean radius when measuring from the center to its surface. The mean radius is the average distance from the physical center to the surface, based on a large number of samples. Find the volume of Earth with mean radius $6.371 \times 106$ m.

55) [Technology Required] A certain bacterium grows in culture in a circular region. The radius of the circle, measured in centimeters, is given by $r(t) = 6 - \frac{5}{t^2+1}$, where $t$ is time measured in hours since a circle of a 1-cm radius of the bacterium was put into the culture.

a. Express the area of the bacteria as a function of time.

b. Find the exact and approximate area of the bacterial culture in 3 hours.

c. Express the circumference of the bacteria as a function of time.

d. Find the exact and approximate circumference of the bacteria in 3 hours.

**Answer**

a. $A(t) = A(r(t)) = \pi \cdot (6 - \frac{5}{t^2+1})^2$
b. Exact: $\frac{121\pi}{4}$; approximately $95\ \text{cm}^2$
c. $C(t) = C(r(t)) = 2\pi(6 - \frac{5}{t^2+1})$
d. Exact: $11\pi$; approximately $35$ cm

56) [Technology Required] An American tourist visits Paris and must convert U.S. dollars to Euros, which can be done using the function $E(x) = 0.79x$, where $x$ is the number of U.S. dollars and $E(x)$ is the equivalent number of Euros. Since conversion rates fluctuate, when the tourist returns to the United States 2 weeks later, the conversion from Euros to U.S. dollars is $D(x) = 1.245x$, where $x$ is the number of Euros and $D(x)$ is the equivalent number of U.S. dollars.

a. Find the composite function that converts directly from U.S. dollars to U.S. dollars via Euros. Did this tourist lose value in the conversion process?

b. Use (a) to determine how many U.S. dollars the tourist would get back at the end of her trip if she converted an extra $200 when she arrived in Paris.

57) [Technology Required] The manager at a skateboard shop pays his workers a monthly salary $S$ of $750 plus a commission of $8.50 for each skateboard they sell.

a. Write a function $y = S(x)$ that models a worker's monthly salary based on the number of skateboards $x$ he or she sells.

b. Find the approximate monthly salary when a worker sells 25, 40, or 55 skateboards.

c. Determine the number of skateboards that must be sold for a worker to earn a monthly income of $1400.

**Answer**

a. $S(x) = 8.5x + 750$ b. $962.50, $1090, $1217.50 c. 77 skateboards

# 1.2: Basic Classes of Functions and Their Graphs

**Learning Objectives**

- Calculate the slope of a linear function and interpret its meaning.
- Recognize the degree of a polynomial.
- Find the roots of a quadratic polynomial.
- Describe the graphs of basic odd and even polynomial functions.
- Identify a rational function.
- Describe the graphs of power and root functions.
- Graph a piecewise-defined function.
- Sketch the graph of a function that has been shifted, stretched, or reflected from its initial graph position.

We have studied the general characteristics of functions, so now let's examine some specific classes of functions. We begin by reviewing the basic properties of linear and quadratic functions, and then generalize to include higher-degree polynomials. We finish the section with examples of piecewise-defined functions and take a look at how to sketch the graph of a function that has been shifted, stretched, or reflected from its initial form.

## Linear Functions and Slope

The easiest type of function to consider is a **linear function**. Linear functions have the form $f(x) = ax + b$, where $a$ and $b$ are constants. In Figure 1.2.1, we see examples of linear functions when $a$ is positive, negative, and zero. Note that if $a > 0$, the graph of the line rises as $x$ increases. In other words, $f(x) = ax + b$ is increasing on $(-\infty, \infty)$. If $a < 0$, the graph of the line falls as $x$ increases. In this case, $f(x) = ax + b$ is decreasing on $(-\infty, \infty)$. If $a = 0$, the line is horizontal.

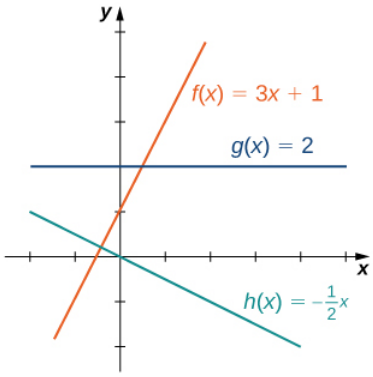

Figure 1.2.1: These linear functions are increasing or decreasing on $(\infty, \infty)$ and one function is a horizontal line.

As suggested by Figure 1.2.1, the graph of any linear function is a line. One of the distinguishing features of a line is its slope. The **slope** is the change in $y$ for each unit change in $x$. The slope measures both the steepness and the direction of a line. If the slope is positive, the line points upward when moving from left to right. If the slope is negative, the line points downward when moving from left to right. If the slope is zero, the line is horizontal. To calculate the slope of a line, we need to determine the ratio of the change in $y$ versus the change in $x$. To do so, we choose any two points $(x_1, y_1)$ and $(x_2, y_2)$ on the line and calculate $\frac{y_2 - y_1}{x_2 - x_1}$. In Figure 1.2.2, we see this ratio is independent of the points chosen.

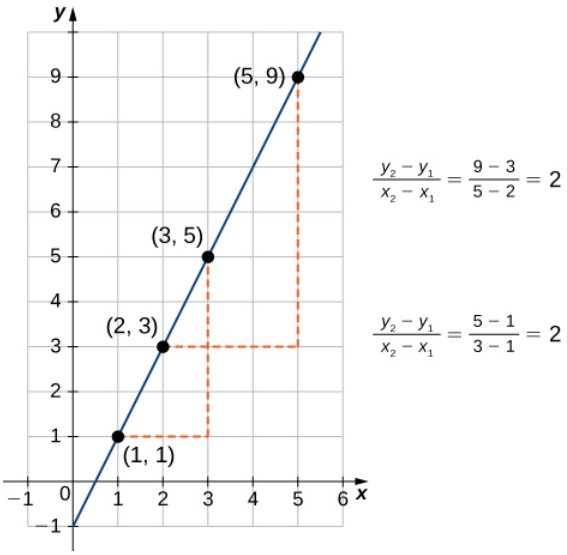

Figure **1.2.2**: For any linear function, the slope $(y_2 - y_1)/(x_2 - x_1)$ is independent of the choice of points $(x_1, y_1)$ and $(x_2, y_2)$ on the line.

### Definition: Slope of a Linear Function

Consider line $L$ passing through points $(x_1, y_1)$ and $(x_2, y_2)$. Let $\Delta y = y_2 - y_1$ and $\Delta x = x_2 - x_1$ denote the changes in $y$ and $x$,respectively. The **slope** of the line is

$$m = \frac{y_2 - y_1}{x_2 - x_1} = \frac{\Delta y}{\Delta x}$$

We now examine the relationship between slope and the formula for a linear function. Consider the linear function given by the formula $f(x) = ax + b$. As discussed earlier, we know the graph of a linear function is given by a line. We can use our definition of slope to calculate the slope of this line. As shown, we can determine the slope by calculating $(y_2 - y_1)/(x_2 - x_1)$ for any points $(x_1, y_1)$ and $(x_2, y_2)$ on the line. Evaluating the function $f$ at $x = 0$, we see that $(0, b)$ is a point on this line. Evaluating this function at $x = 1$, we see that $(1, a + b)$ is also a point on this line. Therefore, the slope of this line is

$$\frac{(a + b) - b}{1 - 0} = a.$$

We have shown that the coefficient $a$ is the slope of the line. We can conclude that the formula $f(x) = ax + b$ describes a line with slope $a$. Furthermore, because this line intersects the $y$-axis at the point $(0, b)$, we see that the $y$-intercept for this linear function is $(0, b)$. We conclude that the formula $f(x) = ax + b$ tells us the slope, $a$, and the $y$-intercept, $(0, b)$, for this line. Since we often use the symbol $m$ to denote the slope of a line, we can write

$$\underbrace{f(x) = mx + b}_{\text{slope-intercept form}}$$

to denote the **slope-intercept form** of a linear function.

Sometimes it is convenient to express a linear function in different ways. For example, suppose the graph of a linear function passes through the point $(x_1, y_1)$ and the slope of the line is $m$. Since any other point $(x, f(x))$ on the graph of $f$ must satisfy the equation

$$m = \frac{f(x) - y_1}{x - x_1},$$

this linear function can be expressed by writing

$$\underbrace{f(x) - y_1 = m(x - x_1)}_{\text{point-slope equation}}.$$

We call this equation the **point-slope equation** for that linear function.

Since every nonvertical line is the graph of a linear function, the points on a nonvertical line can be described using the slope-intercept or point-slope equations. However, a vertical line does not represent the graph of a function and cannot be expressed in either of these forms. Instead, a vertical line is described by the equation $x = k$ for some constant $k$. Since neither the slope-intercept form nor the point-slope form allows for vertical lines, we use the notation

$$\underbrace{ax + by = c,}_{\text{standard form}}$$

where $a, b$ are both not zero, to denote the **standard form of a line.**

### Definition: Point-Slope Equation, and the Slope-Intercept Form and Standard Form of the Equation of a Line

Consider a line passing through the point $(x_1, y_1)$ with slope $m$. The equation

$$y - y_1 = m(x - x_1)$$

is the **point-slope form** for that line.

Consider a line with slope $m$ and $y$-intercept $(0, b)$. The equation

$$y = mx + b$$

is an equation for that line in **slope-intercept form**.

The **standard form** of a line is given by the equation

$$ax + by = c,$$

where $a$ and $b$ are both not zero. This form is more general because it allows for a vertical line, $x = k$.

### Example 1.2.1: Finding the Slope and Equations of Lines

Consider the line passing through the points $(11, -4)$ and $(-4, 5)$, as shown in Figure 1.2.3.

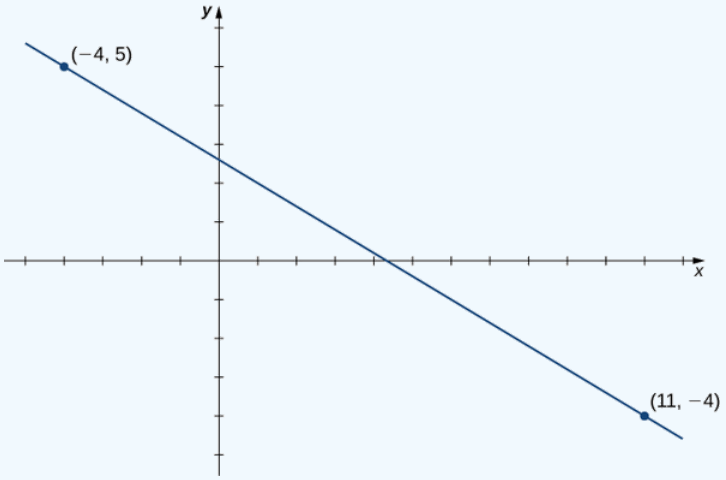

Figure 1.2.3: Finding the equation of a linear function with a graph that is a line between two given points.

1. Find the slope of the line.
2. Find an equation for this linear function in point-slope form.
3. Find an equation for this linear function in slope-intercept form.

#### Solution

1. The slope of the line is

$$m = \frac{y_2 - y_1}{x_2 - x_1} = \frac{5 - (-4)}{-4 - 11} = -\frac{9}{15} = -\frac{3}{5}.$$

2. To find an equation for the linear function in point-slope form, use the slope $m = -3/5$ and choose any point on the line. If we choose the point $(11, -4)$, we get the equation

$$f(x) + 4 = -\frac{3}{5}(x - 11).$$

3. To find an equation for the linear function in slope-intercept form, solve the equation in part b. for $f(x)$. When we do this, we get the equation

$$f(x) = -\frac{3}{5}x + \frac{13}{5}.$$

## ? Exercise 1.2.1

Consider the line passing through points $(-3, 2)$ and $(1, 4)$.

a. Find the slope of the line.
b. Find an equation of that line in point-slope form.
c. Find an equation of that line in slope-intercept form.

**Hint**

The slope $m = \Delta y/\Delta x$.

**Answer a**

$m = 1/2$.

**Answer b**

The point-slope form is $y - 4 = \frac{1}{2}(x - 1)$.

**Answer c**

The slope-intercept form is $y = \frac{1}{2}x + \frac{7}{2}$.

## ✓ Example 1.2.2:

Jessica leaves her house at 5:50 a.m. and goes for a 9-mile run. She returns to her house at 7:08 a.m. Answer the following questions, assuming Jessica runs at a constant pace.

a. Describe the distance $D$ (in miles) Jessica runs as a linear function of her run time $t$ (in minutes).
b. Sketch a graph of $D$.
c. Interpret the meaning of the slope.

**Solution**

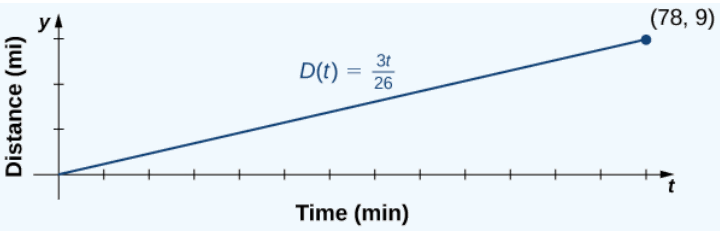
a. At time $t = 0$, Jessica is at her house, so $D(0) = 0$. At time $t = 78$ minutes, Jessica has finished running $9$ mi, so $D(78) = 9$. The slope of the linear function is

$$m = \frac{9 - 0}{78 - 0} = \frac{3}{26}.$$

The $y$-intercept is $(0, 0)$, so the equation for this linear function is

$$D(t) = \frac{3}{26}t.$$

b. To graph $D$, use the fact that the graph passes through the origin and has slope $m = 3/26$.



c. The slope $m = 3/26 \approx 0.115$ describes the distance (in miles) Jessica runs per minute, or her average velocity.

## Polynomials

A linear function is a special type of a more general class of functions: polynomials. A **polynomial function** is any function that can be written in the form

$$f(x) = a_n x^n + a_{n-1} x^{n-1} + \ldots + a_1 x + a_0$$

for some integer $n \geq 0$ and constants $a_n, a_{n-1}, \ldots, a_0$, where $a_n \neq 0$. In the case when $n = 0$, we allow for $a_0 = 0$; if $a_0 = 0$, the function $f(x) = 0$ is called the **zero function**. The value $n$ is called the **degree** of the polynomial; the constant $a_n$ is called the **leading coefficient**. A linear function of the form $f(x) = mx + b$ is a polynomial of degree 1 if $m \neq 0$ and degree 0 if $m = 0$. A polynomial of degree 0 is also called a **constant function**. A polynomial function of degree 2 is called a **quadratic function**. In particular, a quadratic function has the form

$$f(x) = ax^2 + bx + c,$$

where $a \neq 0$. A polynomial function of degree 3 is called a **cubic function**.

## Power Functions

Some polynomial functions are power functions. A **power function** is any function of the form $f(x) = ax^b$, where $a$ and $b$ are any real numbers. The exponent in a power function can be any real number, but here we consider the case when the exponent is a positive integer. (We consider other cases later.) If the exponent is a positive integer, then $f(x) = ax^n$ is a polynomial. If $n$ is even, then $f(x) = ax^n$ is an even function because $f(-x) = a(-x)^n = ax^n$ if $n$ is even. If $n$ is odd, then $f(x) = ax^n$ is an odd function because $f(-x) = a(-x)^n = -ax^n$ if $n$ is odd (Figure 1.2.4).

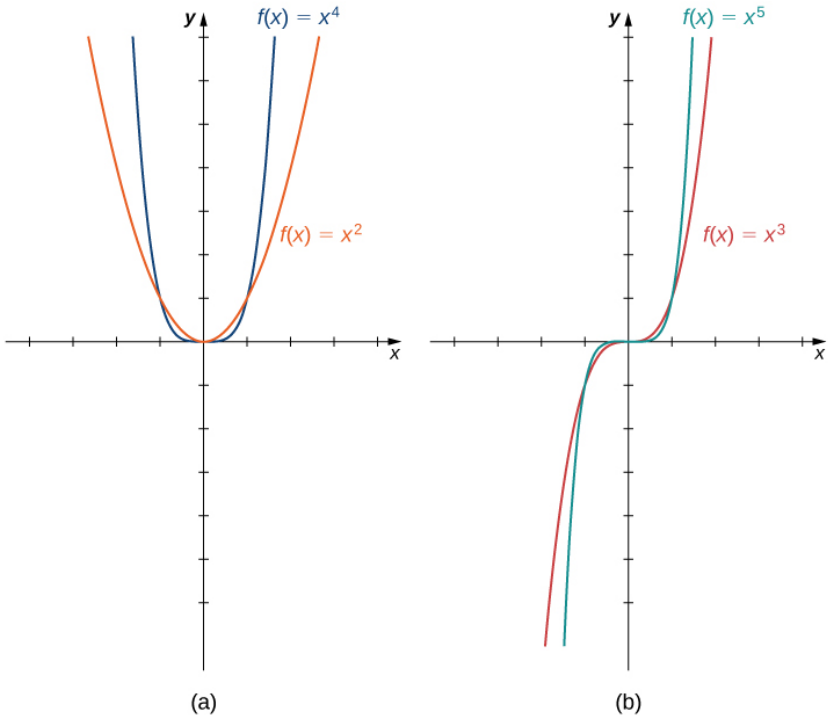


Figure 1.2.4: (a) For any even integer $n, f(x) = ax^n$ is an even function. (b) For any odd integer $n, f(x) = ax^n$ is an odd function.

## Behavior at Infinity

To determine the behavior of a function $f$ as the inputs approach infinity, we look at the values $f(x)$ as the inputs, $x$, become larger. For some functions, the values of $f(x)$ approach a finite number. For example, for the function $f(x) = 2 + 1/x$, the values $1/x$ become closer and closer to zero for all values of $x$ as they get larger and larger. For this function, we say "$f(x)$ approaches two as $x$ goes to infinity," and we write $f(x) \to 2$ as $x \to \infty$. The line $y = 2$ is a **horizontal asymptote** for the function $f(x) = 2 + 1/x$ because the graph of the function gets closer to the line as $x$ gets larger.

For other functions, the values $f(x)$ may not approach a finite number but instead may become larger for all values of $x$ as they get larger. In that case, we say "$f(x)$ approaches infinity as $x$ approaches infinity," and we write $f(x) \to \infty$ as $x \to \infty$. For example, for the function $f(x) = 3x^2$, the outputs $f(x)$ become larger as the inputs $x$ get larger. We can conclude that the function $f(x) = 3x^2$ approaches infinity as $x$ approaches infinity, and we write $3x^2 \to \infty$ as $x \to \infty$. The behavior as $x \to -\infty$ and the meaning of $f(x) \to -\infty$ as $x \to \infty$ or $x \to -\infty$ can be defined similarly. We can describe what happens to the values of $f(x)$ as $x \to \infty$ and as $x \to -\infty$ as the **end behavior** of the function.

To understand the end behavior for polynomial functions, we can focus on quadratic and cubic functions. The behavior for higher-degree polynomials can be analyzed similarly. Consider a quadratic function $f(x) = ax^2 + bx + c$. If $a > 0$, the values $f(x) \to \infty$ as $x \to \pm\infty$. If $a < 0$, the values $f(x) \to -\infty$ as $x \to \pm\infty$. Since the graph of a quadratic function is a parabola, the parabola opens upward if $a > 0$; the parabola opens downward if $a < 0$ (Figure 1.2.5$a$).

Now consider a cubic function $f(x) = ax^3 + bx^2 + cx + d$. If $a > 0$, then $f(x) \to \infty$ as $x \to \infty$ and $f(x) \to -\infty$ as $x \to -\infty$. If $a < 0$, then $f(x) \to -\infty$ as $x \to \infty$ and $f(x) \to \infty$ as $x \to -\infty$. As we can see from both of these graphs, the leading term of the polynomial determines the end behavior (Figure 1.2.5$b$).

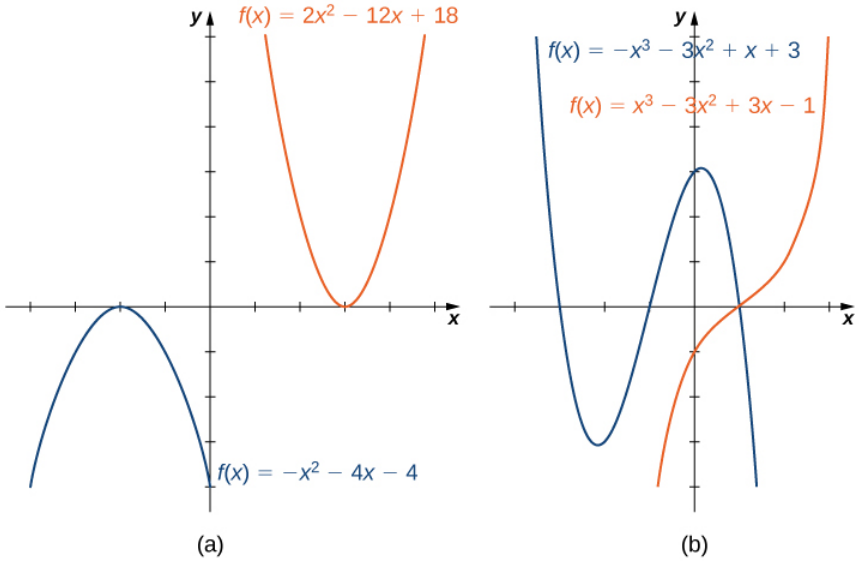

Figure 1.2.5: (a) For a quadratic function, if the leading coefficient $a > 0$,the parabola opens upward. If $a < 0$, the parabola opens downward. (b) For a cubic function $f$, if the leading coefficient $a > 0$, the values $f(x) \to \infty$ as $x \to \infty$ and the values $f(x) \to -\infty$ as $x \to -\infty$. If the leading coefficient $a < 0$, the opposite is true.

## Zeros of Polynomial Functions

Another characteristic of the graph of a polynomial function is where it intersects the $x$-axis. To determine where a function $f$ intersects the $x$-axis, we need to solve the equation $f(x) = 0$ for $x$. In the case of the linear function $f(x) = mx + b$, the $x$-intercept is given by solving the equation $mx + b = 0$. In this case, we see that the $x$-intercept is given by $(-b/m, 0)$. In the case of a quadratic function, finding the $x$-intercept(s) requires finding the zeros of a quadratic equation: $ax^2 + bx + c = 0$. In some cases, it is easy to factor the polynomial $ax^2 + bx + c$ to find the zeros. If not, we make use of the Quadratic Formula.

### Theorem 1.2.1: Quadratic Formula

Consider the quadratic equation

$$ax^2 + bx + c = 0,$$

where $a \neq 0$. The solutions of this equation are given by the Quadratic Formula

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}. \tag{1.2.1}$$

If the **discriminant** $b^2 - 4ac > 0$, Equation 1.2.1 tells us there are two real numbers that satisfy the quadratic equation. If $b^2 - 4ac = 0$, this formula tells us there is only one solution, and it is a real number. If $b^2 - 4ac < 0$, no real numbers satisfy the quadratic equation.

In the case of higher-degree polynomials, it may be more complicated to determine where the graph intersects the $x$-axis. In some instances, it is possible to find the $x$-intercepts by factoring the polynomial to find its zeros. In other cases, it is impossible to calculate the exact values of the $x$-intercepts. However, as we see later in the text, in cases such as this, we can use analytical tools to approximate (to a very high degree) where the $x$-intercepts are located. Here we focus on the graphs of polynomials for which we can calculate their zeros explicitly.

### Example 1.2.3: Graphing Polynomial Functions

For the following functions,

a. $f(x) = -2x^2 + 4x - 1$
b. $f(x) = x^3 - 3x^2 - 4x$

i. describe the behavior of $f(x)$ as $x \to \pm\infty$,

ii. find all zeros of $f$, and

iii. sketch a graph of $f$.

### Solution

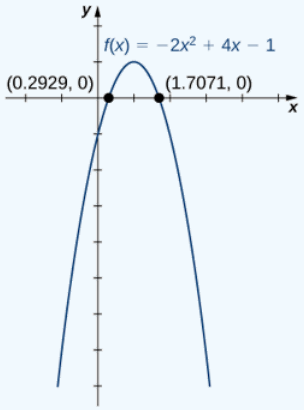
1. The function $f(x) = -2x^2 + 4x - 1$ is a quadratic function.

    1. Because $a = -2 < 0$, as $x \to \pm\infty, f(x) \to -\infty$.

    2. To find the zeros of $f$, use the Quadratic Formula. The zeros are

$$x = \frac{-4 \pm \sqrt{4^2 - 4(-2)(-1)}}{2(-2)} = \frac{-4 \pm \sqrt{8}}{-4} = \frac{-4 \pm 2\sqrt{2}}{-4} = \frac{2 \pm \sqrt{2}}{2}.$$

    3. To sketch the graph of $f$,use the information from your previous answers and combine it with the fact that the graph is a parabola opening downward.



2. The function $f(x) = x^3 - 3x^2 - 4x$ is a cubic function.

    1. Because $a = 1 > 0$, as $x \to \infty$, $f(x) \to \infty$. As $x \to -\infty$, $f(x) \to -\infty$.

    2. To find the zeros of $f$, we need to factor the polynomial. First, when we factor $x$ out of all the terms, we find

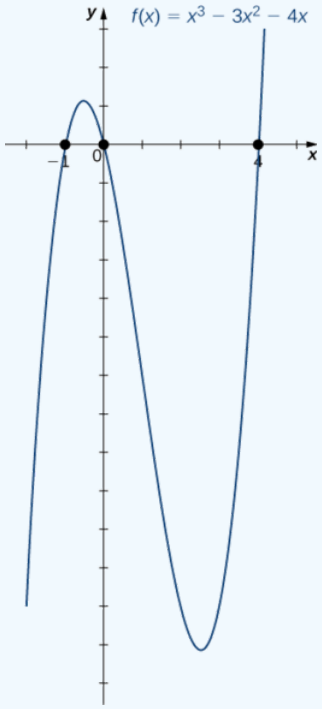
$$f(x) = x(x^2 - 3x - 4).$$

    Then, when we factor the quadratic function $x^2 - 3x - 4$, we find

$$f(x) = x(x - 4)(x + 1).$$

    Therefore, the zeros of $f$ are $x = 0, 4, -1$.

3. Combining the results from parts i. and ii., draw a rough sketch of $f$.



**? Exercise 1.2.3**

Consider the quadratic function $f(x) = 3x^2 - 6x + 2$. Find the zeros of $f$. Does the parabola open upward or downward?

**Hint**

Use the Quadratic Formula.

**Answer**

The zeros are $x = 1 \pm \sqrt{3}/3$. The parabola opens upward.

## Mathematical Models

A large variety of real-world situations can be described using **mathematical models**. A mathematical model is a method of simulating real-life situations with mathematical equations. Physicists, engineers, economists, and other researchers develop models by combining observation with quantitative data to develop equations, functions, graphs, and other mathematical tools to describe the behavior of various systems accurately. Models are useful because they help predict future outcomes. Examples of mathematical models include the study of population dynamics, investigations of weather patterns, and predictions of product sales.

As an example, let's consider a mathematical model that a company could use to describe its revenue for the sale of a particular item. The amount of revenue $R$ a company receives for the sale of $n$ items sold at a price of $p$ dollars per item is described by the equation $R = p \cdot n$. The company is interested in how the sales change as the price of the item changes. Suppose the data in Table 1.2.1 show the number of units a company sells as a function of the price per item.

Table 1.2.1: Number of Units Sold $n$ (in Thousands) as a Function of Price per Unit $p$ (in Dollars)

| $p$ | 6 | 8 | 10 | 12 | 14 |
|---|---|---|---|---|---|
| $n$ | 19.4 | 18.5 | 16.2 | 13.8 | 12.2 |

In Figure 1.2.6, we see the graph the number of units sold (in thousands) as a function of price (in dollars). We note from the shape of the graph that the number of units sold is likely a linear function of price per item, and the data can be closely approximated by

the linear function $n = -1.04p + 26$ for $0 \le p \le 25$, where $n$ predicts the number of units sold in thousands. Using this linear function, the revenue (in thousands of dollars) can be estimated by the quadratic function

$$R(p) = p \cdot (-1.04p + 26) = -1.04p^2 + 26p \text{ for } 0 \le p \le 25.$$

In Example 1.2.4, we use this quadratic function to predict the amount of revenue the company receives depending on the price the company charges per item. Note that we cannot conclude definitively the actual number of units sold for values of $p$, for which no data are collected. However, given the other data values and the graph shown, it seems reasonable that the number of units sold (in thousands) if the price charged is $p$ dollars may be close to the values predicted by the linear function $n = -1.04p + 26$.

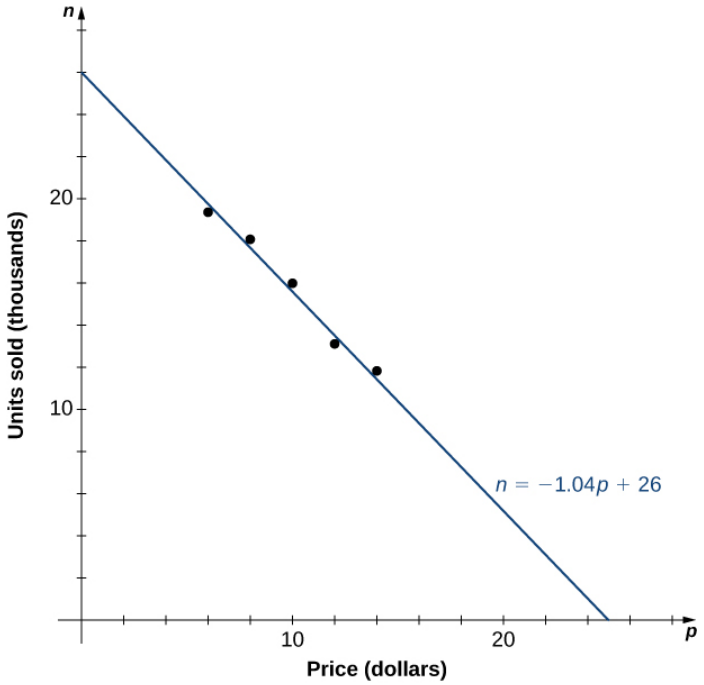


Figure 1.2.6: The data collected for the number of items sold as a function of price is roughly linear. We use the linear function $n = -1.04p + 26$ to estimate this function.

## Example 1.2.4: Maximizing Revenue

A company is interested in predicting the amount of revenue it will receive depending on the price it charges for a particular item. Using the data from Table 1.2.1, the company arrives at the following quadratic function to model revenue $R$ as a function of price per item $p$:

$$R(p) = p \cdot (-1.04p + 26) = -1.04p^2 + 26p$$

for $0 \le p \le 25$.

a. Predict the revenue if the company sells the item at a price of $p = \$5$ and $p = \$17$.
b. Find the zeros of this function and interpret the meaning of the zeros.
c. Sketch a graph of $R$.
d. Use the graph to determine the value of $p$ that maximizes revenue. Find the maximum revenue.

### Solution

a. Evaluating the revenue function at $p = 5$ and $p = 17$, we can conclude that

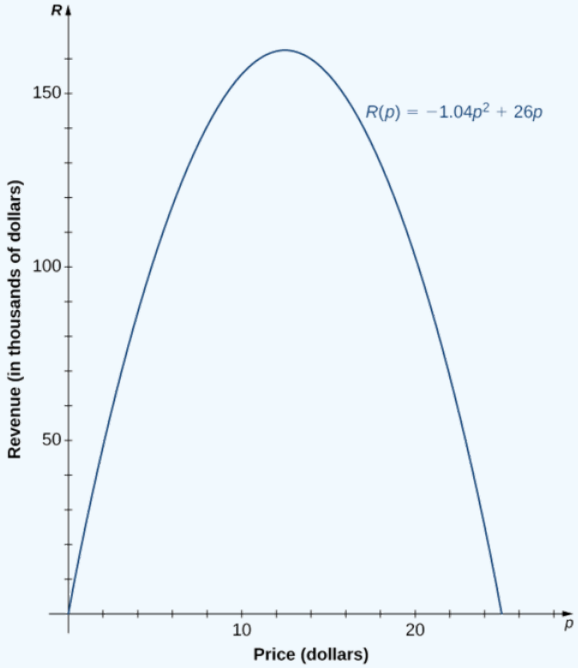
$$R(5) = -1.04(5)^2 + 26(5) = 104, \text{ so revenue} = \$104,000;$$

$$R(17) = -1.04(17)^2 + 26(17) = 141.44, \text{ so revenue} = \$141,440.$$

b. The zeros of this function can be found by solving the equation $-1.04p^2 + 26p = 0$. When we factor the quadratic expression, we get $p(-1.04p + 26) = 0$. The solutions to this equation are given by $p = 0, 25$. For these values of $p$, the

revenue is zero. When $p = \$0$, the revenue is zero because the company is giving away its merchandise for free. When $p = \$25$,the revenue is zero because the price is too high, and no one will buy any items.

c. Knowing the fact that the function is quadratic, we also know the graph is a parabola. Since the leading coefficient is negative, the parabola opens downward. One property of parabolas is that they are symmetric about the axis of symmetry, so since the zeros are at $p = 0$ and $p = 25$, the parabola must be symmetric about the line halfway between them, or $p = 12.5$.



d. The function is a parabola with zeros at $p = 0$ and $p = 25$, and it is symmetric about the line $p = 12.5$, so the maximum revenue occurs at a price of $p = \$12.50$ per item. At that price, the revenue is $R(p) = -1.04(12.5)^2 + 26(12.5) = \$162,500$.

## Algebraic Functions

By allowing for quotients and fractional powers in polynomial functions, we create a larger class of functions. An **algebraic function** is one that involves addition, subtraction, multiplication, division, rational powers, and roots. Two types of algebraic functions are rational functions and root functions.

Just as rational numbers are quotients of integers, rational functions are quotients of polynomials. In particular, a **rational function** is any function of the form $f(x) = p(x)/q(x)$,where $p(x)$ and $q(x)$ are polynomials. For example,

$$f(x) = \frac{3x-1}{5x+2} \text{ and } g(x) = \frac{4}{x^2+1}$$

are rational functions. A **root function** is a power function of the form $f(x) = x^{1/n}$, where $n$ is a positive integer greater than one. For example, $f(x) = x^{1/2} = \sqrt{x}$ is the square-root function and $g(x) = x^{1/3} = \sqrt[3]{x}$ is the cube-root function. By allowing for compositions of root functions and rational functions, we can create other algebraic functions. For example, $f(x) = \sqrt{4-x^2}$ is an algebraic function.

### Example 1.2.5: Finding Domain and Range for Algebraic Functions

For each of the following functions, find the domain and range.

a. $f(x) = \dfrac{3x-1}{5x+2}$
b. $f(x) = \sqrt{4-x^2}$

**Solution**

1. It is not possible to divide by zero, so the domain is the set of real numbers $x$ such that $x \neq -2/5$. To find the range, we need to find the values $y$ for which there exists a real number $x$ such that

$$y = \frac{3x-1}{5x+2}$$

When we multiply both sides of this equation by $5x+2$, we see that $x$ must satisfy the equation

$$5xy + 2y = 3x - 1.$$

From this equation, we can see that $x$ must satisfy

$$2y + 1 = x(3 - 5y).$$

If y=$3/5$, this equation has no solution. On the other hand, as long as $y \neq 3/5$,

$$x = \frac{2y+1}{3-5y}$$

satisfies this equation. We can conclude that the range of $f$ is $\{y \mid y \neq 3/5\}$.

2. To find the domain of $f$, we need $4 - x^2 \geq 0$. When we factor, we write $4 - x^2 = (2-x)(2+x) \geq 0$. This inequality holds if and only if both terms are positive or both terms are negative. For both terms to be positive, we need to find $x$ such that

$$2 - x \geq 0 \text{ and } 2 + x \geq 0.$$

These two inequalities reduce to $2 \geq x$ and $x \geq -2$. Therefore, the set $\{x \mid -2 \leq x \leq 2\}$ must be part of the domain. For both terms to be negative, we need

$$2 - x \leq 0 \text{ and } 2 + x \leq 0.$$

These two inequalities also reduce to $2 \leq x$ and $x \leq -2$. There are no values of $x$ that satisfy both of these inequalities. Thus, we can conclude the domain of this function is $\{x \mid -2 \leq x \leq 2\}$.

If $-2 \leq x \leq 2$, then $0 \leq 4 - x^2 \leq 4$. Therefore, $0 \leq \sqrt{4-x2} \leq 2$, and the range of $f$ is $\{y \mid 0 \leq y \leq 2\}$.

**? Exercise 1.2.5**

Find the domain and range for the function $f(x) = (5x+2)/(2x-1)$.

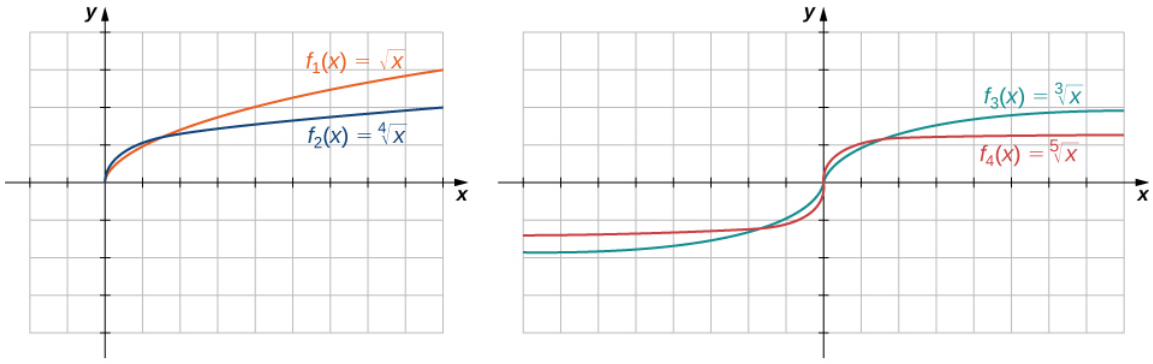
**Hint**

The denominator cannot be zero. Solve the equation $y = (5x+2)/(2x-1)$ for $x$ to find the range.

**Answer**

The domain is the set of real numbers $x$ such that $x \neq 1/2$. The range is the set $\{y \mid y \neq 5/2\}$.

The root functions $f(x) = x^{1/n}$ have defining characteristics depending on whether $n$ is odd or even. For all even integers $n \geq 2$, the domain of $f(x) = x^{1/n}$ is the interval $[0, \infty)$. For all odd integers $n \geq 1$, the domain of $f(x) = x^{1/n}$ is the set of all real numbers. Since $x^{1/n} = (-x)^{1/n}$ for odd integers $n, f(x) = x^{1/n}$ is an odd function if $n$ is odd. See the graphs of root functions for different values of $n$ in Figure 1.2.7.



(a) (b)

Figure 1.2.7: (a) If $n$ is even, the domain of $f(x) = \sqrt[n]{x}$ is $[0, \infty)$. (b) If $n$ is odd, the domain of $f(x) = \sqrt[n]{x}$ is $(-\infty, \infty)$ and the function $f(x) = \sqrt[n]{x}$ is an odd function.

### Example 1.2.6: Finding Domains for Algebraic Functions

For each of the following functions, determine the domain of the function.

a. $f(x) = \dfrac{3}{x^2 - 1}$
b. $f(x) = \dfrac{2x + 5}{3x^2 + 4}$
c. $f(x) = \sqrt{4 - 3x}$
d. $f(x) = \sqrt[3]{2x - 1}$

**Solution**

a. You cannot divide by zero, so the domain is the set of values $x$ such that $x^2 - 1 \neq 0$. Therefore, the domain is $\{x \mid x \neq \pm 1\}$.
b. You need to determine the values of $x$ for which the denominator is zero. Since $3x^2 + 4 \geq 4$ for all real numbers $x$, the denominator is never zero. Therefore, the domain is $(-\infty, \infty)$.
c. Since the square root of a negative number is not a real number, the domain is the set of values $x$ for which $4 - 3x \geq 0$. Therefore, the domain is $\{x \mid x \leq 4/3\}$.
d. The cube root is defined for all real numbers, so the domain is the interval $(-\infty, \infty)$.

### Exercise 1.2.6

Find the domain for each of the following functions: $f(x) = (5 - 2x)/(x^2 + 2)$ and $g(x) = \sqrt{5x - 1}$.

**Hint**

Determine the values of $x$ when the expression in the denominator of $f$ is nonzero, and find the values of $x$ when the expression inside the radical of $g$ is nonnegative.

**Answer**

The domain of $f$ is $(-\infty, \infty)$. The domain of $g$ is $\{x \mid x \geq 1/5\}$.

## Piecewise-Defined Functions

Sometimes a function is defined by different formulas on different parts of its domain. A function with this property is known as a **piecewise-defined function**. The absolute value function is an example of a piecewise-defined function because the formula changes with the sign of $x$:

$$|x| = \begin{cases} x, & \text{if } x \geq 0 \\ -x, & \text{if } x < 0 \end{cases}.$$

Other piecewise-defined functions may be represented by completely different formulas, depending on the part of the domain in which a point falls. To graph a piecewise-defined function, we graph each part of the function in its respective domain, on the same coordinate system. If the formula for a function is different for $x < a$ and $x > a$, we need to pay special attention to what happens at $x = a$ when we graph the function. Sometimes the graph needs to include an open or closed circle to indicate the value of the function at $x = a$. We examine this in the next example.

### Example 1.2.7: Graphing a Piecewise-Defined Function

Sketch a graph of the following piecewise-defined function:

$$f(x) = \begin{cases} x+3, & \text{if } x < 1 \\ (x-2)^2, & \text{if } x \geq 1 \end{cases}$$

#### Solution

Graph the linear function $y = x + 3$ on the interval $(-\infty, 1)$ and graph the quadratic function $y = (x-2)^2$ on the interval $[1, \infty)$. Since the value of the function at $x = 1$ is given by the formula $f(x) = (x-2)^2$, we see that $f(1) = 1$. To indicate this on the graph, we draw a closed circle at the point $(1, 1)$. The value of the function is given by $f(x) = x + 3$ for all $x < 1$, but not at $x = 1$. To indicate this on the graph, we draw an open circle at $(1, 4)$.

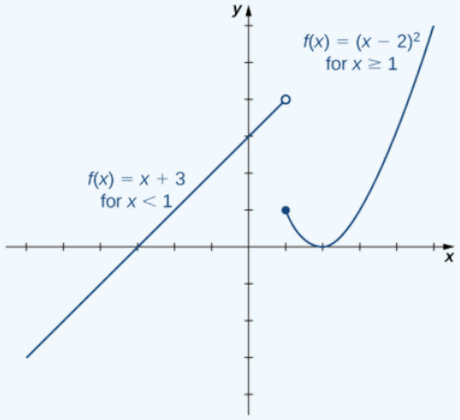


Figure 1.2.8: This piecewise-defined function is linear for $x < 1$ and quadratic for $x \geq 1$.

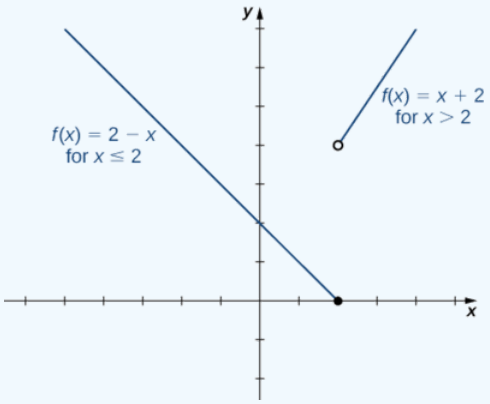
2) Sketch a graph of the function

$$f(x) = \begin{cases} 2-x, & \text{if } x \leq 2 \\ x+2, & \text{if } x > 2 \end{cases}.$$

Solution:



https://math.libretexts.org/@go/page/171822

## Example 1.2.8: Parking Fees Described by a Piecewise-Defined Function

In a big city, drivers are charged variable rates for parking in a parking garage. They are charged $10 for the first hour or any part of the first hour and an additional $2 for each hour or part thereof up to a maximum of $30 for the day. The parking garage is open from 6 a.m. to 12 midnight.

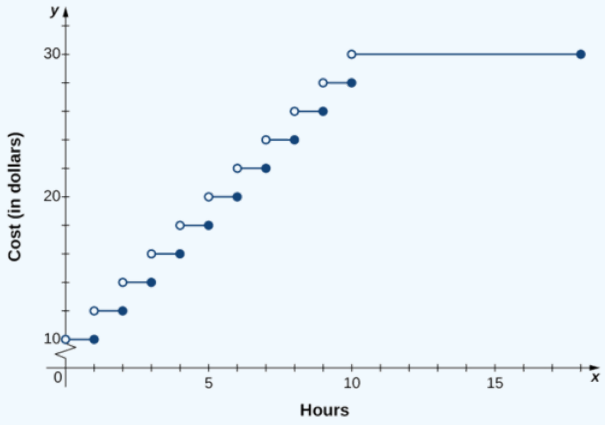
a. Write a piecewise-defined function that describes the cost $C$ to park in the parking garage as a function of hours parked $x$.
b. Sketch a graph of this function $C(x)$.

### Solution

1.Since the parking garage is open 18 hours each day, the domain for this function is $\{x \mid 0 < x \leq 18\}$. The cost to park a car at this parking garage can be described piecewise by the function

$$C(x) = \begin{cases} 10, & \text{for } 0 < x \leq 1 \\ 12, & \text{for } 1 < x \leq 2 \\ 14, & \text{for } 2 < x \leq 3 \\ 16, & \text{for } 3 < x \leq 4 \\ \vdots & \\ 30, & \text{for } 10 < x \leq 18 \end{cases}.$$

2.The graph of the function consists of several horizontal line segments.



## Exercise 1.2.8

The cost of mailing a letter is a function of the weight of the letter. Suppose the cost of mailing a letter is $49¢$ for the first ounce and $21¢$ for each additional ounce. Write a piecewise-defined function describing the cost $C$ as a function of the weight $x$ for $0 < x \leq 3$, where $C$ is measured in cents and $x$ is measured in ounces.

**Hint**

The piecewise-defined function is constant on the intervals $(0, 1]$, $(1, 2]$, ....

**Answer**

$$C(x) = \begin{cases} 49, 0 < x \leq 1 \\ 70, 1 < x \leq 2 \\ 91, 2 < x \leq 3 \end{cases}$$

## Transformations of Functions

We have seen several cases in which we have added, subtracted, or multiplied constants to form variations of simple functions. For instance, suppose we subtract 2 from the argument of the function $y = x^2$ to get the function $f(x) = (x - 2)^2$. This subtraction represents a shift of the function $y = x^2$ two units to the right. A shift, horizontally or vertically, is a type of **transformation of a function**. Other transformations include horizontal and vertical scalings, and reflections about the axes.

A **vertical shift** of a function occurs if we add or subtract the same constant to each output $y$. For $c > 0$, the graph of $f(x) + c$ is a shift of the graph of $f(x)$ up $c$ units, whereas the graph of $f(x) - c$ is a shift of the graph of $f(x)$ down $c$ units. For example, the graph of the function $f(x) = x^3 + 4$ is the graph of $y = x^3$ shifted up $4$ units; the graph of the function $f(x) = x^3 - 4$ is the graph of $y = x^3$ shifted down $4$ units (Figure 1.2.9).

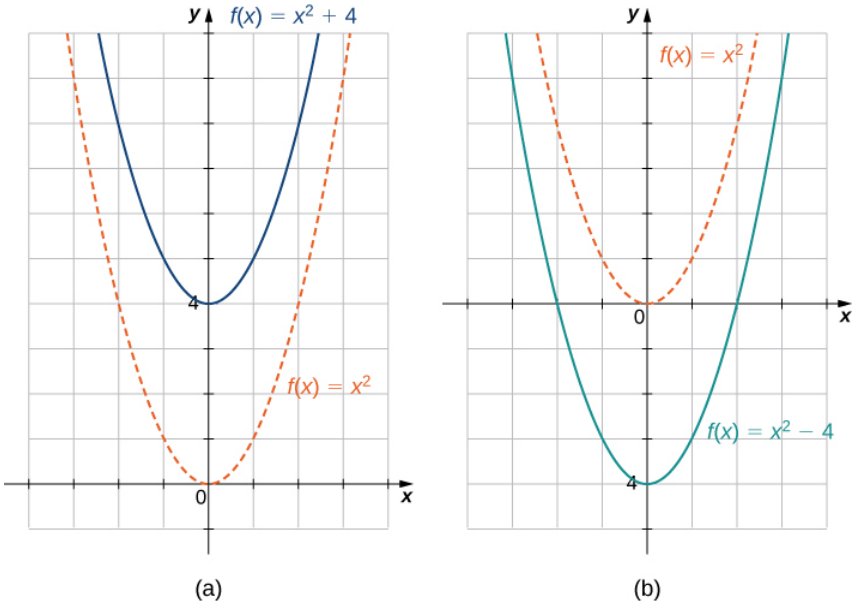


Figure 1.2.9: (a) For $c > 0$, the graph of $y = f(x) + c$ is a vertical shift up $c$ units of the graph of $y = f(x)$. (b) For $c > 0$, the graph of $y = f(x) - c$ is a vertical shift down c units of the graph of $y = f(x)$.

A **horizontal shift** of a function occurs if we add or subtract the same constant to each input $x$. For $c > 0$, the graph of $f(x + c)$ is a shift of the graph of $f(x)$ to the left $c$ units; the graph of $f(x - c)$ is a shift of the graph of $f(x)$ to the right $c$ units. Why does the graph shift left when adding a constant and shift right when subtracting a constant? To answer this question, let's look at an example.

Consider the function $f(x) = |x + 3|$ and evaluate this function at $x - 3$. Since $f(x - 3) = |x|$ and $x - 3 < x$, the graph of $f(x) = |x + 3|$ is the graph of $y = |x|$ shifted left $3$ units. Similarly, the graph of $f(x) = |x - 3|$ is the graph of $y = |x|$ shifted right $3$ units (Figure 1.2.10).

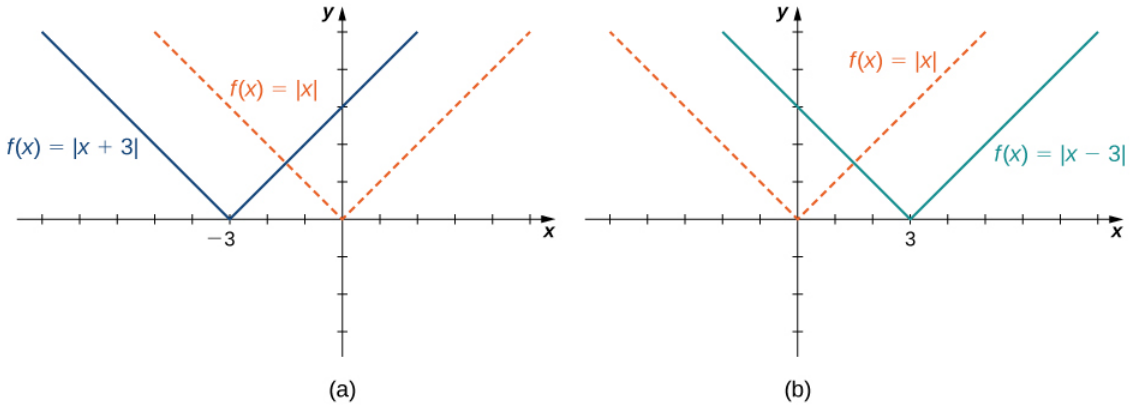

Figure 1.2.10: (a) For $c > 0$, the graph of $y = f(x + c)$ is a horizontal shift left $c$ units of the graph of $y = f(x)$. (b) For $c > 0$, the graph of $y = f(x - c)$ is a horizontal shift right $c$ units of the graph of $y = f(x)$.

A **vertical scaling** of a graph occurs if we multiply all outputs $y$ of a function by the same positive constant. For $c > 0$, the graph of the function $cf(x)$ is the graph of $f(x)$ scaled vertically by a factor of $c$. If $c > 1$, the values of the outputs for the function $cf(x)$ are larger than the values of the outputs for the function $f(x)$; therefore, the graph has been stretched vertically. If $0 < c < 1$, then the outputs of the function $cf(x)$ are smaller, so the graph has been compressed. For example, the graph of the function $f(x) = 3x^2$ is

the graph of $y = x^2$ stretched vertically by a factor of 3, whereas the graph of $f(x) = x^2/3$ is the graph of $y = x^2$ compressed vertically by a factor of 3 (Figure 1.2.11b).

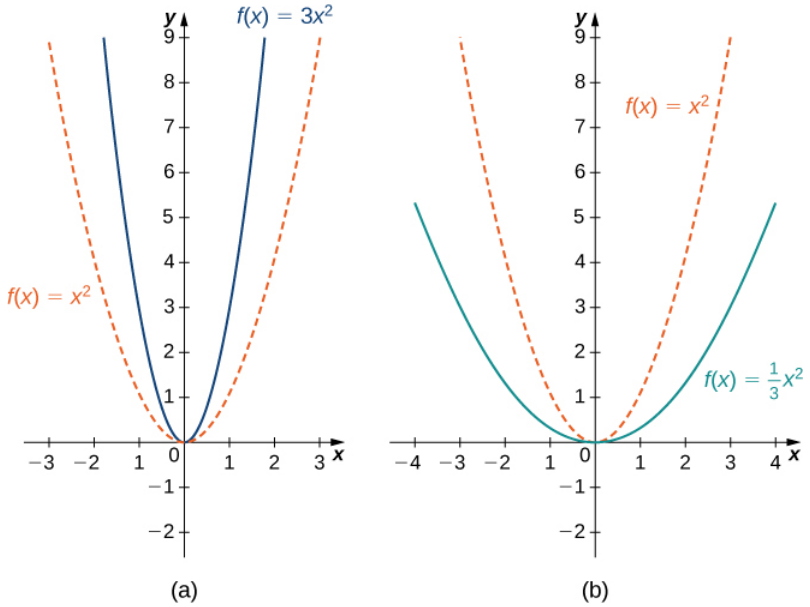

Figure 1.2.11: (a) If $c > 1$, the graph of $y = cf(x)$ is a vertical stretch of the graph of $y = f(x)$. (b) If $0 < c < 1$, the graph of $y = cf(x)$ is a vertical compression of the graph of $y = f(x)$.

The **horizontal scaling** of a function occurs if we multiply the inputs $x$ by the same positive constant. For $c > 0$, the graph of the function $f(cx)$ is the graph of $f(x)$ scaled horizontally by a factor of $c$. If $c > 1$, the graph of $f(cx)$ is the graph of $f(x)$ compressed horizontally. If $0 < c < 1$, the graph of $f(cx)$ is the graph of $f(x)$ stretched horizontally. For example, consider the function $f(x) = \sqrt{2x}$ and evaluate $f$ at $x/2$. Since $f(x/2) = \sqrt{x}$, the graph of $f(x) = \sqrt{2x}$ is the graph of $y = \sqrt{x}$ compressed horizontally. The graph of $y = \sqrt{x/2}$ is a horizontal stretch of the graph of $y = \sqrt{x}$ (Figure 1.2.12).

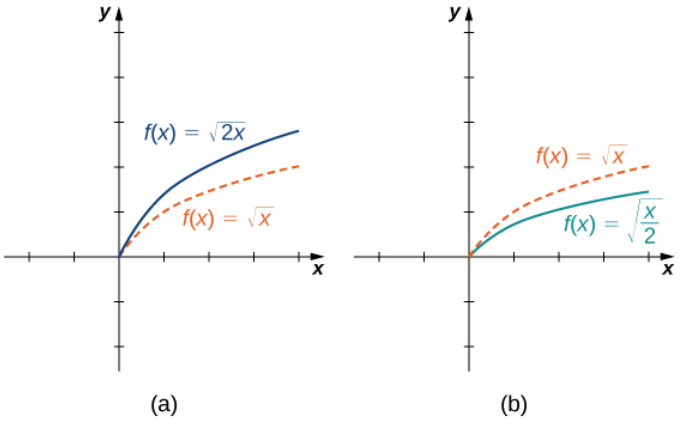

Figure 1.2.12: (a) If $c > 1$, the graph of $y = f(cx)$ is a horizontal compression of the graph of $y = f(x)$. (b) If $0 < c < 1$, the graph of $y = f(cx)$ is a horizontal stretch of the graph of $y = f(x)$.

We have explored what happens to the graph of a function $f$ when we multiply $f$ by a constant $c > 0$ to get a new function $cf(x)$. We have also discussed what happens to the graph of a function $f$when we multiply the independent variable $x$ by $c > 0$ to get a new function $f(cx)$. However, we have not addressed what happens to the graph of the function if the constant $c$ is negative. If we have a constant $c < 0$, we can write $c$ as a positive number multiplied by $-1$; but, what kind of transformation do we get when we multiply the function or its argument by $-1$? When we multiply all the outputs by $-1$, we get a **reflection** about the $x$-axis. When we multiply all inputs by $-1$, we get a reflection about the $y$-axis. For example, the graph of $f(x) = -(x^3 + 1)$ is the graph of $y = (x^3 + 1)$ reflected about the $x$-axis. The graph of $f(x) = (-x)^3 + 1$ is the graph of $y = x^3 + 1$ reflected about the $y$-axis (Figure 1.2.13).

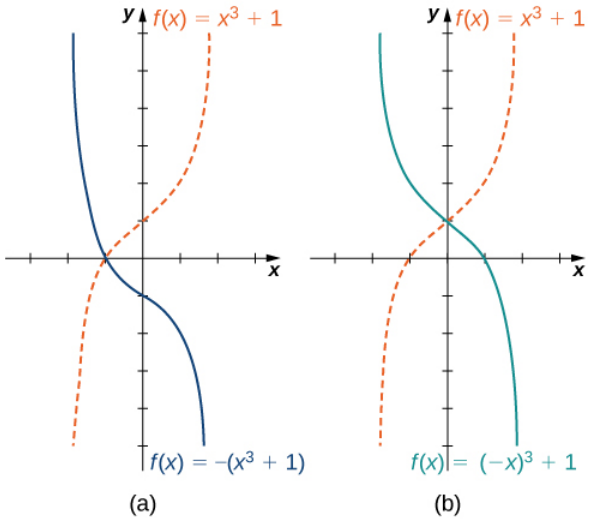

Figure **1.2.13**: (a) The graph of $y = -f(x)$ is the graph of $y = f(x)$ reflected about the $x$-axis. (b) The graph of $y = f(-x)$ is the graph of $y = f(x)$ reflected about the $y$-axis.

If the graph of a function consists of more than one transformation of another graph, it is important to transform the graph in the correct order. Given a function $f(x)$, the graph of the related function $y = cf(a(x + b)) + d$ can be obtained from the graph of $y = f(x)$by performing the transformations in the following order.

- Horizontal shift of the graph of $y = f(x)$. If $b > 0$, shift left. If $b < 0$ shift right.
- Horizontal scaling of the graph of $y = f(x + b)$ by a factor of $|a|$. If $a < 0$, reflect the graph about the $y$-axis.
- Vertical scaling of the graph of $y = f(a(x + b))$ by a factor of $|c|$. If $c < 0$, reflect the graph about the $x$ -axis.
- Vertical shift of the graph of $y = cf(a(x + b))$. If $d > 0$, shift up. If $d < 0$, shift down.

We can summarize the different transformations and their related effects on the graph of a function in the following table.

| Transformation of $f(c > 0)$ | Effect of the graph of $f$ |
|---|---|
| $f(x) + c$ | Vertical shift up $c$ units |
| $f(x) - c$ | Vertical shift down $c$ units |
| $f(x + c)$ | Shift left by $c$ units |
| $f(x - c)$ | Shift right by $c$ units |
| $cf(x)$ | Vertical stretch if $c > 1$; vertical compression if $0 < c < 1$ |
| $f(cx)$ | Horizontal stretch if $0 < c < 1$; horizontal compression if $c > 1$ |
| $-f(x)$ | Reflection about the $x$-axis |
| $f(-x)$ | Reflection about the $y$-axis |

### Example 1.2.9: Transforming a Function

For each of the following functions, a. and b., sketch a graph by using a sequence of transformations of a well-known function.

a. $f(x) = -|x + 2| - 3$
b. $f(x) = \sqrt{x} + 1$

**Solution**

1.Starting with the graph of $y = |x|$, shift $2$ units to the left, reflect about the $x$-axis, and then shift down $3$ units.

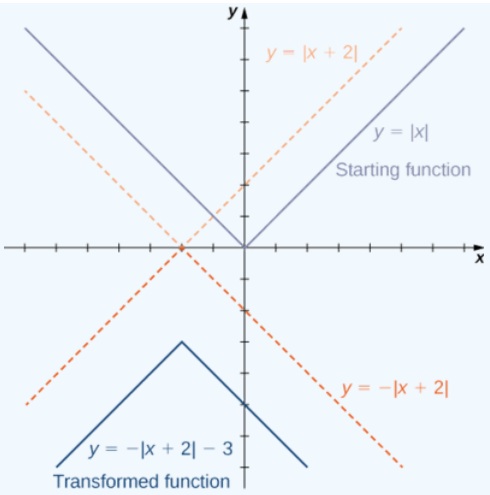

Figure 1.2.14: The function $f(x) = -|x+2| - 3$ can be viewed as a sequence of three transformations of the function $y = |x|$.

2. Starting with the graph of $y = \sqrt{x}$, reflect about the $y$-axis, stretch the graph vertically by a factor of 3, and move up 1 unit.

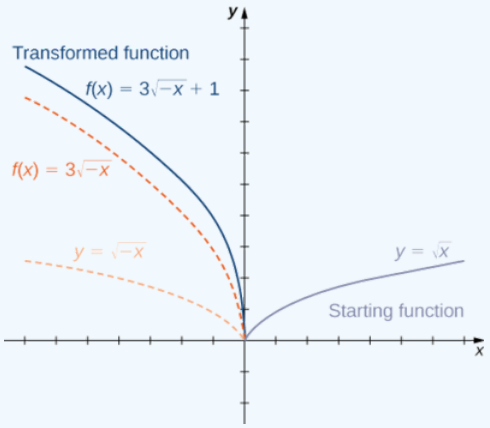

Figure 1.2.15: The function $f(x) = \sqrt{x} + 1$can be viewed as a sequence of three transformations of the function $y = \sqrt{x}$.

**? Exercise 1.2.9**

Describe how the function $f(x) = -(x+1)^2 - 4$ can be graphed using the graph of $y = x^2$ and a sequence of transformations

**Answer**

Shift the graph $y = x^2$ to the left 1 unit, reflect about the $x$-axis, then shift down 4 units.

## Key Concepts

- The power function $f(x) = x^n$ is an even function if n is even and $n \neq 0$, and it is an odd function if $n$ is odd.
- The root function $f(x) = x^{1/n}$ has the domain $[0, \infty)$ if n is even and the domain $(-\infty, \infty)$ if $n$ is odd. If $n$ is odd, then $f(x) = x^{1/n}$ is an odd function.
- The domain of the rational function $f(x) = p(x)/q(x)$, where $p(x)$ and $q(x)$ are polynomial functions, is the set of $x$ such that $q(x) \neq 0$.
- Functions that involve the basic operations of addition, subtraction, multiplication, division, and powers are algebraic functions.
- A polynomial function $f$ with degree $n \geq 1$ satisfies $f(x) \to \pm\infty$ as $x \to \pm\infty$. The sign of the output as $x \to \infty$ depends on the sign of the leading coefficient only and on whether $n$ is even or odd.
- Vertical and horizontal shifts, vertical and horizontal scalings, and reflections about the $x$- and $y$-axes are examples of transformations of functions.

## Key Equations

- **Point-slope equation of a line**

$$y - y_1 = m(x - x_1)$$

- **Slope-intercept form of a line**

$$y = mx + b$$

- **Standard form of a line**

$$ax + by = c$$

- **Polynomial function**

$$f(x) = a_n x^n + a_{n-1} x^{n-1} + \cdots + a_1 x + a_0$$

---

## Glossary

**algebraic function**
a function involving any combination of only the basic operations of addition, subtraction, multiplication, division, powers, and roots applied to an input variable $x$

**cubic function**
a polynomial of degree 3; that is, a function of the form $f(x) = ax^3 + bx^2 + cx + d$, where $a \neq 0$

**degree**
for a polynomial function, the value of the largest exponent of any term

**linear function**
a function that can be written in the form $f(x) = mx + b$

**logarithmic function**
a function of the form $f(x) = \log_b(x)$ for some base $b > 0$, $b \neq 1$ such that $y = \log_b(x)$ if and only if $b^y = x$

**mathematical model**
A method of simulating real-life situations with mathematical equations

**piecewise-defined function**
a function that is defined differently on different parts of its domain

**point-slope equation**
equation of a linear function indicating its slope and a point on the graph of the function

**polynomial function**
a function of the form $f(x) = a_n x^n + a_{n-1} x^{n-1} + \ldots + a_1 x + a_0$

**power function**
a function of the form $f(x) = x^n$ for any positive integer $n \geq 1$

**quadratic function**
a polynomial of degree 2; that is, a function of the form $f(x) = ax^2 + bx + c$ where $a \neq 0$

**rational function**
a function of the form $f(x) = p(x)/q(x)$, where $p(x)$ and $q(x)$ are polynomials

**root function**

a function of the form $f(x) = x^{1/n}$ for any integer $n \geq 2$

**slope**

the change in $y$ for each unit change in $x$

**slope-intercept form**

equation of a linear function indicating its slope and $y$-intercept

**transformation of a function**

a shift, scaling, or reflection of a function

# 1.2E: Exercises

**In exercises 1 - 8, for each pair of points,**

**a. find the slope of the line passing through the points and**

**b. indicate whether the line is increasing, decreasing, horizontal, or vertical.**

1) $(-2,4)$ and $(1,1)$

**Answer**

a. $m=-1$
b. Decreasing

2) $(-1,4)$ and $(3,-1)$

3) $(3,5)$ and $(-1,2)$

**Answer**

a. $m=3/4$
b. Increasing

4) $(6,4)$ and $(4,-3)$

5) $(2,3)$ and $(5,7)$

**Answer**

a. $m=4/3$
b. Increasing

6) $(1,9)$ and $(-8,5)$

7) $(2,4)$ and $(1,4)$

**Answer**

a. $m=0$
b. Horizontal

8) $(1,4)$ and $(1,0)$

**In exercises 9 - 16, write the equation of the line satisfying the given conditions in slope-intercept form.**

9) Slope $=-6$, passes through $(1,3)$

**Answer**

$y=-6x+9$

10) Slope $=3$, passes through $(-3,2)$

11) Slope $=\frac{1}{3}$, passes through $(0,4)$

**Answer**

$y=\frac{1}{3}x+4$

12) Slope $=\frac{2}{5}$, $x$-intercept $=8$

13) Passing through $(2,1)$ and $(-2,-1)$

**Answer**

$y = \frac{1}{2}x$

14) Passing through $(-3, 7)$ and $(1, 2)$

15) $x$-intercept =$5$ and $y$-intercept =$-3$

**Answer**

$y = \frac{3}{5}x - 3$

16) $x$-Intercept =$-6$ and $y$-intercept =$9$

**In exercises 17 - 24, for each linear equation,**

**a. give the slope $m$ and $y$-intercept $b$, if any, and**

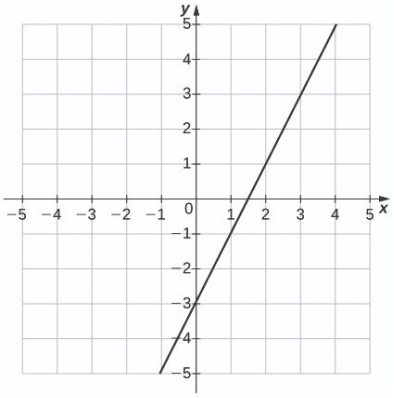
**b. graph the line.**

17) $y = 2x - 3$

**Answer**

a. $m = 2,\ b = -3$

b.



18) $y = -\frac{1}{7}x + 1$

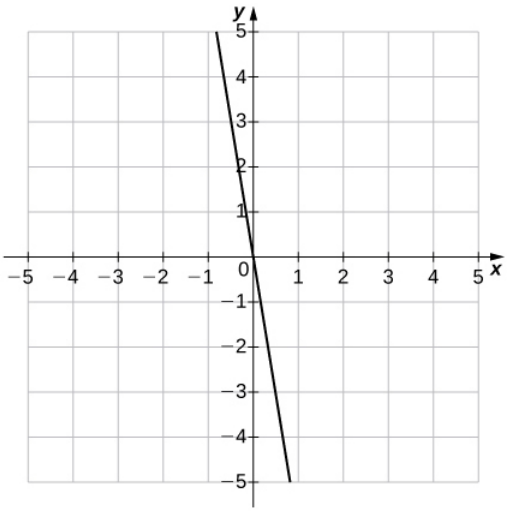
19) $f(x) = -6x$

**Answer**

a. $m = -6,\ b = 0$

b.

https://math.libretexts.org/@go/page/171823



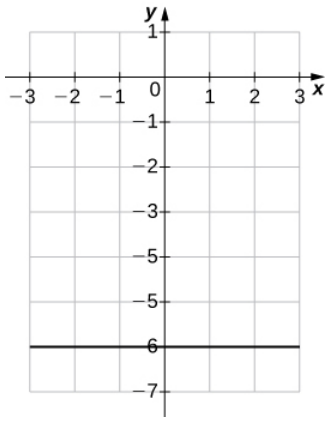
20) $f(x) = -5x + 4$

21) $4y + 24 = 0$

**Answer**

a. $m = 0,\ b = -6$

b.



22) $8x - 4 = 0$

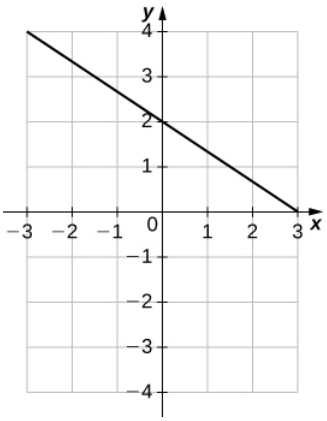
23) $2x + 3y = 6$

**Answer**

a. $m = -\frac{2}{3},\ b = 2$

b.

https://math.libretexts.org/@go/page/171823



24) $6x - 5y + 15 = 0$

**In exercises 25 - 29, for each polynomial,**

**a. find the degree;**

**b. find the zeros, if any;**

**c. find the $y$-intercept(s), if any;**

**d. use the leading coefficient to determine the graph's end behavior; and**

**e. determine algebraically whether the polynomial is even, odd, or neither.**

25) $f(x) = 2x^2 - 3x - 5$

**Answer**

a. $2$
b. $\frac{5}{2}, -1$;
c. $-5$
d. Both ends rise
e. Neither

26) $f(x) = -3x^2 + 6x$

27) $f(x) = \frac{1}{2}x^2 - 1$

**Answer**

a. $2$
b. \pm $\sqrt{2}$
c. $-1$
d. Both ends rise
e. Even

28) $f(x) = x^3 + 3x^2 - x - 3$

29) $f(x) = 3x - x^3$

**Answer**

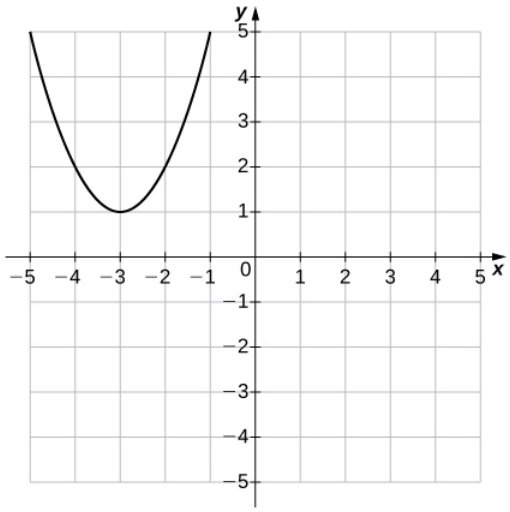
a. $3$
b. $0$, \pm $\sqrt{3}$
c. $0$
d. Left end rises, right end falls
e. Odd

**For exercises 30 - 31, use the graph of $f(x) = x^2$ to graph each transformed function $g$.**

30) $g(x) = x^2 - 1$

31) $g(x) = (x + 3)^2 + 1$

**Answer**

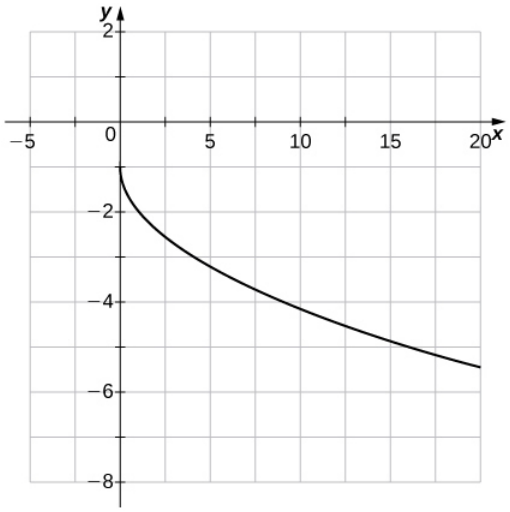


**For exercises 32 - 33, use the graph of $f(x) = \sqrt{x}$ to graph each transformed function $g$.**

32) $g(x) = \sqrt{x + 2}$

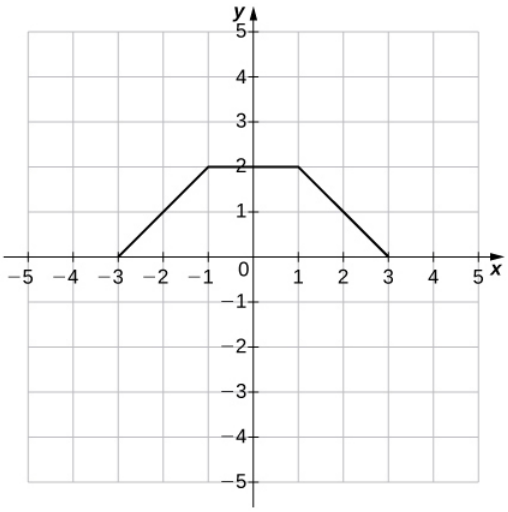
33) $g(x) = -\sqrt{x} - 1$

**Answer**



**For exercises 34 - 35, use the graph of $y = f(x)$ to graph each transformed function $g$.**

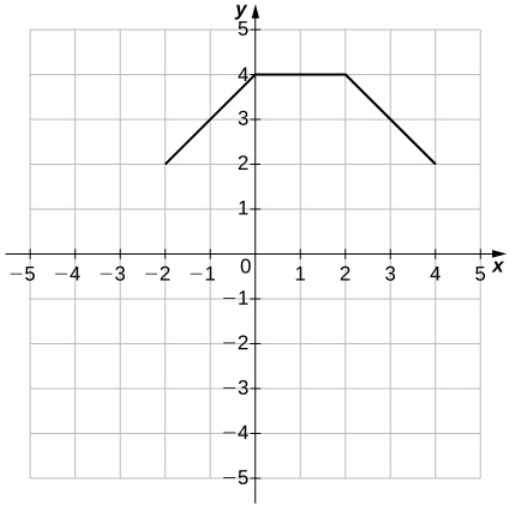
https://math.libretexts.org/@go/page/171823



34) $g(x) = f(x) + 1$

35) $g(x) = f(x - 1) + 2$

**Answer**



**In exercises 36 - 39, for each of the piecewise-defined functions,**

**a. evaluate at the given values of the independent variable, and**

**b. sketch the graph.**

36) $f(x) = \begin{cases} 4x + 3, & \text{if } x \le 0 \\ -x + 1, & \text{if } x > 0 \end{cases}$; $f(-3)$; $f(0)$; $f(2)$

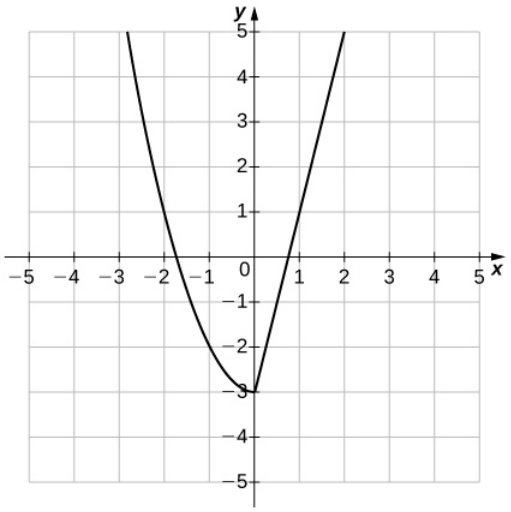
37) $f(x) = \begin{cases} x^2 - 3, & \text{if } x \le 0 \\ 4x - 3, & \text{if } x > 0 \end{cases}$; $f(-4)$; $f(0)$; $f(2)$

**Answer**

a. $f(-4) = 13, \quad f(0) = -3, \quad f(2) = 5$

b.

https://math.libretexts.org/@go/page/171823



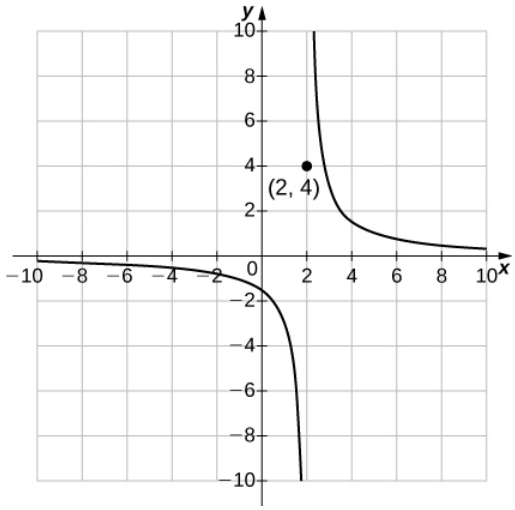
38) $h(x) = \begin{cases} x+1, & \text{if } x \le 5 \\ 4, & \text{if } x > 5 \end{cases}$; $h(0)$; $h(\pi)$; $h(5)$

39) $g(x) = \begin{cases} \dfrac{3}{x-2}, & \text{if } x \neq 2 \\ 4, & \text{if } x = 2 \end{cases}$; $g(0)$; $g(-4)$; $g(2)$

**Answer**

a. $g(0) = -\frac{3}{2}$, $g(-4) = -\frac{1}{2}$, $g(2) = 4$

b.



**In exercises 40 - 43, determine whether the statement is *true or false*. Explain why.**

40) $g(x) = \sqrt[3]{x}$ is an odd root function.

**Answer**

True; $n = 3$

41) A logarithmic function is an algebraic function.

42) A function of the form $f(x) = x^b$, where $b$ is a real valued constant, is an exponential function.

**Answer**

False; $f(x) = x^b$, where $b$ is a real-valued constant, is a power function

43) The domain of an even root function is all real numbers.

44) [Technology Required] A company purchases some computer equipment for $20,500. At the end of a 3-year period, the value of the equipment has decreased linearly to $12,301.

a. Find a function $y = V(t)$ that determines the value $V$ of the equipment at the end of $t$ years.

b. Find and interpret the meaning of the $x$- and $y$-intercepts for this situation.

c. What is the value of the equipment at the end of 5 years?

d. When will the value of the equipment be $3000?

**Answer**

a. $V(t) = -2733t + 20500$

b. $(0, 20,500)$ means that the initial purchase price of the equipment is $20,500; $(7.5, 0)$ means that in $7.5$ years the computer equipment has no value.

c. $6835

d. In approximately $6.4$ years

45) [Technology Required] Total online shopping during the Christmas holidays has increased dramatically during the past 5 years. In 2012 $(t = 0)$,total online holiday sales were $42.3 billion, whereas in 2013 they were $48.1 billion.

a. Find a linear function $S$ that estimates the total online holiday sales in the year $t$.

b. Interpret the slope of the graph of $S$.

c. Use part a. to predict the year when online shopping during Christmas will reach $60 billion.

46) [Technology Required] A family bakery makes cupcakes and sells them at local outdoor festivals. For a music festival, there is a fixed cost of $125 to set up a cupcake stand. The owner estimates that it costs $0.75 to make each cupcake. The owner is interested in determining the total cost $C$ as a function of number of cupcakes made.

a. Find a linear function that relates cost $C$ to $x$, the number of cupcakes made.

b. Find the cost to bake $160$ cupcakes.

c. If the owner sells the cupcakes for $1.50 apiece, how many cupcakes does she need to sell to start making profit? (Hint: Use the INTERSECTION function on a calculator to find this number.)

**Answer**

a. $C = 0.75x + 125$

b. $245

c. $167$ cupcakes

47) [Technology Required] A house purchased for $250,000 is expected to be worth twice its purchase price in 18 years.

a. Find a linear function that models the price $P$ of the house versus the number of years $t$ since the original purchase.

b. Interpret the slope of the graph of $P$.

c. Find the price of the house $15$ years from when it was originally purchased.

48) [Technology Required] A car was purchased for $26,000. The value of the car depreciates by $1500 per year.

a. Find a linear function that models the value $V$ of the car after $t$ years.

b. Find and interpret $V(4)$.

**Answer**

a. $V(t) = -1500t + 26,000$

b. In $4$ years, the value of the car is $20,000.

49) [Technology Required] A condominium in an upscale part of the city was purchased for $432,000. In $35$ years it is worth $60,500. Find the rate of depreciation.

50) [Technology Required] The total cost $C$ (in thousands of dollars) to produce a certain item is modeled by the function $C(x) = 10.50x + 28,500$, where $x$ is the number of items produced. Determine the cost to produce $175$ items.

**Answer**

$30,337,500

51) [Technology Required] A professor asks her class to report the amount of time $t$ they spent writing two assignments. Most students report that it takes them about $45$ minutes to type a four-page assignment and about $1.5$ hours to type a nine-page assignment.

a. Find the linear function $y = N(t)$ that models this situation, where $N$ is the number of pages typed and $t$ is the time in minutes.

b. Use part a. to determine how many pages can be typed in $2$ hours.

c. Use part a. to determine how long it takes to type a 20-page assignment.

52) [Technology Required] The output (as a percent of total capacity) of nuclear power plants in the United States can be modeled by the function $P(t) = 1.8576t + 68.052$, where $t$ is time in years and $t = 0$ corresponds to the beginning of 2000. Use the model to predict the percentage output in 2015.

**Answer**

96% of the total capacity

53) [Technology Required] The admissions office at a public university estimates that 65% of the students offered admission to the class of 2019 will actually enroll.

a. Find the linear function $y = N(x)$, where $N$ is the number of students that actually enroll and $x$ is the number of all students offered admission to the class of 2019.

b. If the university wants the 2019 freshman class size to be 1350, determine how many students should be admitted.

# 1.3: Inverse Functions

**Learning Objectives**

- Determine the conditions for when a function has an inverse.
- Use the Horizontal Line Test to recognize when a function is one-to-one.
- Find the inverse of a given function.
- Draw the graph of an inverse function.

An inverse function reverses the operation done by a particular function. In other words, whatever a function does, the inverse function undoes it. In this section, we define an inverse function formally and state the necessary conditions for an inverse function to exist. We examine how to find an inverse function and study the relationship between the graph of a function and the graph of its inverse.

## Existence of an Inverse Function

We begin with an example. Given a function $f$ and an output $y = f(x)$, we are often interested in finding what value or values $x$ were mapped to $y$ by $f$. For example, consider the function $f(x) = x^3 + 4$. Since any output $y = x^3 + 4$, we can solve this equation for $x$ to find that the input is $x = \sqrt[3]{y-4}$. This equation defines $x$ as a function of $y$. Denoting this function as $f^{-1}$, and writing $x = f^{-1}(y) = \sqrt[3]{y-4}$, we see that for any $x$ in the domain of $f$, $f^{-1}(f(x)) = f^{-1}(x^3 + 4) = x$. Thus, this new function, $f^{-1}$, "undid" what the original function $f$ did. A function with this property is called the **inverse function** of the original function.

**Definition: Inverse Functions**

Given a function $f$ with domain $D$ and range $R$, its **inverse function** (if it exists) is the function $f^{-1}$ with domain $R$ and range $D$ such that $f^{-1}(y) = x$ if and only if $f(x) = y$. In other words, for a function $f$ and its inverse $f^{-1}$,

$$f^{-1}(f(x)) = x$$

for all $x$ in $D$ and

$$f(f^{-1}(y)) = y$$

for all $y$ in $R$.

Note that $f^{-1}$ is read as "$f$ inverse." Here, the $-1$ is not used as an exponent so

$$f^{-1}(x) \neq \frac{1}{f(x)}.$$

Figure **1.3.1**shows the relationship between the domain and range of $f$ and the domain and range of $f^{-1}$.

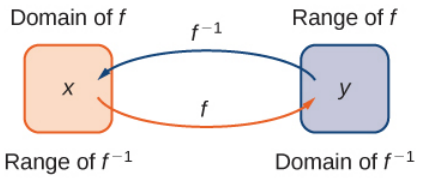

Figure **1.3.1**: Given a function $f$ and its inverse $f^{-1}$, $f^{-1}(y) = x$ if and only if $f(x) = y$. The range of $f$ becomes the domain of $f^{-1}$ and the domain of $f$ becomes the range of $f^{-1}$.

Recall that a function has exactly one output for each input. Therefore, to define an inverse function, we need to map each input to exactly one output. For example, let's try to find the inverse function for $f(x) = x^2$. Solving the equation $y = x^2$ for $x$, we arrive at the equation $x = \pm\sqrt{y}$. This equation does not describe $x$ as a function of $y$ because there are two solutions to this equation for every $y > 0$. The problem with trying to find an inverse function for $f(x) = x^2$ is that two inputs are sent to the same output for each output $y > 0$. The function $f(x) = x^3 + 4$ discussed earlier did not have this problem. For that function, each input was sent to a different output. A function that sends each input to a different output is called a **one-to-one function**.

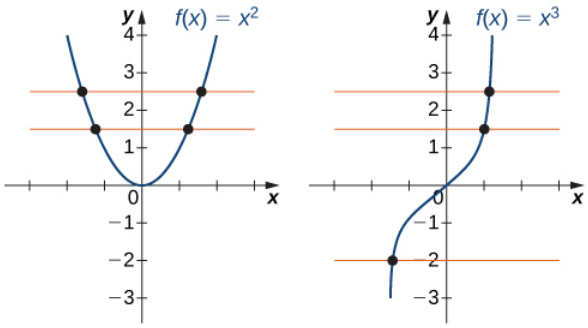
**Definition: One-to-One functions**

We say a function $f$ is a **one-to-one function** if $f(x_1) \neq f(x_2)$ when $x_1 \neq x_2$.

One way to determine whether a function is one-to-one is by looking at its graph. If a function is one-to-one, then no two inputs can be sent to the same output. Therefore, if we draw a horizontal line anywhere in the $xy$-plane, according to the **Horizontal Line Test**, it cannot intersect the graph more than once. We note that the Horizontal Line Test is different from the Vertical Line Test. The Vertical Line Test determines whether a graph is the graph of a function. The Horizontal Line Test determines whether a function is one-to-one (Figure **1.3.2**).

**Theorem 1.3.1: Horizontal Line Test**

A function $f$ is one-to-one if and only if every horizontal line intersects the graph of $f$ no more than once.



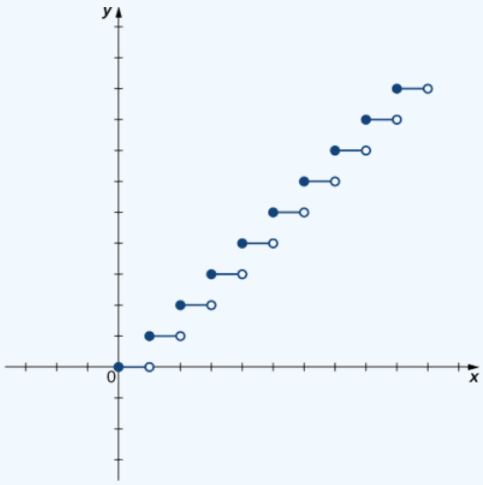
(a) (b)

Figure **1.3.2**: (a) The function $f(x) = x^2$ is not one-to-one because it fails the Horizontal Line Test. (b) The function $f(x) = x^3$ is one-to-one because it passes the Horizontal Line Test.

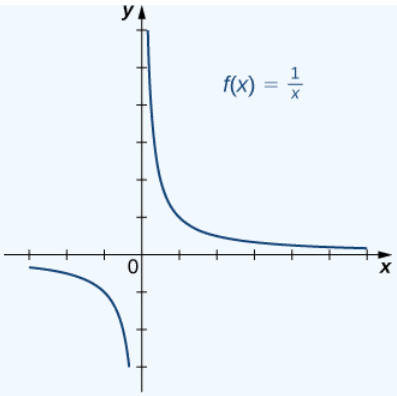
**Example 1.3.1: Determining Whether a Function Is One-to-One**

For each of the following functions, use the Horizontal Line Test to determine whether it is one-to-one.

a)

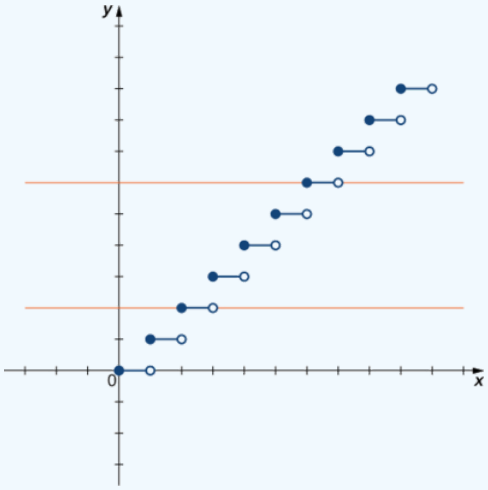


b)

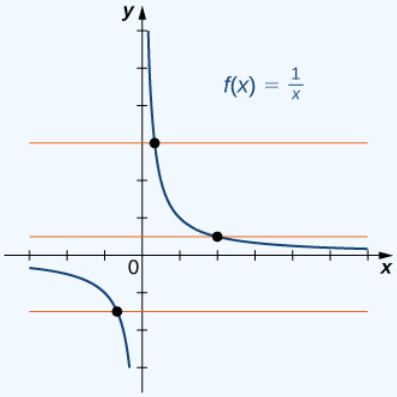


**Solution**

a) Since the horizontal line $y = n$ for any integer $n \geq 0$ intersects the graph more than once, this function is not one-to-one.

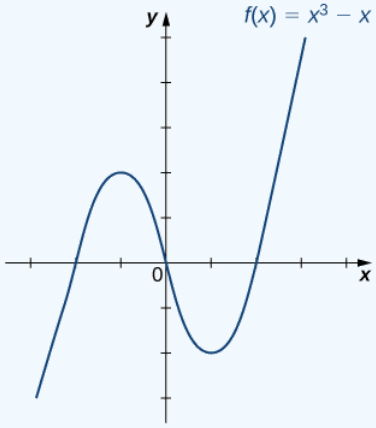


b) Since every horizontal line intersects the graph once (at most), this function is one-to-one.



**? Exercise 1.3.1**

Is the function $f$ graphed in the following image one-to-one?



**Solution**

Use the Horizontal Line Test.

**Answer**

No

## Finding the Inverse of a Function

We can now consider one-to-one functions and show how to find their inverses. Recall that a function maps elements in the domain of $f$ to elements in the range of $f$. The inverse function maps each element from the range of $f$ back to its corresponding element from the domain of $f$. Therefore, to find the inverse function of a one-to-one function $f$, given any $y$ in the range of $f$, we need to determine which $x$ in the domain of $f$ satisfies $f(x) = y$. Since $f$ is one-to-one, there is exactly one such value $x$. We can find that value $x$ by solving the equation $f(x) = y$ for $x$. Doing so, we are able to write $x$ as a function of $y$ where the domain of this function is the range of $f$ and the range of this new function is the domain of $f$. Consequently, this function is the inverse of $f$, and we write $x = f^{-1}(y)$. Since we typically use the variable $x$ to denote the independent variable and y to denote the dependent variable, we often interchange the roles of $x$ and $y$, and write $y = f^{-1}(x)$. Representing the inverse function in this way is also helpful later when we graph a function $f$ and its inverse $f^{-1}$ on the same axes.

### Example 1.3.2: Finding an Inverse Function

Find the inverse for the function $f(x) = 3x - 4$. State the domain and range of the inverse function. Verify that $f^{-1}(f(x)) = x$.

**Solution**

If $y = 3x - 4$, then $3x = y + 4$ and $x = \frac{1}{3}y + \frac{4}{3}$.

Rewrite as $y = \frac{1}{3}x + \frac{4}{3}$ and let $y = f^{-1}(x)$.Therefore, $f^{-1}(x) = \frac{1}{3}x + \frac{4}{3}$.

Since the domain of $f$ is $(-\infty, \infty)$, the range of $f^{-1}$ is $(-\infty, \infty)$. Since the range of $f$ is $(-\infty, \infty)$, the domain of $f^{-1}$ is $(-\infty, \infty)$.

You can verify that $f^{-1}(f(x)) = x$ by writing

$$f^{-1}(f(x)) = f^{-1}(3x - 4) = \frac{1}{3}(3x - 4) + \frac{4}{3} = x - \frac{4}{3} + \frac{4}{3} = x.$$

Note that for $f^{-1}(x)$ to be the inverse of $f(x)$, both $f^{-1}(f(x)) = x$ and $f(f^{-1}(x)) = x$ for all $x$ in the domain of the inside function.

### Exercise 1.3.2

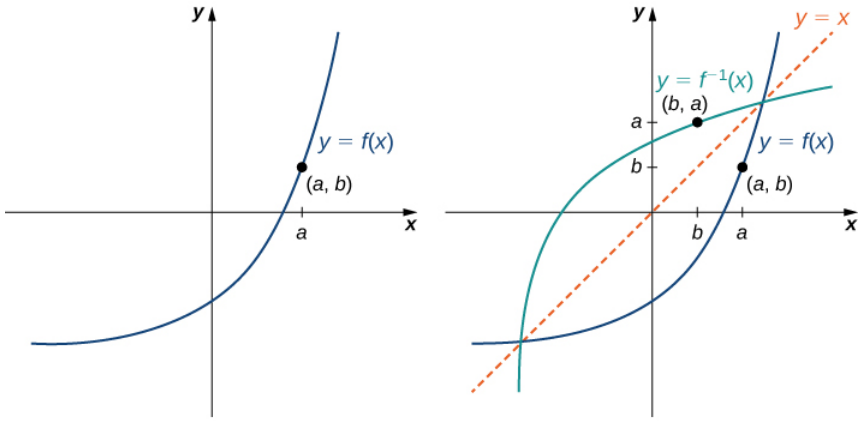
Find the inverse of the function $f(x) = 3x/(x - 2)$. State the domain and range of the inverse function.

**Answer**

$f^{-1}(x) = \dfrac{2x}{x-3}$. The domain of $f^{-1}$ is $\{x \mid x \neq 3\}$. The range of $f^{-1}$ is $\{y \mid y \neq 2\}$.

## Graphing Inverse Functions

Let's consider the relationship between the graph of a function $f$ and the graph of its inverse. Consider the graph of $f$ shown in Figure 1.3.3 and a point $(a, b)$ on the graph. Since $b = f(a)$, then $f^{-1}(b) = a$. Therefore, when we graph $f^{-1}$, the point $(b, a)$ is on the graph. As a result, the graph of $f^{-1}$ is a reflection of the graph of $f$ about the line $y = x$.

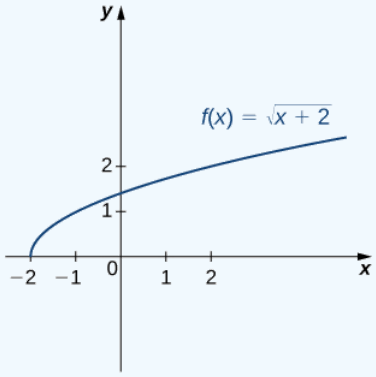


(a) (b)

Figure 1.3.3: (a) The graph of this function $f$ shows point $(a, b)$ on the graph of $f$. (b) Since $(a, b)$ is on the graph of $f$, the point $(b, a)$ is on the graph of $f^{-1}$. The graph of $f^{-1}$ is a reflection of the graph of $f$ about the line $y = x$.

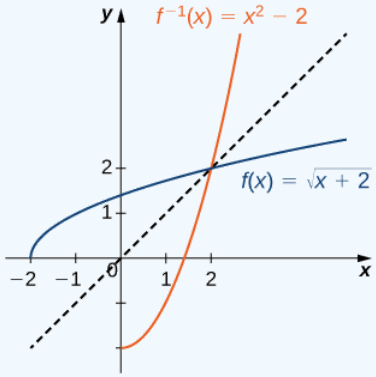
### Example 1.3.3: Sketching Graphs of Inverse Functions

For the graph of $f$ in the following image, sketch a graph of $f^{-1}$ by sketching the line $y = x$ and using symmetry. Identify the domain and range of $f^{-1}$.



**Solution**

Reflect the graph about the line $y = x$. The domain of $f^{-1}$ is $[0, \infty)$. The range of $f^{-1}$ is $[-2, \infty)$. By using the preceding strategy for finding inverse functions, we can verify that the inverse function is $f^{-1}(x) = x^2 - 2$, as shown in the graph.



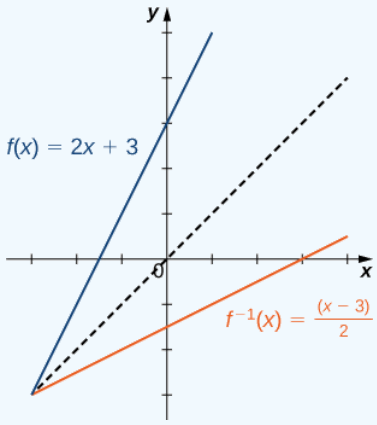
**? Exercise 1.3.3**

Sketch the graph of $f(x) = 2x + 3$ and the graph of its inverse using the symmetry property of inverse functions.

**Hint**

The graphs are symmetric about the line $y = x$

**Answer**



## Restricting Domains

As we have seen, $f(x) = x^2$ does not have an inverse function because it is not one-to-one. However, we can choose a subset of the domain of $f$ such that the function is one-to-one. This subset is called a **restricted domain**. By restricting the domain of $f$, we can define a new function $g$ such that the domain of $g$ is the restricted domain of $f$ and $g(x) = f(x)$ for all $x$ in the domain of $g$. Then we can define an inverse function for $g$ on that domain. For example, since $f(x) = x^2$ is one-to-one on the interval $[0, \infty)$, we can define a new function $g$ such that the domain of $g$ is $[0, \infty)$ and $g(x) = x^2$ for all $x$ in its domain. Since $g$ is a one-to-one function, it has an inverse function, given by the formula $g^{-1}(x) = \sqrt{x}$. On the other hand, the function $f(x) = x^2$ is also one-to-one on the domain $(-\infty, 0]$. Therefore, we could also define a new function $h$ such that the domain of $h$ is $(-\infty, 0]$ and $h(x) = x^2$ for all $x$ in the domain of $h$. Then $h$ is a one-to-one function and must also have an inverse. Its inverse is given by the formula $h^{-1}(x) = -\sqrt{x}$ (Figure 1.3.4).

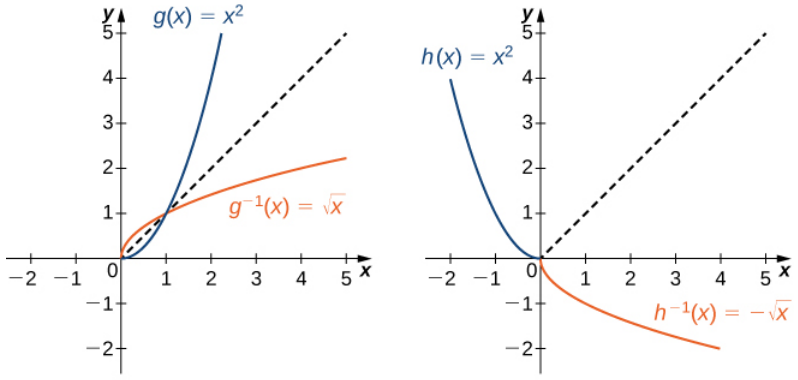


Figure **1.3.4**: (a) For $g(x) = x^2$ restricted to $[0, \infty)$, $g^{-1}(x) = \sqrt{x}$. (b) For $h(x) = x^2$ restricted to $(-\infty, 0]$, $h^{-1}(x) = -\sqrt{x}$.

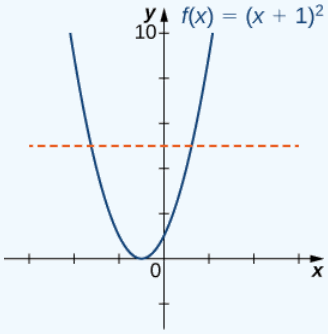
## Example 1.3.4: Restricting the Domain

Consider the function $f(x) = (x + 1)^2$.

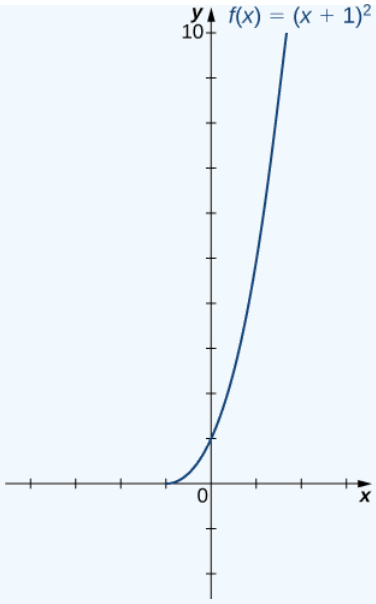
a. Sketch the graph of $f$ and use the Horizontal Line Test to show that $f$ is not one-to-one.
b. Show that $f$ is one-to-one on the restricted domain $[-1, \infty)$. Determine the domain and range for the inverse of $f$ on this restricted domain and find a formula for $f^{-1}$.

### Solution

a) The graph of $f$ is the graph of $y = x^2$ shifted left $1$ unit. Since there exists a horizontal line intersecting the graph more than once, $f$ is not one-to-one.



b) On the interval $[-1, \infty)$, $f$ is one-to-one.



The domain and range of $f^{-1}$ are given by the range and domain of $f$, respectively. Therefore, the domain of $f^{-1}$ is $[0, \infty)$ and the range of $f^{-1}$ is $[-1, \infty)$. To find a formula for $f^{-1}$, solve the equation $y = (x+1)^2$ for $x$. If $y = (x+1)^2$, then $x = -1 \pm \sqrt{y}$. Since we are restricting the domain to the interval where $x \geq -1$, we need $\pm\sqrt{y} \geq 0$. Therefore, $x = -1 + \sqrt{y}$. Interchanging $x$ and $y$, we write $y = -1 + \sqrt{x}$ and conclude that $f^{-1}(x) = -1 + \sqrt{x}$.

### ? Exercise 1.3.4

Consider $f(x) = 1/x^2$ restricted to the domain $(-\infty, 0)$. Verify that $f$ is one-to-one on this domain. Determine the domain and range of the inverse of $f$ and find a formula for $f^{-1}$.

**Hint**

The domain and range of $f^{-1}$ is given by the range and domain of $f$, respectively. To find $f^{-1}$, solve $y = 1/x^2$ for $x$.

**Answer**

The domain of $f^{-1}$ is $(0, \infty)$. The range of $f^{-1}$ is $(-\infty, 0)$. The inverse function is given by the formula $f^{-1}(x) = -1/\sqrt{x}$.

## Key Concepts

- For a function to have an inverse, the function must be one-to-one. Given the graph of a function, we can determine whether the function is one-to-one by using the Horizontal Line Test.
- If a function is not one-to-one, we can restrict the domain to a smaller domain where the function is one-to-one and then define the inverse of the function on the smaller domain.
- For a function $f$ and its inverse $f^{-1}$, $f(f^{-1}(x)) = x$ for all $x$ in the domain of $f^{-1}$ and $f^{-1}(f(x)) = x$ for all $x$ in the domain of $f$.
- The graph of a function $f$ and its inverse $f^{-1}$ are symmetric about the line $y = x$.

## Key Equations

- **Inverse function**

  $f^{-1}(f(x)) = x$ for all $x$ in $D$, and $f(f^{-1}(y)) = y$ for all $y$ in $R$.

## Glossary

**Horizontal Line Test**

a function $f$ is one-to-one if and only if every horizontal line intersects the graph of $f$, at most, once

**inverse function**

for a function $f$, the inverse function $f^{-1}$ satisfies $f^{-1}(y) = x$ if $f(x) = y$

**one-to-one function**

a function $f$ is one-to-one if $f(x_1) \neq f(x_2)$ if $x_1 \neq x_2$

**restricted domain**

a subset of the domain of a function $f$

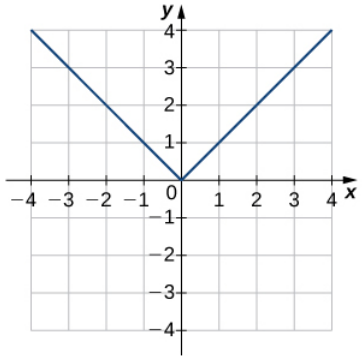
# 1.3E: Exercises

**In exercises 1 - 6, use the horizontal line test to determine whether each of the given graphs is one-to-one.**

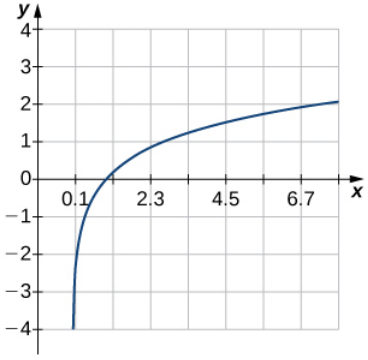
1)



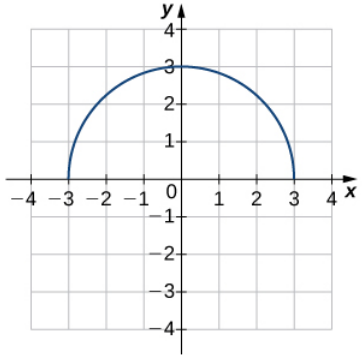
**Answer**

Not one-to-one

2)



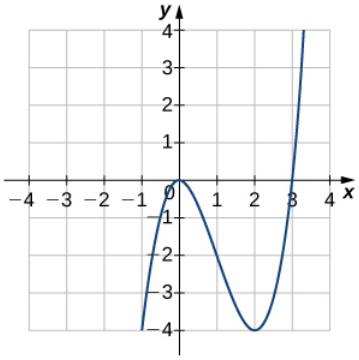
3)



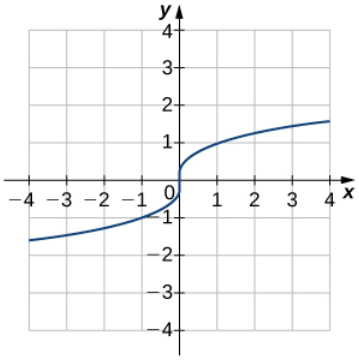
**Answer**

Not one-to-one

4)



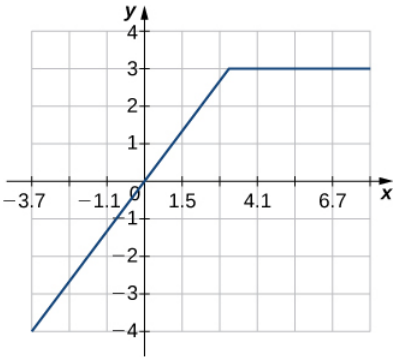
5)



**Answer**

One-to-one

6)



**In exercises 7 - 12,**

**a. find the inverse function, and**

**b. find the domain and range of the inverse function.**

7) $f(x) = x^2 - 4, \quad x \geq 0$

**Answer**

a. $f^{-1}(x) = \sqrt{x+4}$

b. Domain: $x \geq -4$, Range: $y \geq 0$

8) $f(x) = \sqrt[3]{x-4}$

9) $f(x) = x^3 + 1$

**Answer**

a. $f^{-1}(x) = \sqrt[3]{x-1}$

b. Domain: all real numbers, Range: all real numbers

10) $f(x) = (x-1)^2, \quad x \leq 1$

11) $f(x) = \sqrt{x-1}$

**Answer**

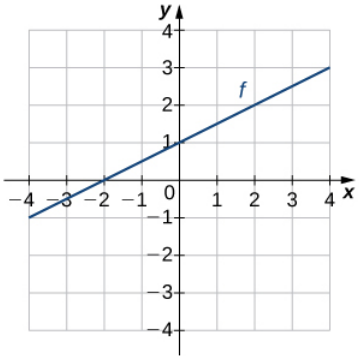
a. $f^{-1}(x) = x^2 + 1$,

b. Domain: $x \geq 0$, Range: $y \geq 1$

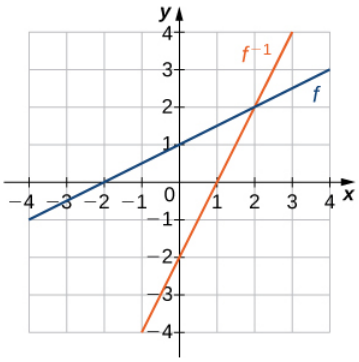
12) $f(x) = \dfrac{1}{x+2}$

**In exercises 13 - 16, use the graph of $f$ to sketch the graph of its inverse function.**

13)

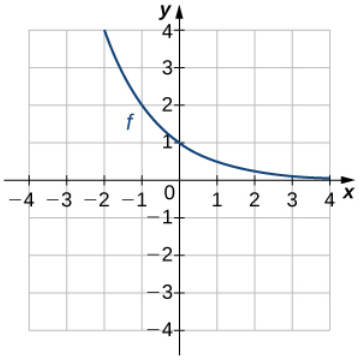


**Answer**

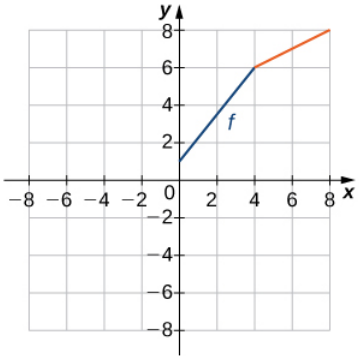


14)

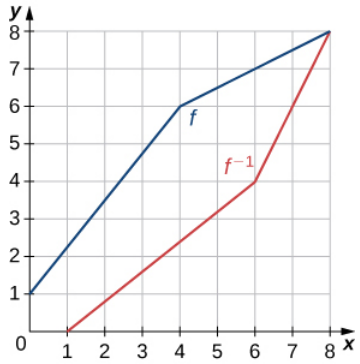
https://math.libretexts.org/@go/page/171825



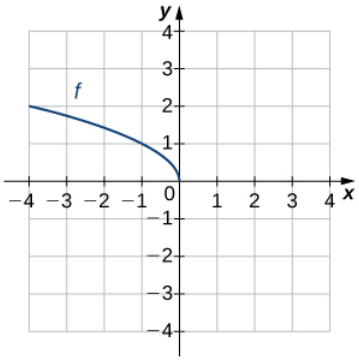
15)



**Answer**



16)



**In exercises 17 - 24, use composition to determine which pairs of functions are inverses.**

17) $f(x) = 8x, \quad g(x) = \frac{x}{8}$

**Answer**

These are inverses.

18) $f(x) = 8x + 3, \quad g(x) = \frac{x - 3}{8}$

19) $f(x) = 5x - 7, \quad g(x) = \frac{x + 5}{7}$

**Answer**

These are not inverses.

20) $f(x) = \frac{2}{3}x + 2, \quad g(x) = \frac{3}{2}x + 3$

21) $f(x) = \frac{1}{x - 1},\ x \neq 1, \quad g(x) = \frac{1}{x} + 1,\ x \neq 0$

**Answer**

These are inverses.

22) $f(x) = x^3 + 1, \quad g(x) = (x - 1)^{1/3}$

23) $f(x) = x^2 + 2x + 1,\ x \geq -1, \quad g(x) = -1 + \sqrt{x},\ x \geq 0$

**Answer**

These are inverses.

24) $f(x) = \sqrt{4 - x^2},\ 0 \leq x \leq 2, \quad g(x) = \sqrt{4 - x^2},\ 0 \leq x \leq 2$

25) The function $C = T(F) = (5/9)(F - 32)$ converts degrees Fahrenheit to degrees Celsius.

a) Find the inverse function $F = T^{-1}(C)$

b) What is the inverse function used for?

26) [Technology Required] The velocity $V$ (in centimeters per second) of blood in an artery at a distance $x$ cm from the center of the artery can be modeled by the function $V = f(x) = 500(0.04 - x^2)$ for $0 \leq x \leq 0.2$.

a) Find $x = f^{-1}(V)$.

b) Interpret what the inverse function is used for.

c) Find the distance from the center of an artery with a velocity of 15 cm/sec, 10 cm/sec, and 5 cm/sec.

**Answer**

a. $x = f^{-1}(V) = \sqrt{0.04 - \frac{V}{500}}$

b. The inverse function determines the distance from the center of the artery at which blood is flowing with velocity $V$.

c. 0.1 cm; 0.14 cm; 0.17 cm

27) A function that converts dress sizes in the United States to those in Europe is given by $D(x) = 2x + 24$.

a) Find the European dress sizes that correspond to sizes 6, 8, 10, and 12 in the United States.

b) Find the function that converts European dress sizes to U.S. dress sizes.

c) Use part b. to find the dress sizes in the United States that correspond to 46, 52, 62, and 70.

28) [Technology Required] The cost to remove a toxin from a lake is modeled by the function $C(p) = \frac{75p}{85 - p}$, where $C$ is the cost (in thousands of dollars) and $p$ is the amount of toxin in a small lake (measured in parts per billion [ppb]). This model is valid only when the amount of toxin is less than 85 ppb.

a) Find the cost to remove 25 ppb, 40 ppb, and 50 ppb of the toxin from the lake.

b) Find the inverse function.

c) Use part b. to determine how much of the toxin is removed for $50,000.

**Answer**

a. $31,250, $66,667, $107,143

b. $p = \frac{85C}{C+75}$

c. 34 ppb

29) [Technology Required] A race car is accelerating at a velocity given by $v(t) = \frac{25}{4}t + 54$,

where $v$ is the velocity (in feet per second) at time $t$.

a) Find the velocity of the car at 10 sec.

b) Find the inverse function.

c) Use part b. to determine how long it takes for the car to reach a speed of 150 ft/sec.

# 1.4: Exponential and Logarithmic Functions

**Learning Objectives**

- Explain the difference between algebraic and transcendental functions.
- Identify the form of an exponential function.
- Explain the difference between the graphs of $x^b$ and $b^x$.
- Recognize the significance of the number $e$.
- Identify the form of a logarithmic function.
- Explain the relationship between exponential and logarithmic functions.
- Describe how to calculate a logarithm to a different base.

In this section we examine exponential and logarithmic functions. We use the properties of these functions to solve equations involving exponential or logarithmic terms, and we study the meaning and importance of the number $e$.

## Transcendental Functions

Thus far, we have discussed algebraic functions. Some functions, however, cannot be described by basic algebraic operations. These functions are known as **transcendental functions** because they are said to "transcend," or go beyond, algebra. The most common transcendental functions are trigonometric, exponential, and logarithmic functions. A trigonometric function relates the ratios of two sides of a right triangle. They are $\sin x, \cos x, \tan x, \cot x, \sec x,$ and $\csc x$. (We discuss trigonometric functions later in the chapter.) An exponential function is a function of the form $f(x) = b^x$, where the base $b > 0$, $b \neq 1$. A logarithmic function is a function of the form $f(x) = \log_b(x)$ for some constant $b > 0$, $b \neq 1$, where $\log_b(x) = y$ if and only if $b^y = x$.

**Example 1.4.1: Classifying Algebraic and Transcendental Functions**

Classify each of the following functions, a. through c., as algebraic or transcendental.

a. $f(x) = \dfrac{\sqrt{x^3+1}}{4x+2}$
b. $f(x) = 2^{x^2}$
c. $f(x) = \sin(2x)$

**Solution**

a. Since this function involves basic algebraic operations only, it is an algebraic function.
b. This function cannot be written as a formula that involves only basic algebraic operations, so it is transcendental. (Note that algebraic functions can only have powers that are rational numbers.)
c. As in part b, this function cannot be written using a formula involving basic algebraic operations only; therefore, this function is transcendental.

**Exercise 1.4.1:**

Is $f(x) = x/2$ an algebraic or a transcendental function?

**Answer**

Algebraic

## Exponential Functions

Exponential functions arise in many applications. One common example is **population growth.** For example, if a population starts with $P_0$ individuals and then grows at an annual rate of $2\%$, its population after 1 year is

$$P(1) = P_0 + 0.02P_0 = P_0(1 + 0.02) = P_0(1.02).$$

Its population after 2 years is

$$P(2) = P(1) + 0.02P(1) = P(1)(1.02) = P_0(1.02)^2.$$

In general, its population after $t$ years is

$$P(t) = P_0(1.02)^t,$$

which is an exponential function. More generally, any function of the form $f(x) = b^x$, where $b > 0$, $b \neq 1$, is an exponential function with **base** $b$ and **exponent** $x$. Exponential functions have constant bases and variable exponents. Note that a function of the form $f(x) = x^b$ for some constant $b$ is *not* an exponential function but a *power* function.

To see the difference between an exponential function and a power function, we compare the functions $y = x^2$ and $y = 2^x$. In Table 1.4.1, we see that both $2^x$ and $x^2$ approach infinity as $x \to \infty$. Eventually, however, $2^x$ becomes larger than $x^2$ and grows more rapidly as $x \to \infty$. In the opposite direction, as $x \to -\infty$, $x^2 \to \infty$, whereas $2^x \to 0$. The line $y = 0$ is a horizontal asymptote for $y = 2^x$.

Table 1.4.1

| $x$ | -3 | -2 | -1 | 0 | 1 | 2 | 3 | 4 | 5 | 6 |
|---|---|---|---|---|---|---|---|---|---|---|
| $x^2$ | 9 | 4 | 1 | 0 | 1 | 4 | 9 | 16 | 25 | 36 |
| $2^x$ | 1/8 | 1/4 | 1/2 | 1 | 2 | 4 | 8 | 16 | 32 | 64 |

In Figure 1.4.1, we graph both $y = x^2$ and $y = 2^x$ to show how the graphs differ.

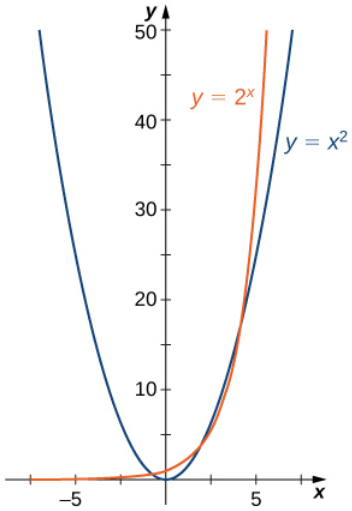

Figure 1.4.1: Both $2^x$ and $x^2$ approach infinity as $x \to \infty$, but $2^x$ grows more rapidly than $x^2$. As $x \to -\infty$, $x^2 \to \infty$, whereas $2^x \to 0$.

## Evaluating Exponential Functions

Recall the properties of exponents: If $x$ is a positive integer, then we define $b^x = b \cdot b \cdots b$ (with $x$ factors of $b$). If $x$ is a negative integer, then $x = -y$ for some positive integer $y$, and we define $b^x = b^{-y} = 1/b^y$. Also, $b^0$ is defined to be 1. If $x$ is a rational number, then $x = p/q$, where $p$ and $q$ are integers and $b^x = b^{p/q} = \sqrt[q]{b^p}$. For example, $9^{3/2} = \sqrt{9^3} = \left(\sqrt{9}\right)^3 = 27$. However, how is $b^x$ defined if $x$ is an irrational number? For example, what do we mean by $2^{\sqrt{2}}$? This is too complex a question for us to answer fully right now; however, we can make an approximation.

Table 1.4.2: Values of $2^x$ for a List of Rational Numbers Approximating $\sqrt{2}$

| $x$ | 1.4 | 1.41 | 1.414 | 1.4142 | 1.41421 | 1.414213 |
|---|---|---|---|---|---|---|
| $2^x$ | 2.639 | 2.65737 | 2.66475 | 2.665119 | 2.665138 | 2.665143 |

In Table 1.4.2, we list some rational numbers approaching $\sqrt{2}$, and the values of $2^x$ for each rational number $x$ are presented as well. We claim that if we choose rational numbers $x$ getting closer and closer to $\sqrt{2}$, the values of $2^x$ get closer and closer to some number $L$. We define that number $L$ to be $2^{\sqrt{2}}$.

It's often strange for students when they first encounter this conversation that $b^x$ has never been defined for them for irrational values of $x$; however, there was no need for such discussion until calculus. For example, up to this point in your mathematical career, you needed to compute values like

$$2^{10}, 2^{-2}, \text{ and } 8^{4/3}.$$

However, do you recall the need to compute $2^\pi$?

### Example 1.4.2: Bacterial Growth

Suppose a particular population of bacteria is known to double in size every 4 hours. If a culture starts with 1000 bacteria, the number of bacteria after 4 hours is $n(4) = 1000 \cdot 2$. The number of bacteria after 8 hours is $n(8) = n(4) \cdot 2 = 1000 \cdot 2^2$. In general, the number of bacteria after $4m$ hours is $n(4m) = 1000 \cdot 2^m$. Letting $t = 4m$, we see that the number of bacteria after t hours is $n(t) = 1000 \cdot 2^{t/4}$. Find the number of bacteria after 6 hours, 10 hours, and 24 hours.

**Solution**

The number of bacteria after 6 hours is given by

$$n(6) = 1000 \cdot 2^{6/4} \approx 2828 \text{ bacteria.}$$

The number of bacteria after 10 hours is given by

$$n(10) = 1000 \cdot 2^{10/4} \approx 5657 \text{ bacteria.}$$

The number of bacteria after 24 hours is given by $n(24) = 1000 \cdot 2^6 = 64,000$ bacteria.

### Exercise 1.4.2

Given the exponential function $f(x) = 100 \cdot 3^{x/2}$, evaluate $f(4)$ and $f(10)$.

**Answer**

$f(4) = 900$

$f(10) = 24,300.$

## Graphing Exponential Functions

For any base $b > 0$, $b \neq 1$, the exponential function $f(x) = b^x$ is defined for all real numbers $x$ and $b^x > 0$. Therefore, the domain of $f(x) = b^x$ is $(-\infty, \infty)$ and the range is $(0, \infty)$. To graph $b^x$, we note that for $b > 1$, $b^x$ is increasing on $(-\infty, \infty)$ and $b^x \to \infty$ as $x \to \infty$, whereas $b^x \to 0$ as $x \to -\infty$. On the other hand, if $0 < b < 1$, $f(x) = b^x$ is decreasing on $(-\infty, \infty)$ and $b^x \to 0$ as $x \to \infty$ whereas $b^x \to \infty$ as $x \to -\infty$ (Figure 1.4.2).

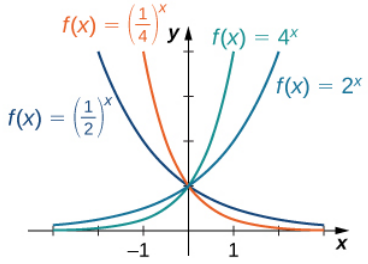

Figure 1.4.2: If $b > 1$, then $b^x$ is increasing on $(-\infty, \infty)$. If $0 < b < 1$, then $b^x$ is decreasing on $(-\infty, \infty)$.

Note that exponential functions satisfy the general Laws of Exponents. To remind you of these laws, we state them as rules.

**Theorem 1.4.1: Laws of Exponents**

For any constants $a > 0$, $b > 0$, and for all $x$ and $y$,

1. $b^x \cdot b^y = b^{x+y}$
2. $\frac{b^x}{b^y} = b^{x-y}$
3. $(b^x)^y = b^{xy}$
4. $(ab)^x = a^x b^x$
5. $\frac{a^x}{b^x} = \left(\frac{a}{b}\right)^x$

**Example 1.4.3: Using the Laws of Exponents**

Use the Laws of Exponents to simplify each of the following expressions.

a. $\frac{(2x^{2/3})^3}{(4x^{-1/3})^2}$

b. $\frac{(x^3y^{-1})^2}{(xy^2)^{-2}}$

**Soution**

a. We can simplify as follows:

$$\frac{(2x^{2/3})^3}{(4x^{-1/3})^2} = \frac{2^3(x^{2/3})^3}{4^2(x^{-1/3})^2} = \frac{8x^2}{16x^{-2/3}} = \frac{x^2x^{2/3}}{2} = \frac{x^{8/3}}{2}.$$

b. We can simplify as follows:

$$\frac{(x^3y^{-1})^2}{(xy^2)^{-2}} = \frac{(x^3)^2(y^{-1})^2}{x^{-2}(y^2)^{-2}} = \frac{x^6y^{-2}}{x^{-2}y^{-4}} = x^6x^2y^{-2}y^4 = x^8y^2.$$

**Exercise 1.4.3**

Use the Laws of Exponents to simplify $\frac{6x^{-3}y^2}{12x^{-4}y^5}$.

**Hint**

$x^a/x^b = x^{a-b}$

**Answer**

$x/(2y^3)$

## The Number e

A special type of exponential function appears frequently in applications related to STEM fields. To describe it, consider the following example of exponential growth, which arises from **compounding interest** in a savings account. Suppose a person invests $P$ dollars in a savings account with an annual interest rate $r$, compounded annually. The amount of money after 1 year is

$$A(1) = P + rP = P(1 + r).$$

The amount of money after $2$ years is

$$A(2) = A(1) + rA(1) = P(1 + r) + rP(1 + r) = P(1 + r)^2.$$

More generally, the amount after $t$ years is

$$A(t) = P(1+r)^t.$$

If the money is compounded 2 times per year, the amount of money after half a year is

$$A\left(\frac{1}{2}\right) = P + \left(\frac{r}{2}\right)P = P\left(1+\left(\frac{r}{2}\right)\right).$$

The amount of money after 1 year is

$$A(1) = A\left(\frac{1}{2}\right) + \left(\frac{r}{2}\right)A\left(\frac{1}{2}\right) = P\left(1+\frac{r}{2}\right) + \frac{r}{2}\left(\left(P(1+\frac{r}{2}\right)\right) = P\left(1+\frac{r}{2}\right)^2.$$

After $t$ years, the amount of money in the account is

$$A(t) = P\left(1+\frac{r}{2}\right)^{2t}.$$

More generally, if the money is compounded $n$ times per year, the amount of money in the account after $t$ years is given by the function

$$A(t) = P\left(1+\frac{r}{n}\right)^{nt}.$$

What happens as $n \to \infty$? To answer this question, we let $m = n/r$ and write

$$\left(1+\frac{r}{n}\right)^{nt} = \left(1+\frac{1}{m}\right)^{mrt},$$

and examine the behavior of $(1+1/m)^m$ as $m \to \infty$, using a table of values (Table 1.4.3).

Table 1.4.3: Values of $\left(1+\frac{1}{m}\right)^m$ as $m \to \infty$

| $m$ | 10 | 100 | 1000 | 10,000 | 100,000 | 1,000,000 |
|---|---|---|---|---|---|---|
| $\left(1+\frac{1}{m}\right)^m$ | 2.5937 | 2.7048 | 2.71692 | 2.71815 | 2.718268 | 2.718280 |

Looking at this table, it appears that $(1+1/m)^m$ is approaching a number between 2.7 and 2.8 as $m \to \infty$. In fact, $(1+1/m)^m$ does approach some number as $m \to \infty$. We call this number $e$. To six decimal places of accuracy,

$$e \approx 2.718282.$$

**Leonhard Euler**

The letter $e$ was first used to represent this number by the Swiss mathematician Leonhard Euler during the 1720s. Although Euler did not discover the number, he showed many important connections between $e$ and logarithmic functions. We still use the notation $e$ today to honor Euler's work because it appears in many areas of mathematics and because we can use it in many practical applications.

Returning to our savings account example, we can conclude that if a person puts $P$ dollars in an account at an annual interest rate $r$, compounded continuously, then $A(t) = Pe^{rt}$. This function may be familiar. Since functions involving base $e$ arise often in applications, we call the function $f(x) = e^x$ the **natural exponential function**. Not only is this function interesting because of the definition of the number $e$, but also, as discussed next, its graph has an important property.

Since $e > 1$, we know $f(x) = e^x$ is increasing on $(-\infty, \infty)$. In Figure 1.4.3, we show a graph of $f(x) = e^x$ along with a **tangent line** to the graph of $f$ at $x = 0$. We give a precise definition of tangent line in the next chapter; but, informally, we say a tangent line to a graph of $f$ at $x = a$ is a line that passes through the point $(a, f(a))$ and has the same "slope" as $f$ at that point (as we will learn, using the word "slope" for a nonlinear curve is generally frowned upon, but it will have to suffice for now). The function $f(x) = e^x$ is the only exponential function $b^x$ with tangent line at $x = 0$ that has a slope of 1. As we see later in the text, having this property makes the natural exponential function the most simple exponential function to use in many instances.

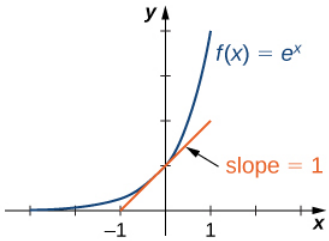

Figure 1.4.3: The graph of $f(x) = e^x$ has a tangent line with slope 1 at $x = 0$.

### Example 1.4.4: Compounding Interest

Suppose $500 is invested in an account at an annual interest rate of $r = 5.5\%$, compounded continuously.

a. Let $t$ denote the number of years after the initial investment and $A(t)$ denote the amount of money in the account at time $t$. Find a formula for $A(t)$.
b. Find the amount of money in the account after 10 years and after 20 years.

**Solution**

a. If $P$ dollars are invested in an account at an annual interest rate $r$, compounded continuously, then $A(t) = Pe^{rt}$. Here $P = \$500$ and $r = 0.055$. Therefore, $A(t) = 500e^{0.055t}$.

b. After 10 years, the amount of money in the account is

$$A(10) = 500e^{0.055 \cdot 10} = 500e^{0.55} \approx \$866.63.$$

After 20 years, the amount of money in the account is

$$A(20) = 500e^{0.055 \cdot 20} = 500e^{1.1} \approx \$1,502.08.$$

### Exercise 1.4.4

If $750 is invested in an account at an annual interest rate of 4%, compounded continuously, find a formula for the amount of money in the account after $t$ years. Find the amount of money after 30 years.

**Hint**

$A(t) = Pe^{rt}$

**Answer**

$A(t) = 750e^{0.04t}$. After 30 years, there will be approximately $\$2,490.09$.

## Logarithmic Functions

Using our understanding of exponential functions, we can discuss their inverses, which are the logarithmic functions. These come in handy when we need to consider any phenomenon that varies over a wide range of values, such as the pH scale in chemistry or decibels in sound levels.

The exponential function $f(x) = b^x$ is one-to-one, with domain $(-\infty, \infty)$ and range $(0, \infty)$. Therefore, it has an inverse function, called the **logarithmic function** with base $b$. For any $b > 0$, $b \neq 1$, the logarithmic function with base $b$, denoted $\log_b$, has domain $(0, \infty)$ and range $(-\infty, \infty)$,and satisfies

$$\log_b(x) = y$$

if and only if $b^y = x$.

For example,

$$\log_2(8) = 3$$

since $2^3 = 8$,

$$\log_{10}\left(\frac{1}{100}\right) = -2$$

since $10^{-2} = \frac{1}{10^2} = \frac{1}{100}$,

$$\log_b(1) = 0$$

since $b^0 = 1$ for any base $b > 0$.

Furthermore, since $y = \log_b(x)$ and $y = b^x$ are inverse functions,

$$\log_b(b^x) = x$$

and

$$b^{\log_b(x)} = x.$$

The most commonly used logarithmic function is the function $\log_e$. Since this function uses natural $e$ as its base, it is called the **natural logarithm**. Here we use the notation $\ln(x)$ or $\ln x$ to mean $\log_e(x)$. For example,

$$\ln(e) = \log_e(e) = 1$$
$$\ln(e^3) = \log_e(e^3) = 3$$
$$\ln(1) = \log_e(1) = 0.$$

Since the functions $f(x) = e^x$ and $g(x) = \ln(x)$ are inverses of each other,

$$\ln(e^x) = x \text{ and } e^{\ln x} = x,$$

and their graphs are symmetric about the line $y = x$ (Figure 1.4.4).

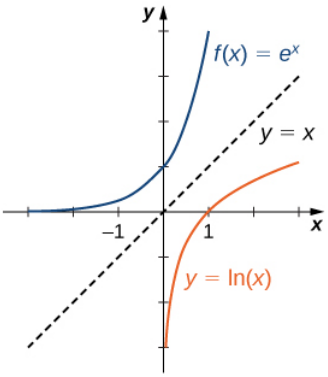

Figure 1.4.4: The functions $y = e^x$ and $y = \ln(x)$ are inverses of each other, so their graphs are symmetric about the line $y = x$.

In general, for any base $b > 0$, $b \neq 1$, the function $g(x) = \log_b(x)$ is symmetric about the line $y = x$ with the function $f(x) = b^x$. Using this fact and the graphs of the exponential functions, we graph functions $\log_b$ for several values of $b > 1$ ( Figure 1.4.5).

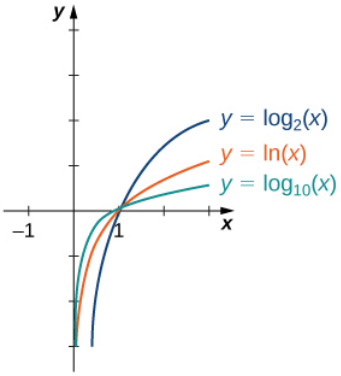

Figure 1.4.5: Graphs of $y = \log_b(x)$ are depicted for $b = 2, e, 10$.

Before solving some equations involving exponential and logarithmic functions, let's review the basic properties of logarithms.

### Theorem 1.4.2: Laws of Logarithms

If $a, b, c > 0$, $b \neq 1$, and $r$ is any real number, then

- **Product property**

$$\log_b(ac) = \log_b(a) + \log_b(c) \tag{1.4.1}$$

- **Quotient property**

$$\log_b\left(\frac{a}{c}\right) = \log_b(a) - \log_b(c) \tag{1.4.2}$$

- **Power property**

$$\log_b(a^r) = r\log_b(a) \tag{1.4.3}$$

### Example 1.4.5: Solving Equations Involving Exponential Functions

Solve each of the following equations for $x$.

a. $5^x = 2$

b. $e^x + 6e^{-x} = 5$

#### Solution

a. Applying the natural logarithm function to both sides of the equation, we have

$$\ln 5^x = \ln 2.$$

Using the power property of logarithms,

$$x \ln 5 = \ln 2.$$

Therefore,

$$x = \frac{\ln 2}{\ln 5}.$$

b. Multiplying both sides of the equation by $e^x$,we arrive at the equation

$$e^{2x} + 6 = 5e^x.$$

Rewriting this equation as

$$e^{2x} - 5e^x + 6 = 0,$$

we can then rewrite it as a quadratic equation in $e^x$:

$$(e^x)^2 - 5(e^x) + 6 = 0.$$

Now we can solve the quadratic equation. Factoring this equation, we obtain

$$(e^x - 3)(e^x - 2) = 0.$$

Therefore, the solutions satisfy $e^x = 3$ and $e^x = 2$. Taking the natural logarithm of both sides gives us the solutions $x = \ln 3, \ln 2$.

### Exercise 1.4.5

Solve

$$e^{2x}/(3 + e^{2x}) = 1/2.$$

**Hint**

First solve the equation for $e^{2x}$

**Answer**

$x = \dfrac{\ln 3}{2}$.

### Example 1.4.6: Solving Equations Involving Logarithmic Functions

Solve each of the following equations for $x$.

a. $\ln\left(\dfrac{1}{x}\right) = 4$

b. $\log_{10}\sqrt{x} + \log_{10} x = 2$

c. $\ln(2x) - 3\ln(x^2) = 0$

**Solution**

a. By the definition of the natural logarithm function,

$$\ln\left(\frac{1}{x}\right) = 4$$

if and only if $e^4 = \dfrac{1}{x}$.

Therefore, the solution is $x = 1/e^4$.

b. Using the product (Equation 1.4.1) and power (Equation 1.4.3) properties of logarithmic functions, rewrite the left-hand side of the equation as

$$\begin{aligned}\log_{10}\sqrt{x} + \log_{10} x &= \log_{10} x\sqrt{x} \\ &= \log_{10} x^{3/2} \\ &= \frac{3}{2}\log_{10} x.\end{aligned}$$

Therefore, the equation can be rewritten as

$$\frac{3}{2}\log_{10} x = 2$$

or

$$\log_{10} x = \frac{4}{3}.$$

The solution is $x = 10^{4/3} = 10\sqrt[3]{10}$.

c. Using the power property (Equation 1.4.3) of logarithmic functions, we can rewrite the equation as $\ln(2x) - \ln(x^6) = 0$.

Using the quotient property (Equation 1.4.2), this becomes

$$\ln\left(\frac{2}{x^5}\right) = 0$$

Therefore, $2/x^5 = 1$, which implies $x = \sqrt[5]{2}$. We should then check for any extraneous solutions.

### Exercise 1.4.6

Solve $\ln(x^3) - 4\ln(x) = 1$.

**Hint**

First use the power property, then use the product property of logarithms.

**Answer**

$x = \dfrac{1}{e}$

When evaluating a logarithmic function with a calculator, you may have noticed that the only options are $\log_{10}$ or $\log$, called the **common logarithm**, or $\ln$, which is the natural logarithm. However, exponential functions and logarithm functions can be expressed in terms of any desired base $b$. If you need to use a calculator to evaluate an expression with a different base, you can apply the **Change of Base Formulas** first. Using this change of base, we typically write a given exponential or logarithmic function in terms of the natural exponential and natural logarithmic functions.

### Theorem 1.4.3: Change of Base Formula

Let $a > 0$, $b > 0$, and $a \neq 1$, $b \neq 1$.

1. $a^x = b^{x \log_b a}$ for any real number $x$.

   If $b = e$, this equation reduces to $a^x = e^{x \log_e a} = e^{x \ln a}$.

2. $\log_a x = \dfrac{\log_b x}{\log_b a}$ for any real number $x > 0$.

   If $b = e$, this equation reduces to $\log_a x = \dfrac{\ln x}{\ln a}$.

**Proof**

For the first Change of Base Formula, we begin by making use of the power property of logarithmic functions. We know that for any base $b > 0$, $b \neq 1$, $\log_b(a^x) = x \log_b a$. Therefore,

$$b^{\log_b(a^x)} = b^{x \log_b a}.$$

In addition, we know that $b^x$ and $\log_b(x)$ are inverse functions. Therefore,

$$b^{\log_b(a^x)} = a^x.$$

Combining these last two equalities, we conclude that $a^x = b^{x \log_b a}$.

To prove the second property, we show that

$$(\log_b a) \cdot (\log_a x) = \log_b x.$$

Let $u = \log_b a, v = \log_a x$, and $w = \log_b x$. We will show that $u \cdot v = w$. By the definition of logarithmic functions, we know that $b^u = a$, $a^v = x$, and $b^w = x$. From the previous equations, we see that

$$b^{uv} = (b^u)^v = a^v = x = b^w.$$

Therefore, $b^{uv} = b^w$. Since exponential functions are one-to-one, we can conclude that $u \cdot v = w$.

*Q.E.D.*

### Example 1.4.7: Changing Bases

Use a calculating utility to evaluate $\log_3 7$ with the Change of Base Formula presented earlier.

**Solution**

Use the second equation with $a = 3$ and $b = e$: $\log_3 7 = \dfrac{\ln 7}{\ln 3} \approx 1.77124$.

### Exercise 1.4.7

Use the Change of Base Formula and a calculating utility to evaluate $\log_4 6$.

**Hint**

Use the change of base to rewrite this expression in terms of expressions involving the natural logarithm function.

**Answer**

$$\log_4 6 = \frac{\ln 6}{\ln 4} \approx 1.29248$$

### Example 1.4.8: The Richter Scale for Earthquakes

In 1935, Charles Richter developed a scale (now known as the Richter scale) to measure the magnitude of an earthquake. The scale is a base-10 logarithmic scale, and it can be described as follows: Consider one earthquake with magnitude $R_1$ on the Richter scale and a second earthquake with magnitude $R_2$ on the Richter scale. Suppose $R_1 > R_2$, which means the earthquake of magnitude $R_1$ is stronger, but how much stronger is it than the other earthquake?

Figure 1.4.6: (credit: modification of work by Robb Hannawacker, NPS)

A way of measuring the intensity of an earthquake is by using a seismograph to measure the amplitude of the earthquake waves. If $A_1$ is the amplitude measured for the first earthquake and $A_2$ is the amplitude measured for the second earthquake, then the amplitudes and magnitudes of the two earthquakes satisfy the following equation:

$$R_1 - R_2 = \log_{10}\left(\frac{A1}{A2}\right).$$

Consider an earthquake that measures 8 on the Richter scale and an earthquake that measures 7 on the Richter scale. Then,

$$8 - 7 = \log_{10}\left(\frac{A1}{A2}\right).$$

Therefore,

$$\log_{10}\left(\frac{A1}{A2}\right) = 1,$$

which implies $A_1/A_2 = 10$ or $A_1 = 10A_2$. Since $A_1$ is 10 times the size of $A_2$, we say that the first earthquake is 10 times as intense as the second earthquake. On the other hand, if one earthquake measures 8 on the Richter scale and another measures 6, then the relative intensity of the two earthquakes satisfies the equation

$$\log_{10}\left(\frac{A1}{A2}\right) = 8 - 6 = 2.$$

Therefore, $A_1 = 100A_2$.That is, the first earthquake is 100 times more intense than the second earthquake.

How can we use logarithmic functions to compare the relative severity of the magnitude 9 earthquake in Japan in 2011 with the magnitude 7.3 earthquake in Haiti in 2010?

#### Solution

To compare the Japan and Haiti earthquakes, we can use an equation presented earlier:

$$9 - 7.3 = \log_{10}\left(\frac{A1}{A2}\right).$$

Therefore, $A_1/A_2 = 10^{1.7}$, and we conclude that the earthquake in Japan was approximately 50 times more intense than the earthquake in Haiti.

### Exercise 1.4.8

Compare the relative severity of a magnitude 8.4 earthquake with a magnitude 7.4 earthquake.

**Hint**

$R_1 - R_2 = \log_{10}(A1/A2)$.

**Answer**

The magnitude 8.4 earthquake is roughly 10 times as severe as the magnitude 7.4 earthquake.

## Key Concepts

- Trigonometric, exponential, and logarithmic functions are examples of transcendental functions.
- The exponential function $y = b^x$ is increasing if $b > 1$ and decreasing if $0 < b < 1$. Its domain is $(-\infty, \infty)$ and its range is $(0, \infty)$.
- The logarithmic function $y = \log_b(x)$ is the inverse of $y = b^x$. Its domain is $(0, \infty)$ and its range is $(-\infty, \infty)$.
- The natural exponential function is $y = e^x$ and the natural logarithmic function is $y = \ln x = \log_e x$.
- Given an exponential function or logarithmic function in base $a$, we can make a change of base to convert this function to any base $b > 0$, $b \neq 1$. We typically convert to base $e$.

## Glossary

**base**

the number $b$ in the exponential function $f(x) = b^x$ and the logarithmic function $f(x) = \log_b x$

**exponent**

the value $x$ in the expression $b^x$

**natural exponential function**

the function $f(x) = e^x$

**natural logarithm**

the function $\ln x = \log_e x$

**number e**

as $m$ gets larger, the quantity $(1 + (1/m)^m$ gets closer to some real number; we define that real number to be $e$; the value of $e$ is approximately $2.718282$

**transcendental function**

a function that cannot be expressed by a combination of basic arithmetic operations

# 1.4E: Exercises

**In exercise 1, determine whether the statement is *true or false*. Explain why.**

1) $f(x) = \dfrac{4x+1}{7x-2}$ is a transcendental function.

**In exercises 2 - 5, evaluate the given exponential functions as indicated, accurate to two significant digits after the decimal.**

2) $f(x) = 5^x$

a. $x = 3$

b. $x = \frac{1}{2}$

c. $x = \sqrt{2}$

**Answer**

a. $125$

b. $2.24$

c. $9.74$

3) $f(x) = (0.3)^x$

a. $x = -1$

b. $x = 4$

c. $x = -1.5$

4) $f(x) = 10^x$

a. $x = -2$

b. $x = 4$

c. $x = \frac{5}{3}$

**Answer**

a. $0.01$

b. $10,000$

c. $46.42$

5) $f(x) = e^x$

a. $x = 2$

b. $x = -3.2$

c. $x = \pi$

**In exercises 6 - 11, match the exponential equation to the correct graph.**

a. $y = 4^{-x}$

b. $y = 3^{x-1}$

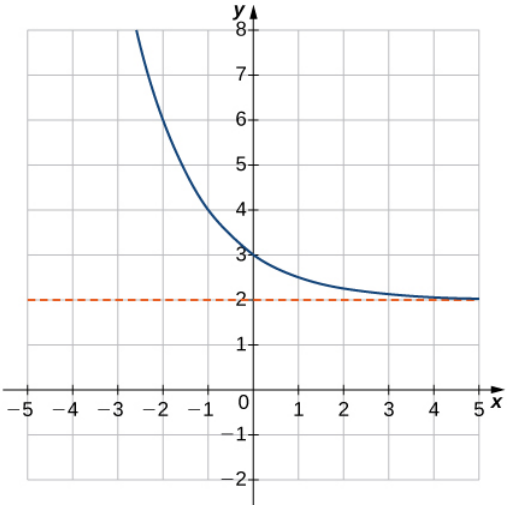
c. $y = 2^{x+1}$

d. $y = \left(\frac{1}{2}\right)^x + 2$

e. $y = -3^{-x}$

f. $y = 1 - 5^x$

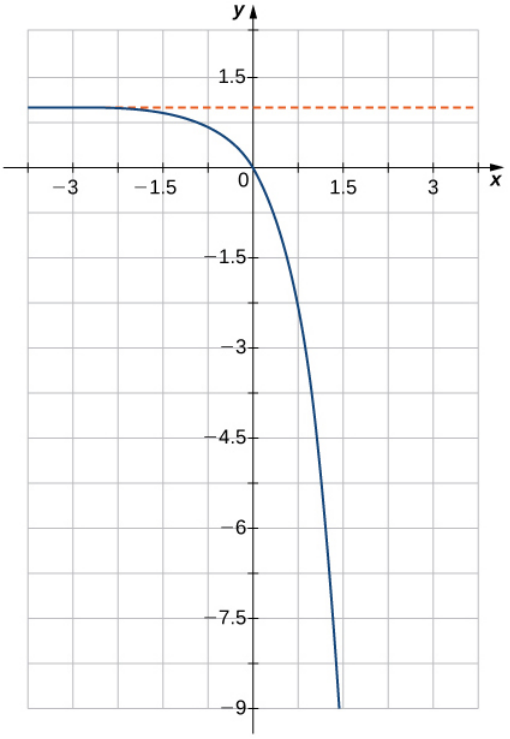
6)



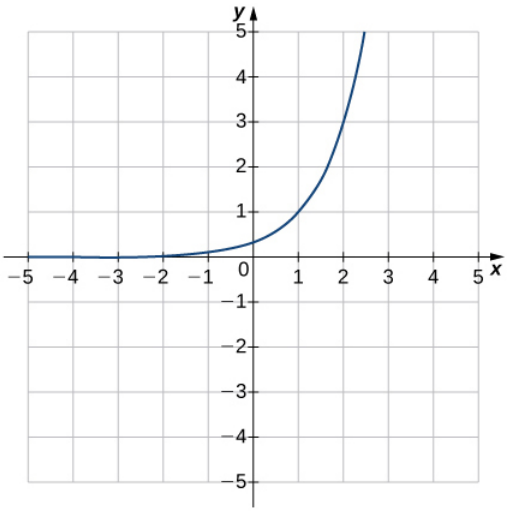
**Answer**

d

7)



8)

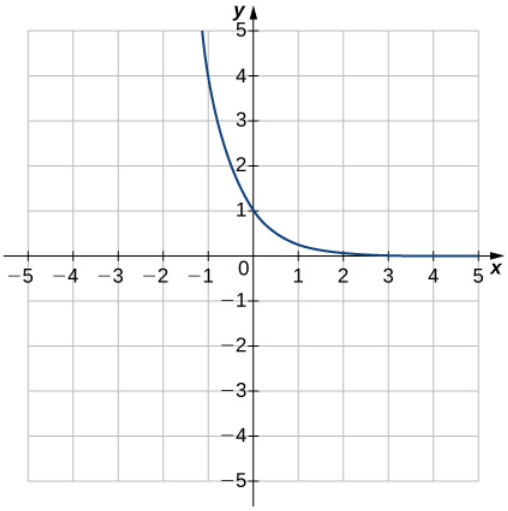


y
x
−5 −4 −3 −2 −1 0 1 2 3 4 5
5 4 3 2 1 −1 −2 −3 −4 −5

**Answer**

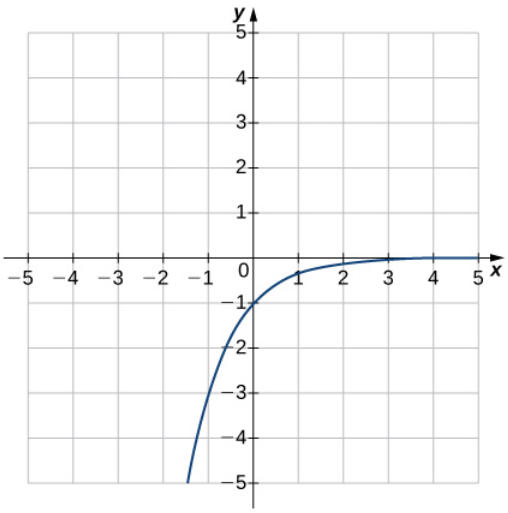
b

9)



y
x
−5 −4 −3 −2 −1 0 1 2 3 4 5
5 4 3 2 1 −1 −2 −3 −4 −5

10)

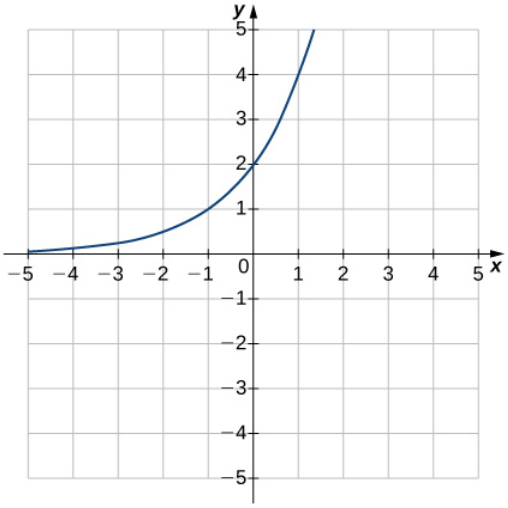


y
x
−5 −4 −3 −2 −1 0 1 2 3 4 5
5 4 3 2 1 −1 −2 −3 −4 −5

**Answer**

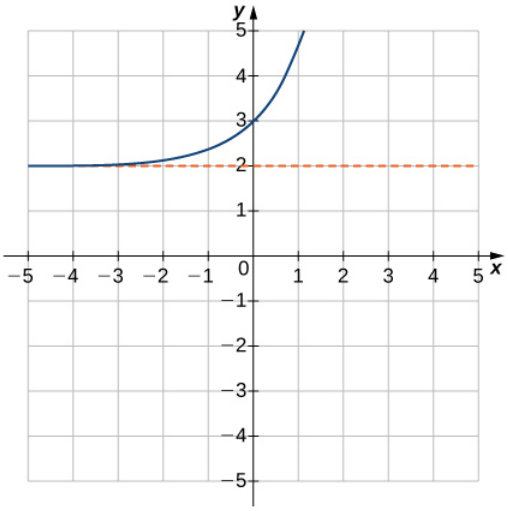
e

11)



**In exercises 12 - 18, sketch the graph of the exponential function. Determine the domain, range, and horizontal asymptote.**

12) $f(x) = e^x + 2$

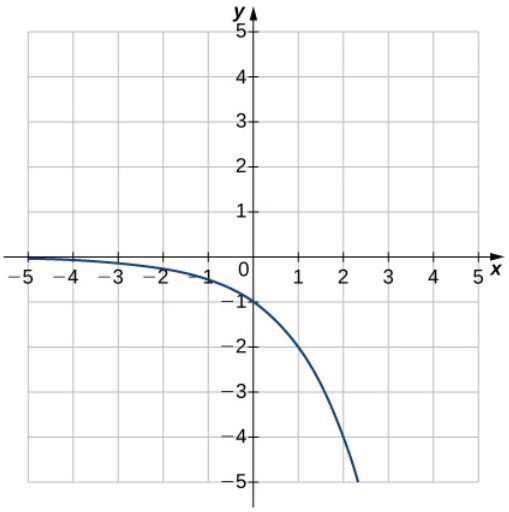


**Answer**

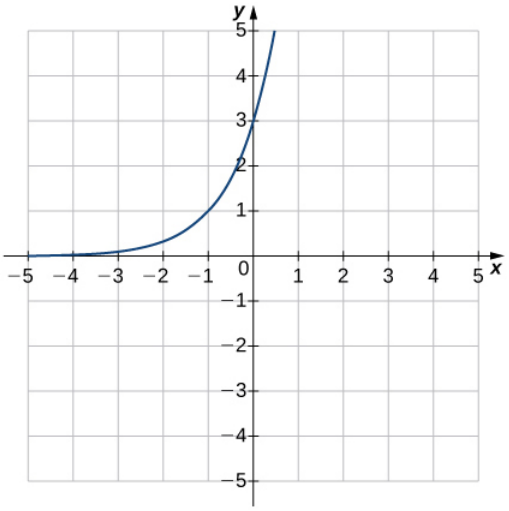
Domain: all real numbers, Range: $(2, \infty)$, $y = 2$

13) $f(x) = -2^x$

https://math.libretexts.org/@go/page/171827



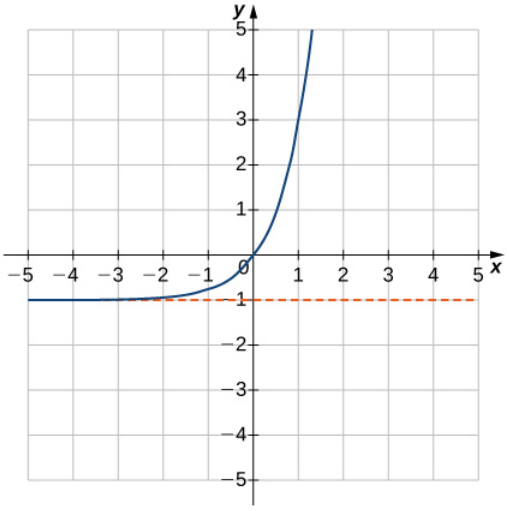
14) $f(x) = 3^{x+1}$



**Answer**

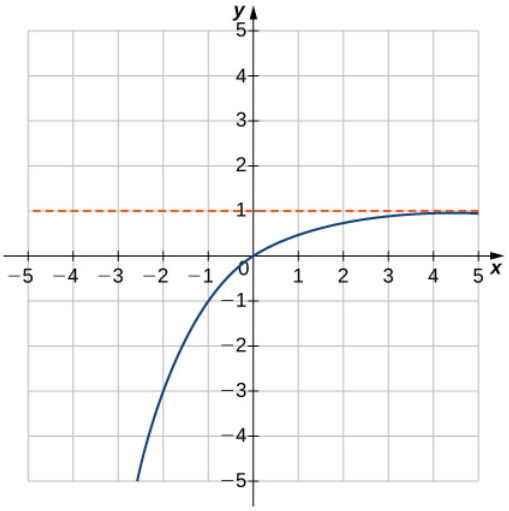
Domain: all real numbers, Range: $(0, \infty)$, $y = 0$

15) $f(x) = 4^x - 1$



https://math.libretexts.org/@go/page/171827

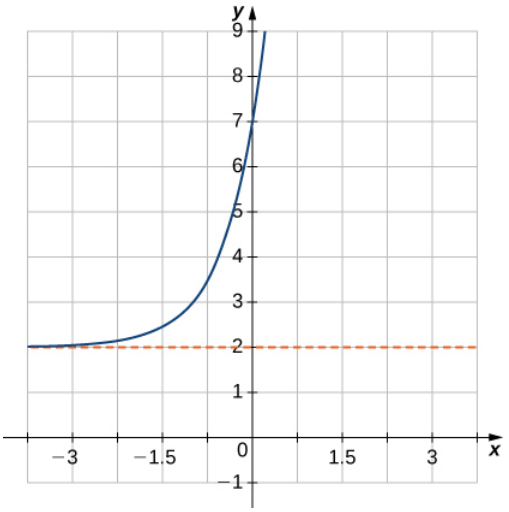
16) $f(x) = 1 - 2^{-x}$



**Answer**

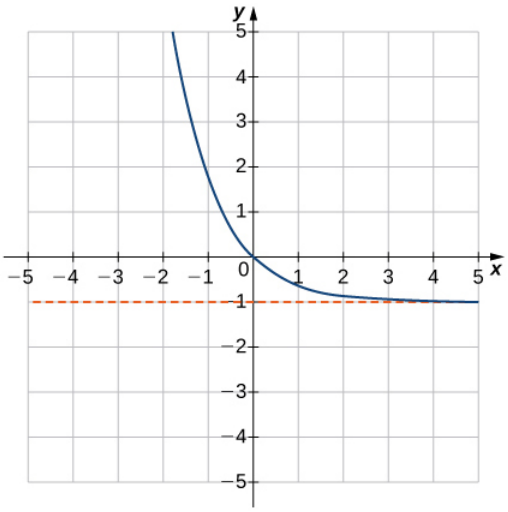
Domain: all real numbers, Range: $(-\infty, 1)$, $y = 1$

17) $f(x) = 5^{x+1} + 2$



18) $f(x) = e^{-x} - 1$

https://math.libretexts.org/@go/page/171827



**Answer**

Domain: all real numbers, Range: $(-1, \infty)$, $y = -1$

**In exercises 19 - 26, write the equation in equivalent exponential form.**

19) $\log_3 81 = 4$

20) $\log_8 2 = \frac{1}{3}$

**Answer**

$8^{1/3} = 2$

21) $\log_5 1 = 0$

22) $\log_5 25 = 2$

**Answer**

$5^2 = 25$

23) $\log 0.1 = -1$

24) $\ln\left(\frac{1}{e^3}\right) = -3$

**Answer**

$e^{-3} = \frac{1}{e^3}$

25) $\log_9 3 = 0.5$

26) $\ln 1 = 0$

**Answer**

$e^0 = 1$

**In exercises 27 - 36, write the equation in equivalent logarithmic form.**

27) $2^3 = 8$

28) $4^{-2} = \frac{1}{16}$

**Answer**

$\log_4\left(\frac{1}{16}\right) = -2$

29) $10^2 = 100$

30) $9^0 = 1$

**Answer**

$\log_9 1 = 0$

31) $\left(\frac{1}{3}\right)^3 = \frac{1}{27}$

32) $\sqrt[3]{64} = 4$

**Answer**

$\log_{64} 4 = \frac{1}{3}$

33) $e^x = y$

34) $9^y = 150$

**Answer**

$\log_9 150 = y$

35) $b^3 = 45$

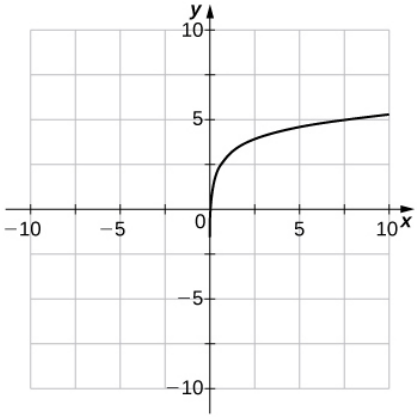
36) $4^{-3/2} = 0.125$

**Answer**

$\log_4 0.125 = -\frac{3}{2}$

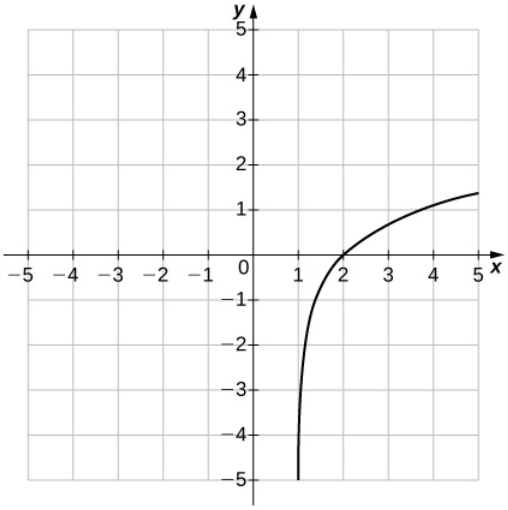
**In exercises 37 - 42, sketch the graph of the logarithmic function. Determine the domain, range, and vertical asymptote.**

37) $f(x) = 3 + \ln x$



38) $f(x) = \ln(x - 1)$

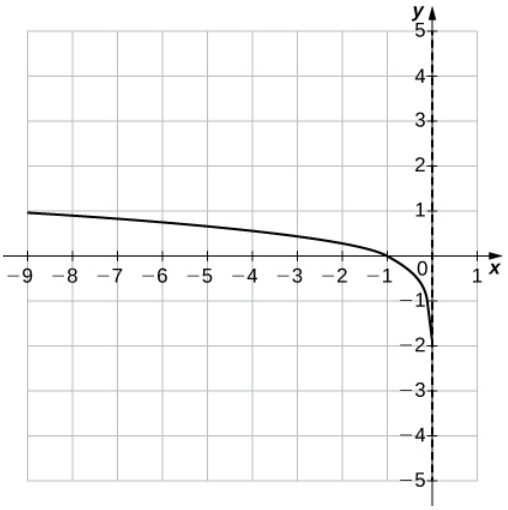
https://math.libretexts.org/@go/page/171827



**Answer**

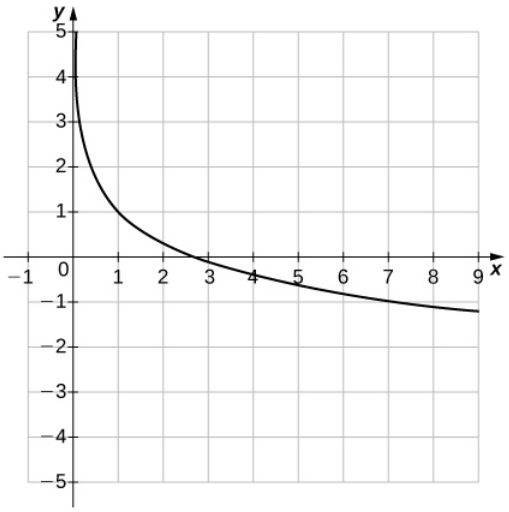
Domain: $(1, \infty)$, Range: $(-\infty, \infty)$, $x = 1$

39) $f(x) = \ln(-x)$



40) $f(x) = 1 - \ln x$

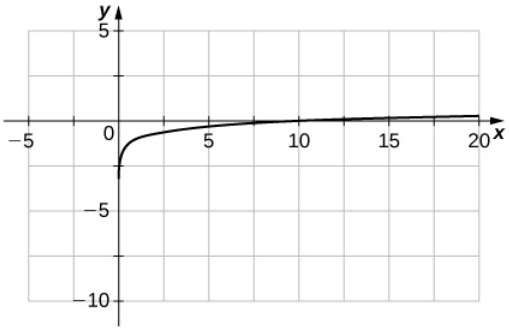
https://math.libretexts.org/@go/page/171827



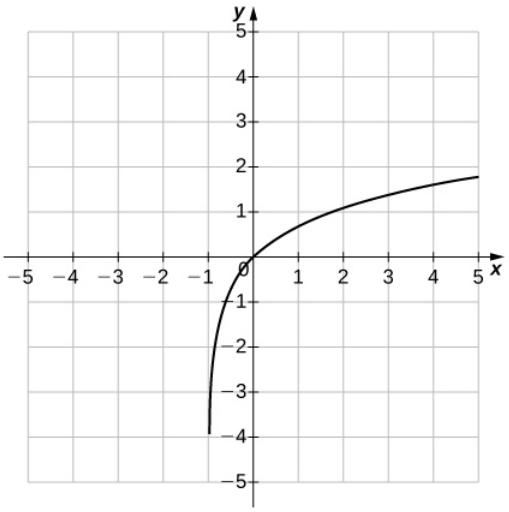
**Answer**

Domain: $(0, \infty)$, Range: $(-\infty, \infty)$, $x = 0$

41) $f(x) = \log x - 1$



42) $f(x) = \ln(x + 1)$



**Answer**

Domain: $(-1, \infty)$, Range: $(-\infty, \infty)$, $x = -1$

**In exercises 43 - 48, use properties of logarithms to write the expressions as a sum, difference, and/or product of logarithms.**

43) $\log x^4 y$

44) $\log_3 \frac{9a^3}{b}$

**Answer**

$2 + 3\log_3 a - \log_3 b$

45) $\ln a\sqrt[3]{b}$

46) $\log_5 \sqrt{125xy^3}$

**Answer**

$\frac{3}{2} + \frac{1}{2}\log_5 x + \frac{3}{2}\log_5 y$

47) $\log_4 \frac{\sqrt[3]{xy}}{64}$

48) $\ln\left(\frac{6}{\sqrt{e^3}}\right)$

**Answer**

$-\frac{3}{2} + \ln 6$

**In exercises 49 - 56, solve the exponential equation exactly.**

49) $5^x = 125$

50) $e^{3x} - 15 = 0$

**Answer**

$\frac{\ln 15}{3}$

51) $8^x = 4$

52) $4^{x+1} - 32 = 0$

**Answer**

$\frac{3}{2}$

53) $3^{x/14} = \frac{1}{10}$

54) $10^x = 7.21$

**Answer**

$\log 7.21$

55) $4 \cdot 2^{3x} - 20 = 0$

56) $7^{3x-2} = 11$

**Answer**

$\frac{2}{3} + \frac{\log 11}{3\log 7}$

**In exercises 57 - 64, solve the logarithmic equation exactly, if possible.**

57) $\log_3 x = 0$

58) $\log_5 x = -2$

**Answer**

$x = \frac{1}{25}$

https://math.libretexts.org/@go/page/171827

59) $\log_4(x+5)=0$

60) $\log(2x-7)=0$

**Answer**

$x=4$

61) $\ln\sqrt{x+3}=2$

62) $\log_6(x+9)+\log_6 x=2$

**Answer**

$x=3$

63) $\log_4(x+2)-\log_4(x-1)=0$

64) $\ln x+\ln(x-2)=\ln 4$

**Answer**

$1+\sqrt{5}$

**In exercises 65 - 70, use the Change of Base Formula and either base 10 or base $e$ to evaluate the given expressions. Answer in exact form and in approximate form, rounding to four decimal places.**

65) $\log_5 47$

66) $\log_7 82$

**Answer**

$\frac{\log 82}{\log 7}\approx 2.2646$

67) $\log_6 103$

68) $\log_{0.5} 211$

**Answer**

$\frac{\log 211}{\log 0.5}\approx -7.7211$

69) $\log_2 \pi$

70) $\log_{0.2} 0.452$

**Answer**

$\frac{\log 0.452}{\log 0.2}\approx 0.4934$

71) [Technology Required] The number of bacteria $N$ in a culture after $t$ days can be modeled by the function $N(t)=1300\cdot(2)^{t/4}$. Find the number of bacteria present after $15$ days.

**Answer**

$\sim 17,491$

72) [Technology Required] The demand $D$ (in millions of barrels) for oil in an oil-rich country is given by the function $D(p)=150\cdot(2.7)^{-0.25p}$, where $p$ is the price (in dollars) of a barrel of oil. Find the amount of oil demanded (to the nearest million barrels) when the price is between $15 and $20.

73) [Technology Required] The amount $A$ of a $100,000 investment paying continuously and compounded for t years is given by $A(t)=100,000\cdot e^{0.055t}$. Find the amount $A$ accumulated in $5$ years.

**Answer**

Approximately $131,653 is accumulated in 5 years.

74) [Technology Required] An investment is compounded monthly, quarterly, or yearly and is given by the function $A = P\left(1+\frac{j}{n}\right)^{nt}$, where $A$ is the value of the investment at time $t$, $P$ is the initial principle that was invested, $j$ is the annual interest rate, and $n$ is the number of time the interest is compounded per year. Given a yearly interest rate of 3.5% and an initial principle of $100,000, find the amount $A$ accumulated in 5 years for interest that is compounded a. daily, b., monthly, c. quarterly, and d. yearly.

75) [Technology Required] The concentration of hydrogen ions in a substance is denoted by $[H+]$, measured in moles per liter. The pH of a substance is defined by the logarithmic function $pH = -\log[H+]$. This function is used to measure the acidity of a substance. The pH of water is 7. A substance with a pH less than 7 is an acid, whereas one that has a pH of more than 7 is a base.

a. Find the pH of the following substances. Round answers to one digit.

b. Determine whether the substance is an acid or a base.

i. Eggs: $[H+] = 1.6 \times 10^{-8}$ mol/L

ii. Beer: $[H+] = 3.16 \times 10^{-3}$ mol/L

iii. Tomato Juice: $[H+] = 7.94 \times 10^{-5}$ mol/L

**Answer**

i. a. pH = 8 b. Base
ii. a. pH = 3 b. Acid
iii. a. pH = 4 b. Acid

76) [Technology Required] Iodine-131 is a radioactive substance that decays according to the function $Q(t) = Q_0 \cdot e^{-0.08664t}$, where $Q_0$ is the initial quantity of a sample of the substance and $t$ is in days. Determine how long it takes (to the nearest day) for 95% of a quantity to decay.

77) [Technology Required] According to the World Bank, at the end of 2013 $(t = 0)$ the U.S. population was 316 million and was increasing according to the following model:

$$P(t) = 316e^{0.0074t},$$

where $P$ is measured in millions of people and $t$ is measured in years after 2013.

a. Based on this model, what will be the population of the United States in 2020?

b. Determine when the U.S. population will be twice what it is in 2013.

**Answer**

a. $\sim 333$ million
b. 94 years from 2013, or in 2107

78) [Technology Required] The amount $A$ accumulated after $1000$ dollars is invested for $t$ years at an interest rate of 4% is modeled by the function $A(t) = 1000(1.04)^t$.

a. Find the amount accumulated after $5$ years and $10$ years.

b. Determine how long it takes for the original investment to triple.

79) [Technology Required] A bacterial colony grown in a lab is known to double in number in $12$ hours. Suppose, initially, there are $1000$ bacteria present.

a. Use the exponential function $Q = Q_0 e^{kt}$ to determine the value $k$, which is the growth rate of the bacteria. Round to four decimal places.

b. Determine approximately how long it takes for $200,000$ bacteria to grow.

**Answer**

a. $k \approx 0.0578$

b. \approx $92$ hours

80) [Technology Required] The rabbit population on a game reserve doubles every $6$ months. Suppose there were $120$ rabbits initially.

a. Use the exponential function $P = P_0 a^t$ to determine the growth rate constant $a$. Round to four decimal places.

b. Use the function in part a. to determine approximately how long it takes for the rabbit population to reach 3500.

81) [Technology Required] The 1906 earthquake in San Francisco had a magnitude of 8.3 on the Richter scale. At the same time, in Japan, an earthquake with magnitude 4.9 caused only minor damage. Approximately how much more energy was released by the San Francisco earthquake than by the Japanese earthquake?

**Answer**

The San Francisco earthquake had $10^{3.4}$ or $\sim 2512$ times more energy than the Japan earthquake.

# 1.5: Trigonometry

**Learning Objectives**

- Convert angle measures between degrees and radians.
- Recognize the triangular and circular definitions of the basic trigonometric functions.
- Write the basic trigonometric identities.
- Identify the graphs and periods of the trigonometric functions.
- Describe the shift of a sine or cosine graph from the equation of the function.

Trigonometric functions are used to model many phenomena, including sound waves, vibrations of strings, alternating electrical current, and the motion of pendulums. In fact, almost any repetitive, or cyclical, motion can be modeled by some combination of trigonometric functions. In this section, we define the six basic trigonometric functions and look at some of the main identities involving these functions.

## Radian Measure

To use trigonometric functions, we first must understand how to measure the angles. Although we can use both radians and degrees, **radians** are a more natural measurement because they are related directly to the **unit circle**, a circle with radius 1. The radian measure of an angle is defined as follows. Given an angle $\theta$, let $s$ be the length of the corresponding arc on the unit circle (Figure 1.5.1). We say the angle corresponding to the arc of length 1 has radian measure 1.

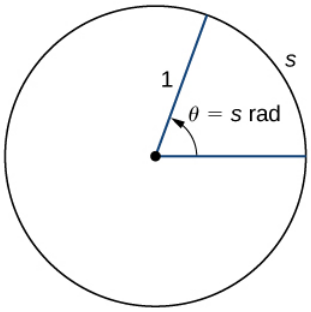

Figure 1.5.1: The radian measure of an angle $\theta$ is the arc length $s$ of the associated arc on the unit circle.

Since an angle of $360°$ corresponds to the circumference of a circle, or an arc of length $2\pi$, we conclude that an angle with a degree measure of $360°$ has a radian measure of $2\pi$. Similarly, we see that $180°$ is equivalent to $\pi$ radians. Table 1.5.1 shows the relationship between common degree and radian values.

Table 1.5.1: Common Angles Expressed in Degrees and Radians

| Degrees | Radians | Degrees | Radians |
|---|---|---|---|
| 0 | 0 | 120 | $2\pi/3$ |
| 30 | $\pi/6$ | 135 | $3\pi/4$ |
| 45 | $\pi/4$ | 150 | $5\pi/6$ |
| 60 | $\pi/3$ | 180 | $\pi$ |
| 90 | $\pi/2$ | | |

**Example 1.5.1: Converting between Radians and Degrees**

a. Express $225°$ using radians.
b. Express $5\pi/3$ rad using degrees.

**Solution**

Use the fact that $180^{\circ}$ is equivalent to $\pi$ radians as a conversion factor (Table 1.5.1):

$$1 = \frac{\pi \text{ rad}}{180^{\circ}} = \frac{180^{\circ}}{\pi \text{ rad}}.$$

a. $225^{\circ} = 225^{\circ} \cdot \left(\frac{\pi}{180^{\circ}}\right) = \left(\frac{5\pi}{4}\right)$ rad

b. $\frac{5\pi}{3}$ rad $= \frac{5\pi}{3} \cdot \frac{180^{\circ}}{\pi} = 300^{\circ}$

**? Exercise 1.5.1**

a. Express $210^{\circ}$ using radians.

b. Express $11\pi/6$ rad using degrees.

**Hint**

$\pi$ radians is equal to $180^{\circ}$

**Answer**

a. $7\pi/6$

b. $330^{\circ}$

## The Six Basic Trigonometric Functions

Trigonometric functions allow us to use angle measures, in radians or degrees, to find the coordinates of a point on any circle - not only on a unit circle - or to find an angle given a point on a circle. They also define the relationship between the sides and angles of a triangle.

To define the trigonometric functions, first consider the unit circle centered at the origin and a point $P = (x, y)$ on the unit circle. Let $\theta$ be an angle with an initial side that lies along the positive $x$-axis and with a terminal side that is the line segment $OP$. An angle in this position is said to be in standard position (Figure 1.5.2). We can then define the values of the six trigonometric functions for $\theta$ in terms of the coordinates $x$ and $y$.

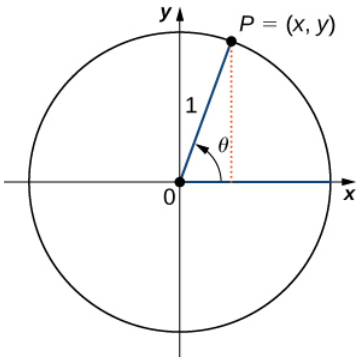

Figure 1.5.2: The angle $\theta$ is in standard position. The values of the trigonometric functions for $\theta$ are defined in terms of the coordinates $x$ and $y$.

**Definition: Trigonometric functions**

Let $P = (x, y)$ be a point on the unit circle centered at the origin $O$. Let $\theta$ be an angle with an initial side along the positive $x$-axis and a terminal side given by the line segment $OP$. The trigonometric functions are then defined as

| | |
|---|---|
| $\sin\theta = y$ | $\csc\theta = \frac{1}{y}$ |
| $\cos\theta = x$ | $\sec\theta = \frac{1}{x}$ |
| $\tan\theta = \frac{y}{x}$ | $\cot\theta = \frac{x}{y}$ |

If $x = 0, \sec\theta$ and $\tan\theta$ are undefined. If $y = 0$, then $\cot\theta$ and $\csc\theta$ are undefined.

We can see that for a point $P = (x, y)$ on a circle of radius $r$ with a corresponding angle $\theta$, the coordinates $x$ and $y$ satisfy

$$\cos\theta = \frac{x}{r} \tag{1.5.1}$$
$$x = r\cos\theta \tag{1.5.2}$$

and

$$\sin\theta = \frac{y}{r} \tag{1.5.3}$$
$$y = r\sin\theta. \tag{1.5.4}$$

The values of the other trigonometric functions can be expressed in terms of $x, y$, and $r$ (Figure 1.5.3).

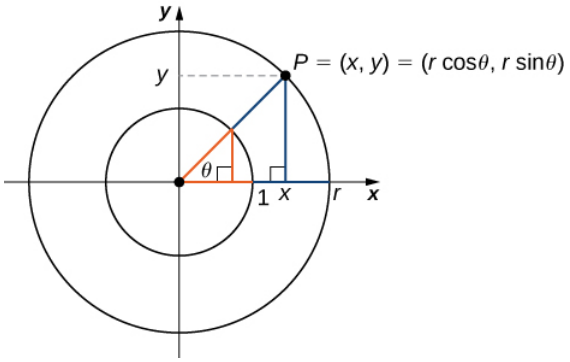

Figure 1.5.3: For a point $P = (x, y)$ on a circle of radius $r$, the coordinates $x$ and $y$ satisfy $x = r\cos\theta$ and $y = r\sin\theta$.

Table 1.5.2 shows the values of sine and cosine at the major angles in the first quadrant. From this table, we can determine the values of sine and cosine at the corresponding angles in the other quadrants. The values of the other trigonometric functions are calculated easily from the values of $\sin\theta$ and $\cos\theta$.

Table 1.5.2: Values of $\sin\theta$ and $\cos\theta$ at Major Angles $\theta$ in the First Quadrant

| $\theta$ | $\sin\theta$ | $\cos\theta$ |
|---|---|---|
| 0 | 0 | 1 |
| $\frac{\pi}{6}$ | $\frac{1}{2}$ | $\frac{\sqrt{3}}{2}$ |
| $\frac{\pi}{4}$ | $\frac{\sqrt{2}}{2}$ | $\frac{\sqrt{2}}{2}$ |
| $\frac{\pi}{3}$ | $\frac{\sqrt{3}}{2}$ | $\frac{1}{2}$ |
| $\frac{\pi}{2}$ | 1 | 0 |

## Example 1.5.2: Evaluating Trigonometric Functions

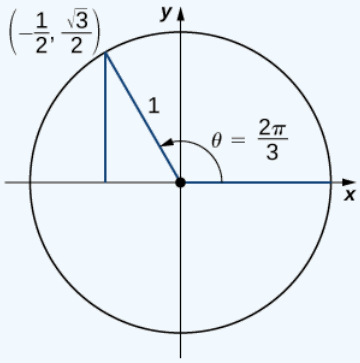
Evaluate each of the following expressions.

a. $\sin\left(\frac{2\pi}{3}\right)$
b. $\cos\left(-\frac{5\pi}{6}\right)$
c. $\tan\left(\frac{15\pi}{4}\right)$

### Solution

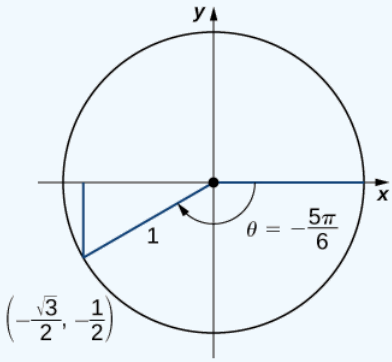
a) On the unit circle, the angle $\theta = \frac{2\pi}{3}$ corresponds to the point $\left(-\frac{1}{2}, \frac{\sqrt{3}}{2}\right)$. Therefore,

$$\sin\left(\frac{2\pi}{3}\right) = y = \left(\frac{\sqrt{3}}{2}\right).$$



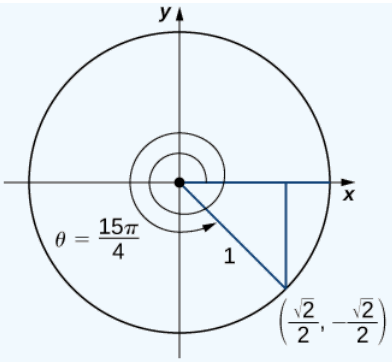
b) An angle $\theta = -\frac{5\pi}{6}$ corresponds to a revolution in the negative direction, as shown. Therefore,

$$\cos\left(-\frac{5\pi}{6}\right) = x = -\frac{\sqrt{3}}{2}.$$



c) An angle $\theta = \frac{15\pi}{4} = 2\pi + \frac{7\pi}{4}$. Therefore, this angle corresponds to more than one revolution, as shown. Knowing the fact that an angle of $\frac{7\pi}{4}$ corresponds to the point $\left(\frac{\sqrt{2}}{2}, -\frac{\sqrt{2}}{2}\right)$, we can conclude that

$$\tan\left(\frac{15\pi}{4}\right) = \frac{y}{x} = -1.$$



**? Exercise 1.5.2**

Evaluate $\cos(3\pi/4)$ and $\sin(-\pi/6)$.

**Hint**

Look at angles on the unit circle.

**Answer**

$$\cos(3\pi/4) = -\sqrt{2}/2$$

$$\sin(-\pi/6) = -1/2$$

As mentioned earlier, the ratios of the side lengths of a right triangle can be expressed in terms of the trigonometric functions evaluated at either of the acute angles of the triangle. Let $\theta$ be one of the acute angles. Let $A$ be the length of the adjacent leg, $O$ be the length of the opposite leg, and $H$ be the length of the hypotenuse. By inscribing the triangle into a circle of radius $H$, as shown in Figure 1.5.4, we see that $A, H$, and $O$ satisfy the following relationships with $\theta$:

| | |
|---|---|
| $\sin\theta = \frac{O}{H}$ | $\csc\theta = \frac{H}{O}$ |
| $\cos\theta = \frac{A}{H}$ | $\sec\theta = \frac{H}{A}$ |
| $\tan\theta = \frac{O}{A}$ | $\cot\theta = \frac{A}{O}$ |

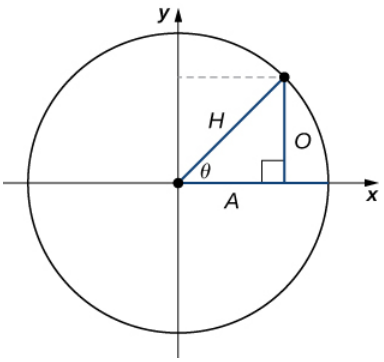


Figure 1.5.4: By inscribing a right triangle in a circle, we can express the ratios of the side lengths in terms of the trigonometric functions evaluated at $\theta$.

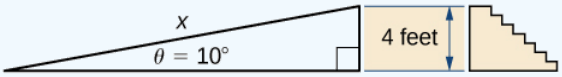
**✓ Example 1.5.3: Constructing a Wooden Ramp**

A wooden ramp is to be built with one end on the ground and the other end at the top of a short staircase. If the top of the staircase is 4 ft from the ground and the angle between the ground and the ramp is to be 10°, how long does the ramp need to

be?

### Solution

Let $x$ denote the length of the ramp. In the following image, we see that $x$ needs to satisfy the equation $\sin(10°) = 4/x$. Solving this equation for $x$, we see that $x = 4\sin(10°) \approx 23.035$ ft.



## Exercise 1.5.3

A house painter wants to lean a 20-ft ladder against a house. If the angle between the base of the ladder and the ground is to be 60°, how far from the house should she place the base of the ladder?

**Hint**

Draw a right triangle with hypotenuse 20.

**Answer**

10 ft

---

## Trigonometric Identities

A **trigonometric identity** is an equation involving trigonometric functions that is true for all angles $\theta$ for which the functions are defined. We can use the identities to help us solve or simplify equations. The main trigonometric identities are listed below.

### Theorem 1.5.1: Trigonometric Identities

**Reciprocal Identities**

$$\tan\theta = \frac{\sin\theta}{\cos\theta}$$

$$\cot\theta = \frac{\cos\theta}{\sin\theta}$$

$$\csc\theta = \frac{1}{\sin\theta}$$

$$\sec\theta = \frac{1}{\cos\theta}$$

**Pythagorean Identities**

$$\sin^2\theta + \cos^2\theta = 1 \tag{1.5.5}$$

$$1 + \tan^2\theta = \sec^2\theta \tag{1.5.6}$$

$$1 + \cot^2\theta = \csc^2\theta \tag{1.5.7}$$

**Addition and Subtraction Identities**

$$\sin(\alpha \pm \beta) = \sin\alpha\cos\beta \pm \cos\alpha\sin\beta$$

$$\cos(\alpha \pm \beta) = \cos\alpha\cos\beta \mp \sin\alpha\sin\beta$$

**Double-Angle Identities**

$$\sin(2\theta) = 2\sin\theta\cos\theta \tag{1.5.8}$$

$$\cos(2\theta) = 2\cos^2\theta - 1 \tag{1.5.9}$$
$$= 1 - 2\sin^2\theta \tag{1.5.10}$$
$$= \cos^2\theta - \sin^2\theta \tag{1.5.11}$$

### Example 1.5.4: Solving Trigonometric Equations

For each of the following equations, use a trigonometric identity to find all solutions.

a. $1 + \cos(2\theta) = \cos\theta$
b. $\sin(2\theta) = \tan\theta$

**Solution**

a) Using the Double-Angle Identity for $\cos(2\theta)$, we see that $\theta$ is a solution of

$$1 + \cos(2\theta) = \cos\theta$$

if and only if

$$1 + 2\cos^2\theta - 1 = \cos\theta,$$

which is true if and only if

$$2\cos^2\theta - \cos\theta = 0.$$

To solve this equation, it is important to note that we need to factor the left-hand side and not divide both sides of the equation by $\cos\theta$. The problem with dividing by $\cos\theta$ is that it is possible that $\cos\theta$ is zero. In fact, if we did divide both sides of the equation by $\cos\theta$, we would miss some of the solutions of the original equation. Factoring the left-hand side of the equation, we see that $\theta$ is a solution of this equation if and only if

$$\cos\theta(2\cos\theta - 1) = 0.$$

Since $\cos\theta = 0$ when

$$\theta = \frac{\pi}{2}, \frac{\pi}{2} \pm \pi, \frac{\pi}{2} \pm 2\pi, \ldots,$$

and $\cos\theta = 1/2$ when

$$\theta = \frac{\pi}{3}, \frac{\pi}{3} \pm 2\pi, \ldots \text{ or } \theta = -\frac{\pi}{3}, -\frac{\pi}{3} \pm 2\pi, \ldots,$$

we conclude that the set of solutions to this equation is

$$\theta = \frac{\pi}{2} + n\pi, \ \theta = \frac{\pi}{3} + 2n\pi$$

and

$$\theta = -\frac{\pi}{3} + 2n\pi, \ n = 0, \pm 1, \pm 2, \ldots.$$

b) Using the Double-Angle Identity for $\sin(2\theta)$ and the reciprocal identity for $\tan(\theta)$, the equation can be written as

$$2\sin\theta\cos\theta = \frac{\sin\theta}{\cos\theta}.$$

To solve this equation, we multiply both sides by $\cos\theta$ to eliminate the denominator, and say that if $\theta$ satisfies this equation, then $\theta$ satisfies the equation

$$2\sin\theta\cos^2\theta - \sin\theta = 0.$$

However, we need to be a little careful here. Even if $\theta$ satisfies this new equation, it may not satisfy the original equation because, to satisfy the original equation, we would need to be able to divide both sides of the equation by $\cos\theta$. However, if $\cos\theta = 0$, we cannot divide both sides of the equation by $\cos\theta$. Therefore, it is possible that we may arrive at extraneous

solutions. So, at the end, it is important to check for extraneous solutions. Returning to the equation, it is important that we factor $\sin\theta$ out of both terms on the left-hand side instead of dividing both sides of the equation by $\sin\theta$. Factoring the left-hand side of the equation, we can rewrite this equation as

$$\sin\theta(2\cos^2\theta - 1) = 0.$$

Therefore, the solutions are given by the angles $\theta$ such that $\sin\theta = 0$ or $\cos^2\theta = 1/2$. The solutions of the first equation are $\theta = 0, \pm\pi, \pm 2\pi, \ldots$. The solutions of the second equation are $\theta = \pi/4, (\pi/4) \pm (\pi/2), (\pi/4) \pm \pi, \ldots$. After checking for extraneous solutions, the set of solutions to the equation is

$$\theta = n\pi$$

and

$$\theta = \frac{\pi}{4} + \frac{n\pi}{2}$$

with $n = 0, \pm 1, \pm 2, \ldots$.

**? Exercise 1.5.4**

Find all solutions to the equation $\cos(2\theta) = \sin\theta$.

**Hint**

Use the Double-Angle Identity for cosine (Equation 1.5.8).

**Answer**

$\theta = \frac{3\pi}{2} + 2n\pi, \frac{\pi}{6} + 2n\pi, \frac{5\pi}{6} + 2n\pi$

for $n = 0, \pm 1, \pm 2, \ldots$.

**✓ Example 1.5.5: Proving a Trigonometric Identity**

Prove the trigonometric identity $1 + \tan^2\theta = \sec^2\theta$.

**Solution**

We start with the Pythagorean Identity (Equation 1.5.5)

$$\sin^2\theta + \cos^2\theta = 1.$$

Dividing both sides of this equation by $\cos^2\theta$, we obtain

$$\frac{\sin^2\theta}{\cos^2\theta} + 1 = \frac{1}{\cos^2\theta}.$$

Since $\sin\theta/\cos\theta = \tan\theta$ and $1/\cos\theta = \sec\theta$, we conclude that

$$\tan^2\theta + 1 = \sec^2\theta.$$

**? Exercise 1.5.5**

Prove the trigonometric identity $1 + \cot^2\theta = \csc^2\theta$.

**Answer**

Divide both sides of the identity $\sin^2\theta + \cos^2\theta = 1$ by $\sin^2\theta$.

## Graphs and Periods of the Trigonometric Functions

We have seen that as we travel around the unit circle, the values of the trigonometric functions repeat. We can see this pattern in the graphs of the functions. Let $P = (x, y)$ be a point on the unit circle and let $\theta$ be the corresponding angle . Since the angle $\theta$ and $\theta + 2\pi$ correspond to the same point $P$, the values of the trigonometric functions at $\theta$ and at $\theta + 2\pi$ are the same. Consequently, the trigonometric functions are **periodic functions**. The period of a function $f$ is defined to be the smallest positive value $p$ such that $f(x + p) = f(x)$ for all values $x$ in the domain of $f$. The sine, cosine, secant, and cosecant functions have a period of $2\pi$. Since the tangent and cotangent functions repeat on an interval of length $\pi$, their period is $\pi$ (Figure 1.5.5).

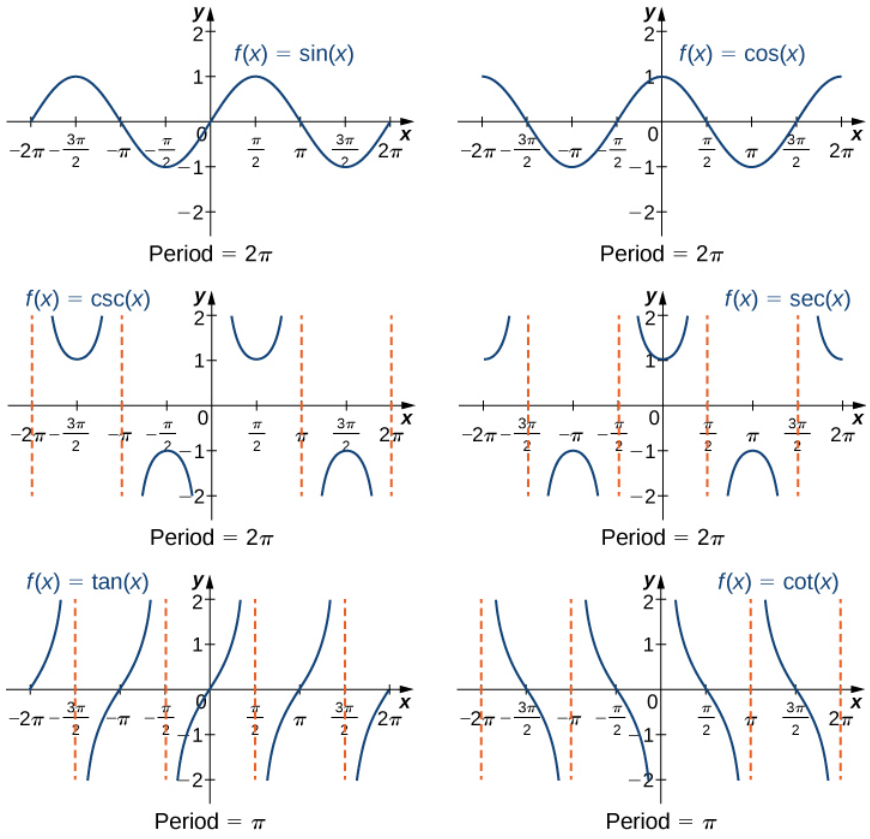


Figure 1.5.5: The six trigonometric functions are periodic.

Just as with algebraic functions, we can apply transformations to trigonometric functions. In particular, consider the following function:

$$f(x) = A\sin(B(x - \alpha)) + C.$$

In Figure 1.5.6, the constant $\alpha$ causes a horizontal or phase shift. The factor $B$ changes the period. This transformed sine function will have a period $2\pi/|B|$. The factor $A$ results in a vertical stretch by a factor of $|A|$. We say $|A|$ is the "amplitude of $f$." The constant $C$ causes a vertical shift.

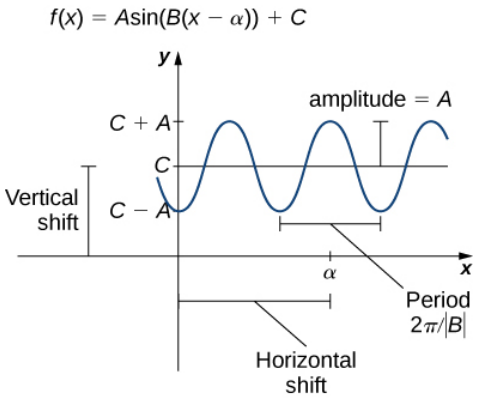

Figure 1.5.6: A graph of a general sine function.

Notice in Figure 1.5.6 that the graph of $y = \cos x$ is the graph of $y = \sin x$ shifted to the left $\pi/2$ units. Therefore, we can write

$$\cos x = \sin(x + \pi/2).$$

Similarly, we can view the graph of $y = \sin x$ as the graph of $y = \cos x$ shifted right $\pi/2$ units, and state that $\sin x = \cos(x - \pi/2)$.

A shifted sine curve arises naturally when graphing the number of hours of daylight in a given location as a function of the day of the year. For example, suppose a city reports that June 21 is the longest day of the year with 15.7 hours and December 21 is the shortest day of the year with 8.3 hours. It can be shown that the function

$$h(t) = 3.7 \sin\left(\frac{2\pi}{365}(x - 80.5)\right) + 12$$

is a model for the number of hours of daylight $h$ as a function of day of the year $t$ (Figure 1.5.7).

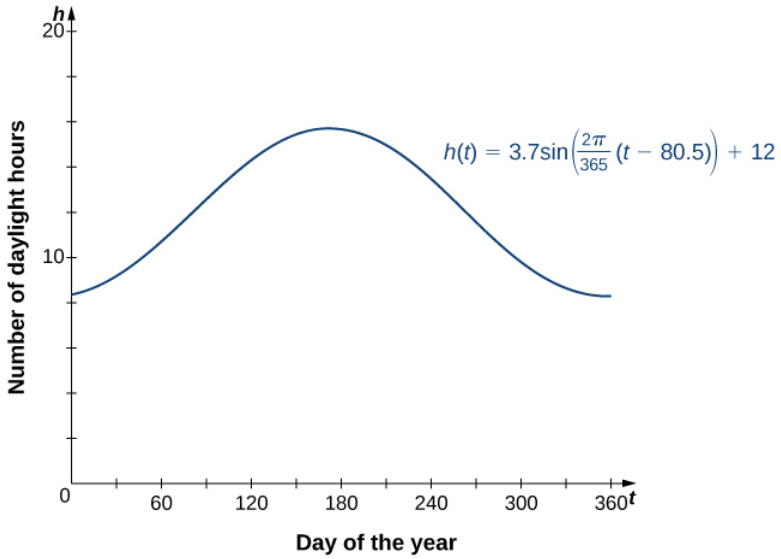

Figure 1.5.7: The hours of daylight as a function of day of the year can be modeled by a shifted sine curve.

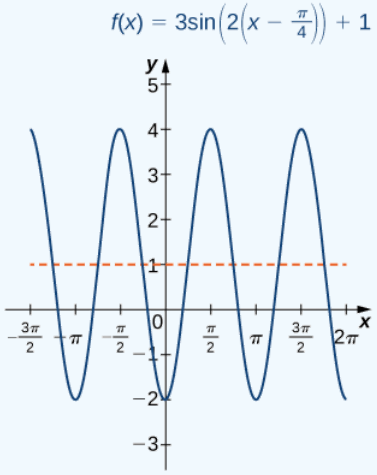
**Example 1.5.6: Sketching the Graph of a Transformed Sine Curve**

Sketch a graph of $f(x) = 3\sin(2(x - \frac{\pi}{4})) + 1$.

**Solution**

This graph is a phase shift of $y = \sin(x)$ to the right by $\pi/4$ units, followed by a horizontal compression by a factor of 2, a vertical stretch by a factor of 3, and then a vertical shift by 1 unit. The period of $f$ is $\pi$.



**? Exercise 1.5.6**

Describe the relationship between the graph of $f(x) = 3\sin(4x) - 5$ and the graph of $y = \sin(x)$.

**Hint**

The graph of $f$ can be sketched using the graph of $y = \sin(x)$ and a sequence of three transformations.

**Answer**

To graph $f(x) = 3\sin(4x) - 5$, the graph of $y = \sin(x)$ needs to be compressed horizontally by a factor of 4, then stretched vertically by a factor of 3, then shifted down 5 units. The function $f$ will have a period of $\pi/2$ and an amplitude of 3.

## Inverse Trigonometric Functions

The six basic trigonometric functions are periodic, and therefore they are not one-to-one. However, if we restrict the domain of a trigonometric function to an interval where it is one-to-one, we can define its inverse. Consider the sine function. The sine function is one-to-one on an infinite number of intervals, but the standard convention is to restrict the domain to the interval $[-\frac{\pi}{2}, \frac{\pi}{2}]$. By doing so, we define the inverse sine function on the domain $[-1, 1]$ such that for any $x$ in the interval $[-1, 1]$, the inverse sine function tells us which angle $\theta$ in the interval $[-\frac{\pi}{2}, \frac{\pi}{2}]$ satisfies $\sin\theta = x$. Similarly, we can restrict the domains of the other trigonometric functions to define **inverse trigonometric functions**, which are functions that tell us which angle in a certain interval has a specified trigonometric value.

**Definition: Inverse Trigonometric Functions**

The inverse sine function, denoted $\sin^{-1}$ or **arcsin**, and the inverse cosine function, denoted $\cos^{-1}$ or **arccos**, are defined on the domain $D = \{y \mid -1 \le y \le 1\}$ as follows:

$$\begin{aligned} \sin^{-1}(y) = \theta \quad &\text{if and only if} \quad \sin(\theta) = y \quad \text{where} \quad \theta \in [-\tfrac{\pi}{2}, \tfrac{\pi}{2}] \\ \cos^{-1}(y) = \theta \quad &\text{if and only if} \quad \cos(\theta) = y \quad \text{where} \quad \theta \in [0, \pi]\,. \end{aligned}$$

The inverse tangent function, denoted $\tan^{-1}$ or **arctan**, and inverse cotangent function, denoted $\cot^{-1}$ or **arccot**, are defined on the domain $D = \{y \mid -\infty < y < \infty\}$ as follows:

$$\begin{aligned} \tan^{-1}(y) = \theta \quad &\text{if and only if} \quad \tan(\theta) = y \quad \text{where} \quad \theta \in (-\tfrac{\pi}{2}, \tfrac{\pi}{2}) \\ \cot^{-1}(y) = \theta \quad &\text{if and only if} \quad \cot(\theta) = y \quad \text{where} \quad \theta \in (0, \pi)\,. \end{aligned}$$

The inverse cosecant function, denoted $\csc^{-1}$ or **arccsc**, and inverse secant function, denoted $\sec^{-1}$ or **arcsec**, are defined on the domain $D = \{y \mid |y| \ge 1\}$ as follows:

$$\csc^{-1}(y) = \theta \quad \text{if and only if} \quad \csc(\theta) = y \quad \text{where} \quad \theta \in (0, \tfrac{\pi}{2}] \cup (\pi, \tfrac{3\pi}{2}]$$
$$\sec^{-1}(y) = \theta \quad \text{if and only if} \quad \sec(\theta) = y \quad \text{where} \quad \theta \in [0, \tfrac{\pi}{2}) \cup [\pi, \tfrac{3\pi}{2}).$$

To graph the inverse trigonometric functions, we use the graphs of the trigonometric functions restricted to the domains defined earlier and reflect the graphs about the line $y = x$ (Figures 1.5.8 – 1.5.10).

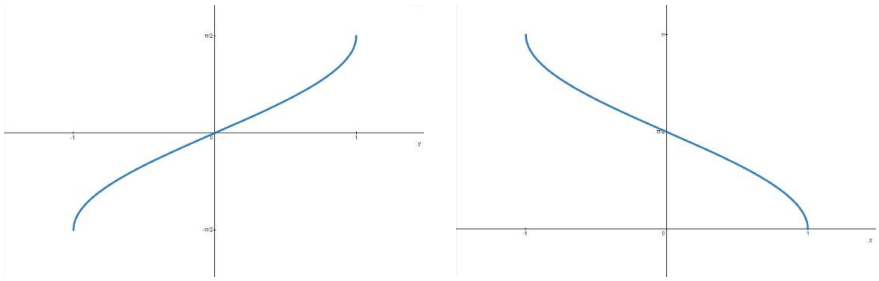


Figure 1.5.8: The graphs of the arcsine (left) and arccosine (right).

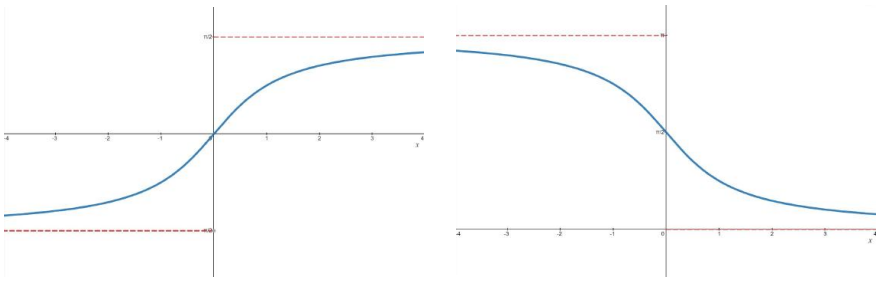

Figure 1.5.9: The graphs of the arctangent (left) and arccotangent (right).

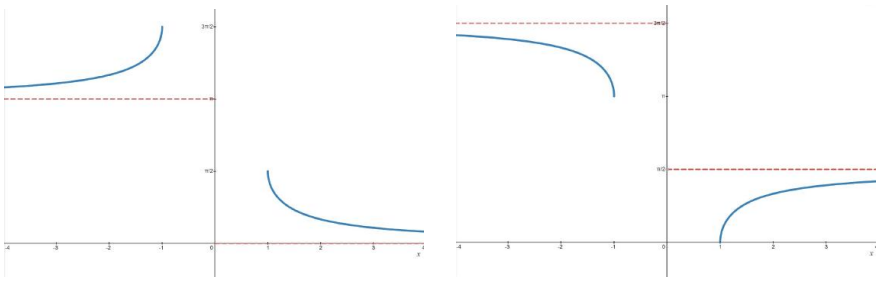

Figure 1.5.10: The graphs of the arccosecant (left) and arcsecant (right).

**Note**

All the inverse trigonometric functions return angles in quadrant I (where all trigonometric functions are positive) and one other quadrant where the corresponding trigonometric function is negative. The returned quadrants where the corresponding trigonometric functions are negative are fairly standard and agreed upon (quadrant IV for arctangent and arcsine, and quadrant II for arccosine and arccotangent); **however**, the quadrants chosen for the ranges of the arcsecant and arccosecant are *not* universally agreed upon.

In this text, we choose arcsecant and arccosecant to return angles in quadrants I and **III** for a special reason - it makes our work in calculus slightly easier. I mention this because you might have seen a slightly different choice for the ranges of these functions in another textbook. The difference is insignificant other than the ease our choice makes for our work in calculus.

When evaluating an inverse trigonometric function, the output is an angle. For example, to evaluate $\cos^{-1}\left(\frac{1}{2}\right)$, we need to find an angle $\theta$ such that $\cos\theta = \frac{1}{2}$. Clearly, many angles have this property. However, given the definition of $\cos^{-1}$, we need the angle $\theta$ that not only solves this equation, but also lies in the interval $[0, \pi]$. We conclude that $\cos^{-1}\left(\frac{1}{2}\right) = \frac{\pi}{3}$.

We now consider a composition of a trigonometric function and its inverse. For example, consider the two expressions $\sin\left(\sin^{-1}\left(\frac{\sqrt{2}}{2}\right)\right)$ and $\sin^{-1}(\sin(\pi))$.

For the first one, we simplify as follows:

$$\sin\left(\sin^{-1}\left(\frac{\sqrt{2}}{2}\right)\right) = \sin\left(\frac{\pi}{4}\right) = \frac{\sqrt{2}}{2}.$$

For the second one, we have

$$\sin^{-1}(\sin(\pi)) = \sin^{-1}(0) = 0.$$

The inverse function is supposed to "undo" the original function, so why isn't $\sin^{-1}(\sin(\pi)) = \pi$? Recalling our definition of inverse functions, a function $f$ and its inverse $f^{-1}$ satisfy the conditions $f(f^{-1}(y)) = y$ for all $y$ in the domain of $f^{-1}$ and $f^{-1}(f(x)) = x$ for all $x$ in the domain of $f$, so what happened here? The issue is that the inverse sine function, $\sin^{-1}$, is the inverse of the restricted sine function defined on the domain $[-\frac{\pi}{2}, \frac{\pi}{2}]$. Therefore, for $x$ in the interval $[-\frac{\pi}{2}, \frac{\pi}{2}]$, it is true that $\sin^{-1}(\sin x) = x$. However, for values of $x$ outside this interval, the equation does not hold, even though $\sin^{-1}(\sin x)$ is defined for all real numbers $x$.

What about $\sin(\sin^{-1} y)$? Does that have a similar issue? The answer is no. Since the domain of $\sin^{-1}$ is the interval $[-1, 1]$, we conclude that $\sin\left(\sin^{-1} y\right) = y$ if $-1 \le y \le 1$ and the expression is not defined for other values of $y$. To summarize,

$$\sin(\sin^{-1} y) = y \text{ if } -1 \le y \le 1$$

and

$$\sin^{-1}(\sin x) = x \text{ if } -\tfrac{\pi}{2} \le x \le \tfrac{\pi}{2}.$$

Similarly, for the cosine function,

$$\cos(\cos^{-1} y) = y \text{ if } -1 \le y \le 1$$

and

$$\cos^{-1}(\cos x) = x \text{ if } 0 \le x \le \pi.$$

Similar properties hold for the other trigonometric functions and their inverses.

### Example 1.5.7: Evaluating Expressions Involving Inverse Trigonometric Functions

Evaluate each of the following expressions.

a. $\sin^{-1}\left(-\frac{\sqrt{3}}{2}\right)$
b. $\tan\left(\tan^{-1}\left(-\frac{1}{\sqrt{3}}\right)\right)$
c. $\cos^{-1}\left(\cos\left(\frac{5\pi}{4}\right)\right)$
d. $\sin^{-1}\left(\cos\left(\frac{2\pi}{3}\right)\right)$

**Solution**

a. Evaluating $\sin^{-1}(-\sqrt{3}/2)$ is equivalent to finding the angle $\theta$ such that $\sin\theta = -\sqrt{3}/2$ and $-\pi/2 \le \theta \le \pi/2$. The angle $\theta = -\pi/3$ satisfies these two conditions. Therefore, $\sin^{-1}(-\sqrt{3}/2) = -\pi/3$.
b. First we use the fact that $\tan^{-1}(-1/\sqrt{3}) = -\pi/6$. Then $\tan(-\pi/6) = -1/\sqrt{3}$. Therefore, $\tan(\tan^{-1}(-1/\sqrt{3})) = -1/\sqrt{3}$.
c. To evaluate $\cos^{-1}(\cos(5\pi/4))$,first use the fact that $\cos(5\pi/4) = -\sqrt{2}/2$. Then we need to find the angle $\theta$ such that $\cos(\theta) = -\sqrt{2}/2$ and $0 \le \theta \le \pi$. Since $3\pi/4$ satisfies both these conditions, we have $\cos^{-1}(\cos(5\pi/4)) = \cos^{-1}(-\sqrt{2}/2)) = 3\pi/4$.
d. Since $\cos(2\pi/3) = -1/2$, we need to evaluate $\sin^{-1}(-1/2)$. That is, we need to find the angle $\theta$ such that $\sin(\theta) = -1/2$ and $-\pi/2 \le \theta \le \pi/2$. Since $-\pi/6$ satisfies both these conditions, we can conclude that $\sin^{-1}(\cos(2\pi/3)) = \sin^{-1}(-1/2) = -\pi/6$.

### The Maximum Value of a Function

In many areas of science, engineering, and mathematics, it is useful to know the maximum value a function can obtain, even if we don't know its exact value at a given instant. For instance, if we have a function describing the strength of a roof beam, we would want to know the maximum weight the beam can support without breaking. If we have a function that describes the

speed of a train, we would want to know its maximum speed before it jumps off the rails. Safe design often depends on knowing maximum values.

This project describes a simple example of a function with a maximum value that depends on two equation coefficients. We will see that maximum values can depend on several factors other than the independent variable $x$.

1. Consider the graph in Figure 1.5.9 of the function $y = \sin x + \cos x$. Describe its overall shape. Is it periodic? How do you know?

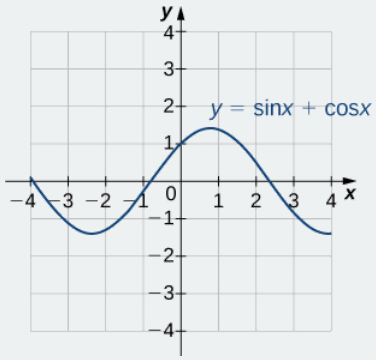

Figure 1.5.9: The graph of $y = \sin x + \cos x$.

Using a graphing calculator or other graphing device, estimate the $x$- and $y$-values of the maximum point for the graph (the first such point where $x > 0$). It may be helpful to express the $x$-value as a multiple of $\pi$.

2. Now consider other graphs of the form $y = A\sin x + B\cos x$ for various values of $A$ and $B$. Sketch the graph when $A = 2$ and $B = 1$, and find the $x$- and $y$-values for the maximum point. (Remember to express the $x$-value as a multiple of $\pi$, if possible.) Has it moved?

3. Repeat for $A = 1,\ B = 2$. Is there any relationship to what you found in part (2)?

4. Complete the following table, adding a few choices of your own for $A$ and $B$:

| $A$ | $B$ | $x$ | $y$ | $A$ | $B$ | $x$ | $y$ |
|---|---|---|---|---|---|---|---|
| 0 | 1 | | | 3 | 4 | | |
| 1 | 0 | | | 4 | 3 | | |
| 1 | 1 | | | $\sqrt{3}$ | 1 | | |
| 1 | 2 | | | 1 | $\sqrt{3}$ | | |
| 2 | 1 | | | 12 | 5 | | |
| 2 | 2 | | | 5 | 12 | | |

5. Try to figure out the formula for the $y$-values.

6. The formula for the $x$-values is a little harder. The most helpful points from the table are $(1,1)$, $(1,\sqrt{3})$, $(\sqrt{3},1)$. (Hint: Consider inverse trigonometric functions.)

7. If you found formulas for parts (5) and (6), show that they work together. That is, substitute the $x$-value formula you found into $y = A\sin x + B\cos x$ and simplify it to arrive at the $y$-value formula you found.

## Key Concepts

- Radian measure is defined such that the angle associated with the arc of length 1 on the unit circle has radian measure 1. An angle with a degree measure of $180°$ has a radian measure of $\pi$ rad.
- For acute angles $\theta$,the values of the trigonometric functions are defined as ratios of two sides of a right triangle in which one of the acute angles is $\theta$.

- For a general angle $\theta$, let $(x, y)$ be a point on a circle of radius $r$ corresponding to this angle $\theta$. The trigonometric functions can be written as ratios involving $x$, $y$, and $r$.
- The trigonometric functions are periodic. The sine, cosine, secant, and cosecant functions have period $2\pi$. The tangent and cotangent functions have period $\pi$.

## Key Equations

- **Generalized sine function**

$$f(x) = A\sin(B(x - \alpha)) + C$$

## Glossary

**periodic function**

a function is periodic if it has a repeating pattern as the values of $x$ move from left to right

**radians**

for a circular arc of length $s$ on a circle of radius 1, the radian measure of the associated angle $\theta$ is $s$

**trigonometric functions**

functions of an angle defined as ratios of the lengths of the sides of a right triangle

**trigonometric identity**

an equation involving trigonometric functions that is true for all angles $\theta$ for which the functions in the equation are defined

# 1.5E: Exercises

**In exercises 1 - 5, convert each angle in degrees to radians. Write the answer as a multiple of $\pi$.**

1) $240^\circ$

**Answer**

$\frac{4\pi}{3}$ rad

2) $15^\circ$

3) $60^\circ$

**Answer**

$\frac{\pi}{3}$ rad

4) $-225^\circ$

5) $330^\circ$

**Answer**

$\frac{11\pi}{6}$ rad

**In exercises 6 - 10, convert each angle in radians to degrees.**

6) $\frac{\pi}{2}$ rad

7) $\frac{7\pi}{6}$ rad

**Answer**

$210^\circ$

8) $\frac{11\pi}{2}$ rad

9) $-3\pi$ rad

**Answer**

$-540^\circ$

10) $\frac{5\pi}{12}$ rad

**In exercises 11 - 16, evaluate the functional values.**

11) $\cos\frac{4\pi}{3}$

**Answer**

$\cos\frac{4\pi}{3} = -0.5$

12) $\tan\frac{19\pi}{4}$

13) $\sin\left(-\frac{3\pi}{4}\right)$

**Answer**

$\sin\left(-\frac{3\pi}{4}\right) = -\frac{\sqrt{2}}{2}$

14) $\sec\left(-\frac{\pi}{6}\right)$

15) $\sin\left(-\frac{\pi}{12}\right)$

**Answer**

$$\sin\left(-\frac{\pi}{12}\right)=\frac{\sqrt{3}-1}{2\sqrt{2}}$$

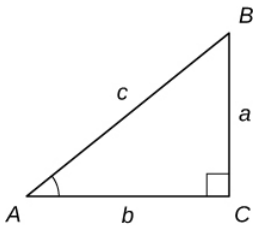
16) $\cos\left(-\frac{5\pi}{12}\right)$

**In exercises 17 - 22, consider triangle $ABC$, a right triangle with a right angle at $C$.**

**a. Find the missing side of the triangle.**

**b. Find the six trigonometric function values for the angle at $A$.**

**Where necessary, round to one decimal place.**



= 225^{\circ} \cdot

17) $a=4,\ c=7$

**Answer**

a. $b=5.7$

b. $\sin A=\frac{4}{7},\ \cos A=\frac{5.7}{7},\ \tan A=\frac{4}{5.7},\ \csc A=\frac{7}{4},\ \sec A=\frac{7}{5.7},\ \cot A=\frac{5.7}{4}$

18) $a=21,\ c=29$

19) $a=85.3,\ b=125.5$

**Answer**

a. $c=151.7$

b. $\sin A=0.5623,\ \cos A=0.8273,\ \tan A=0.6797,\ \csc A=1.778,\ \sec A=1.209,\ \cot A=1.471$

20) $b=40,\ c=41$

21) $a=84,\ b=13$

**Answer**

a. $c=85$

b. $\sin A=\frac{84}{85},\ \cos A=\frac{13}{85},\ \tan A=\frac{84}{13},\ \csc A=\frac{85}{84},\ \sec A=\frac{85}{13},\ \cot A=\frac{13}{84}$

22) $b=28,\ c=35$

**In exercises 23 - 26, $P$ is a point on the unit circle.**

**a. Find the (exact) missing coordinate value of each point and**

**b. find the values of the six trigonometric functions for the angle $\theta$ with a terminal side that passes through point $P$.**

**Rationalize denominators.**

23) $P\left(\frac{7}{25},y\right),\quad y>0$

**Answer**

a. $y=\frac{24}{25}$

b. $\sin\theta=\frac{24}{25},\ \cos\theta=\frac{7}{25},\ \tan\theta=\frac{24}{7},\ \csc\theta=\frac{25}{24},\ \sec\theta=\frac{25}{7},\ \cot\theta=\frac{7}{24}$

24) $P\left(-\frac{15}{17},y\right),\quad y>0$

25) $P\left(x, \frac{\sqrt{7}}{3}\right), \quad x > 0$

**Answer**

a. $x = -\frac{\sqrt{2}}{3}$

b. $\sin\theta = \frac{\sqrt{7}}{3}, \ \cos\theta = -\frac{\sqrt{2}}{3}, \ \tan\theta = -\frac{\sqrt{14}}{2}, \ \csc\theta = \frac{3\sqrt{7}}{7}, \ \sec\theta = -\frac{3\sqrt{2}}{2}, \ \cot\theta = -\frac{\sqrt{14}}{7}$

26) $P\left(x, -\frac{\sqrt{15}}{4}\right), \quad y > 0$

**In exercises 27 - 34, simplify each expression by writing it in terms of sines and cosines, then simplify. The final answer does not have to be in terms of sine and cosine only.**

27) $\tan^2 x + \sin x \csc x$

**Answer**

$\sec^2 x$

28) $\sec x \sin x \cot x$

29) $\frac{\tan^2 x}{\sec^2 x}$

**Answer**

$\sin^2 x$

30) $\sec x - \cos x$

31) $(1 + \tan\theta)^2 - 2\tan\theta$

**Answer**

$\sec^2\theta$

32) $(\sin x)(\csc x - \sin x)$

33) $\frac{\cos t}{\sin t} + \frac{\sin t}{1 + \cos t}$

**Answer**

$\frac{1}{\sin t} = \csc t$

34) $\frac{1 + \tan^2\alpha}{1 + \cot^2\alpha}$

**In exercises 35 - 42, verify that each equation is an identity.**

35) $\frac{\tan\theta\cot\theta}{\csc\theta} = \sin\theta$

36) $\frac{\sec^2\theta}{\tan\theta} = \sec\theta\csc\theta$

37) $\frac{\sin t}{\csc t} + \frac{\cos t}{\sec t} = 1$

38) $\frac{\sin x}{\cos x + 1} + \frac{\cos x - 1}{\sin x} = 0$

39) $\cot\gamma + \tan\gamma = \sec\gamma\csc\gamma$

40) $\sin^2\beta + \tan^2\beta + \cos^2\beta = \sec^2\beta$

41) $\frac{1}{1 - \sin\alpha} + \frac{1}{1 + \sin\alpha} = 2\sec^2\alpha$

42) $\frac{\tan\theta - \cot\theta}{\sin\theta\cos\theta} = \sec^2\theta - \csc^2\theta$

**In exercises 43 - 50, solve the trigonometric equations on the interval $0 \le \theta < 2\pi$.**

43) $2\sin\theta - 1 = 0$

**Answer**

$\left\{\frac{\pi}{6}, \frac{5\pi}{6}\right\}$

44) $1 + \cos\theta = \frac{1}{2}$

45) $2\tan^2\theta = 2$

**Answer**

$\left\{\frac{\pi}{4}, \frac{3\pi}{4}, \frac{5\pi}{4}, \frac{7\pi}{4}\right\}$

46) $4\sin^2\theta - 2 = 0$

47) $\sqrt{3}\cot\theta + 1 = 0$

**Answer**

$\left\{\frac{2\pi}{3}, \frac{5\pi}{3}\right\}$

48) $3\sec\theta - 2\sqrt{3} = 0$

49) $2\cos\theta\sin\theta = \sin\theta$

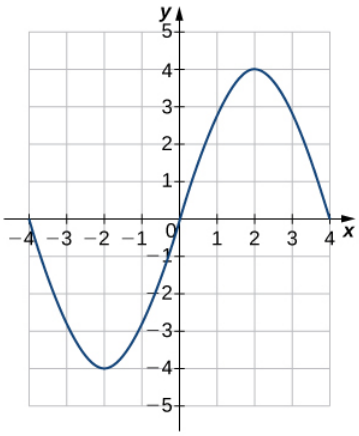
**Answer**

$\left\{0, \pi, \frac{\pi}{3}, \frac{5\pi}{3}\right\}$

50) $\csc^2\theta + 2\csc\theta + 1 = 0$

**In exercises 51 - 54, each graph is of the form $y = A\sin Bx$ or $y = A\cos Bx$, where $B > 0$. Write the equation of the graph.**

51)

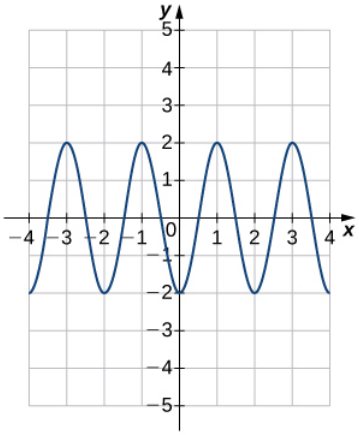


**Answer**

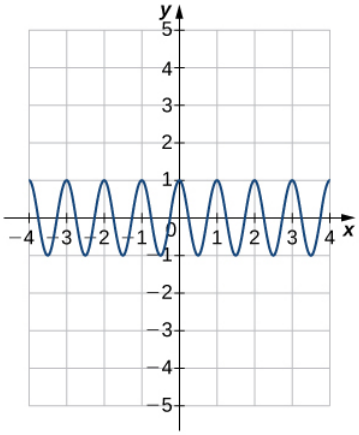
$y = 4\sin\left(\frac{\pi}{4}x\right)$

52)

https://math.libretexts.org/@go/page/171829



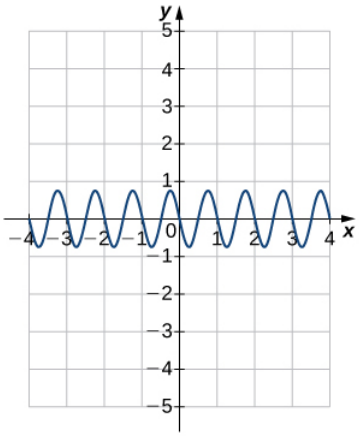
53)



**Answer**

$y = \cos 2\pi x$

54)



**In exercises 55 - 60, find**

**a. the amplitude,**

**b. the period, and**

**c. the phase shift with direction for each function.**

55) $y = \sin\left(x - \frac{\pi}{4}\right)$

**Answer**

a. $1$
b. $2\pi$
c. $\frac{\pi}{4}$ units to the right

56) $y = 3\cos(2x + 3)$

57) $y = -\frac{1}{2}\sin\left(\frac{1}{4}x\right)$

**Answer**

a. $\frac{1}{2}$
b. $8\pi$
c. No phase shift

58) $y = 2\cos\left(x - \frac{\pi}{3}\right)$

59) $y = -3\sin(\pi x + 2)$

**Answer**

a. $3$
b. $2$
c. $\frac{2}{\pi}$ units to the left

60) $y = 4\cos\left(2x - \frac{\pi}{2}\right)$

61) [Technology Required] The diameter of a wheel rolling on the ground is $40$ in. If the wheel rotates through an angle of $120°$, how many inches does it move? Approximate to the nearest whole inch.

**Answer**

Approximately $42$ in.

62) [Technology Required] Find the length of the arc intercepted by central angle $\theta$ in a circle of radius $r$. Round to the nearest hundredth.

a. $r = 12.8$ cm, $\theta = \frac{5\pi}{6}$ rad b. $r = 4.378$ cm, $\theta = \frac{7\pi}{6}$ rad c. $r = 0.964$ cm, $\theta = 50°$ d. $r = 8.55$ cm, $\theta = 325°$

63) [Technology Required] As a point $P$ moves around a circle, the measure of the angle changes. The measure of how fast the angle is changing is called angular speed, $\omega$, and is given by $\omega = \theta/t$, where $\theta$ is in radians and $t$ is time. Find the angular speed for the given data. Round to the nearest thousandth.

a. $\theta = \frac{7\pi}{4}$ rad, $t = 10$ sec b. $\theta = \frac{3\pi}{5}$ rad, $t = 8$ sec c. $\theta = \frac{2\pi}{9}$ rad, $t = 1$ min d. $\theta = 23.76$ rad, $t = 14$ min

**Answer**

a. $0.550$ rad/sec
b. $0.236$ rad/sec
c. $0.698$ rad/min
d. $1.697$ rad/min

64) [Technology Required] A total of $250,000\ \text{m}^2$ of land is needed to build a nuclear power plant. Suppose it is decided that the area on which the power plant is to be built should be circular.

a)Find the radius of the circular land area.

b)If the land area is to form a $45°$ sector of a circle instead of a whole circle, find the length of the curved side.

65) [Technology Required] The area of an isosceles triangle with equal sides of length $x$ is $\frac{1}{2}x^2 \sin\theta$, where $\theta$ is the angle formed by the two sides. Find the area of an isosceles triangle with equal sides of length $8$ in. and angle $\theta = \frac{5\pi}{12}$ rad.

**Answer**

$\approx 30.9 \text{ in}^2$

66) [Technology Required] A particle travels in a circular path at a constant angular speed $\omega$. The angular speed is modeled by the function $\omega = 9\,|\cos(\pi t - \pi/12)|$. Determine the angular speed at $t = 9$ sec.

67) [Technology Required] An alternating current for outlets in a home has voltage given by the function $V(t) = 150\cos 368t$,

where $V$ is the voltage in volts at time $t$ in seconds.

a) Find the period of the function and interpret its meaning.

b) Determine the number of periods that occur when $1$ sec has passed.

**Answer**

a. $\frac{\pi}{184}$; the voltage repeats every $\frac{\pi}{184}$ sec
b. Approximately $59$ periods

68) [Technology Required] The number of hours of daylight in a northeast city is modeled by the function

$$N(t) = 12 + 3\sin\left[\frac{2\pi}{365}(t - 79)\right],$$

where $t$ is the number of days after January 1.

a) Find the amplitude and period.

b) Determine the number of hours of daylight on the longest day of the year.

c) Determine the number of hours of daylight on the shortest day of the year.

d) Determine the number of hours of daylight 90 days after January 1.

e) Sketch the graph of the function for one period starting on January 1.

69) [Technology Required] Suppose that $T = 50 + 10\sin\left[\frac{\pi}{12}(t - 8)\right]$ is a mathematical model of the temperature (in degrees Fahrenheit) at $t$ hours after midnight on a certain day of the week.

a) Determine the amplitude and period.

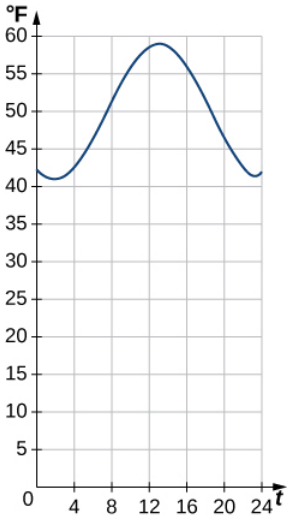
b) Find the temperature 7 hours after midnight.

c) At what time does $T = 60°$ ?

d) Sketch the graph of $T$ over $0 \le t \le 24$.

**Answer**

a. Amplitude = $10$; Period=$24$
b. $47.4°$ F
c. $14$ hours later, or 2 p.m.
d.



70) [Technology Required] The function $H(t) = 8\sin\left(\frac{\pi}{6}t\right)$ models the height $H$ (in feet) of the tide $t$ hours after midnight. Assume that $t = 0$ is midnight.

a) Find the amplitude and period.

b) Graph the function over one period.

c) What is the height of the tide at 4:30 a.m.?

**In exercises 71 - 79, evaluate the functions. Give the exact value.**

71) $\tan^{-1}\left(\frac{\sqrt{3}}{3}\right)$

**Answer**

$\frac{\pi}{6}$

72) $\cos^{-1}\left(-\frac{\sqrt{2}}{2}\right)$

73) $\cot^{-1}(1)$

**Answer**

$\frac{\pi}{4}$

74) $\sin^{-1}(-1)$

75) $\cos^{-1}\left(\frac{\sqrt{3}}{2}\right)$

**Answer**

$\frac{\pi}{6}$

76) $\cos\left(\tan^{-1}(\sqrt{3})\right)$

77) $\sin\left(\cos^{-1}\left(\frac{\sqrt{2}}{2}\right)\right)$

**Answer**

$\frac{\sqrt{2}}{2}$

78) $\sin^{-1}\left(\sin\left(\frac{\pi}{3}\right)\right)$

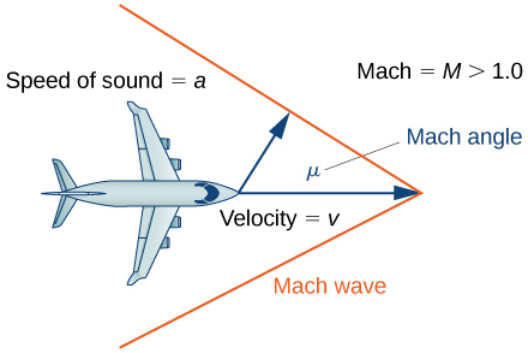
79) $\tan^{-1}\left(\tan\left(-\frac{\pi}{6}\right)\right)$

**Answer**

$-\frac{\pi}{6}$

80) [Technology Required] An airplane's Mach number $M$ is the ratio of its speed to the speed of sound. When a plane is flying at a constant altitude, then its Mach angle is given by $\mu = 2\sin^{-1}\left(\frac{1}{M}\right)$.

Find the Mach angle (to the nearest degree) for the following Mach numbers.



a. $\mu = 1.4$

b. $\mu = 2.8$

c. $\mu = 4.3$

**Answer**

a. $\sim 92°$ b. $\sim 42°$ c. $\sim 27°$

81) [Technology Required] Using $\mu = 2\sin^{-1}\left(\frac{1}{M}\right)$, find the Mach number M for the following angles.

a. $\mu = \frac{\pi}{6}$

b. $\mu = \frac{2\pi}{7}$

c. $\mu = \frac{3\pi}{8}$

82) [Technology Required] The temperature (in degrees Celsius) of a city in the northern United States can be modeled by the function

$$T(x) = 5 + 18\sin\left[\frac{\pi}{6}(x - 4.6)\right],$$

where $x$ is time in months and $x = 1.00$ corresponds to January 1. Determine the month and day when the temperature is $21°C$.

**Answer**

$x \approx 6.69, 8.51$; so, the temperature occurs on June 21 and August 15

83) [Technology Required] The depth (in feet) of water at a dock changes with the rise and fall of tides. It is modeled by the function $D(t) = 5\sin\left(\frac{\pi}{6}t - \frac{7\pi}{6}\right) + 8$, where $t$ is the number of hours after midnight. Determine the first time after midnight when the depth is $11.75$ ft.

84) [Technology Required] An object moving in simple harmonic motion is modeled by the function $s(t) = -6\cos\left(\frac{\pi t}{2}\right)$, where $s$ is measured in inches and $t$ is measured in seconds. Determine the first time when the distance moved is $4.5$ in.

**Answer**

$\sim 1.5$ sec

85) [Technology Required] A local art gallery has a portrait 3 ft in height that is hung 2.5 ft above the eye level of an average person. The viewing angle $\theta$ can be modeled by the function $\theta = \tan^{-1}\frac{5.5}{x} - \tan^{-1}\frac{2.5}{x}$, where $x$ is the distance (in feet) from the portrait. Find the viewing angle when a person is 4 ft from the portrait.

86) [Technology Required] Use a calculator to evaluate $\tan^{-1}(\tan(2.1))$ and $\cos^{-1}(\cos(2.1))$. Explain the results of each.

**Answer**

$\tan^{-1}(\tan(2.1)) \approx -1.0416$; the expression does not equal $2.1$ since $2.1 > 1.57 = \frac{\pi}{2}$—in other words, it is not in the restricted domain of $\tan x$. $\cos^{-1}(\cos(2.1)) = 2.1$, since $2.1$ is in the restricted domain of $\cos x$.

87) [Technology Required] Use a calculator to evaluate $\sin(\sin^{-1}(-2))$ and $\tan(\tan^{-1}(-2))$. Explain the results of each.

# 1.6: Hyperbolic Functions

**Learning Objectives**

- Identify the hyperbolic functions, their graphs, and basic identities.

Hawk A.I. Section-Specific Tutor

Please note that, to access the Hawk A.I. Tutor, you will need a (free) OpenAI account.

Hanging cables form a curve called a catenary. These curves are modeled using a new (to you) family of functions called the hyperbolic functions.

Unlike all the functions encountered in Calculus up to this point, the functions in this section should be unfamiliar to you. Here we define hyperbolic and inverse hyperbolic functions, which involve combinations of exponential and logarithmic functions. These provide a unique bridge between two groups of transcendental functions - exponential and trigonometric.

## From Circular to Hyperbolic Functions

Before introducing the hyperbolic functions, it is worthwhile to review a particular feature of the trigonometric functions.

Most people refer to the sine, cosine, tangent, and their reciprocals as trigonometric functions; however, they are also known as **circular functions**. This is because their entire definition is based on the unit circle. Recall that the unit circle is defined by the relation

$$x^2 + y^2 = 1.$$

The graph of this relation can be seen in Figure **1.6.1** below.

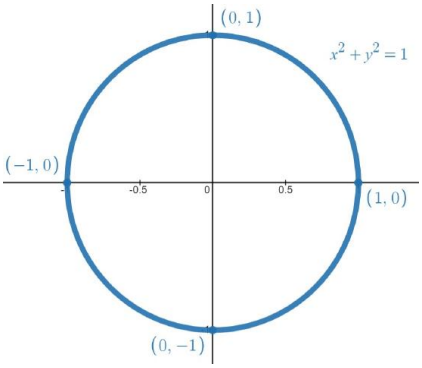

*Figure* **1.6.1***: The unit circle.*

During our journey through Trigonometry, we discovered that the length of the arc on the unit circle subtended by an angle $\theta$ (in radians) is $s = \theta$. Moreover, we derived the area of a sector formula to be

$$A = \frac{1}{2} r^2 \theta.$$

Since the radius of the unit circle is $r = 1$ and $\theta = s$, we arrived at the fact that the area seen in Figure 1.6.2 is

$$A = \frac{s}{2}.$$

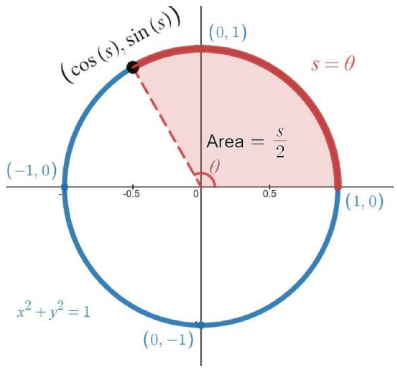

*Figure* 1.6.2*: The area of the sector of the unit circle having arc length* $s$ *is* $\frac{s}{2}$.

Stated clearly, the area of the region bounded by the positive $x$-axis, the unit circle, and the line segment connecting the origin to the point $(\cos(s), \sin(s))$ is $s/2$.

In this section, we ask the following question:

> *Could we develop a set of functions, let's call them* $\cosh(s)$ *and* $\sinh(s)$*, such that the area of the region bounded by the positive* $x$*-axis, the unit hyperbola, and the line segment connecting the origin to the point* $(\cosh(s), \sinh(s))$ *is* $s/2$*?*

Before we can answer this question, we need to define the unit hyperbola. For our purposes, the **unit hyperbola** will be defined by the relation

$$x^2 - y^2 = 1.$$

Furthermore, we restrict our work to the right branch of this hyperbola (see Figure 1.6.3).

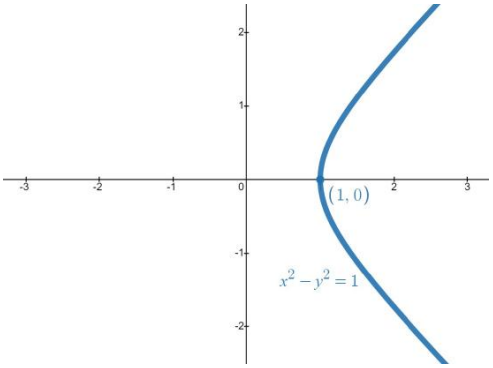

*Figure* 1.6.3*: The unit hyperbola (right branch only).*

We plot a point $(x, y) = (\cosh(s), \sinh(s))$ on this branch, highlight the arc length along the unit hyperbola to this point, draw a line segment connecting the origin to this point, and shade the bounded region (see Figure 1.6.4).

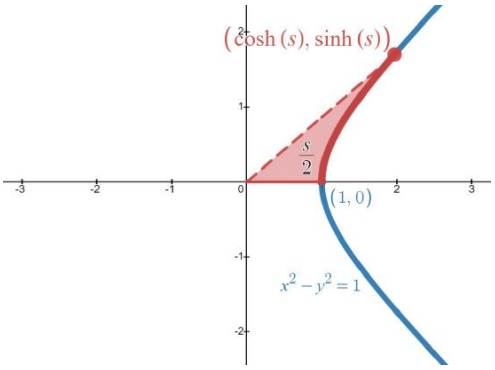

*Figure* 1.6.4*: We desire* $\cosh(s)$ *and* $\sinh(s)$ *so that the shaded region is* $s/2$.

We want to define these new functions, $\cosh(s)$ and $\sinh(s)$, so that the shaded region is $s/2$.

**Caution: The Argument of a Hyperbolic Function is Not an Angle, Nor an Arc Length**

It is *critical* to point out here that the highlighted arc length will *not* be $s$. In fact, the angle between the positive $x$-axis and the line segment connecting the origin to the point $(\cosh(s), \sinh(s))$ will also *not* be $s$. Our goal with this discussion is *not* to find the arc length *nor* to find the angle, but instead to create functions, $\cosh(s)$ and $\sinh(s)$, so that the area of the bounded region is $s/2$.

As you can see in Figure 1.6.4, we define the **hyperbolic cosine** to be the $x$-value of this terminal point, and the **hyperbolic sine** as the $y$-value. We denote these functions as $\cosh(s)$ and $\sinh(s)$, respectively.

## Hyperbolic Functions

The previous discussion considered the hyperbolic cosine and hyperbolic sine as functions of $s$; however, most textbooks work exclusively with these as functions of $t$. Since $s$ is a "dummy variable," we can replace it easily with $t$ for the remainder of this section.

It turns out (and can be proven in Calculus II) that the hyperbolic cosine and the hyperbolic sine can be written in terms of specific combinations of $e^t$ and $e^{-t}$. These functions arise naturally in various engineering and physics applications, including the study of water waves and vibrations of elastic membranes. Another common use, at least for the hyperbolic cosine, is the representation of a hanging chain or cable, also known as a **catenary** (Figure 1.6.5). If we introduce a coordinate system so that the low point of the chain lies along the $y$-axis, we can describe the height of the chain in terms of the hyperbolic cosine.

*Figure* 1.6.5*: The shape of a strand of silk in a spider's web can be described in terms of a hyperbolic function. The same shape applies to a chain or cable hanging from two supports with only its own weight. (credit: "Mtpaley", Wikimedia Commons)*

### Theorem: Hyperbolic Functions

Let $\frac{t}{2}$ be the area of the region bounded by the arc along the right branch of the unit hyperbola $x^2 - y^2 = 1$ whose initial point is $(1, 0)$ and terminal point is $(x, y)$, the $x$-axis, and the line segment connecting the origin to $(x, y)$. Then, the **hyperbolic functions** in terms of twice this bounded area, are defined (and derived) as follows:[1]

**Hyperbolic cosine**

$$x = \cosh(t) = \frac{e^t + e^{-t}}{2}$$

**Hyperbolic sine**

$$y = \sinh(t) = \frac{e^t - e^{-t}}{2}$$

**Hyperbolic tangent**

$$\tanh(t) = \frac{\sinh(t)}{\cosh(t)} = \frac{e^t - e^{-t}}{e^t + e^{-t}}$$

**Hyperbolic cosecant**

$$\operatorname{csch}(t) = \frac{1}{\sinh(t)} = \frac{2}{e^t - e^{-t}}$$

**Hyperbolic secant**

$$\operatorname{sech}(t) = \frac{1}{\cosh(t)} = \frac{2}{e^t + e^{-t}}$$

**Hyperbolic cotangent**

$$\coth(t) = \frac{\cosh(t)}{\sinh(t)} = \frac{e^t + e^{-t}}{e^t - e^{-t}}$$

Despite writing this as a theorem, we have not *proven* that the hyperbolic functions are equal to these exponential forms. The reality is that you need Integral Calculus (Calculus II) to prove these relationships.

The name **cosh** rhymes with "gosh," whereas the name **sinh** is pronounced "sinch." **Tanh, sech, csch,** and **coth** are pronounced "tanch," "seech," "coseech," and "cotanch," respectively.

### Example 1.6.1

Simplify $\sinh(5\ln(x))$.

**Solution**

Using the definition of the **sinh** function, we get

$$\begin{aligned}
\sinh(5\ln(x)) &= \frac{e^{5\ln(x)} - e^{-5\ln(x)}}{2} && \text{(definition of Hyperbolic Functions)} \\
&= \frac{e^{\ln(x^5)} - e^{\ln(x^{-5})}}{2} && \text{(Laws of Logarithms)} \\
&= \frac{x^5 - x^{-5}}{2} && \text{(inverse property of exponential and logarithmic functions)}
\end{aligned}$$

**? Checkpoint 1.6.1**

Simplify $\cosh(2\ln x)$.

**Hint**

Use the definition of the cosh function and the power property of logarithm functions.

**Answer**

$(x^2 + x^{-2})/2$

## Graphs of Hyperbolic Functions

To investigate the graphs of the hyperbolic functions, we need to start with a discussion related to Calculus - what happens to $e^{-x}$ as $x \to \infty$? Drawing on our work with limits, we know that $e^{-x} \to 0$ as $x \to \infty$ and $e^{x} \to 0$ as $x \to -\infty$. Therefore,

$$\sinh(x) = \frac{e^x - e^{-x}}{2} \to \frac{e^x}{2}, \text{ as } x \to \infty, \text{ and } \cosh(x) = \frac{e^x + e^{-x}}{2} \to \frac{e^x}{2}, \text{ as } x \to \infty.$$

We purposefully did not write these using true limit notation because we are trying to discover the end behavior of the graphs of these functions. As similar analysis shows that,

$$\sinh(x) = \frac{e^x - e^{-x}}{2} \to \frac{-e^{-x}}{2}, \text{ as } x \to -\infty, \text{ and } \cosh(x) = \frac{e^x + e^{-x}}{2} \to \frac{e^{-x}}{2}, \text{ as } x \to -\infty.$$

Hence, using the graphs of $\frac{1}{2}e^x$, $\frac{1}{2}e^{-x}$, and $-\frac{1}{2}e^{-x}$ as guides, we can graph $\cosh(x)$ and $\sinh(x)$ (see Figure 1.6.6 below).

To graph $\tanh(x)$, we recognize the fact that $\tanh(0) = 0$. Moreover,

$$\begin{aligned}
\lim_{x\to\infty} \tanh(x) &= \lim_{x\to\infty} \frac{e^x - e^{-x}}{e^x + e^{-x}} \\
&= \lim_{x\to\infty} \frac{e^x - e^{-x}}{e^x + e^{-x}} \cdot \frac{e^{-x}}{e^{-x}} && \left(\text{multiplying numerator and denominator by } \frac{e^{-x}}{e^{-x}}\right) \\
&= \lim_{x\to\infty} \frac{1 - e^{-2x}}{1 + e^{-2x}} && \text{(simplifying)} \\
&= \frac{1 - \lim_{x\to\infty} e^{-2x}}{1 + \lim_{x\to\infty} e^{-2x}} && \text{(Limit Laws)} \\
&= \frac{1 - 0}{1 + 0} && \left(\lim_{x\to\infty} e^{-x} = 0\right) \\
&= 1
\end{aligned}$$

A similar argument shows $\lim_{x\to-\infty} \tanh(x) = -1$.

The graphs of the other three hyperbolic functions can be sketched using the graphs of $\cosh(x)$, $\sinh(x)$, and $\tanh(x)$ (Figure 1.6.6).[2]

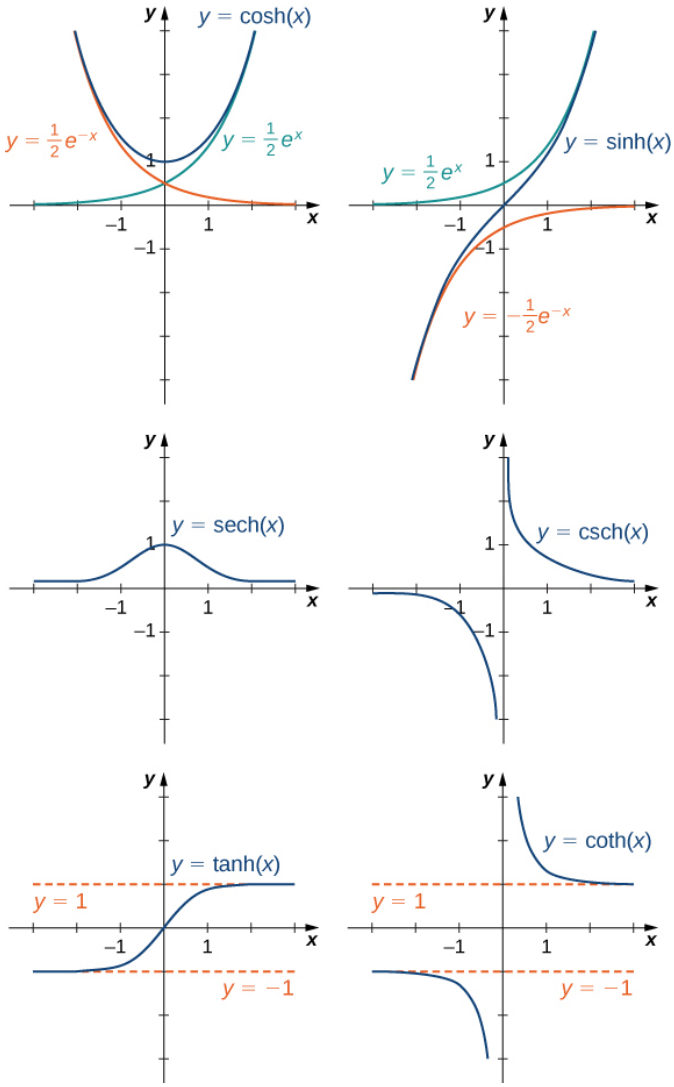

*Figure* **1.6.6***: The hyperbolic functions involve combinations of* $e^x$ *and* $e^{-x}$.

## Hyperbolic Identities

Once you grasp that the hyperbolic functions are based on the unit hyperbola, $x^2 - y^2 = 1$, you immediately arrive at the first of many hyperbolic identities.

**Theorem: The Fundamental Hyperbolic Identity**

$$\cosh^2(t) - \sinh^2(t) = 1$$

**Proof**

Since $x = \cosh(t)$ and $y = \sinh(t)$ on the unit hyperbola $x^2 - y^2 = 1$, we substitute to arrive at $\cosh^2(t) - \sinh^2(t) = 1$.

It is also important to note that this can be proved using the exponential form of the hyperbolic functions.

The Fundamental Hyperbolic Identity is one of many identities involving the hyperbolic functions, *some* of which are listed next.[3] The first four properties follow quickly from the definitions of hyperbolic sine and hyperbolic cosine. Except for some differences in signs, most of these properties are analogous to identities for trigonometric functions.

**Theorem: Basic Hyperbolic Identities**

1. $\cosh(-t) = \cosh(t)$
2. $\sinh(-t) = -\sinh(t)$
3. $\cosh(t) + \sinh(t) = e^t$
4. $\cosh(t) - \sinh(t) = e^{-t}$
5. $1 - \tanh^2(t) = \operatorname{sech}^2(t)$
6. $\coth^2(t) - 1 = \operatorname{csch}^2(t)$
7. $\sinh(t \pm v) = \sinh(t)\cosh(v) \pm \cosh(t)\sinh(v)$
8. $\cosh(t \pm v) = \cosh(t)\cosh(v) \pm \sinh(t)\sinh(v)$

**Example 1.6.2**

If $\sinh(t) = 3/4$, find the values of the remaining five hyperbolic functions.

**Solution**

Using the identity $\cosh^2(t) - \sinh^2(t) = 1$,we see that

$$\cosh^2(t) = 1 + \left(\frac{3}{4}\right)^2 = \frac{25}{16}.$$

Since $\cosh x \geq 1$ for all $x$, we must have $\cosh x = 5/4$. Then, using the definitions for the other hyperbolic functions, we conclude that $\tanh x = 3/5, \operatorname{csch} x = 4/3, \operatorname{sech} x = 4/5$, and $\coth x = 5/3$.

**Example 1.6.3**

Without using $\cosh(t \pm v) = \cosh(t)\cosh(v) \pm \sinh(t)\sinh(v)$, prove

$$\cosh(2t) = \sinh^2(t) + \cosh^2(t).$$

**Solution**

$$\begin{aligned}
\cosh^2(t) + \sinh^2(t) &= \left(\frac{e^t + e^{-t}}{2}\right)^2 + \left(\frac{e^t - e^{-t}}{2}\right)^2 && \text{(exponential form of hyperbolic functions)} \\
&= \frac{e^{2t} + 2 + e^{-2t}}{4} + \frac{e^{2t} - 2 + e^{-2t}}{4} && \text{(distributing and Laws of Exponents)} \\
&= \frac{2e^{2t} + 2e^{-2t}}{4} && \text{(combining like terms)} \\
&= \frac{\cancel{2}\left(e^{2t} + e^{-2t}\right)}{\cancel{2} \cdot 2} && \text{(factoring out the GCF and canceling like factors)} \\
&= \frac{e^{2t} + e^{-2t}}{2} && \text{(canceling like factors)} \\
&= \cosh(2t) && \text{(exponential form of hyperbolic functions)}
\end{aligned}$$

## Inverse Hyperbolic Functions

From the graphs of the hyperbolic functions, we see that all of them are one-to-one except $\cosh x$ and $\operatorname{sech} x$. If we restrict the domains of these two functions to the interval $[0, \infty)$, then all the hyperbolic functions are one-to-one, and we can define the **inverse hyperbolic functions**. Since the hyperbolic functions themselves involve exponential functions, it should make sense to the reader that the inverse hyperbolic functions involve logarithmic functions.

### Theorem: Inverse Hyperbolic Functions

$$\sinh^{-1} x = \operatorname{arcsinh} x = \ln\left(x + \sqrt{x^2+1}\right) \qquad \cosh^{-1} x = \operatorname{arccosh} x = \ln\left(x + \sqrt{x^2-1}\right)$$

$$\tanh^{-1} x = \operatorname{arctanh} x = \frac{1}{2}\ln\left(\frac{1+x}{1-x}\right) \qquad \coth^{-1} x = \operatorname{arccot} x = \frac{1}{2}\ln\left(\frac{x+1}{x-1}\right)$$

$$\operatorname{sech}^{-1} x = \operatorname{arcsech} x = \ln\left(\frac{1+\sqrt{1-x^2}}{x}\right) \qquad \operatorname{csch}^{-1} x = \operatorname{arccsch} x = \ln\left(\frac{1}{x} + \frac{\sqrt{1+x^2}}{|x|}\right)$$

**Proof that $\sinh^{-1} x = \ln\left(x + \sqrt{x^2+1}\right)$**

Suppose $y = \sinh^{-1} x$. Then, $x = \sinh y$ and, by the definition of the hyperbolic sine function, $x = \dfrac{e^y - e^{-y}}{2}$. Therefore,

$$e^y - 2x - e^{-y} = 0.$$

Multiplying this equation by $e^y$, we obtain

$$e^{2y} - 2xe^y - 1 = 0.$$

This can be solved like a quadratic equation, with the solution

$$e^y = \frac{2x \pm \sqrt{4x^2+4}}{2} = x \pm \sqrt{x^2+1}.$$

Since $e^y > 0$,the only solution is the one with the positive sign. Applying the natural logarithm to both sides of the equation, we conclude that

$$y = \ln(x + \sqrt{x^2+1}).$$

*Q.E.D.*

### Caution

The independent variable $x$ in the previous theorem is a *dummy variable*. It is *not* the $x$-coordinate of the terminal point of the arc of length $t$ along the unit hyperbola.

### Example 1.6.4

Evaluate each of the following expressions.

$$\sinh^{-1}(2) \quad \text{and} \quad \tanh^{-1}(1/4)$$

**Solution**

$$\sinh^{-1}(2) = \ln(2 + \sqrt{2^2+1}) = \ln(2+\sqrt{5}) \approx 1.4436$$

$$\tanh^{-1}(1/4) = \frac{1}{2}\ln\left(\frac{1+1/4}{1-1/4}\right) = \frac{1}{2}\ln\left(\frac{5/4}{3/4}\right) = \frac{1}{2}\ln\left(\frac{5}{3}\right) \approx 0.2554$$

### Checkpoint 1.6.4

Evaluate $\tanh^{-1}(1/2)$.

**Hint**

Use the definition of $\tanh^{-1} x$ and simplify.

**Answer**

$\dfrac{1}{2}\ln(3) \approx 0.5493.$

## Footnotes

[1] The $x$-value of the terminal point along the unit hyperbola is *defined* to be $\cosh(t)$ and the $y$-value is *defined* to be $\sinh(t)$. The exponential forms,

$$\cosh(t) = \frac{e^t + e^{-t}}{2} \text{ and } \sinh(t) = \frac{e^t - e^{-t}}{2}$$

are *derived* using techniques in Calculus II. The remaining hyperbolic functions are *defined* as ratios of the $\sinh(t)$ and $\cosh(t)$.

[2] While you will be expected to know the basic shapes of the graphs of $\cosh(x)$ and $\sinh(x)$. The graphs of the remaining four hyperbolic functions are rarely used in practice.

[3] As with identities encountered in Trigonometry, the number of identities involving hyperbolic functions is too numerous to contain within a single table.

# 1.6E: Exercises

## Reading Questions

1. What is the algebraic relation that defines the unit circle? What analogous relation defines the unit hyperbola (right branch)?
2. How are $\cosh(t)$ and $\sinh(t)$ defined in terms of exponential functions?
3. What is the Fundamental Hyperbolic Identity, and how does it relate to the Pythagorean identity for trigonometric functions?
4. Express $\tanh(t)$ in terms of $\sinh(t)$ and $\cosh(t)$, and then in terms of exponential functions.
5. Which hyperbolic function represents the shape of a catenary (a hanging cable)?
6. How does the graph of $\cosh(x)$ differ from $\sinh(x)$ in terms of symmetry and y-intercept?
7. What are the horizontal asymptotes of $y = \tanh(x)$?
8. Are all hyperbolic functions one-to-one? If not, which ones require domain restrictions to define their inverses, and what is a common restriction?
9. How is $\sinh^{-1}x$ defined in terms of a natural logarithm?
10. How is $\cosh^{-1}x$ defined in terms of a natural logarithm? What is the domain for this inverse function?
11. Is $\cosh(x)$ an even or odd function? How about $\sinh(x)$?

## Homework

### Evaluations

1. Evaluate the given function. Round your answers to 3 decimal places, if necessary.
   a. $\coth(-7)$
   b. $\operatorname{csch}(\ln(3))$
   c. $\cosh(3)$
   d. $\sinh(0)$
   e. $\tanh(1)$
   f. $\operatorname{sech}(\ln(7))$
   g. $\sinh^{-1}(3)$
   h. $\cosh^{-1}\left(\frac{3}{2}\right)$
   i. $\tanh^{-1}\left(\frac{1}{2}\right)$

### Simplifications

2. Rewrite the following expressions in terms of exponentials and simplify.
   a. $2\cosh(\ln x)$
   b. $\cosh 4x + \sinh 4x$
   c. $\cosh 2x - \sinh 2x$
   d. $\ln(\cosh x + \sinh x) + \ln(\cosh x - \sinh x)$

### Proofs

3. Prove the identity. Your work should be legible, and all your logic should be clear and justified.

$$\cosh(x+y) = \cosh(x)\cosh(y) + \sinh(x)\sinh(y)$$

4. Prove the identity. Your work should be legible, and all your logic should be clear and justified.

$$\sinh(x+y) = \sinh(x)\cosh(y) + \cosh(x)\sinh(y)$$

5. Prove the identity. Your work should be legible, and all your logic should be clear and justified.

$$\cosh(2x) = \cosh^2(x) + \sinh^2(x)$$

6. Prove the identity. Your work should be legible, and all your logic should be clear and justified.

$$\sinh(2x) = 2\sinh(x)\cosh(x)$$

7. Prove that $f(x) = \cosh(x)$ is an even function.
8. Prove that $f(x) = \sinh(x)$ is an odd function.
9. Prove the identitiy. Your work should be legible, and all your logic should be clear and justified.

$$\cosh(x) + \sinh(x))^n = \cosh(nx) + \sinh(nx)$$

10. Prove the expression for $\sinh^{-1}(x)$. Multiply $x = \sinh(y) = \dfrac{e^y - e^{-y}}{2}$ by $2e^y$ and solve for $y$. Does your expression match the textbook?
11. Prove the expression for $\cosh^{-1}(x)$. Multiply $x = \cosh(y) = \dfrac{e^y + e^{-y}}{2}$ by $2e^y$ and solve for $y$. Does your expression match the textbook?

# CHAPTER OVERVIEW

## 2: Learning Limits

The idea of a limit is central to all of calculus. We begin this chapter by examining why limits are so important. Then, we go on to describe how to find the limit of a function at a given point. Not all functions have limits at all points, and we discuss what this means and how we can tell if a function does or does not have a limit at a particular value. This chapter has been created in an informal, intuitive fashion, but this is not always enough if we need to prove a mathematical statement involving limits. The last section of this chapter presents the more precise definition of a limit and shows how to prove whether a function has a limit.

# 2.1: Tangent Lines and Velocity

**Absolute Prerequisites**

The following prerequisite topics are critical building blocks for this section and others in the course. They are usually too basic to be covered in a support course, though your instructor may offer quick remediation if time allows. Struggling with one or two of these skills is normal, but consistent difficulty suggests you may be in the wrong course. If so, please discuss alternative options with your instructor.

- Algebra
  - Functions
    - Evaluating at a constant
    - Linear Functions
      - Equation of a line
      - Slope
    - Rate of Change

***If you are consistently struggling with these skills, you would be better served enrolling in a Math Boot Camp at Cosumnes River College. Please speak with your instructor about when the next Math Boot Camp starts.***

**Learning Objectives**

- Relate the rate of change of a function to the slope of a secant line.
- Describe the concept and process of approximating the tangent line to a function at a given point.
- Recognize a tangent to a curve at a point as the limit of secant lines.
- Identify instantaneous velocity as the limit of average velocity over a small time interval.
- Distinguish when technology is appropriate to use within a given problem.

As we embark on our study of Calculus, we shall see how its development arose from common solutions to practical problems in areas such as engineering physics. Two key problems led to the initial formulation of calculus: (1) the tangent problem, or how to determine the slope of a line tangent to a curve at a point; and (2) the area problem, or how to determine the area under a curve. Chapters two through four focus on the first of these problems. We will approach the area problem at the end of this course.

## Rates of Change

Rate of change is one of the most critical concepts in Calculus. We begin our investigation of rates of change by looking at the graphs of the three lines $f(x) = -2x - 3$, $g(x) = \frac{1}{2}x + 1$, and $h(x) = 2$, shown in Figure 2.1.1.

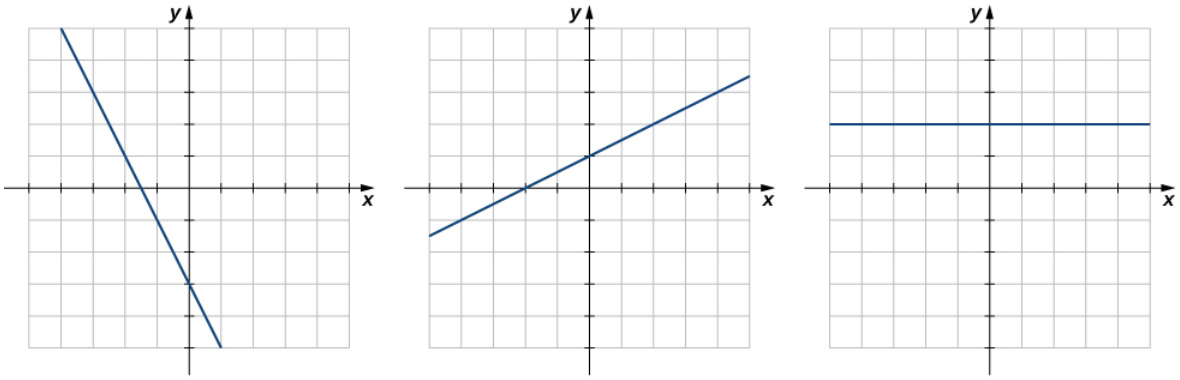

Figure 2.1.1: The rate of change of a linear function is constant in each of these three graphs, with the constant determined by the

slope.

As we move from left to right along the graph of $f(x) = -2x - 3$, we see that the graph decreases at a constant rate. For every $1$ unit we move to the right along the $x$-axis, the $y$-coordinate decreases by $2$ units. This rate of change is determined by the slope $(-2)$ of the line. Similarly, the slope of $1/2$ in the function $g(x)$ tells us that for every change in $x$ of $1$ unit there is a corresponding change in $y$ of $1/2$ unit. The function $h(x) = 2$ has a slope of zero, indicating that the values of the function remain constant. We see that the slope of each linear function indicates the rate of change of the function.

**Theorem: Rates of Change of Linear Functions**

The rate of change at any given point, $(a, f(a))$, of a linear function is constant and equal to the slope of the function.

Compare the graphs of these three functions with the graph of $k(x) = x^2$ (Figure 2.1.2). The graph of $k(x) = x^2$ starts from the left by decreasing rapidly, then begins to decrease more slowly and level off, and then finally begins to increase - slowly at first, followed by an increasing rate of increase as it moves toward the right. Unlike a linear function, no single number represents the rate of change for this function. We quite naturally ask: How do we measure the rate of change of a nonlinear function? Since the rate of change for a nonlinear function is ever-changing, is it possible to determine the rate of change at a specific point?

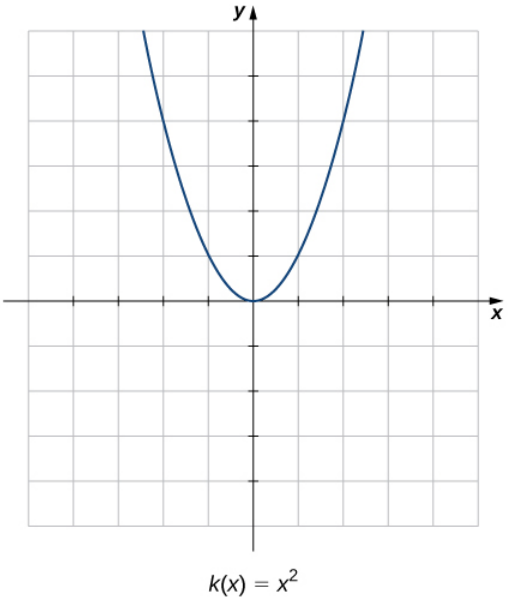

Figure 2.1.2: The function $k(x) = x^2$ does not have a constant rate of change.

Before we go any further, a word of caution is needed.

**Caution: Nonlinear functions do not have slopes**

Lines have slopes; however, nonlinear curves do not. That is, it's incorrect to talk about the "slope" of the nonlinear function $k(x) = x^2$.

How do we overcome this restriction in language? When referencing the "steepness" of a nonlinear function at a point $(a, f(a))$, we instead refer to the slope of the **tangent line** at this point.

**Definition: Tangent Line (Informal)**

In geometry, the **tangent line** (or simply **tangent**) to a plane curve at a given point is the straight line that "just touches" the curve at that point.[1] As it passes through the point where the tangent line and the curve meet, called the **point of tangency**, the tangent line is "going in the same direction" as the curve, and is thus the best straight-line approximation to the curve at that point.

Therefore, if you wanted to tell someone how steep the function $k(x) = x^2$ is at the point $(a, f(a))$, you would reference the slope of the tangent line to the function at that point. Another phrase used for the slope of the tangent line is the **instantaneous rate of change** of $f(x)$ at $(a, f(a))$.

## Tangent and Secant Lines

We can approximate the instantaneous rate of change of a function $f(x)$ at a point $(a, f(a))$ on its graph by taking another point $(x, f(x))$ on the graph of $f(x)$, drawing a line through the two points, and calculating the slope of the resulting line. Such a line is called a **secant line**. Figure **2.1.3** shows a secant line to a function $f(x)$ at a point $(a, f(a))$.

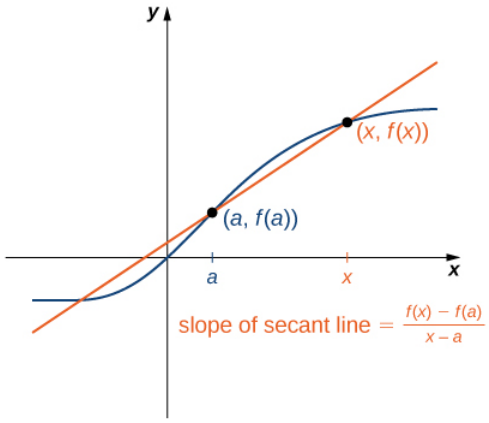

Figure **2.1.3**: The slope of a secant line through a point $(a, f(a))$ estimates the instantaneous rate of change of the function at the point $(a, f(a))$.

We formally define a secant line as follows:

**Definition: Secant Line**

The **secant line** (also known simply as the **secant**) to the function $f(x)$ through the points $(a, f(a))$ and $(x, f(x))$ is the line passing through these points. Its slope is given by

$$m_{sec} = \frac{f(x) - f(a)}{x - a}. \tag{2.1.1}$$

The accuracy of approximating the instantaneous rate of change of the function with a secant line depends on how close $x$ is to $a$. As we see in Figure **2.1.4**, if $x$ is closer to $a$, the slope of the secant line looks to be a better measure of the instantaneous rate of change of $f(x)$ at $a$. There are times when dragging $(x, f(x))$ closer to $(a, f(a))$ will not provide a better estimate of the tangent line, but we will avoid those instances for now.

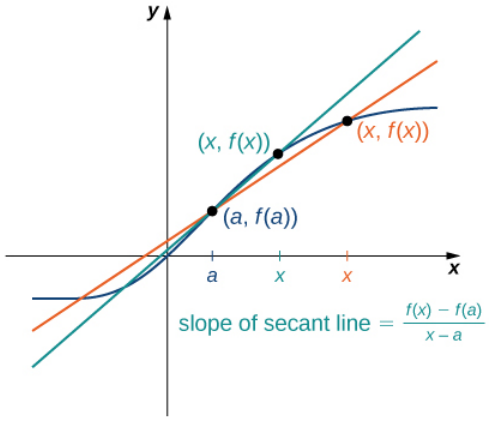

Figure **2.1.4**: As $x$ gets closer to $a$, the slope of the secant line becomes a better approximation to the rate of change of the function $f(x)$ at $a$.

The secant lines themselves approach the tangent line to the function $f(x)$ at $a$ (Figure 2.1.5). As stated previously, the slope of the tangent line to the graph at $a$ is a measure of the instantaneous rate of change of the function at $a$. This value is incredibly important in Calculus.

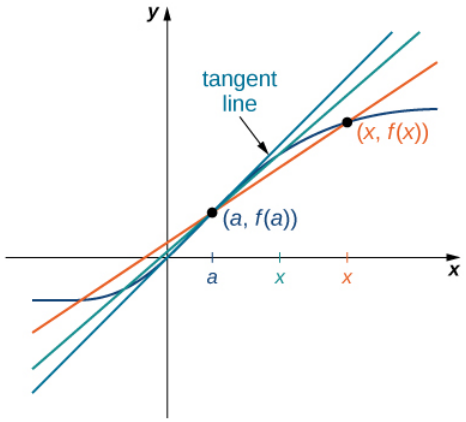

Figure 2.1.5: Solving the Tangent Problem: As $x$ approaches $a$, the secant lines approach the tangent line.

**Note: Anchor Points**

This entire section is focused on using the slopes of the secant lines to *approximate* the slope of the tangent line to $f(x)$ at $(a, f(a))$. The point $(a, f(a))$ is commonly referred to as the **anchor point** because it is "anchored" to a single spot while the secondary point, $(x, f(x))$, is moved toward it. In Figures 2.1.4 and 2.1.5, you can see the secant lines each include the anchor point $(a, f(a))$.

## Approximating the Slope of the Tangent Line

The next example illustrates how to find slopes of secant lines. These slopes estimate the slope of the tangent line or, equivalently, the instantaneous rate of change of the function at the point at which the slopes are calculated.

**Example 2.1.1: Finding Slopes of Secant Lines**

Estimate the instantaneous rate of change (slope of the tangent line) to $f(x) = x^2$ at $x = 1$ by finding slopes of secant lines through $(1, 1)$ and each of the following points on the graph of $f(x) = x^2$.

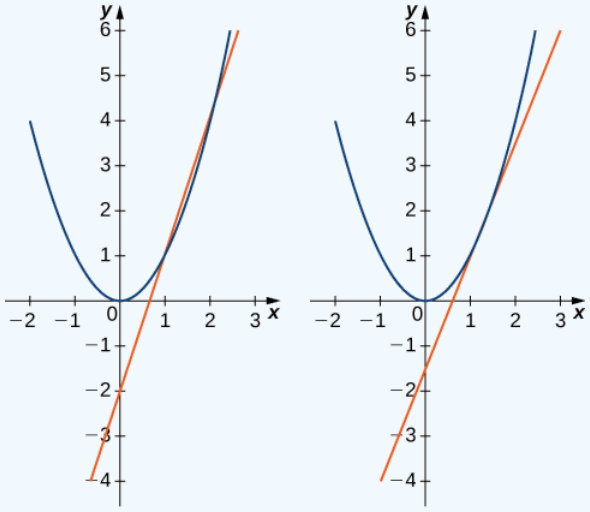
a. $(2, 4)$
b. $\left(\frac{3}{2}, \frac{9}{4}\right)$

**Solutions**

Use the formula for the slope of a secant line (Equation 2.1.1).

a. $m_{sec} = \frac{4-1}{2-1} = 3$
b. $m_{sec} = \frac{\frac{9}{4}-1}{\frac{3}{2}-1} = \frac{5}{2} = 2.5$

The point in part b. is closer to the point $(1, 1)$, so the slope of 2.5 is closer to the slope of the tangent line. A good estimate for the slope of the tangent would be in the range of 2 to 2.5 (Figure 2.1.6).



The secant lines to $f(x) = x^2$ at $(1,1)$ through (a) $(2,4)$ and (b) $\left(\frac{3}{2}, \frac{9}{4}\right)$ provide successively closer approximations to the tangent line to $f(x) = x^2$ at $(1,1)$.

## ? Checkpoint 2.1.1

Estimate the slope of the tangent line (instantaneous rate of change) to $f(x) = x^2$ at $x = 1$ by finding slopes of secant lines through $(1,1)$ and the point $\left(\frac{5}{4}, \frac{25}{16}\right)$ on the graph of $f(x) = x^2$.

**Answer**

2.25

## ✓ Example 2.1.2: Finding Slopes of Secant Lines

Estimate the slope of the tangent line to the function $g(x) = -2\sin(\pi x) + 2$ at $x = \frac{1}{4}$ to three decimal places.

**Solution**

In this example, we are not given an *explicit* list of points to try. Instead, there is an *implicit* assumption that we will create our own list of $x$-values approaching $\frac{1}{4}$. It is important to include $x$-values both greater than and less than $\frac{1}{4}$ in our trials. I will demonstrate two different approaches *both of which should be read for understanding*.

In either approach, we will need to use the formula for the slope of the secant line (Equation 2.1.1); however, the implementation of the formula will differ between methods. Before going into the methods, we need to compute $g\left(\frac{1}{4}\right)$.

$$\begin{aligned} g\left(\frac{1}{4}\right) &= -2\sin\left(\frac{\pi}{4}\right) + 2 \\ &= -\frac{2}{\sqrt{2}} + 2 \\ &= -\sqrt{2} + 2 \\ &= 2 - \sqrt{2} \end{aligned}$$

**Method #1: Explicitly Choosing Values Near $1/4 = 0.25$**

The first approach is the one most students will start with because it mimics how they learned slope. We successively pick numbers closer and closer to 0.25 (from the right and left of 0.25 on the number line) to get an approximation to the slope of

the tangent line.

Prior to "plugging in" values near $0.25$, we write the secant slope formula, substitute any values we have been given (or have computed), and then simplify.

$$\begin{aligned} m_{sec} &= \frac{g(x)-g(a)}{x-a} \\ &= \frac{-2\sin(\pi x)+2-g\left(\frac{1}{4}\right)}{x-\frac{1}{4}} \\ &= \frac{-2\sin(\pi x)+2-\left(2-\sqrt{2}\right)}{x-\frac{1}{4}} \\ &= \frac{-2\sin(\pi x)+2-2+\sqrt{2}}{x-\frac{1}{4}} \\ &= \frac{-2\sin(\pi x)+\sqrt{2}}{x-\frac{1}{4}} \\ &= \frac{-8\sin(\pi x)+4\sqrt{2}}{4x-1} \end{aligned}$$

> Being able to do the algebraic "pre-work" for a problem is critical to success in Calculus. If you were lost on any of the manipulations above, it is best to review Chapter 1 of this text, or review your College Algebra textbook.

At this point, we are ready to substitute values for $x$ that approach $0.25$. The following table contains values approaching $0.25$ from the right (on the number line).

| $x$ | $m_{sec}=\frac{-8\sin(\pi x)+4\sqrt{2}}{4x-1}$ |
|---|---|
| 0.35 | $\approx -3.6779949$ |
| 0.26 | $\approx -4.3723692$ |
| 0.251 | $\approx -4.4358968$ |
| 0.2501 | $\approx -4.442185$ |
| 0.25001 | $\approx -4.4428131$ |
| 0.250001 | $\approx -4.442876$ |

The next table shows similar computations for values of $x$ approaching $0.25$ from the left (on the number line).

| $x$ | $m_{sec} = \frac{-8\sin(\pi x)+4\sqrt{2}}{4x-1}$ |
|---|---|
| 0.15 | $\approx -5.0623256$ |
| 0.24 | $\approx -4.5119351$ |
| 0.249 | $\approx -4.4498545$ |
| 0.2499 | $\approx -4.4435808$ |
| 0.24999 | $\approx -4.4429527$ |
| 0.249999 | $\approx -4.4428899$ |

In both cases, it looks like the slopes of the secant lines are approaching roughly $-4.443$ (when rounded to the third decimal place).

**Caution: Calculus Requires Radians**

Are your values not matching those in the table?

Remember, Calculus requires angles in radians. From this point forward, whenever you are working on a problem involving trigonometric functions and you require a calculator, be sure to set the calculator to radian mode!

### Method #2: Choosing "Wiggles"

The second approach is the preferred approach for the rest of Calculus. We successively pick smaller and smaller numbers to decrease the "wiggled distance" between $a$ and $x$.

The "pre-work" is slightly different than what we did previously. Instead working with $x$, we let $x = a + h$ and allow $h$ to get smaller and smaller. The lower the value of $h$, the closer $x = a + h$ is to $a$. Like before, prior to "plugging in" smaller and smaller values of $h$, we write the secant slope formula, substitute any values we have been given (or have computed), and then simplify.

$$\begin{aligned} m_{sec} &= \frac{g(x)-g(a)}{x-a} \\ &= \frac{g(a+h)-g(a)}{a+h-a} \\ &= \frac{g(a+h)-g(a)}{h} \\ &= \frac{g(0.25+h)-g(0.25)}{h} \\ &= \frac{-2\sin(\pi(0.25+h))+2-g(0.25)}{h} \\ &= \frac{-2\sin(\pi(0.25+h))+2-\left(2-\sqrt{2}\right)}{h} \\ &= \frac{-2\sin(\pi(0.25+h))+2-2+\sqrt{2}}{h} \\ &= \frac{-2\sin(\pi(0.25+h))+\sqrt{2}}{h} \end{aligned}$$

At this point, we are ready to substitute values for $h$ that approach $0$. The following table contains values approaching $0$ from the right (on the number line).

| $h$ | $m_{sec} = \frac{-2\sin(\pi(0.25+h))+\sqrt{2}}{h}$ |
|---|---|
| 0.1 | $\approx -3.6779949$ |
| 0.01 | $\approx -4.3723692$ |
| 0.001 | $\approx -4.4358968$ |
| 0.0001 | $\approx -4.442185$ |
| 0.00001 | $\approx -4.4428131$ |
| 0.000001 | $\approx -4.442876$ |

The next table shows similar computations for values of $x$ approaching $0$ from the left (on the number line).

| $h$ | $m_{sec} = \frac{-2\sin(\pi(0.25+h))+\sqrt{2}}{h}$ |
|---|---|
| -0.1 | $\approx -5.0623256$ |
| -0.01 | $\approx -4.5119351$ |
| -0.001 | $\approx -4.4498545$ |
| -0.0001 | $\approx -4.4435808$ |
| -0.00001 | $\approx -4.4429527$ |
| -0.000001 | $\approx -4.4428899$ |

In both cases, it looks like the slopes of the secant lines are approaching roughly $-4.443$ (when rounded to the third decimal place).

**Result**

In the end, both methods produce the same results, however, the second method demonstrates a significant building block for the study of Calculus. While the "pre-work" was slightly more involved, the inputs (the values that were being substituted in for $h$) not only were easier to work with, but conceptually made sense. We are just decreasing the "space" between the anchor point and $(x, f(x))$ to something near zero.

## Instantaneous Velocity

We continue our investigation by exploring a related question. Keeping in mind that **velocity** may be thought of as the rate of change of position, suppose that we have a function, $s(t)$, that gives the position of an object along a coordinate axis at any given time $t$. Can we use these same ideas to create a reasonable definition of the instantaneous velocity at a given time $t = a$? We start by approximating the instantaneous velocity with an average velocity. First, recall that the speed of an object traveling at a constant rate is the ratio of the distance traveled to the length of time it has traveled. We define the **average velocity** of an object over a time period to be the change in its position divided by the length of the time period.

**Definition: Average Velocity**

Let $s(t)$ be the position of an object moving along a coordinate axis at time $t$. The **average velocity** of the object over a time interval $[a, t]$ where $a < t$ (or $[t, a]$ if $t < a$) is

$$v_{avg} = \frac{s(t) - s(a)}{t - a}. \tag{2.1.2}$$

As $t$ is chosen closer to $a$, the average velocity becomes closer to the instantaneous velocity. Note that finding the average velocity of a position function over a time interval is essentially the same as finding the slope of a secant line to a function. Furthermore, to find the slope of a tangent line at a point $a$, we let the $x$-values approach $a$ in the slope of the secant line. Similarly, to find the instantaneous velocity at time $a$, we let the $t$-values approach $a$ in the average velocity. This process of letting $x$ or $t$ approach $a$ in an expression is called taking a **limit**. Thus, we may define the **instantaneous velocity** as follows.

**Definition: Instantaneous Velocity**

For a position function $s(t)$, the **instantaneous velocity** at a time $t = a$ is the value that the average velocities approach on intervals of the form $[a, t]$ and $[t, a]$ as the values of $t$ become closer to $a$, provided such a value exists.

Example **2.1.3** illustrates this concept of limits and average velocity.

**Example 2.1.3: Finding Average Velocity**

A rock is dropped from a height of 64 ft. It is determined that its height (in feet) above ground t seconds later (for $0 \le t \le 2$) is given by $s(t) = -16t^2 + 64$. Find the average velocity of the rock over each of the given time intervals. Use this information to guess the instantaneous velocity of the rock at time $t = 0.5$.

a. $[0.49, 0.5]$
b. $[0.5, 0.51]$

**Solutions**

Substitute the data into Equation 2.1.2 for the definition of average velocity.

a. $v_{avg} = \frac{s(0.49)-s(0.5)}{0.49-0.5} = -15.84$
b. $v_{avg} = \frac{s(0.51)-s(0.5)}{0.51-0.5} = -16.016$

The instantaneous velocity is somewhere between −15.84 and −16.16 ft/sec. A good guess might be −16 ft/sec.

**Checkpoint 2.1.3**

An object moves along a coordinate axis so that its position at time $t$ is given by $s(t) = t^3$. Estimate its instantaneous velocity at time $t = 2$ by computing its average velocity over the time interval $[2, 2.001]$.

**Hint**

Use Equation 2.1.2 with $v_{avg} = \frac{s(2.001)-s(2)}{2.001-2}$.

**Answer**

12.006001

## Technology in Calculus

Before we leave this section, it is a good time to mention an important point about using technology in this course. Most of your Calculus course should be done *without* the use of technology. As such, you might find it difficult to identify when you are allowed to use technology to help you with a problem. Moreover, if you are allowed technology on a given problem, it is critical to know how to use that technology.

### When to Use Technology

An exercise or homework problem typically requires the using of technology if any of the following are true:

- you are asked to round the answer to a certain number of decimal places or significant figures
- the problem specifically states that a calculator or graphing technology must be used
- you are asked to "build a table of values" or "obtain a numerical approximation"

## How to Efficiently Use Technology to Build Tables

For the material in this section, understanding how to effectively and efficiently use technology to build tables of values is critical. The following example illustrates the importance of knowing how to employ these skills, along with the significance of having a mastery of our prerequisite algebra.

### ✔ Example 2.1.2 Revisted: Efficiently Approximating the Instantaneous Rate of Change Using Algebra and Technology

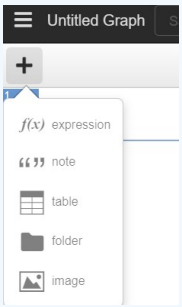
Estimate the instantaneous rate of change of the function $g(x) = -2\sin(\pi x) + 2$ at $x = \frac{1}{4}$ to three decimal places.

**Solution**

The fact that we are being asked to approximate to three decimal places means that we can grab some type of technology to help us with the computations. Recall that, with the second method, we eventually arrived at

$$m_{sec} = \frac{-2\sin(\pi(0.25+h)) + \sqrt{2}}{h}.$$

If you go to the Desmos graphing calculator, you can insert a table by clicking on the "plus" sign and selecting "table".



You will be presented with an unfilled table where the independent variable is $x_1$ and the dependent variable is $y_1$. Replace $y_1$ with $\frac{-2\sin(\pi(0.25+x_1))+\sqrt{2}}{x_1}$ (notice I have traded out $h$ for $x_1$ in our secant slope formula). At this point, you can fill in the values for $x_1$ (which are our values of $h$).

| $x_1$ | $\frac{-2\sin(\pi(0.25+x_1))+\sqrt{2}}{x_1}$ |
|---|---|
| 0.1 | −3.6779949 |
| 0.01 | −4.3723692 |
| 0.001 | −4.4358968 |
| 0.0001 | −4.442185 |
| 0.00001 | −4.4428131 |
| 0.000001 | −4.442876 |
| −0.1 | −5.0623256 |
| −0.01 | −4.5119351 |
| −0.001 | −4.4498545 |
| −0.0001 | −4.4435808 |
| −0.00001 | −4.4429527 |
| −0.000001 | −4.4428899 |

The graphing calculator in Desmos is in radian mode by default, so you do not have to worry about incorrect values in a Calculus course (however, the scientific calculator in Desmos is in degree mode by default).

**Note**

This table of values also can be built in Excel, Google Sheets, and many other applications very easily.

## Footnotes

[1] Leibniz defined the tangent line to a curve at a point as the line through a pair of infinitely close points on the curve.

# 2.1E: Exercises

**For exercises 1 - 3 , points $P(1,2)$ and $Q(x,y)$ are on the graph of the function $f(x)=x^2+1$.**

1. [Technology Required] Complete the following table with the appropriate values: $y$-coordinate of $Q$, the point $Q(x,y)$, and the slope of the secant line passing through points $P$ and $Q$. Round your answer to eight significant digits.

| $x$ | $y$ | $Q(x,y)$ | $m_{sec}$ |
|---|---|---|---|
| 1.1 | | | |
| 1.01 | | | |
| 1.001 | | | |
| 1.0001 | | | |

2. Use the values in the right column of the table in the preceding exercise to guess the value of the slope of the line tangent to $f$ at $x=1$.
3. Use the value in the preceding exercise to find the equation of the tangent line at point $P$. Graph $f(x)$ and the tangent line.

**Answer**

$y=2x$

**For the exercises 4-6, points $P(1,1)$ and $Q(x,y)$ are on the graph of the function $f(x)=x^3$.**

4. [Technology Required] Complete the following table with the appropriate values: $y$-coordinate of $Q$, the point $Q(x,y)$, and the slope of the secant line passing through points $P$ and $Q$. Round your answer to eight significant digits.

| $x$ | $y$ | $Q(x,y)$ | $m_{sec}$ |
|---|---|---|---|
| 1.1 | | | |
| 1.01 | | | |
| 1.001 | | | |
| 1.0001 | | | |

5. Use the values in the right column of the table in the preceding exercise to guess the value of the slope of the tangent line to $f$ at $x=1$.

**Answer**

**3**

6. Use the value in the preceding exercise to find the equation of the tangent line at point $P$. Graph $f(x)$ and the tangent line.

**For the exercises 7 - 9, points $P(4,2)$ and $Q(x,y)$ are on the graph of the function $f(x)=\sqrt{x}$.**

7) [Technology Required] Complete the following table with the appropriate values: $y$-coordinate of $Q$, the point $Q(x,y)$, and the slope of the secant line passing through points $P$ and $Q$. Round your answer to eight significant digits.

| $x$ | $y$ | $Q(x,y)$ | $m_{sec}$ |
|---|---|---|---|
| 4.1 | a. | e. | i. |
| 4.01 | b. | f. | j. |
| 4.001 | c. | g. | k. |
| 4.0001 | d. | h. | l. |

**Answer**

a. 2.0248457
b. 2.0024984
c. 2.0002500
d. 2.0000250
e. (4.1000000,2.0248457)
f. (4.0100000,2.0024984)
g. (4.0010000,2.0002500)
h. (4.00010000,2.0000250)
i. 0.24845673
j. 0.24984395
k. 0.24998438
l. 0.24999844

8) Use the values in the right column of the table in the preceding exercise to guess the value of the slope of the tangent line to $f$ at $x = 4$.

9) Use the value in the preceding exercise to find the equation of the tangent line at point $P$.

**Answer**

$y = \frac{x}{4} + 1$

**For exercises 10 - 12, points $P(1.5, 0)$ and $Q(\phi, y)$ are on the graph of the function $f(\phi) = \cos(\pi\phi)$.**

10) [Technology Required] Complete the following table with the appropriate values: $y$-coordinate of $Q$, the point $Q(\phi, y)$, and the slope of the secant line passing through points $P$ and $Q$. Round your answer to eight significant digits.

| $x$ | $y$ | $Q(\phi,y)$ | $m_{sec}$ |
|---|---|---|---|
| 1.4 | a. | e. | i. |
| 1.49 | b. | f. | j. |
| 1.499 | c. | g. | k. |
| 1.4999 | d. | h. | l. |

11) Use the values in the right column of the table in the preceding exercise to guess the value of the slope of the tangent line to f at $\phi = 1.5$.

**Answer**

$\pi$

12) Use the value in the preceding exercise to find the equation of the tangent line at point $P$.

**For exercises 13 - 15, points $P(-1, -1)$ and $Q(x, y)$ are on the graph of the function $f(x) = \frac{1}{x}$.**

13) [Technology Required] Complete the following table with the appropriate values: $y$-coordinate of $Q$, the point $Q(x,y)$, and the slope of the secant line passing through points $P$ and $Q$. Round your answer to eight significant digits.

| $x$ | $y$ | $Q(x,y)$ | $m_{sec}$ |
|---|---|---|---|
| -1.05 | a. | e. | i. |
| -1.01 | b. | f. | j. |
| -1.005 | c. | g. | k. |
| -1.001 | d. | h. | l. |

j. −0.99009901
k. −0.99502488
l. −0.99900100

14) Use the values in the right column of the table in the preceding exercise to guess the value of the slope of the line tangent to $f$ at $x=-1$.

15) Use the value in the preceding exercise to find the equation of the tangent line at point $P$.

**Answer**

$y=-x-2$

**For exercises 16 - 17, the position function of a ball dropped from the top of a 200-meter tall building is given by $s(t)=200-4.9t^2$, where position $s$ is measured in meters and time $t$ is measured in seconds. Round your answer to eight significant digits.**

16) [Technology Required] Compute the average velocity of the ball over the given time intervals.

a. [4.99,5]

b. [5,5.01]

c. [4.999,5]

d. [5,5.001]

17) Use the preceding exercise to guess the instantaneous velocity of the ball at $t=5$ sec.

**Answer**

$-49$ m/sec (velocity of the ball is 49 m/sec downward)

**For exercises 18 - 19, consider a stone tossed into the air from ground level with an initial velocity of 15 m/sec. Its height in meters at time t seconds is $h(t)=15t-4.9t^2$.**

18) [Technology Required] Compute the average velocity of the stone over the given time intervals.

a. [1,1.05]

b. [1,1.01]

c. [1,1.005]

d. [1,1.001]

19) Use the preceding exercise to guess the instantaneous velocity of the stone at $t = 1$ sec.

**Answer**

$5.2$ m/sec

**For exercises 20 - 21, consider a rocket shot into the air that then returns to Earth. The height of the rocket in meters is given by $h(t) = 600 + 78.4t - 4.9t^2$, where $t$ is measured in seconds.**

20) [Technology Required] Compute the average velocity of the rocket over the given time intervals.

a. [9,9.01]

b. [8.99,9]

c. [9,9.001]

d. [8.999,9]

21) Use the preceding exercise to guess the instantaneous velocity of the rocket at $t = 9$ sec.

**Answer**

$-9.8$ m/sec

**For exercises, consider an athlete running a 40-m dash. The position of the athlete is given by $d(t) = \frac{t^3}{6} + 4t$, where $d$ is the position in meters and $t$ is the time elapsed, measured in seconds.**

22) [Technology Required] Compute the average velocity of the runner over the given time intervals.

a. [1.95,2.05]

b. [1.995,2.005]

c. [1.9995,2.0005]

d. [2,2.00001]

23) Use the preceding exercise to guess the instantaneous velocity of the runner at $t = 2$ sec.

**Answer**

$6$ m/sec

24) Estimate the slope of the tangent line to the function at $t = 1$ for the given function.

a. $\sinh(x)$

b. $\cosh(x)$

c. $\tanh(x)$

# 2.2: The Limit of a Function - A Numerical and Graphical Investigation

**Note to the Instructor (click to expand)**

This section should be used to introduce the intuitive idea of a limit at a finite number by way of building tables and using non-graphing technology (graphs are saved for the next section). Note that limits at infinity are avoided at this point because we are using computational technology to approximate limit values. Single-sided limits are introduced (again, intuitively) and the "DNE" notation is presented. Warnings should abound that this is the weakest form of limit approximation.

---

To succeed in this section, you'll need to use some skills from previous courses. While you should already know them, this is the first time they've been required. You can review these skills in CRC's Corequisite Codex. If you have a support class, it might cover some, **but not all**, of these topics.

**Prerequisite Skills and Support Topics (click to expand)**

- **Sets and Numbers**
  - The Language of Algebra: Essential for understanding the symbolic representation of functions and limits, such as $f(x)$, $\lim_{x \to a} f(x) = L$, and the variables involved.
  - Scientific Notation: While not an explicit skill used within the lecture material within this section, you will inevitably need to understand the basic form of scientific notation when working with calculators or computational technology.
  - Intervals and Interval Notation: The intuitive definition of a limit refers to function behavior within an "open interval containing $a$", making familiarity with interval concepts necessary.
- **Arithmetic**
  - Mathematical Operations - Addition, Subtraction, Multiplication, and Division: These are fundamental for evaluating function values when constructing tables, as seen in all examples (e.g., calculating $x^2 - 4$ in Table 1 or $\sqrt{x} - 2$ in Example 2).
  - Mathematical Operations - Powers and Square Roots: Required for evaluating functions involving powers (e.g., $f(x) = \frac{x^2-4}{x-2}$ in Table 1) or roots (e.g., $f(x) = \frac{\sqrt{x}-2}{x-4}$ in Example 2).
  - The Absolute Value of a Number: Needed to understand and evaluate functions involving absolute values, such as $g(x) = \frac{|x-2|}{x-2}$ discussed in the context of one-sided limits (Table 8) and for homework problems.
- **An Overview of Functions**
  - Evaluating Functions: The core technique of this section, numerical investigation of limits, relies entirely on the student's ability to evaluate $f(x)$ for various $x$-values to construct tables (e.g., Tables 1, 2, and 4).

Hawk A.I. Section-Specific Tutor

COSUMNES RIVER COLLEGE MATHEMATICS

To access the Hawk A.I. Tutor, you will need to be logged into your campus Gmail account.

- Piecewise Functions: Example 4 involves a piecewise-defined function, requiring students to understand how to evaluate such functions based on the input $x$. Some homework problems also feature piecewise functions.

- **Exponential Functions**
  - The Basics of Exponential Functions: Necessary for evaluating exponential expressions that appear in homework problems and understanding the base $e$ in the context of $(1+x)^{1/x}$ (in the homework).
- **Logarithmic Functions**
  - The Basics of Logarithmic Functions: Required for evaluating logarithmic expressions in homework problems.
- **Trigonometry**
  - Radian Measure and Arc Length: The section explicitly cautions that "Calculus Does Not Work in Degrees", meaning an understanding of radian measure is crucial for working with trigonometric functions in limits.
  - Evaluating Trigonometric Functions at Special Angles: Needed to understand and evaluate trigonometric functions like $\sin\theta$ in Example 1, $\sin(1/x)$ in Example 3, and $\sin(\pi/x)$ in Example 6, as well as for homework problems involving trigonometric functions.

---

The following is a list of learning objectives for this section.

**Learning Objectives (click to expand)**

- Describe the limit of a function and use proper limit notation.
- Use a table of values to estimate the limit of a function or to identify when the limit does not exist.
- Define and investigate one-sided limits.
- Explain the relationship between one-sided and two-sided limits.
- Using correct notation, describe an infinite limit.
- Explain why investigating limits using technology is inherently flawed.

The concept of a limit or limiting process, essential to understanding Calculus, has been around for thousands of years. Early mathematicians used a limiting process to obtain better and better approximations of areas of circles. Yet, the formal definition of a limit - as we know and understand it today - did not appear until the late $19^{th}$ century. Therefore, we begin our quest to understand limits, as our mathematical ancestors did, using an intuitive approach. Only after we have had time to play with this intuitive approach do we examine the formal definition of a limit.

## Finite Limit at a Finite Number

Let's consider how the function $f(x)=\frac{x^2-4}{x-2}$ behaves around $x=2$. Building a quick table of values, we get the following.

**Table 2.2.1**

| $x$ | $f(x)$ | $x$ | $f(x)$ |
|---|---|---|---|
| **1.5** | 3.5 | **2.5** | 4.5 |
| **1.9** | 3.9 | **2.1** | 4.1 |
| **1.99** | 3.99 | **2.01** | 4.01 |
| **1.999** | 3.999 | **2.001** | 4.001 |

As the values of $x$ approach $2$ from either side of $2$, the values of $y = f(x)$ look to be approaching $4$. If correct, we would then say that the **limit** of $f(x)$ as $x$ approaches $2$ is $4$. Symbolically, we express this limit as

$$\lim_{x \to 2} \frac{x^2 - 4}{x - 2} = 4.$$

From this very brief informal look at one limit, let's start to develop an intuitive definition of the **finite limit at a finite number**.

We can think of the limit of a function at a finite number $a$ as being the single finite number $L$ (the **finite limit**) that the functional values approach as the $x$-values approach $a$, provided such a real number $L$ exists. Stated more carefully, we have the following (intuitive, but not precise) definition.

**Definition (Intuitive): Finite Limit at a Finite Number**

Let $f(x)$ be a function defined at all values in an open interval containing a finite number $a$, with the possible exception of $a$ itself, and let $L$ be a finite real number. If the values of the function $f(x)$ approach the real number $L$ as the values of $x$ ($\neq a$) approach the number $a$, then we say that the **finite limit** of $f(x)$ as $x$ approaches the finite number $a$ is $L$. (Said more succinctly, as $x$ gets closer to $a$, $f(x)$ gets closer to $L$.) Symbolically, we express this idea as

$$\lim_{x \to a} f(x) = L. \tag{2.2.1}$$

Often, this is simply referred to as a **limit** (rather than a finite limit at a finite number).

**Caution: $x \neq a$**

The intuitive definition of a finite limit at a finite number states that $x$ need not equal $a$. This is critical to understand. The $x$-values are allowed to get very close to $a$ but will never become $a$. In a very real sense, the limit,

$$\lim_{x \to a} f(x) = L,$$

is concerned with the function values as $x$ gets closer and closer to $a$; however, it is *not* asking, "What is $f(a)$?" In fact, it could be the case that $f(a)$ does not exist or $L \neq f(a)$.

In this section, we explore how to *estimate* the value of a limit using a combination of tables and computational technology. We will refer to this method of investigation as a **numerical approximation of the limit**. This can also be rephrased as, "investigating the limit **numerically**." In practice, using a numerical approximation to state the value of a limit presents three issues:

1. they can lead to incorrect presumptions about the true value of the limit,
2. as Calculus is the study of the infinite and infinitesimal, and technology uses finite precision arithmetic, limit computations attempted via technology can lead to massively incorrect values, and
3. using technology or tables to gain an approximation of the value of a limit is *not* Calculus - it is button pushing. Your task in Calculus is to gain a demonstrable understanding of the fundamental concepts of Calculus, and this includes how to work with limits without touching technology or building tables.

These warnings stated, we still take the time to investigate limits numerically in order to gain an intuitive understanding of limits.

## Using Tables to Estimate Limits

To begin our investigation of evaluating $\lim_{x\to a} f(x)$ numerically, we build a table of function values. Choosing two sets of $x$-values - one set approaching $a$ from "below" (these are $x$-values less than $a$), and another set of values approaching $a$ from "above" (these are $x$-values greater than $a$), we get something like Table 2.2.2.

**Table 2.2.2**

| $x$ | $f(x)$ | $x$ | $f(x)$ |
|---|---|---|---|
| $a-0.1$ | $f(a-0.1)$ | $a+0.1$ | $f(a+0.1)$ |
| $a-0.01$ | $f(a-0.01)$ | $a+0.01$ | $f(a+0.01)$ |
| $a-0.001$ | $f(a-0.001)$ | $a+0.001$ | $f(a+0.001)$ |
| $a-0.0001$ | $f(a-0.0001)$ | $a+0.0001$ | $f(a+0.0001)$ |
| Use additional values as necessary. | | Use additional values as necessary. | |

Next, we look at the values in each of the $f(x)$ columns and determine whether the values *seem* to be approaching a single value as we move down the column. In our columns, we look at the sequence of function values $f(a-0.1)$, $f(a-0.01)$, $f(a-0.001)$, $f(a-0.0001)$, and so on, and the sequence of function values $f(a+0.1)$, $f(a+0.01)$, $f(a+0.001)$, $f(a+0.0001)$, and so on.

**Caution: Be prepared to try "wiggle" sizes other than powers of ten**

We have chosen the $x$-values $a\pm 0.1$, $a\pm 0.01$, $a\pm 0.001$, $a\pm 0.0001$, and so forth. These changes, $\pm 0.1$, $\pm 0.01$, $\pm 0.001$, and $0.0001$, I will informally called "wiggles" in the $x$-value. While "wiggles" of these sizes will work most of the time, we may need to modify our choice of "wiggle" sizes on some occasions.

If both function value columns approach a common, $L$, we are inclined to think that

$$\lim_{x\to a} f(x) = L.$$

If unsure of our result, we could evaluate the given function at values closer (but not equal) to $a$; however, due to finite precision arithmetic, the technology we use will round our input to $a$ if our "wiggle" from $a$ is too small.

For example, when we were trying to evaluate $\lim_{x\to 2} \dfrac{x^2-4}{x-2}$ using a table of values, this is what Desmos would have returned if we allowed our $x$-values to get too close to 2 (i.e., allowing our "wiggles" to get too small for Desmos to handle).

**Table 2.2.3**

| $x$ | $f(x)=\frac{x^2-4}{x-2}$ | $x$ | $f(x)=\frac{x^2-4}{x-2}$ |
|---|---|---|---|
| 1.9 | 3.9 | 2.1 | 4.1 |
| 1.9999 | 3.9999 | 2.0001 | 4.0001 |
| 1.9999999 | 3.9999999 | 2.0000001 | 4.0000001 |
| 1.9999999999999999 | undefined | 2.0000000000000001 | undefined |

**Example 2.2.1**

Evaluate

$$\lim_{\theta\to 0} \frac{\sin\theta}{\theta}$$

using a table of function values.

**Solution**

We have calculated some values of $f(\theta) = \frac{\sin\theta}{\theta}$ for $\theta$ near to $0$ in Table 2.2.4.

**Table 2.2.4**

| $\theta$ | $\frac{\sin\theta}{\theta}$ | $\theta$ | $\frac{\sin\theta}{\theta}$ |
|---|---|---|---|
| -0.1 | 0.99833417 | 0.1 | 0.99833417 |
| -0.01 | 0.99998333 | 0.01 | 0.99998333 |
| -0.001 | 0.99999983 | 0.001 | 0.99999983 |
| -0.0001 | 1 | 0.0001 | 1 |

As we read down each $\frac{\sin\theta}{\theta}$ column, we see that the values appear to be approaching $1$. In fact, Desmos (the technology I used to build this table of values) is confidently stating that the function evaluated at $\theta = \pm 0.001$ is *exactly* 1; however, this is not true. In fact, the value of $\frac{\sin(\pm 0.001)}{\pm 0.001}$ is approximately 0.9999998333. Nevertheless, it is *somewhat* reasonable to conclude that

$$\lim_{\theta\to 0}\frac{\sin\theta}{\theta} = 1$$

based on this table of values.

**Caution: Calculus Does Not Work in Degrees**

For reasons we will discuss later, when working with trigonometric functions in Calculus, you *must* work in radians - not degrees.

**Example 2.2.2**

Evaluate

$$\lim_{x\to 4}\frac{\sqrt{x}-2}{x-4}$$

using a table of function values.

**Solution**

As before, we use a table to list values of the function as $x$ gets close to $4$ (from both sides of $4$).

**Table 2.2.5**

| $x$ | $\frac{\sqrt{x}-2}{x-4}$ | $x$ | $\frac{\sqrt{x}-2}{x-4}$ |
|---|---|---|---|
| 3.9 | 0.251582341869 | 4.1 | 0.248456731317 |
| 3.99 | 0.25015644562 | 4.01 | 0.24984394501 |
| 3.999 | 0.250015627 | 4.001 | 0.249984377 |
| 3.9999 | 0.250001563 | 4.0001 | 0.249998438 |
| 3.99999 | 0.25000016 | 4.00001 | 0.24999984 |

After inspecting this table, the function values for $x < 4$ appear to decrease toward $0.25$. Likewise, the function values for $x > 4$ appear to be increasing toward $0.25$. We conclude that

$$\lim_{x\to 4}\frac{\sqrt{x}-2}{x-4} = 0.25.$$

**? Checkpoint 2.2.2**

Estimate

$$\lim_{x\to 1}\frac{\frac{1}{x}-1}{x-1}$$

using a table of functional values. Use a graph to confirm your estimate.

**Hint**

Use **0.9**, **0.99**, **0.999**, **0.9999**, **0.99999** and **1.1**, **1.01**, **1.001**, **1.0001**, **1.00001** as your table values.

**Answer**

$$\lim_{x\to 1}\frac{\frac{1}{x}-1}{x-1}=-1$$

## Two Important Limits

Generating a table of function values provides useful insight into the value of a function's limit at a given point. However, this technique relies too much on technology and the hope that your technology is not "lying" to you. We eventually need to develop alternative methods of evaluating limits. These new methods are more algebraic in nature, and we explore them later in this chapter. At this point, we introduce two particular limits foundational to the techniques to come.

**Theorem: Two Important Limits**

Let $a$ be a real number and $c$ be a constant.

1. $\lim_{x\to a} x = a$ (**Limit of the Identity Function**)
2. $\lim_{x\to a} c = c$ (**Limit of a Constant**)

We can make the following observations about these two limits.

1. For the first limit, observe that as $x$ approaches $a$, so does $f(x)$, because $f(x)=x$. Consequently, $\lim_{x\to a} x = a$.
2. For the second limit, consider Table **2.2.6**.

**Table 2.2.6**

| $x$ | $f(x)=c$ | $x$ | $f(x)=c$ |
|---|---|---|---|
| $a-0.1$ | $c$ | $a+0.1$ | $c$ |
| $a-0.01$ | $c$ | $a+0.01$ | $c$ |
| $a-0.001$ | $c$ | $a+0.001$ | $c$ |
| $a-0.0001$ | $c$ | $a+0.0001$ | $c$ |

Observe that for all values of $x$, the value of $f(x)$ remains constant. We have no choice but to conclude $\lim_{x\to a} c = c$.

**Caution: Observations Are Not Proofs**

As you move through this course (and toward higher-level courses in Mathematics), you must have a clear understanding between an observation and a proof. What we have observed above (that $\lim_{x\to a} c$ looks to be $c$) is **not a proof**. We will learn how to prove these types of statements later.

## The Existence of a Limit

As we consider the limit in the following example, keep in mind that for a function's limit to exist at a point, the function values must approach a single real number. If the function values do not approach a single value, then the limit does not exist.

### Example 2.2.3

Evaluate

$$\lim_{x \to 0} \sin\left(\frac{1}{x}\right)$$

using a table of values.

**Solution**

Table 2.2.7 lists values for the function $\sin(1/x)$ as $x$ approaches $0$ from both the left and the right.

**Table 2.2.7**

| $x$ | $\sin(1/x)$ | $x$ | $\sin(1/x)$ |
|---|---|---|---|
| -0.1 | 0.544021110889 | 0.1 | −0.544021110889 |
| -0.01 | 0.50636564111 | 0.01 | −0.50636564111 |
| -0.001 | −0.8268795405312 | 0.001 | 0.8268795405312 |
| -0.0001 | 0.305614388888 | 0.0001 | −0.305614388888 |
| -0.00001 | −0.035748797987 | 0.00001 | 0.035748797987 |
| -0.000001 | 0.349993504187 | 0.000001 | −0.349993504187 |

After examining the table of function values, we can see that the $y$-values do not seem to approach any one single value. It appears the limit **does not exist**. Before drawing this conclusion, let's take a more systematic approach. Take the following sequence of $x$-values approaching $0$:

$$\frac{2}{\pi}, \frac{2}{3\pi}, \frac{2}{5\pi}, \frac{2}{7\pi}, \frac{2}{9\pi}, \frac{2}{11\pi}, \ldots.$$

The corresponding $y$-values are

$$1, -1, 1, -1, 1, -1, \ldots.$$

At this point, we conclude that

$$\lim_{x \to 0} \sin\left(\frac{1}{x}\right)$$

does not exist. Mathematicians frequently abbreviate "does not exist" as **DNE**. Thus, we would write

$$\lim_{x \to 0} \sin\left(\frac{1}{x}\right) \quad \text{DNE}.$$

### Notation: DNE

When a limit does not become a single value (whether finite or infinity), it is an agreed mathematical convention to write **DNE**, which tells the reader the limit **does not exist**.

**Checkpoint 2.2.3**

Use a table of values to evaluate

$$\lim_{x\to 2}\frac{|\,x^2-4\,|}{x-2},$$

if possible.

**Answer**

$\lim_{x\to 2}\frac{|\,x^2-4\,|}{x-2}$ does not exist.

## One-Sided Limits

Sometimes, indicating that the limit of a function fails to exist at a number does not provide us with enough information about the behavior of the function near that particular number. To see this, consider the function

$$g(x)=\frac{|x-2|}{x-2}.$$

**Table 2.2.8**

| $x$ | $g(x)=\frac{\lvert x-2\rvert}{x-2}$ | $x$ | $g(x)=\frac{\lvert x-2\rvert}{x-2}$ |
|---|---|---|---|
| 1.9 | −1 | 2.1 | 1 |
| 1.99 | −1 | 2.01 | 1 |
| 1.999 | −1 | 2.001 | 1 |
| 1.9999 | −1 | 2.0001 | 1 |

As we pick values of $x$ close to 2, $g(x)$ does not approach a single value, so the limit as $x$ approaches 2 does not exist. That is,

$$\lim_{x\to 2} g(x) \text{ DNE.}$$

However, this statement alone does not give us a complete picture of the behavior of the function around $x=2$. To provide a more accurate description, we introduce the idea of a **one-sided limit** (also known as a **single-sided limit**).

For all values to the left of 2 (or the "below" 2), $g(x)=-1$. Thus, as $x$ approaches 2 from the left, $g(x)$ approaches $-1$. Mathematically, we say that the limit as $x$ approaches 2 from the left is $-1$. Symbolically, we express this idea as

$$\lim_{x\to 2^-} g(x)=-1.$$

Similarly, as $x$ approaches 2 from the right (or from "above"), $g(x)$ approaches 1. Symbolically, we express this idea as

$$\lim_{x\to 2^+} g(x)=1.$$

We can now present an informal definition of one-sided limits.

**Definition: One-sided Limits**

**Limit from the left:** Let $f(x)$ be a function defined at all values in an open interval of the form $(z,a)$, and let $L$ be a real number. If the values of the function $f(x)$ approach the real number $L$ as the values of $x$ (where $x<a$) approach the number $a$, then we say that $L$ is the limit of $f(x)$ as $x$ approaches $a$ from the left. Symbolically, we express this idea as

$$\lim_{x\to a^-} f(x)=L.$$

**Limit from the right:** Let $f(x)$ be a function defined at all values in an open interval of the form $(a,c)$, and let $L$ be a real number. If the values of the function $f(x)$ approach the real number $L$ as the values of $x$ (where $x>a$) approach the number $a$,

then we say that $L$ is the limit of $f(x)$ as $x$ approaches $a$ from the right. Symbolically, we express this idea as

$$\lim_{x \to a^+} f(x) = L.$$

## Example 2.2.4

For the function

$$f(x) = \begin{cases} x+1, & \text{if } x < 2 \\ x^2 - 4, & \text{if } x \geq 2 \end{cases},$$

evaluate each of the following limits.

a. $\lim_{x \to 2^-} f(x)$
b. $\lim_{x \to 2^+} f(x)$

**Solutions**

We can use tables of values again. Observe in Table 2.2.9, for values of $x$ less than 2, we use $f(x) = x + 1$, and for values of $x$ greater than 2, we use $f(x) = x^2 - 4$.

**Table 2.2.9**

| $x$ | $f(x) = x+1$ | $x$ | $f(x) = x^2 - 4$ |
|---|---|---|---|
| 1.9 | 2.9 | 2.1 | 0.41 |
| 1.99 | 2.99 | 2.01 | 0.0401 |
| 1.999 | 2.999 | 2.001 | 0.004001 |
| 1.9999 | 2.9999 | 2.0001 | 0.00040001 |
| 1.99999 | 2.99999 | 2.00001 | 0.0000400001 |

Based on this table, we can conclude the following.

$$\lim_{x \to 2^-} f(x) = 3 \quad \text{and} \quad \lim_{x \to 2^+} f(x) = 0.$$

Therefore, the (two-sided) limit of $f(x)$ does not exist at $x = 2$.

## Checkpoint 2.2.4

Use a table of values to estimate the following limits, if possible.

a. $\lim_{x \to 2^-} \dfrac{|x^2 - 4|}{x - 2}$
b. $\lim_{x \to 2^+} \dfrac{|x^2 - 4|}{x - 2}$

**Answers**

a. $\lim_{x \to 2^-} \dfrac{|x^2 - 4|}{x - 2} = -4$
b. $\lim_{x \to 2^+} \dfrac{|x^2 - 4|}{x - 2} = 4$

Let's now consider the relationship between the limit of a function at a point and the limits from the right and left at that point. If the limit from the right and the limit from the left share a common value, then that is the limit of the function at that point. Similarly, suppose the limit from the left and the right take on different values. In that case, the limit of the function does not exist. These conclusions are summarized in the following theorem.

**Theorem: Relating One-Sided and Two-Sided Limits**

Let $f(x)$ be a function defined at all values in an open interval containing $a$, with the possible exception of $a$ itself, and let $L$ be a real number, $\infty$, or $-\infty$. Then,

$$\lim_{x \to a} f(x) = L$$

if and only if

$$\lim_{x \to a^-} f(x) = L \quad \text{and} \quad \lim_{x \to a^+} f(x) = L.$$

## Infinite Limit at a Finite Number

Evaluating the limit of a function at a point, or evaluating the limit of a function from the right and left at a point, helps us to characterize the behavior of a function around a given value. As we shall see, we can also describe the behavior of functions that do not have finite limits.

Consider the function $h(x) = \dfrac{1}{(x-2)^2}$. Let's build a table of values to help us determine the value of $\lim_{x \to 2} h(x)$.

**Table 2.2.10**

| $x$ | $h(x) = \frac{1}{(x-2)^2}$ | $x$ | $h(x) = \frac{1}{(x-2)^2}$ |
|---|---|---|---|
| 1.9 | 100 | 2.1 | 100 |
| 1.99 | 10000 | 2.01 | 10000 |
| 1.999 | 1000000 | 2.001 | 1000000 |
| 1.9999 | $10^8$ | 2.0001 | $10^8$ |

We can clearly see that as the values of $x$ approach 2, the values of $h(x) = \frac{1}{(x-2)^2}$ become larger and larger (in fact, the values approach infinity). Mathematically, we say that the limit of $h(x)$ as $x$ approaches 2 is positive infinity. Symbolically, we express this idea as

$$\lim_{x \to 2} h(x) = +\infty.$$

More generally, we define (again, in an intuitive, but not precise way) an **infinite limit at a finite number** as follows.

**Definitions (Intuitive): Infinite Limits at Finite Numbers**

**Infinite limits from the left:** Let $f(x)$ be a function defined at all values in an open interval of the form $(b, a)$.

i. If the values of $f(x)$ increase without bound as the values of $x$ (where $x < a$) approach the number $a$, then we say that the limit as $x$ approaches $a$ from the left is positive infinity and we write

$$\lim_{x \to a^-} f(x) = +\infty.$$

ii. If the values of $f(x)$ decrease without bound as the values of $x$ (where $x < a$) approach the number $a$, then we say that the limit as $x$ approaches $a$ from the left is negative infinity and we write

$$\lim_{x \to a^-} f(x) = -\infty.$$

**Infinite limits from the right:** Let $f(x)$ be a function defined at all values in an open interval of the form $(a, c)$.

i. If the values of $f(x)$ increase without bound as the values of $x$ (where $x > a$) approach the number $a$, then we say that the limit as $x$ approaches $a$ from the right is positive infinity and we write

$$\lim_{x \to a^+} f(x) = +\infty.$$

ii. If the values of $f(x)$ decrease without bound as the values of $x$ (where $x > a$) approach the number $a$, then we say that the limit as $x$ approaches $a$ from the right is negative infinity and we write

$$\lim_{x \to a^+} f(x) = -\infty.$$

**Two-sided infinite limit:** Let $f(x)$ be defined for all $x \neq a$ in an open interval containing $a$

i. If the values of $f(x)$ increase without bound as the values of $x$ (where $x \neq a$) approach the number $a$, then we say that the limit as $x$ approaches $a$ is positive infinity and we write

$$\lim_{x \to a} f(x) = +\infty.$$

ii. If the values of $f(x)$ decrease without bound as the values of $x$ (where $x \neq a$) approach the number $a$, then we say that the limit as $x$ approaches $a$ is negative infinity and we write

$$\lim_{x \to a} f(x) = -\infty.$$

It is important to understand that when we write statements such as $\lim_{x \to a} f(x) = \infty$ or $\lim_{x \to a} f(x) = -\infty$, we are describing the behavior of the function. We are not asserting that the limit exists. Recall that for the limit of a function $f$ to exist at $a$, the function values must approach a finite, real number $L$ as $x$ approaches $a$. That said, if $\lim_{x \to a} f(x) = \infty$, we always write $\lim_{x \to a} f(x) = \infty$ rather than saying the limit does not exist.[1]

## Example 2.2.5

Evaluate each of the following limits, if possible.

a. $\lim_{x \to 0^-} \frac{1}{x}$
b. $\lim_{x \to 0^+} \frac{1}{x}$
c. $\lim_{x \to 0} \frac{1}{x}$

**Solutions**

Begin by constructing a table of function values.

**Table 2.2.11**

| $x$ | $\frac{1}{x}$ | $x$ | $\frac{1}{x}$ |
|---|---|---|---|
| -0.1 | -10 | 0.1 | 10 |
| -0.01 | -100 | 0.01 | 100 |
| -0.001 | -1000 | 0.001 | 1000 |
| -0.0001 | -10,000 | 0.0001 | 10,000 |
| -0.00001 | -100,000 | 0.00001 | 100,000 |
| -0.000001 | -1,000,000 | 0.000001 | 1,000,000 |

The values of $1/x$ decrease without bound as $x$ approaches $0$ from the left. We conclude that

$$\lim_{x \to 0^-} \frac{1}{x} = -\infty.$$

The values of $1/x$ increase without bound as $x$ approaches $0$ from the right. We conclude that

$$\lim_{x \to 0^+} \frac{1}{x} = +\infty.$$

Since $\lim_{x\to 0^-}\frac{1}{x}=-\infty$ and $\lim_{x\to 0^+}\frac{1}{x}=+\infty$ have different values, we conclude that

$$\lim_{x\to 0}\frac{1}{x} \quad \text{DNE.}$$

**Checkpoint 2.2.5**

If possible, evaluate each of the following limits using a table.

a. $\lim_{x\to 0^-}\frac{1}{x^2}$
b. $\lim_{x\to 0^+}\frac{1}{x^2}$
c. $\lim_{x\to 0}\frac{1}{x^2}$

**Answers**

a. $\lim_{x\to 0^-}\frac{1}{x^2}=+\infty$
b. $\lim_{x\to 0^+}\frac{1}{x^2}=+\infty$
c. $\lim_{x\to 0}\frac{1}{x^2}=+\infty$

## A Final Warning About Using Tables

Up to this point, the only way you know how to evaluate the limit of a function is by building a table of values to estimate the limit. Although you will be allowed to while doing the homework in this section, you will rarely (if ever) use a table of values to approximate the value of a limit as we move forward. Moreover, consider the following warning.

**Caution: Using Tables for Limits is a Terrible Idea**

Outside of the homework in this section, attempting to estimate a limit using a table of values is horrendously bad. Again, read the following sentence carefully:

**Beyond this section, and unless specifically asked to do so, you are to never use a table of values to estimate a limit.**

To illustrate why this warning is so important, consider the following example.

**Example 2.2.6**

Evaluate

$$\lim_{x\to 0}\sin\left(\frac{\pi}{x}\right)$$

using a table of functional values.

**Solution**

We have calculated the values of $f(x)=\sin\left(\frac{\pi}{x}\right)$ for the values of $x$ listed in Table 2.2.12.

**Table 2.2.12**

| $x$ | $\sin\left(\frac{\pi}{x}\right)$ | $x$ | $\sin\left(\frac{\pi}{x}\right)$ | $x$ | $\sin\left(\frac{\pi}{x}\right)$ | $x$ | $\sin\left(\frac{\pi}{x}\right)$ |
|---|---|---|---|---|---|---|---|
| 0.1 | 0 | 0.3 | -0.8660254 | 0.6 | -0.8660254 | 0.7 | -0.97492791 |
| 0.01 | 0 | 0.03 | -0.8660254 | 0.06 | 0.8660254 | 0.07 | 0.78183148 |
| 0.001 | 0 | 0.003 | -0.8660254 | 0.006 | 0.8660254 | 0.007 | 0.43388374 |
| 0.0001 | 0 | 0.0003 | -0.8660254 | 0.0006 | 0.8660254 | 0.0007 | 0.97492791 |

The values chosen for $x$ in each column approach $0$; however, having the last digit as $1$ tempts us into thinking the limit of this function is $0$. Having the final digit as $3$, makes $-0.8660254$ seem like the limiting value. With a $6$ as the final digit, we *think* the limit is $0.8660254$. Finally, the $7$ as the final digit leaves us completely confused. Is there an actual value for the limit? We will have to wait until the next section to see...

---

[1] Some Calculus texts blur this line by stating limits of the form $\lim_{x\to a} f(x) = \infty$ exist, while limits of the form $\lim_{x\to a} f(x) = L$ exist and are finite. This is more of a definitional issue. For this text, a function having an infinite limit at a finite point is considered *not* to have a limit that exists at that finite point; however, we still describe the behavior of the function using the notation $\lim_{x\to a} f(x) = \infty$ or $\lim_{x\to a} f(x) = -\infty$.

# 2.2E: Exercises

## Reading Questions

1. What is the intuitive meaning of the statement $\lim_{x \to a} f(x) = L$?
2. When evaluating $\lim_{x \to a} f(x)$ numerically using a table, why is it important that $x$ approaches $a$ but $x \neq a$?
3. Describe the general process of using a table of values to estimate the limit of a function.
4. What are the three issues the text mentions regarding the use of numerical approximation (tables/technology) to state the value of a limit?
5. What does the notation $\lim_{x \to a^-} f(x)$ represent?
6. What does the notation $\lim_{x \to a^+} f(x)$ represent?
7. How is the existence and value of a two-sided limit, $\lim_{x \to a} f(x)$, related to its corresponding one-sided limits?
8. What does it mean for a function to have an infinite limit, such as $\lim_{x \to a} f(x) = \infty$? According to the text, does this mean the limit "exists" in the same way a finite limit does?
9. What does "DNE" signify when discussing limits?
10. Why is it crucial to use radians instead of degrees when dealing with trigonometric functions in calculus limits?
11. State the "Limit of the Identity Function" and the "Limit of a Constant" as presented in the "Two Important Limits" theorem.
12. What is the primary warning given at the end of the section regarding the use of tables to estimate limits in future calculus work?

## Homework

**For exercises 1 - 2, consider the function $f(x) = \dfrac{x^2 - 1}{|x - 1|}$.**

1) Complete the following table for the function. Round your solutions to four decimal places.

| $x$ | $f(x)$ | $x$ | $f(x)$ |
|---|---|---|---|
| 0.9 | a. | 1.1 | e. |
| 0.99 | b. | 1.01 | f. |
| 0.999 | c. | 1.001 | g. |
| 0.9999 | d. | 1.0001 | h. |

2) What do your results in the preceding exercise indicate about the two-sided limit $\lim_{x \to 1} f(x)$? Explain your response.

**For exercises 3 - 5, consider the function $f(x) = (1 + x)^{1/x}$.**

3) Make a table showing the values of $f$ for $x = -0.01,\ -0.001,\ -0.0001,\ -0.00001$ and for $x = 0.01,\ 0.001,\ 0.0001,\ 0.00001$. Round your solutions to five decimal places.

| $x$ | $f(x)$ | $x$ | $f(x)$ |
|---|---|---|---|
| -0.01 | a. | 0.01 | e. |
| -0.001 | b. | 0.001 | f. |
| -0.0001 | c. | 0.0001 | g. |
| -0.00001 | d. | 0.00001 | h. |

4) What does the table of values in the preceding exercise indicate about the function $f(x) = (1 + x)^{1/x}$?

5) To which mathematical constant do the values in the preceding exercise appear to be approaching? This is the actual limit here.

**In exercises 6 - 8, use the given values to set up a table to evaluate the limits. Round your solutions to eight decimal places.**

6) $\lim_{x\to 0}\dfrac{\sin 2x}{x}$; $\pm 0.1,\ \pm 0.01,\ \pm 0.001,\ \pm .0001$

| $x$ | $\frac{\sin 2x}{x}$ | $x$ | $\frac{\sin 2x}{x}$ |
|---|---|---|---|
| -0.1 | a. | 0.1 | e. |
| -0.01 | b. | 0.01 | f. |
| -0.001 | c. | 0.001 | g. |
| -0.0001 | d. | 0.0001 | h. |

7) $\lim_{x\to 0}\dfrac{\sin 3x}{x}$ $\pm 0.1,\ \pm 0.01,\ \pm 0.001,\ \pm 0.0001$

| $x$ | $\frac{\sin 3x}{x}$ | $x$ | $\frac{\sin 3x}{x}$ |
|---|---|---|---|
| -0.1 | a. | 0.1 | e. |
| -0.01 | b. | 0.01 | f. |
| -0.001 | c. | 0.001 | g. |
| -0.0001 | d. | 0.0001 | h. |

8) Use the preceding two exercises to conjecture (guess) the value of the following limit: $\lim_{x\to 0}\dfrac{\sin ax}{x}$ for $a$, a positive real value.

**In exercises 9 - 14, set up a table of values to find the indicated limit. Round to eight significant digits.**

9) $\lim_{x\to 2}\dfrac{x^2-4}{x^2+x-6}$

| $x$ | $\frac{x^2-4}{x^2+x-6}$ | $x$ | $\frac{x^2-4}{x^2+x-6}$ |
|---|---|---|---|
| 1.9 | a. | 2.1 | e. |
| 1.99 | b. | 2.01 | f. |
| 1.999 | c. | 2.001 | g. |
| 1.9999 | d. | 2.0001 | h. |

10) $\lim_{x\to 1}(1-2x)$

| $x$ | $1-2x$ | $x$ | $1-2x$ |
|---|---|---|---|
| 0.9 | a. | 1.1 | e. |
| 0.99 | b. | 1.01 | f. |
| 0.999 | c. | 1.001 | g. |
| 0.9999 | d. | 1.0001 | h. |

11) $\lim_{x\to 0}\dfrac{5}{1-e^{1/x}}$

| $x$ | $\frac{5}{1-e^{1/x}}$ | $x$ | $\frac{5}{1-e^{1/x}}$ |
|---|---|---|---|
| -0.1 | a. | 0.1 | e. |
| -0.01 | b. | 0.01 | f. |
| -0.001 | c. | 0.001 | g. |
| -0.0001 | d. | 0.0001 | h. |

12) $\lim_{z\to 0} \frac{z-1}{z^2(z+3)}$

| $z$ | $\frac{z-1}{z^2(z+3)}$ | $z$ | $\frac{z-1}{z^2(z+3)}$ |
|---|---|---|---|
| -0.1 | a. | 0.1 | e. |
| -0.01 | b. | 0.01 | f. |
| -0.001 | c. | 0.001 | g. |
| -0.0001 | d. | 0.0001 | h. |

13) $\lim_{t\to 0^+} \frac{\cos t}{t}$

| $t$ | $\frac{\cos t}{t}$ |
|---|---|
| 0.1 | a. |
| 0.01 | b. |
| 0.001 | c. |
| 0.0001 | d. |

14) $\lim_{x\to 2} \frac{1-\frac{2}{x}}{x^2-4}$

| $x$ | $\frac{1-\frac{2}{x}}{x^2-4}$ | $x$ | $\frac{1-\frac{2}{x}}{x^2-4}$ |
|---|---|---|---|
| 1.9 | a. | 2.1 | e. |
| 1.99 | b. | 2.01 | f. |
| 1.999 | c. | 2.001 | g. |
| 1.9999 | d. | 2.0001 | h. |

**In exercises 15 - 16, set up a table of values and round to eight significant digits. Based on the table of values, make a guess about what the limit is. Then, use a calculator to graph the function and determine the limit. Was the conjecture correct? If not, why does the method of tables fail?**

15) $\lim_{\theta\to 0} \sin\left(\frac{\pi}{\theta}\right)$

| $\theta$ | $\sin\left(\frac{\pi}{\theta}\right)$ | $\theta$ | $\sin\left(\frac{\pi}{\theta}\right)$ |
|---|---|---|---|
| -0.1 | a. | 0.1 | e. |
| -0.01 | b. | 0.01 | f. |
| -0.001 | c. | 0.001 | g. |
| -0.0001 | d. | 0.0001 | h. |

16) $\lim_{\alpha \to 0^+} \frac{1}{\alpha} \cos\left(\frac{\pi}{\alpha}\right)$

| $a$ | $\frac{1}{\alpha}\cos\left(\frac{\pi}{\alpha}\right)$ |
|---|---|
| 0.1 | a. |
| 0.01 | b. |
| 0.001 | c. |
| 0.0001 | d. |

17) A track coach uses a camera with a fast shutter to estimate the position of a runner with respect to time. A table of the values of position of the athlete versus time is given here, where $x$ is the position in meters of the runner and $t$ is time in seconds. What is $\lim_{t \to 2} x(t)$? What does it mean physically?

| $t(sec)$ | $x(m)$ |
|---|---|
| 1.75 | 4.5 |
| 1.95 | 6.1 |
| 1.99 | 6.42 |
| 2.01 | 6.58 |
| 2.05 | 6.9 |
| 2.25 | 8.5 |

# 2.3: The Limit Laws - Limits at Finite Numbers

**Note to the Instructor (click to expand)**

The Limit Laws are introduced, but algebraic manipulations are avoided (for now). Focus on making the students comfortable with the meticulous, step-by-step use of evaluating limits using the Limit Laws. Care should be taken to repeatedly inform the students that these laws only apply when the component limits exist and are finite. The Squeeze Theorem is introduced as an alternative to evaluating a limit when all other methods fail. Finally, take the time in class to derive the limit theorems involving the sine. These proofs should convey the tone of the course - that students should be attentive and prerequisite skills are of utmost importance.

---

To succeed in this section, you'll need to use some skills from previous courses. While you should already know them, this is the first time they've been required. You can review these skills in CRC's Corequisite Codex. If you have a support class, it might cover some, **but not all**, of these topics.

**Prerequisite Skills and Support Topics (click to expand)**

- **Arithmetic**
  - Fractions: Simplifying and manipulating fractions is essential when dealing with rational functions and certain algebraic manipulations for limits. These occur in the homework and when combining terms.
- **Simplifying Expressions**
  - Multiplying and Distributing Polynomial Expressions: Used when expanding expressions before applying limit laws or simplifying, for instance, if a function involved $(x-h)^2$.
  - Properties of Radicals and Simplifying Expressions Involving Roots: The Root Law for limits is introduced. Simplifying radical expressions is a key technique.
- **Solving Inequalities**
  - Solving Compound Inequalities: Understanding inequalities is foundational for the Squeeze Theorem, e.g., establishing bounds like $-1 \leq \cos(x) \leq 1$ in Example 8.
- **An Overview of Functions**
  - The Definition of a Function: Understanding function notation and behavior is central to the concept of limits.
- **Polynomial Functions**
  - The Basics of Polynomial Functions: The Direct Substitution Property applies directly to polynomial functions.
- **Trigonometry**
  - Trigonometric Identities - The Pythagorean Identities: Used in simplifying expressions, for example, $1-\cos^2\theta = \sin^2\theta$ in the evaluation of $\lim_{\theta\to 0}\frac{1-\cos\theta}{\theta}$ (Example 9).
  - Trigonometric Functions - Unit Circle Definition: The unit circle is used in the proofs for the limits of sine and

Hawk A.I. Section-Specific Tutor

cosine as $\theta \to 0$ (Figure 5, Figure 6).

The following is a list of learning objectives for this section.

**Learning Objectives (click to expand)**

- Describe the Limit Laws and understand when they can be used (and, importantly, when they cannot).
- Use the Limit Laws to evaluate the limit of a function.
- Use the Direct Substitution Property to evaluate the limit of a polynomial or rational function.
- Evaluate the limit of a function by using the Squeeze Theorem, when appropriate.
- Evaluate limits involving ratios of sine or cosine and angles.

In the previous section, we evaluated limits by looking at graphs or by constructing a table of values. In this section, we establish laws for calculating limits and learn how to apply these laws. In the Student Project at the end of this section, you have the opportunity to use the Limit Laws to derive the formula for the area of a circle by adapting a method devised by the Greek mathematician Archimedes.

We begin by restating two useful limit results from the previous section. These two results, which we will call the Basic Limit Laws, together with the Limit Laws we will be introducing momentarily, serve as a foundation for calculating many limits.

**Corollary: Basic Limit Laws**

For any real number $a$ and any constant $c$,

I. $\lim\limits_{x \to a} x = a$
II. $\lim\limits_{x \to a} c = c$

**Example 2.3.1: Using the Basic Limit Laws**

Evaluate each of the following limits.

a. $\lim\limits_{x \to 2} x$
b. $\lim\limits_{x \to 2} 5$

**Solutions**

a. The limit of $x$ as $x$ approaches $a$ is $a$: $\lim\limits_{x \to 2} x = 2$.
b. The limit of a constant is that constant: $\lim\limits_{x \to 2} 5 = 5$.

## Evaluating Finite Limits with the Limit Laws

We now take a look at the **Limit Laws**, the individual properties of limits. The proofs that these laws hold are omitted at this time; however, we will prove some of these once we have formalized the definition of a limit.

**Theorem: Limit Laws**

Let $f(x)$ and $g(x)$ be defined for all $x \neq a$ over some open interval containing $a$. Assume that $L$ and $M$ are real numbers such that $\lim\limits_{x \to a} f(x) = L$ and $\lim\limits_{x \to a} g(x) = M$. Let $c$ be a constant. Then, each of the following statements holds:

- **Sum Law for Limits**:

$$\lim_{x\to a}(f(x)+g(x)) = \lim_{x\to a} f(x) + \lim_{x\to a} g(x) = L + M$$

- **Difference Law for Limits**:

$$\lim_{x\to a}(f(x)-g(x)) = \lim_{x\to a} f(x) - \lim_{x\to a} g(x) = L - M$$

- **Constant Multiple Law for Limits**:

$$\lim_{x\to a} cf(x) = c\cdot \lim_{x\to a} f(x) = cL$$

- **Product Law for Limits**:

$$\lim_{x\to a}(f(x)\cdot g(x)) = \lim_{x\to a} f(x)\cdot \lim_{x\to a} g(x) = L\cdot M$$

- **Quotient Law for Limits**:

$$\lim_{x\to a}\frac{f(x)}{g(x)} = \frac{\lim\limits_{x\to a} f(x)}{\lim\limits_{x\to a} g(x)} = \frac{L}{M}$$

  for $M \neq 0$.
- **Power Law for Limits**:

$$\lim_{x\to a}\big(f(x)\big)^n = \Big(\lim_{x\to a} f(x)\Big)^n = L^n$$

  for every positive integer $n$.
- **Root Law for Limits**:

$$\lim_{x\to a}\sqrt[n]{f(x)} = \sqrt[n]{\lim_{x\to a} f(x)} = \sqrt[n]{L}$$

  for all $L$ if $n$ is odd and for $L \geq 0$ if $n$ is even.

Before we go any further, a cautionary statement is required.

**Caution: The Limit Laws Require Limits to Exist**

A common mistake is to think that the Limit Laws apply to every limit encountered by the student. To be able to use the Limit Laws, both of the component limits

$$\lim_{x\to a} f(x) \quad \text{and} \quad \lim_{x\to a} g(x)$$

must exist and be **finite**.

**Example 2.3.2: Evaluating a Limit Using the Limit Laws**

Use the Limit Laws to evaluate

$$\lim_{x\to -3}(4x+2).$$

**Solution**

Let's apply the Limit Laws one step at a time to be sure we understand how they work. We need to remember that, at each application of a limit law, new limits must exist for the limit law to be applied.

$$\begin{aligned}
\lim_{x\to -3}(4x+2) &= \lim_{x\to -3} 4x + \lim_{x\to -3} 2 && \text{(Sum Law)}\\
&= 4\cdot \lim_{x\to -3} x + \lim_{x\to -3} 2 && \text{(Constant Multiple Law)}\\
&= 4\cdot(-3)+2 && \text{(Basic Limit Laws)}\\
&= -10
\end{aligned}$$

### Example 2.3.3: Evaluating a Limit Using the Limit Laws

Use the Limit Laws to evaluate

$$\lim_{x\to 2}\frac{2x^2-3x+1}{x^3+4}.$$

**Solution**

To find this limit, we need to apply the Limit Laws several times. Again, we must remember that as we rewrite the limit in terms of other limits, each new limit must exist for the limit law to be applied.

$$\begin{aligned}
\lim_{x\to 2}\frac{2x^2-3x+1}{x^3+4} &= \frac{\lim_{x\to 2}(2x^2-3x+1)}{\lim_{x\to 2}(x^3+4)} && \text{(Quotient Law)}\\
&= \frac{2\cdot\lim_{x\to 2}x^2-3\cdot\lim_{x\to 2}x+\lim_{x\to 2}1}{\lim_{x\to 2}x^3+\lim_{x\to 2}4} && \text{(Sum and Constant Multiple Laws)}\\
&= \frac{2\cdot\left(\lim_{x\to 2}x\right)^2-3\cdot\lim_{x\to 2}x+\lim_{x\to 2}1}{\left(\lim_{x\to 2}x\right)^3+\lim_{x\to 2}4} && \text{(Power Law)}\\
&= \frac{2(4)-3(2)+1}{(2)^3+4} && \text{(Basic Limit Laws)}\\
&= \frac{1}{4}
\end{aligned}$$

### Checkpoint 2.3.3

Use the Limit Laws to evaluate $\lim_{x\to 6}\left[(2x-1)\sqrt{x+4}\right]$. In each step, indicate the limit law applied.

**Answer**

$11\sqrt{10}$

## Limits of Polynomial and Rational Functions

By now you have probably noticed that, in each of the previous examples, it has been the case that $\lim_{x\to a}f(x)=f(a)$. This is not always true; however, we will focus on such functions for the rest of this section. Specifically, it holds for all polynomials for any choice of $a$ and for all rational functions at all values of $a$ in the domain of the rational function.

### Theorem: Direct Substitution Property (for polynomial and rational functions)

Let $p(x)$ and $q(x)$ be polynomial functions. Let $a$ be a real number. Then,

$$\lim_{x\to a}p(x)=p(a)$$

and

$$\lim_{x\to a}\frac{p(x)}{q(x)}=\frac{p(a)}{q(a)}$$

when $q(a)\neq 0$.

**Proof**

Let

$$p(x) = c_n x^n + c_{n-1}x^{n-1} + \cdots + c_1 x + c_0.$$

Then by applying the Sum, Constant Multiple, and Power Laws, we end up with

$$\begin{aligned}
\lim_{x\to a} p(x) &= \lim_{x\to a}(c_n x^n + c_{n-1}x^{n-1} + \cdots + c_1 x + c_0) \\
&= \lim_{x\to a}(c_n x^n) + \lim_{x\to a}(c_{n-1}x^{n-1}) + \cdots + \lim_{x\to a}(c_1 x) + \lim_{x\to a} c_0 && \text{(Sum Law)} \\
&= c_n \lim_{x\to a} x^n + c_{n-1}\lim_{x\to a} x^{n-1} + \cdots + c_1 \lim_{x\to a} x + c_0 && \text{(Constant Multiple Law)} \\
&= c_n \left(\lim_{x\to a} x\right)^n + c_{n-1}\left(\lim_{x\to a} x\right)^{n-1} + \cdots + c_1\left(\lim_{x\to a} x\right) + c_0 && \text{(Power Law)} \\
&= c_n a^n + c_{n-1}a^{n-1} + \cdots + c_1 a + c_0 \\
&= p(a)
\end{aligned}$$

It now follows from the Quotient Law that if $p(x)$ and $q(x)$ are polynomials for which $q(a) \neq 0$, then

$$\lim_{x\to a} \frac{p(x)}{q(x)} = \frac{p(a)}{q(a)}.$$

### Example 2.3.4: Using the Direct Substitution Property

Evaluate the $\lim_{x\to 3} \dfrac{2x^2 - 3x + 1}{5x + 4}$.

**Solution**

Since 3 is in the domain of the rational function $f(x) = \dfrac{2x^2 - 3x + 1}{5x + 4}$, we can calculate the limit by substituting 3 for $x$ into the function. Thus,

$$\lim_{x\to 3} \frac{2x^2 - 3x + 1}{5x + 4} = \frac{10}{19}.$$

### Checkpoint 2.3.4

Evaluate $\lim_{x\to -2}(3x^3 - 2x + 7)$.

**Answer**

−13

### Critical Mistake: Misapplying the Direct Substitution Property

**Question:** Evaluate $\lim_{x\to a} \dfrac{p(x)}{q(x)}$, where $\lim_{x\to a} q(x) = 0$.

**Student Answer:** $\frac{p(a)}{0}$ = DNE

**Mistake:** The Direct Substitution Property (for rational functions) can only be applied if the limit in the denominator is **nonzero**. Your answer will only be "DNE" if you have evaluated both left- and right-hand limits and found them to not be equal.

## Revisiting One-Sided Limits

Simple modifications to the Limit Laws allow us to apply them to one-sided limits. For example, to apply the Limit Laws to a limit of the form $\lim_{x\to a^-} h(x)$, we require the function $h(x)$ to be defined over an open interval of the form $(b, a)$; for a limit of the form $\lim_{x\to a^+} h(x)$, we require the function $h(x)$ to be defined over an open interval of the form $(a, c)$. Example **2.3.5** illustrates this point.

### Example 2.3.5: Evaluating a One-Sided Limit Using the Limit Laws

Evaluate each of the following limits, if possible.

a. $\lim\limits_{x\to 3^-}\sqrt{x-3}$
b. $\lim\limits_{x\to 3^+}\sqrt{x-3}$

**Solutions**

Figure 2.3.1 illustrates the function $f(x)=\sqrt{x-3}$ and aids in our understanding of these limits.

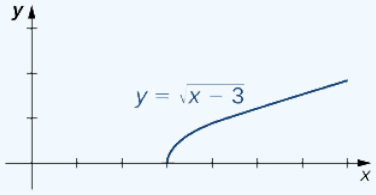

*Figure 2.3.1: The graph shows the function $f(x)=\sqrt{x-3}$.*

a. The function $f(x)=\sqrt{x-3}$ is defined over the interval $[3,\infty)$. Since this function is not defined to the left of 3, we cannot apply the Limit Laws to compute $\lim\limits_{x\to 3^-}\sqrt{x-3}$. In fact, since $f(x)=\sqrt{x-3}$ is undefined to the left of 3, $\lim\limits_{x\to 3^-}\sqrt{x-3}$ does not exist.
b. Since $f(x)=\sqrt{x-3}$ is defined for $x>3$, the Limit Laws apply to $\lim\limits_{x\to 3^+}\sqrt{x-3}$. By applying these Limit Laws we obtain $\lim\limits_{x\to 3^+}\sqrt{x-3}=0$.

In Example 2.3.6, we look at the one-sided limits of a piecewise-defined function and use these limits to draw a conclusion about a two-sided limit of the same function.

### Example 2.3.6: Evaluating a Two-Sided Limit Using the Limit Laws

For

$$f(x)=\begin{cases}4x-3, & \text{if } x<2\\ (x-3)^2, & \text{if } x\geq 2\end{cases},$$

evaluate each of the following limits:

a. $\lim\limits_{x\to 2^-}f(x)$
b. $\lim\limits_{x\to 2^+}f(x)$
c. $\lim\limits_{x\to 2}f(x)$

**Solutions**

Figure 2.3.2 illustrates the function $f(x)$ and aids in our understanding of these limits.

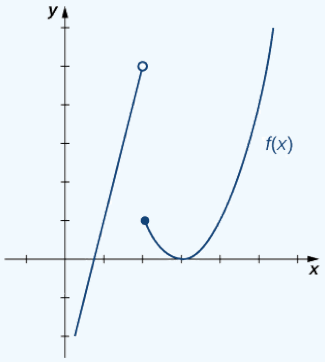

*Figure 2.3.2: This graph shows a function $f(x)$.*

https://math.libretexts.org/@go/page/175431

a. Since $f(x) = 4x - 3$ for all $x$ in $(-\infty, 2)$, replace $f(x)$ in the limit with $4x - 3$ and apply the Limit Laws:

$$\lim_{x \to 2^-} f(x) = \lim_{x \to 2^-} (4x - 3) = 5$$

b. Since $f(x) = (x - 3)^2$ for all $x$ in $(2, +\infty)$, replace $f(x)$ in the limit with $(x - 3)^2$ and apply the Limit Laws:

$$\lim_{x \to 2^+} f(x) = \lim_{x \to 2^-} (x - 3)^2 = 1.$$

c. Since $\lim_{x \to 2^-} f(x) = 5$ and $\lim_{x \to 2^+} f(x) = 1$, we conclude that $\lim_{x \to 2} f(x)$ does not exist.

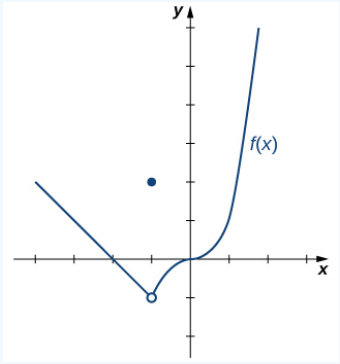
## ? Checkpoint 2.3.6

Graph

$$f(x) = \begin{cases} -x - 2, & \text{if } x < -1 \\ 2, & \text{if } x = -1 \\ x^3, & \text{if } x > -1 \end{cases}$$

and evaluate $\lim_{x \to -1^-} f(x)$.

**Answer**



$$\lim_{x \to -1^-} f(x) = -1$$

## Breaking the (Limit) Laws

As stated in earlier, the Limit Laws can only be applied when the component limits are finite. A very common mistake made early in Calculus is for a student to think that they can apply the Limit Laws to any limit - again, this is not true.

## ✓ Example 2.3.7: Breaking the (Limit) Laws

Evaluate each of the following limits.

a. $\lim_{x \to 3^+} \left( (x - 3) \cdot \frac{1}{x - 3} \right)$
b. $\lim_{x \to 3^-} \left( (x - 3)^2 \cdot \frac{1}{x - 3} \right)$
c. $\lim_{x \to 3^+} \left( (x - 3) \cdot \frac{1}{(x - 3)^3} \right)$

**Solutions**

a. If we were to try to apply the Product Law for Limits, we would arrive at

$$\lim_{x \to 3^+} (x - 3) \cdot \lim_{x \to 3^+} \frac{1}{x - 3} = 0 \cdot \infty = 0 \text{ or is it } \infty?$$

This is wrong on several levels.

First, what is the product of something *approaching* $0$ and something *approaching* $\infty$? This is a *key* difference between Algebra and Calculus. In Algebra, you are consistently dealing with *finite* values and, as such, the rules of Arithmetic apply neatly. In Calculus, you are dealing with levels of infinity (and the infinitesimal). These concepts do *not* obey the traditional rules of Arithmetic.

The second issue is that we are breaking the Limit Laws! Remember, **you can only use the Limit Laws if the component limits exist and are finite**.

So, how would you deal with the given limit? We begin by performing some very simple Algebra.

$$\lim_{x\to 3^+}\left((x-3)\cdot\frac{1}{x-3}\right)=\lim_{x\to 3^+}\left(\cancel{(x-3)}\cdot\frac{1}{\cancel{(x-3)}}\right)=\lim_{x\to 3^+}1=1$$

b. Trying to apply the Product Law for Limits, we would get

$$\lim_{x\to 3^-}(x-3)^2\cdot\lim_{x\to 3^-}\frac{1}{x-3}=0\cdot-\infty=0 \text{ or is it } -\infty?$$

Just like part a, we are improperly trying to apply the Limit Laws in a situation where they are not applicable. That second limit, approaching $-\infty$, prevents us from using the Limit Laws. Instead, the proper way to evaluate this limit is to use some simple Algebra first.

$$\lim_{x\to 3^-}\left((x-3)^2\cdot\frac{1}{x-3}\right)=\lim_{x\to 3^-}(x-3)=0$$

c. Again, incorrectly applying the Product Law for Limits, we would get

$$\lim_{x\to 3^+}(x-3)\cdot\lim_{x\to 3^+}\frac{1}{(x-3)^3}=0\cdot\infty=0 \text{ or is it } \infty?$$

As in the previous two examples, we are breaking the Limit Laws because one of the component limits is not finite. We should have performed some simple Algebra first.

$$\lim_{x\to 3^+}\left((x-3)\cdot\frac{1}{(x-3)^3}\right)=\lim_{x\to 3^+}\left(\frac{1}{\cancel{(x-3)^2}}\right)=\infty$$

Pay close attention to Example **2.3.7**. It should serve as a warning that anytime you reach an "answer" of the form $0\cdot\infty$, you are wrong.

## The Squeeze Theorem

The techniques we have developed thus far work well for algebraic functions. However, we still need to evaluate the limits of elementary trigonometric functions. The next theorem, called the **Squeeze Theorem**, proves very useful for establishing basic trigonometric limits. It also helps us evaluate very abstract and theoretical limits for functions that cannot be described using simple functions from our Algebra courses. This theorem allows us to calculate limits by "squeezing" a function, with a limit at a point $a$ that is unknown, between two functions having a common known limit at $a$. Figure **2.3.3** illustrates this idea.

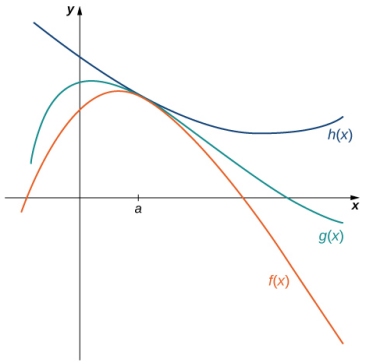


*Figure* **2.3.3**: *The Squeeze Theorem applies when* $f(x) \le g(x) \le h(x)$ *and* $\lim_{x \to a} f(x) = \lim_{x \to a} h(x)$.

**Theorem: Squeeze Theorem**

Let $f(x)$ ,$g(x)$, and $h(x)$ be defined for all $x \neq a$ over an open interval containing $a$. If

$$f(x) \le g(x) \le h(x)$$

for all $x \neq a$ in an open interval containing $a$ and

$$\lim_{x \to a} f(x) = L = \lim_{x \to a} h(x)$$

where $L$ is a real number, then $\lim_{x \to a} g(x) = L$.

**Example 2.3.8: Applying the Squeeze Theorem**

Evaluate $\lim_{x \to 0} (x \cos(x))$.

**Solution**

If we were to try to evaluate this limit using the Limit Laws, we would arrive at

$$\lim_{x \to 0} (x \cos(x)) = \lim_{x \to 0} (x) \cdot \lim_{x \to 0} \cos(x) = 0 \cdot \ldots \text{ ummm... what is this?}$$

I get it, you are going to say, "But, I know that $\cos(x)$ approaches $1$ as $x$ approaches $0$!" However, our theory up to this point only includes algebraic functions (specifically, polynomial and rational functions). Therefore, our "intuition" of what this limit will be is not allowed.

We have the limit of the product of two functions. We know the limit of one of those functions; however, if we don't know the limit of the other function, or if we know the limit of the other function does not exist, the Squeeze Theorem can be very helpful if you can bound the function with the unknown or undefined limit.

In this case, we don't (officially) know the limit of the cosine as $x$ is approaching $1$. So, we build a bound for this function.

$$-1 \le \cos(x) \le 1$$

We now rebuild the original limit by multiplying all three "sides" of this inequality by $x$. Before we do so, it is important to note two things: $x \neq 0$ and we don't know the sign of $x$. The first statement is just peripherally important so we know that we are not getting something trivial like $0 \le 0 \le 0$. The second statement is just for completeness. If $x > 0$, then we would get

$$-x \le x \cos(x) \le x$$

If $x < 0$, then the inequality signs switch direction to

$$-x \ge x \cos(x) \ge x$$

In either case, since $\lim_{x \to 0} (-x) = 0 = \lim_{x \to 0} (x)$, from the Squeeze Theorem, we obtain $\lim_{x \to 0} (x \cos (x)) = 0$. The graphs of $f(x) = -x$, $g(x) = x \cos x$, and $h(x) = x$ are shown in Figure 2.3.4.

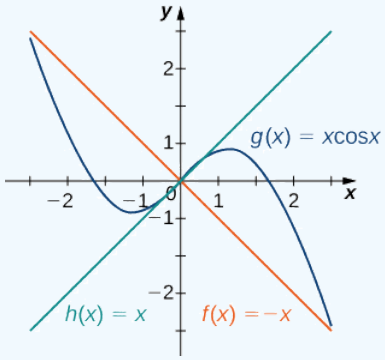

*Figure 2.3.4: The graphs of $f(x)$, $g(x)$, and $h(x)$ are shown around the point $x = 0$.*

**Checkpoint 2.3.8**

Use the Squeeze Theorem to evaluate $\lim_{x \to 0} x^2 \sin \frac{1}{x}$.

**Hint**

Use the fact that $-x^2 \leq x^2 \sin(1/x) \leq x^2$ to help you find two functions such that $x^2 \sin(1/x)$ is squeezed between them.

**Answer**

0

## Limits Involving the Sine and Cosine

We now use the Squeeze Theorem to tackle several fundamental limits presented as a theorem here. Although this discussion is lengthy, these limits prove invaluable for the development of the material involving trigonometric functions for the rest of Calculus.

**Theorem**

$$\lim_{\theta \to 0} (\sin (\theta)) = 0$$

and

$$\lim_{\theta \to 0} (\cos (\theta)) = 1$$

**Proof**

The first of these limits is $\lim_{\theta \to 0} (\sin (\theta))$. Consider the unit circle shown in Figure 2.3.5. In the figure, we see that $\sin (\theta)$ is the $y$-coordinate on the unit circle, and it corresponds to the line segment shown in blue. The radian measure of angle $\theta$ is the length of the arc it subtends on the unit circle. Therefore, we see that for $0 < \theta < \frac{\pi}{2}$, we have $0 < \sin (\theta) < \theta$.

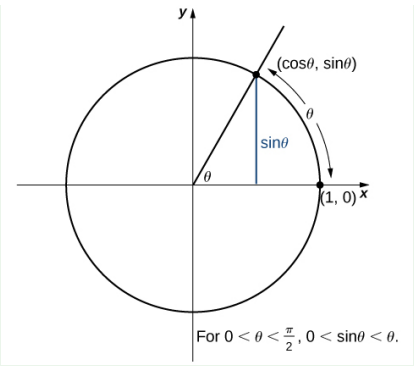

*Figure* **2.3.5***: The sine function is shown as a line on the unit circle.*

Because $\lim_{\theta \to 0^+} 0 = 0$ and $\lim_{\theta \to 0^+} \theta = 0$, by using the Squeeze Theorem we conclude that

$$\lim_{\theta \to 0^+} (\sin(\theta)) = 0.$$

To see that $\lim_{\theta \to 0^-} (\sin(\theta)) = 0$ as well, observe that for $-\frac{\pi}{2} < \theta < 0, 0 < -\theta < \frac{\pi}{2}$ and hence, $0 < \sin(-\theta) < -\theta$. Consequently, $0 < -\sin(\theta) < -\theta$. It follows that $0 > \sin(\theta) > \theta$. An application of the Squeeze Theorem produces the desired limit. Thus, since $\lim_{\theta \to 0^+} \sin(\theta) = 0$ and $\lim_{\theta \to 0^-} \sin(\theta) = 0$,

$$\lim_{\theta \to 0} \sin(\theta) = 0$$

Next, using the identity $\cos(\theta) = \sqrt{1 - \sin^2(\theta)}$ for $-\frac{\pi}{2} < \theta < \frac{\pi}{2}$, we see that

$$\lim_{\theta \to 0} (\cos(\theta)) = \lim_{\theta \to 0} \sqrt{1 - \sin^2(\theta)} = 1.$$

**Caution: Calculus Requires Radian Measure**

The theorem just introduced is the reason we stated way back in the first section that radians must be used when working in Calculus. The proof of both limits require radian measure. As such, all of the Calculus we build surrounding the trigonometric functions relies on us using radian measure. That is, Calculus and degree measure do not get along!

We now take a look at two limits that play important roles in later chapters.

**Theorem**

$$\lim_{\theta \to 0} \frac{\sin\theta}{\theta} = 1$$

and

$$\lim_{\theta \to 0} \frac{1 - \cos\theta}{\theta} = 0$$

**Proof**

To prove the first of these limits, we use the unit circle in Figure **2.3.6**. Notice that this figure adds one additional triangle to Figure **2.3.6** from the proof of the previous theorem. We see that the length of the side opposite angle $\theta$ in this new triangle is $\tan(\theta)$. Thus, we see that for $0 < \theta < \frac{\pi}{2}$, we have $\sin(\theta) < \theta < \tan(\theta)$.

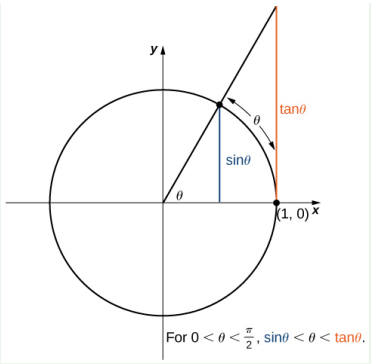

Figure **2.3.6**: The sine and tangent functions are shown as lines on the unit circle.

By dividing by $\sin(\theta)$ in all parts of the inequality, we obtain

$$1 < \frac{\theta}{\sin(\theta)} < \frac{1}{\cos(\theta)}.$$

Equivalently, we have

$$1 > \frac{\sin(\theta)}{\theta} > \cos(\theta).$$

Since $\lim_{\theta \to 0^+} 1 = 1 = \lim_{\theta \to 0^+} \cos(\theta)$, we conclude that $\lim_{\theta \to 0^+} \frac{\sin(\theta)}{\theta} = 1$, by the Squeeze Theorem. By applying a manipulation similar to that used in demonstrating that $\lim_{\theta \to 0^-} (\sin(\theta)) = 0$, we can show that $\lim_{\theta \to 0^-} \frac{\sin(\theta)}{\theta} = 1$. Thus,

$$\lim_{\theta \to 0} \frac{\sin(\theta)}{\theta} = 1.$$

In Example **2.3.9**, we use this limit to establish $\lim_{\theta \to 0} \frac{1 - \cos(\theta)}{\theta} = 0$. This limit will also prove useful in later chapters.

## Example 2.3.9: Evaluating an Important Trigonometric Limit

Evaluate $\lim_{\theta \to 0} \frac{1 - \cos\theta}{\theta}$.

**Solution**

In the first step, we multiply by the conjugate so that we can use a trigonometric identity to convert the cosine in the numerator to a sine:

$$\begin{aligned}
\lim_{\theta \to 0} \frac{1 - \cos\theta}{\theta} &= \lim_{\theta \to 0} \frac{1 - \cos\theta}{\theta} \cdot \frac{1 + \cos\theta}{1 + \cos\theta} \\
&= \lim_{\theta \to 0} \frac{1 - \cos^2\theta}{\theta(1 + \cos\theta)} \\
&= \lim_{\theta \to 0} \frac{\sin^2\theta}{\theta(1 + \cos\theta)} \\
&= \lim_{\theta \to 0} \frac{\sin\theta}{\theta} \cdot \frac{\sin\theta}{1 + \cos\theta} \\
&= \left(\lim_{\theta \to 0} \frac{\sin\theta}{\theta}\right) \cdot \left(\lim_{\theta \to 0} \frac{\sin\theta}{1 + \cos\theta}\right) \\
&= 1 \cdot \frac{0}{2} = 0.
\end{aligned}$$

Therefore,

$$\lim_{\theta \to 0} \frac{1 - \cos\theta}{\theta} = 0.$$

### Example 2.3.10: Evaluating Finite Limits of Trigonometric Functions at Finite Points

Evaluate the following limit.

$$\lim_{\theta \to 0} \frac{7\theta}{\sin(5\theta)}$$

**Solution**

$$\begin{aligned}
\lim_{\theta \to 0} \frac{7\theta}{\sin(5\theta)} &= \lim_{\theta \to 0} \frac{\frac{7}{5}}{\frac{\sin(5\theta)}{5\theta}} \\
&= \frac{\lim_{\theta \to 0} \frac{7}{5}}{\lim_{\theta \to 0} \frac{\sin(5\theta)}{5\theta}} && \text{(Limit Law)} \\
&= \frac{\frac{7}{5}}{\lim_{\theta \to 0} \frac{\sin(5\theta)}{5\theta}} && \text{(Limit Law)} \\
&= \frac{7}{5} \cdot \frac{1}{\lim_{x \to 0} \frac{\sin(x)}{x}} && \text{(Let } x = 5\theta\text{. Then } x \to 0 \text{ as } \theta \to 0\text{)} \\
&\overset{\text{D.S.}}{=} \frac{7}{5} \cdot \frac{1}{1} && \text{(Direct Substitution)} \\
&= \frac{7}{5}
\end{aligned}$$

### Checkpoint 2.3.10

Evaluate $\lim_{\theta \to 0} \frac{1 - \cos\theta}{\sin\theta}$.

**Answer**

0

## Student Project

### Deriving the Formula for the Area of a Circle

Some of the geometric formulas we take for granted today were first derived by methods that anticipate some of the methods of calculus. The Greek mathematician *Archimedes* (ca. 287−212; BCE) was particularly inventive, using polygons inscribed within circles to approximate the area of the circle as the number of sides of the polygon increased. He never came up with the idea of a limit. Still, we can use this idea to see what his geometric constructions could have predicted about the limit.

We can estimate the area of a circle by computing the area of an inscribed regular polygon. Think of the regular polygon as being made up of $n$ triangles. By taking the limit as the vertex angle of these triangles goes to zero, you can obtain the area of the circle. To see this, carry out the following steps:

1. Express the height $h$ and the base $b$ of the isosceles triangle in Figure 2.3.7 in terms of $\theta$ and $r$.

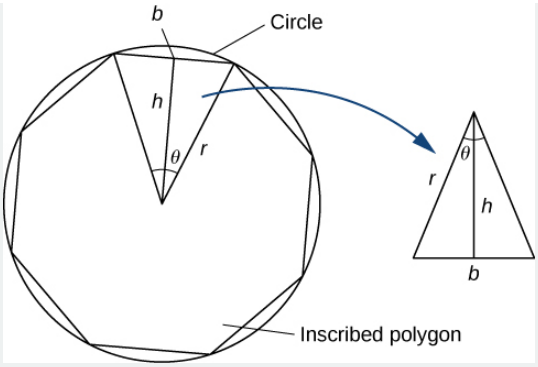

*Figure* **2.3.7**

2. Using the expressions that you obtained in step 1, express the area of the isosceles triangle in terms of $\theta$ and $r$. (Substitute $\frac{1}{2}\sin\theta$ for $\sin\left(\frac{\theta}{2}\right)\cos\left(\frac{\theta}{2}\right)$ in your expression.)
3. If an $n$-sided regular polygon is inscribed in a circle of radius $r$, find a relationship between $\theta$ and $n$. Solve this for $n$. Keep in mind there are $2\pi$ radians in a circle. (Use radians, not degrees.)
4. Find an expression for the area of the $n$-sided polygon in terms of $r$ and $\theta$.
5. To find a formula for the circle's area, find the expression's limit in step 4 as $\theta$ goes to zero. (Hint: $\lim_{\theta\to 0}\frac{\sin\theta}{\theta}=1$).

The technique of estimating areas of regions by using polygons is revisited later in this course.

# 2.3E: EXERCISES

## READING QUESTIONS

1. What are the two Basic Limit Laws for $\lim\limits_{x\to a} x$ and $\lim\limits_{x\to a} c$?
2. State the Sum Law for Limits. What condition must be met for it to apply?
3. Under what condition can the Quotient Law for Limits be applied?
4. When can the Direct Substitution Property be used to evaluate the limit of a polynomial function?
5. When can the Direct Substitution Property be used to evaluate the limit of a rational function $\frac{p(x)}{q(x)}$ at $x=a$? What must be true about $q(a)$?
6. If direct substitution into a rational function yields $\frac{0}{0}$, what kind of algebraic manipulation might be useful before re-evaluating the limit?
7. How do the Limit Laws apply to one-sided limits? What condition must be met for the function's domain?
8. Explain the Squeeze Theorem in your own words. What three conditions must be met to use it to find $\lim\limits_{x\to a} g(x)$?
9. What is the value of $\lim\limits_{\theta\to 0} \sin(\theta)$?
10. What is the value of $\lim\limits_{\theta\to 0} \cos(\theta)$?
11. What is the important limit $\lim\limits_{\theta\to 0} \dfrac{\sin\theta}{\theta}$?
12. What is the important limit $\lim\limits_{\theta\to 0} \dfrac{1-\cos\theta}{\theta}$?
13. Why is it crucial to use radian measure (not degrees) when working with limits of trigonometric functions in calculus?
14. What does it mean if applying Limit Laws leads to an indeterminate form like $0\cdot\infty$? What should be done instead?

## HOMEWORK

**In exercises 1 - 4, use the Limit Laws to evaluate each limit. Justify each step by indicating the appropriate Limit Law(s).**

1) $\lim\limits_{x\to 0} (4x^2-2x+3)$

2) $\lim\limits_{x\to 1} \dfrac{x^3+3x^2+5}{4-7x}$

3) $\lim\limits_{x\to -2} \sqrt{x^2-6x+3}$

4) $\lim\limits_{x\to -1} (9x+1)^2$

**In exercises 5 - 8, use the Direct Substitution Property to evaluate the limit of each function.**

5) $\lim\limits_{x\to 7} x^2$

6) $\lim\limits_{x\to -2} (4x^2-1)$

7) $\lim\limits_{x\to 0} \dfrac{1}{1+\sin x}$

8) $\lim\limits_{x\to 1} \dfrac{2-7x}{x+6}$

**In exercises 9 - 16, assume that $\lim\limits_{x\to 6} f(x)=4$, $\lim\limits_{x\to 6} g(x)=9$, and $\lim\limits_{x\to 6} h(x)=6$. Use these three facts and the Limit Laws to evaluate each limit.**

9) $\lim\limits_{x\to 6} 2f(x)g(x)$

10) $\lim\limits_{x\to 6} \dfrac{g(x)-1}{f(x)}$

11) $\lim\limits_{x\to 6} \left(f(x)+\dfrac{1}{3}g(x)\right)$

12) $\lim\limits_{x\to 6} \dfrac{\big(h(x)\big)^3}{2}$

13) $\lim\limits_{x\to 6} \sqrt{g(x)-f(x)}$

14) $\lim\limits_{x\to 6} x\cdot h(x)$

15) $\lim\limits_{x\to 6} [(x+1)\cdot f(x)]$

16) $\lim\limits_{x\to 6} (f(x)\cdot g(x)-h(x))$

**In exercises 17 - 19, evaluate the limits using the given piecewise-defined function and the Limit Laws.**

17) $f(x)=\begin{cases}x^2, & x\le 3\\ x+4, & x>3\end{cases}$

a. $\lim\limits_{x\to 3^-} f(x)$

b. $\lim\limits_{x\to 3^+} f(x)$

18) $g(x)=\begin{cases}x^3-1, & x\le 0\\ 1, & x>0\end{cases}$

a. $\lim\limits_{x\to 0^-} g(x)$

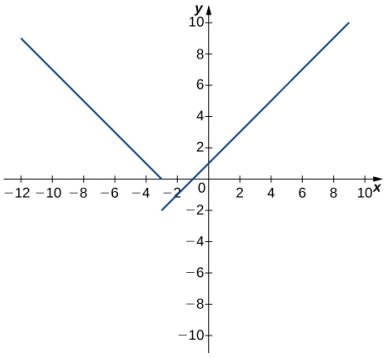
b. $\lim\limits_{x\to 0^+} g(x)$

19) $h(x)=\begin{cases}x^2-2x+1, & x<2\\ 3-x, & x\ge 2\end{cases}$

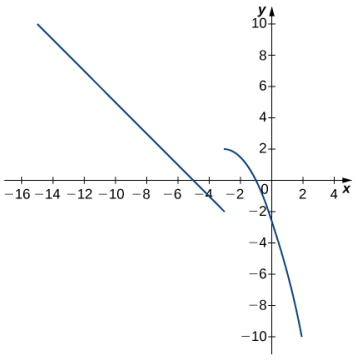
a. $\lim\limits_{x\to 2^-} h(x)$

b. $\lim\limits_{x\to 2^+} h(x)$

**In exercises 20 - 27, use the following graphs and the Limit Laws to evaluate each limit.**



$y = f(x)$



$y = g(x)$

20) $\lim\limits_{x\to -3^+}(f(x)+g(x))$

21) $\lim\limits_{x\to -3^-}(f(x)-3g(x))$

22) $\lim\limits_{x\to 0}\dfrac{f(x)g(x)}{3}$

23) $\lim\limits_{x\to -5}\dfrac{2+g(x)}{f(x)}$

24) $\lim\limits_{x\to 1}(f(x))^2$

25) $\lim\limits_{x\to 1}\sqrt[3]{f(x)-g(x)}$

26) $\lim\limits_{x\to -7}(x\cdot g(x))$

27) $\lim\limits_{x\to -9}[x\cdot f(x)+2\cdot g(x)]$

**For exercises 28 - 30, evaluate the limit using the Squeeze Theorem. Graph the functions $f(x)$, $g(x)$, and $h(x)$ when possible.**

28) True or False? If $2x-1 \le g(x) \le x^2-2x+3$, then $\lim_{x\to 2} g(x) = 0$.

29) $\lim_{\theta\to 0} \theta^2 \cos\left(\frac{1}{\theta}\right)$

30) $\lim_{x\to 0} f(x)$, where $f(x) = \begin{cases} 0, & x \text{ rational} \\ x^2, & x \text{ irrrational} \end{cases}$

31) In physics, the magnitude of an electric field generated by a point charge at a distance $r$ in vacuum is governed by Coulomb's law: $E(r) = \frac{q}{4\pi\epsilon_0 r^2}$, where $E$ represents the magnitude of the electric field, $q$ is the charge of the particle, $r$ is the distance between the particle and where the strength of the field is measured, and $\frac{1}{4\pi\epsilon_0}$ is Coulomb's constant: $8.988 \times 109 N \cdot m^2/C^2$.

a. Use a graphing calculator to graph $E(r)$ given that the charge of the particle is $q = 10^{-10}$.

b. Evaluate $\lim_{r\to 0^+} E(r)$. What is the physical meaning of this quantity? Is it physically relevant? Why are you evaluating from the right?

32) The density of an object is given by its mass divided by its volume: $\rho = m/V$.

a. Use a calculator to plot the volume as a function of density $(V = m/\rho)$, assuming you are examining something of mass $8$ kg $(m = 8)$.

b. Evaluate $\lim_{x\to 0^+} V(\rho)$ and explain the physical meaning.

# 2.4: The Limit Laws - Limits at Infinity

**Note to the Instructor (click to expand)**

We now turn our attention to limits at infinity and horizontal asymptotes. We still have not introduced the precise definition of limits, so all of the content is from a conceptual standpoint.

---

To succeed in this section, you'll need to use some skills from previous courses. While you should already know them, this is the first time they've been required. You can review these skills in CRC's Corequisite Codex. If you have a support class, it might cover some, **but not all**, of these topics.

**Prerequisite Skills and Support Topics (click to expand)**

- **Simplifying Expressions**
  - Laws of Exponents: Used when dividing numerator and denominator by the highest power of $x$ (e.g., simplifying $\frac{x^3}{x^5} = \frac{1}{x^2}$ in Example 2a).
- **An Overview of Functions**
  - Inverse Functions: The limit of $\arctan(x)$ as $x \to \pm\infty$ is determined by considering the graph of $\tan(x)$ (Example 3).
- **Trigonometry**
  - The Inverse Trigonometric Functions: Specifically, $\arctan(x)$ is analyzed for its limits at infinity (Example 3).

---

The following is a list of learning objectives for this section.

**Learning Objectives (click to expand)**

- Calculate the limit of a function as $x$ increases or decreases without bound.
- Define a horizontal asymptote in terms of a finite limit at infinity.
- Evaluate a finite limit at infinity by initially performing algebraic manipulations.
- Conceptually investigate an infinite limit at infinity.
- Describe when the Limit Laws cannot be applied.

Hawk A.I. Section-Specific Tutor

To access the Hawk A.I. Tutor, you will need to be logged into your campus Gmail account.

In this section, we continue delving into limits by considering limits as $x$ tends to $\pm\infty$. These are known collectively as **limits at infinity**.

## Finite Limits at Infinity and Horizontal Asymptotes

Recall that $\lim_{x \to a} f(x) = L$ means $f(x)$ becomes arbitrarily close to $L$ as long as $x$ is sufficiently close to $a$. We can extend this idea to limits at infinity. For example, consider the function $f(x) = 2 + \frac{1}{x}$. As can be seen graphically in Figure 2.4.1 and numerically in Table 2.4.1, as the values of $x$ get larger, the values of $f(x)$ approach 2. We say the limit as $x$ approaches $\infty$ of $f(x)$ is 2 and write $\lim_{x \to \infty} f(x) = 2$. Similarly, for $x < 0$, as the values $|x|$ get larger, the values of $f(x)$ approach 2. We say the limit as $x$ approaches $-\infty$ of $f(x)$ is 2 and write $\lim_{x \to -\infty} f(x) = 2$.

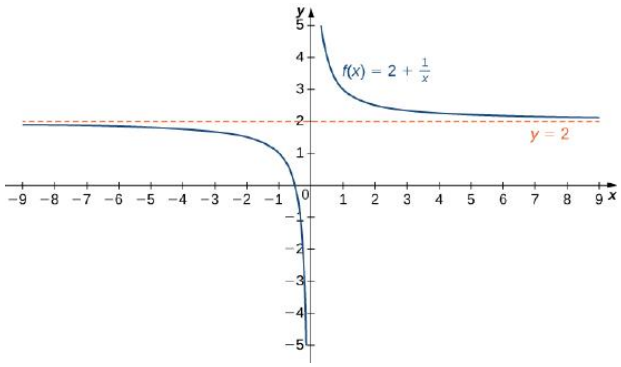


*Figure* **2.4.1***:The function approaches the asymptote* $y = 2$ *as* $x$ *approaches* $\pm\infty$.

**Table 2.4.1: Values of a function $f$ as $x \to \pm\infty$**

| $x$ | 10 | 100 | 1,000 | 10,000 |
|---|---|---|---|---|
| $2+\frac{1}{x}$ | 2.1 | 2.01 | 2.001 | 2.0001 |
| $x$ | $-10$ | $-100$ | $-1000$ | $-10,000$ |
| $2+\frac{1}{x}$ | 1.9 | 1.99 | 1.999 | 1.9999 |

More generally, for any function $f$, we say the limit as $x \to \infty$ of $f(x)$ is $L$ if $f(x)$ becomes arbitrarily close to $L$ as long as $x$ is sufficiently large. In that case, we write $\lim\limits_{x\to\infty} f(x) = L$. Similarly, we say the limit as $x \to -\infty$ of $f(x)$ is $L$ if $f(x)$ becomes arbitrarily close to $L$ as long as $x < 0$ and $|x|$ is sufficiently large. In that case, we write $\lim\limits_{x\to-\infty} f(x) = L$. We now look at the definition of a function having a limit at infinity.

### Definition: Finite Limit at Infinity (Informal)

If the values of $f(x)$ become arbitrarily close to the finite value $L$ as $x$ becomes sufficiently large, we say the function $f$ has a **finite limit at infinity** and write

$$\lim_{x\to\infty} f(x) = L.$$

If the values of $f(x)$ becomes arbitrarily close to the finite value $L$ for $x < 0$ as $|x|$ becomes sufficiently large, we say that the function $f$ has a finite limit at negative infinity and write

$$\lim_{x\to-\infty} f(x) = L.$$

If the values $f(x)$ are getting arbitrarily close to some finite value $L$ as $x \to \infty$ or $x \to -\infty$, the graph of $f$ approaches the line $y = L$. In that case, the line $y = L$ is a horizontal asymptote of $f$ (Figure 2.4.2). For example, for the function $f(x) = \dfrac{1}{x}$, since $\lim\limits_{x\to\infty} f(x) = 0$, the line $y = 0$ is a horizontal asymptote of $f(x) = \dfrac{1}{x}$.

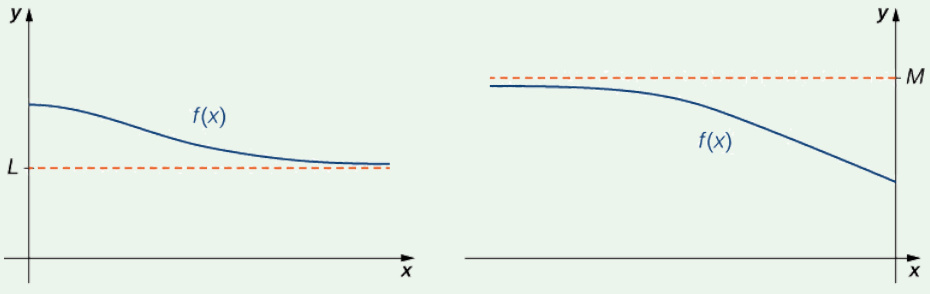

*Figure* **2.4.2a***: As* $x \to \infty$*, the values of* $f$ *are getting arbitrarily close to* $L$*. The line* $y = L$ *is a horizontal asymptote of* $f$*.*
*Figure* **2.4.2b***: As* $x \to -\infty$*, the values of* $f$ *are getting arbitrarily close to* $M$*. The line* $y = M$ *is a horizontal asymptote of* $f$*.*

**Definition: Horizontal Asymptote**

If $\lim_{x\to\infty} f(x) = L$ or $\lim_{x\to-\infty} f(x) = L$, we say the line $y = L$ is a **horizontal asymptote** of $f$.

As a very important aside, we know from Algebra that a function cannot intersect a vertical asymptote; however, a function *can* cross a horizontal asymptote. In fact, a function may cross a horizontal asymptote an unlimited number of times. For example, the function $f(x) = \dfrac{\cos x}{x} + 1$ shown in Figure **2.4.3** intersects the horizontal asymptote $y = 1$ an infinite number of times as it oscillates around the asymptote with ever-decreasing amplitude.

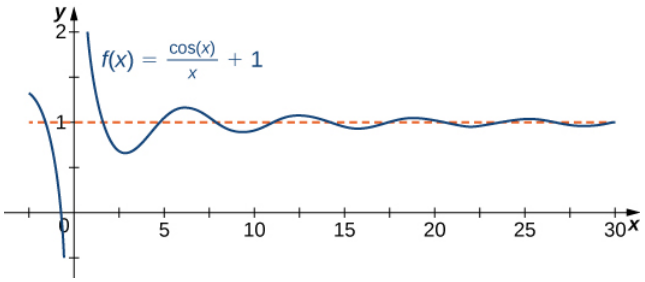

*Figure* **2.4.3***: The graph of* $f(x) = \frac{\cos(x)}{x} + 1$ *crosses its horizontal asymptote* $y = 1$ *an infinite number of times.*

## Revisiting the Limit Laws

Now that we have an informal definition of a finite limit at infinity, it's time we begin evaluating some limits *without* resorting to building tables of values. Before we do, however, we need some theory. The Limit Laws introduced earlier in this chapter still apply as long as the limit values are finite. These are restated here for your convenience.

**Theorem: Limit Laws for Limits at Infinity**

Let $f(x)$ and $g(x)$ be defined for all $x > a$, where $a$ is a real number. Assume that $L$ and $M$ are real numbers such that $\lim_{x\to\infty} f(x) = L$ and $\lim_{x\to\infty} g(x) = M$. Let $c$ be a constant. Then, each of the following statements holds:

- **Sum and Difference Laws for Limits**:

$$\lim_{x\to\infty}(f(x) \pm g(x)) = \lim_{x\to\infty} f(x) \pm \lim_{x\to\infty} g(x) = L \pm M$$

- **Constant Multiple Law for Limits**:

$$\lim_{x\to\infty} cf(x) = c \cdot \lim_{x\to\infty} f(x) = cL$$

- **Product Law for Limits**:

$$\lim_{x\to\infty}(f(x) \cdot g(x)) = \lim_{x\to\infty} f(x) \cdot \lim_{x\to\infty} g(x) = L \cdot M$$

- **Quotient Law for Limits**:

$$\lim_{x\to\infty} \frac{f(x)}{g(x)} = \frac{\lim_{x\to\infty} f(x)}{\lim_{x\to\infty} g(x)} = \frac{L}{M}$$

  for $M \neq 0$.

- **Power Law for Limits**:

$$\lim_{x\to\infty} \big(f(x)\big)^n = \big(\lim_{x\to\infty} f(x)\big)^n = L^n$$

  for every positive integer $n$.

- **Root Law for Limits**:

$$\lim_{x\to\infty}\sqrt[n]{f(x)}=\sqrt[n]{\lim_{x\to\infty}f(x)}=\sqrt[n]{L}$$

for all $L$ if $n$ is odd and for $L\geq 0$ if $n$ is even.

Each of these Limit Laws can be adjusted for $x\to-\infty$ as long as $f(x)$ and $g(x)$ are defined for all $x<a$, where $a$ is a real number.

We add to our theory arsenal a small, but powerful lemma.

**Lemma**

$$\lim_{x\to\infty}x=\infty,$$

$$\lim_{x\to-\infty}x=-\infty,$$

and

$$\lim_{x\to\pm\infty}\frac{1}{x}=0.$$

While the results of this lemma are intuitively obvious, we will still prove them once we reach the precise definition of a limit later in this chapter. For now, this lemma allows us to prove the following theorem.

**Theorem**

If $p>0$ is a rational number, then

$$\lim_{x\to\infty}\frac{1}{x^p}=0.$$

If $p>0$ is a rational number such that $x^p$ is defined for all $x$, then

$$\lim_{x\to-\infty}\frac{1}{x^p}=0.$$

**Proof**

Let $p$ be a rational number. The only constraint on using the Limit Laws is that the values of the limits must be finite. Therefore, $a$ is allowed to be $\pm\infty$. Thus,

$$\begin{aligned}\lim_{x\to\infty}\frac{1}{x^p} &= \lim_{x\to\infty}\left(\frac{1}{x}\right)^p \\ &= \left(\lim_{x\to\infty}\frac{1}{x}\right)^p && \text{(Power and Root Limit Laws)} \\ &= 0^p && \text{(Lemma)} \\ &= 0\end{aligned}$$

If we allow $x\to-\infty$, then additional restrictions on $p$ must be made. Specifically, since $p$ is a rational number, it cannot be equivalent to a simplified fraction with an even denominator. Otherwise, the even denominator would imply an even-indexed root of $x$, and this would result in imaginary numbers. Hence, as long as $x^p$ is defined,

$$\lim_{x\to-\infty}\frac{1}{x^p}=0$$

by a similar derivation.

## Evaluating Finite Limits at Infinity

### Example 2.4.1: Computing a Finite Limit at Infinity

Evaluate

$$\lim_{x\to\infty}\left(5-\frac{2}{x^2}\right)$$

and

$$\lim_{x\to-\infty}\left(5-\frac{2}{x^2}\right).$$

Determine the horizontal asymptote(s) for this function.

**Solution**

Using the Limit Laws, we have

$$\lim_{x\to\infty}\left(5-\frac{2}{x^2}\right)=\lim_{x\to\infty}5-2\left(\lim_{x\to\infty}\frac{1}{x}\right)^2=5-2\cdot 0=5.$$

Similarly, $\lim_{x\to-\infty}\left(5-\frac{2}{x^2}\right)=5$. Therefore, $f(x)=5-\frac{2}{x^2}$ has a horizontal asymptote of $y=5$ and $f$ approaches this horizontal asymptote as $x\to\pm\infty$ as shown in the following graph.

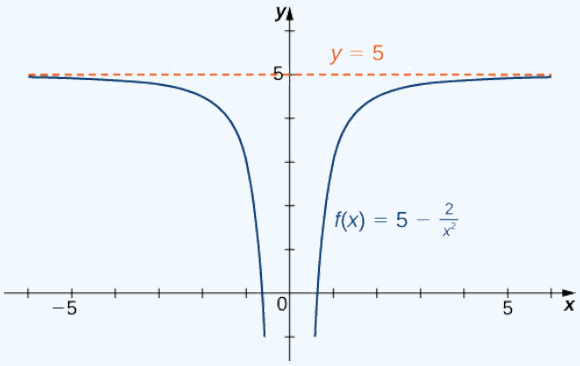

*Figure 2.4.4: This function approaches a horizontal asymptote as $x\to\pm\infty$.*

### Checkpoint 2.4.1

Evaluate $\lim_{x\to-\infty}\left(3+\frac{4}{x}\right)$ and $\lim_{x\to\infty}\left(3+\frac{4}{x}\right)$. Determine the horizontal asymptotes of $f(x)=3+\frac{4}{x}$, if any.

**Answer**

Both limits are 3. The line $y=3$ is a horizontal asymptote.

In Example 2.4.1, there was no need to perform any initial manipulations using Arithmetic, Algebra, or Trigonometry; however, finite limits at infinity are often disguised as indeterminate forms (e.g., where the limit approaches $\frac{\infty}{\infty}$ or $\infty-\infty$). For these cases, we should keep in mind the Mathematical Mantra when evaluating finite limits at infinity.

### Example 2.4.2: Evaluating Finite Limits at Infinity Having Indeterminate Forms

Evaluate each of the following limits.

a. $\lim_{x\to\infty}\dfrac{\pi x^5+x^3-1}{3x^5+x+2}$

b. $\lim_{x\to\infty}\dfrac{\sqrt{1-x+x^2}}{3-x}$

c. $\lim_{x\to-\infty}\dfrac{\sqrt{1-x+x^2}}{3-x}$

d. $\lim_{x\to-\infty}\left(\sqrt{1-x+9x^2}+3x\right)$

**Solutions**

a. A quick investigation of this limit shows that

$$\lim_{x\to\infty}\frac{\pi x^5+x^3-1}{3x^5+x+2}\quad\begin{matrix}\nearrow\ \infty\\ \\ \searrow\ \infty\end{matrix}$$

Therefore, the limit is indeterminate of the form $\infty/\infty$. What can we do? Following a creative use of the Mathematical Mantra, we could begin by dividing both numerator and denominator by $x^p$, where $p$ is the largest existing power of $x$ within the function. Doing so (and using the fact that $\lim_{x\to\infty}\frac{1}{x^p}=0$ when $p>0$), the limit becomes

$$\lim_{x\to\infty}\frac{\pi x^5+x^3-1}{3x^5+x+2}=\lim_{x\to\infty}\frac{\pi+\frac{1}{x^2}-\frac{1}{x^5}}{3+\frac{1}{x^4}+\frac{2}{x^5}}=\frac{\pi+0-0}{3+0+0}=\frac{\pi}{3}$$

b. This limit is even more confounding than the previous one when you consider that, as $x\to\infty$, the numerator tends to the square root of $-\infty+\infty$ while the denominator tends to $-\infty$. There are so many issues preventing us from considering the Limit Laws. First, what is $-\infty+\infty$? Is it $0$? Is it $-\infty$ (and, if so, does the world blow up because we are trying to take the square root of a negative number)? Is it $+\infty$? Second, *if* we can determine what the numerator is, will dividing by a value approaching $-\infty$ cause issues? As in the previous example, following the Mathematical Mantra and using a little Algebra at the beginning can go a long way here.

$$\begin{aligned}
\lim_{x\to\infty}\frac{\sqrt{1-x+x^2}}{3-x} &= \lim_{x\to\infty}\frac{\sqrt{x^2\left(\frac{1}{x^2}-\frac{1}{x}+1\right)}}{3-x} \\
&= \lim_{x\to\infty}\frac{\sqrt[2]{x^2}\sqrt{\frac{1}{x^2}-\frac{1}{x}+1}}{3-x} \\
&= \lim_{x\to\infty}\frac{|x|\sqrt{\frac{1}{x^2}-\frac{1}{x}+1}}{3-x} && \left(\sqrt[n]{x^n}=\begin{cases}x & \text{if } n \text{ is odd}\\ |x| & \text{if } n \text{ is even}\end{cases}\right) \\
&= \lim_{x\to\infty}\frac{x\sqrt{\frac{1}{x^2}-\frac{1}{x}+1}}{3-x} \\
&= \lim_{x\to\infty}\frac{\sqrt{\frac{1}{x^2}-\frac{1}{x}+1}}{\frac{3}{x}-1} \\
&= \frac{\sqrt{0-0+1}}{0-1} && \left(\lim_{x\to\infty}\frac{1}{x^p}=0, \text{ when } p>0\right) \\
&= -1
\end{aligned}$$

c. This is similar to part b; however, the limit approaching $-\infty$ requires some special attention.

$$\begin{aligned}
\lim_{x\to-\infty}\frac{\sqrt{1-x+x^2}}{3-x} &= \lim_{x\to-\infty}\frac{\sqrt{x^2\left(\frac{1}{x^2}-\frac{1}{x}+1\right)}}{3-x} \\
&= \lim_{x\to-\infty}\frac{\sqrt[2]{x^2}\sqrt{\frac{1}{x^2}-\frac{1}{x}+1}}{3-x} \\
&= \lim_{x\to-\infty}\frac{|x|\sqrt{\frac{1}{x^2}-\frac{1}{x}+1}}{3-x} && \left(\sqrt[n]{x^n}=\begin{cases}x & \text{if } n \text{ is odd}\\ |x| & \text{if } n \text{ is even}\end{cases}\right) \\
&= \lim_{x\to-\infty}\frac{-x\sqrt{\frac{1}{x^2}-\frac{1}{x}+1}}{3-x} && (x\to-\infty, \text{ so } x<0. \text{ Thus, } |x|=-x.) \\
&= \lim_{x\to-\infty}\frac{-\sqrt{\frac{1}{x^2}-\frac{1}{x}+1}}{\frac{3}{x}-1} \\
&= \frac{-\sqrt{0-0+1}}{0-1} && \left(\lim_{x\to\infty}\frac{1}{x^p}=0, \text{ when } p>0\right) \\
&= 1
\end{aligned}$$

d. It is tempting with this final example to think it has the form $\infty+\infty$; however, $x$ is approaching **negative** $\infty$. As such, the second term within the limit is approaching $-\infty$, and this limit is genuinely of the indeterminate form $\infty-\infty$. Again, the Mathematical Mantra comes to the rescue!

$$\begin{aligned}
\lim_{x\to-\infty}\left(\sqrt{1-x+9x^2}+3x\right) &= \lim_{x\to-\infty}\left(\sqrt{1-x+9x^2}+3x\right)\left(\frac{\sqrt{1-x+9x^2}-3x}{\sqrt{1-x+9x^2}-3x}\right)\\
&= \lim_{x\to-\infty}\frac{1-x+9x^2-9x^2}{\sqrt{1-x+9x^2}-3x}\\
&= \lim_{x\to-\infty}\frac{1-x}{\sqrt{1-x+9x^2}-3x}\\
&= \lim_{x\to-\infty}\frac{1-x}{\sqrt[2]{x^2}\sqrt{\frac{1}{x^2}-\frac{1}{x}+9}-3x}\\
&= \lim_{x\to-\infty}\frac{1-x}{|x|\sqrt{\frac{1}{x^2}-\frac{1}{x}+9}-3x} && \left(\sqrt[n]{x^n}=\begin{cases}x & \text{if } n \text{ is odd}\\ |x| & \text{if } n \text{ is even}\end{cases}\right)\\
&= \lim_{x\to-\infty}\frac{1-x}{-x\sqrt{\frac{1}{x^2}-\frac{1}{x}+9}-3x} && \left(\lim_{x\to\infty}\frac{1}{x^p}=0,\ \text{when } p>0\right)\\
&= \lim_{x\to-\infty}\frac{\frac{1}{x}-1}{-\sqrt{\frac{1}{x^2}-\frac{1}{x}+9}-3}\\
&= \frac{0-1}{-\sqrt{0-0+9}-3} && \left(\lim_{x\to\infty}\frac{1}{x^p}=0,\ \text{when } p>0\right)\\
&= \frac{-1}{-6}\\
&= \frac{1}{6}
\end{aligned}$$

As we have encountered in previous sections, conceptual investigations of limits based on our prerequisite knowledge of base graphs is a valid technique. The following example (and subsequent theorem) showcases such an investigation.

### Example 2.4.3: Evaluating Finite Limits at Infinity Conceptually

Evaluate $\lim_{x\to\infty}\tan^{-1}(x)$ and $\lim_{x\to-\infty}\tan^{-1}(x)$. Determine the horizontal asymptote(s) for $\arctan(x)$.

**Solution**

To evaluate $\lim_{x\to\infty}\tan^{-1}(x)$ and $\lim_{x\to-\infty}\tan^{-1}(x)$, we first consider the graph of $y=\tan(x)$ over the interval $\left(-\frac{\pi}{2},\frac{\pi}{2}\right)$ as shown in the following graph.

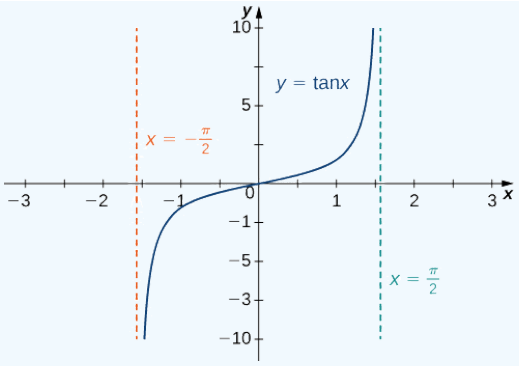

*Figure* **2.4.5***: The graph of* $y = \tan x$ *has vertical asymptotes at* $x = \pm\frac{\pi}{2}$

Since

$$\lim_{x \to \frac{\pi}{2}^-} \tan(x) = \infty,$$

it follows that

$$\lim_{x \to \infty} \tan^{-1}(x) = \frac{\pi}{2}.$$

Similarly, since

$$\lim_{x \to -\frac{\pi}{2}^+} \tan(x) = -\infty,$$

it follows that

$$\lim_{x \to -\infty} \tan^{-1}(x) = -\frac{\pi}{2}.$$

As a result, $y = \frac{\pi}{2}$ and $y = -\frac{\pi}{2}$ are horizontal asymptotes of $f(x) = \tan^{-1}(x)$ as shown in the following graph.

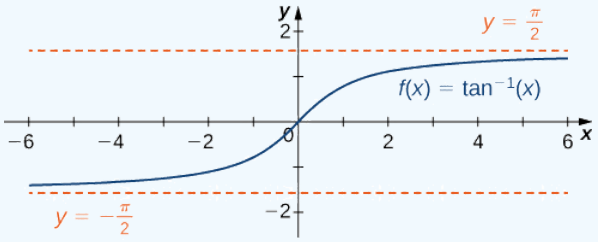

*Figure* **2.4.6***: This function has two horizontal asymptotes.*

This limit can be useful enough that it is good to formalize it in a theorem along with some other common limits.

**Theorem**

$$\lim_{x \to \infty} \tan^{-1}(x) = \frac{\pi}{2}$$

$$\lim_{x \to -\infty} \tan^{-1}(x) = -\frac{\pi}{2}$$

$$\lim_{x \to \infty} b^{-x} = 0 \quad \text{where } b > 1.$$

## Revisiting the Squeeze Theorem

We have already seen that a lot of our original theory of finite limits at finite numbers can be applied to finite limits at infinity. We round out this collection of common theorems by revisiting the Squeeze Theorem.

### Theorem: The Squeeze Theorem for Limits at Infinity

Let $f(x), g(x)$, and $h(x)$ be defined for all $x > a$, where $a$ is a real number. If

$$f(x) \leq g(x) \leq h(x)$$

for all $x > a$ and

$$\lim_{x \to \infty} f(x) = L = \lim_{x \to \infty} h(x)$$

where $L$ is a real number, then $\lim_{x \to \infty} g(x) = L$.

Likewise, let $f(x), g(x)$, and $h(x)$ be defined for all $x < a$, where $a$ is a real number. If

$$f(x) \leq g(x) \leq h(x)$$

for all $x < a$ and

$$\lim_{x \to -\infty} f(x) = L = \lim_{x \to -\infty} h(x)$$

where $L$ is a real number, then $\lim_{x \to -\infty} g(x) = L$.

### Example 2.4.4

Evaluate $\lim_{x \to \infty} \frac{\sin(x)}{x}$ and $\lim_{x \to -\infty} \frac{\sin(x)}{x}$. Determine the horizontal asymptote(s) for $f(x) = \frac{\sin(x)}{x}$.

**Solution**

Since $-1 \leq \sin x \leq 1$ for all $x$, we have

$$\frac{-1}{x} \leq \frac{\sin x}{x} \leq \frac{1}{x}$$

for all $x \neq 0$. Also, since

$$\lim_{x \to \infty} \frac{-1}{x} = 0 = \lim_{x \to \infty} \frac{1}{x},$$

we can apply the Squeeze Theorem to conclude that

$$\lim_{x \to \infty} \frac{\sin x}{x} = 0.$$

Similarly,

$$\lim_{x \to -\infty} \frac{\sin x}{x} = 0.$$

Thus, $f(x) = \frac{\sin x}{x}$ has a horizontal asymptote of $y = 0$ and $f(x)$ approaches this horizontal asymptote as $x \to \pm\infty$ as shown in the following graph.

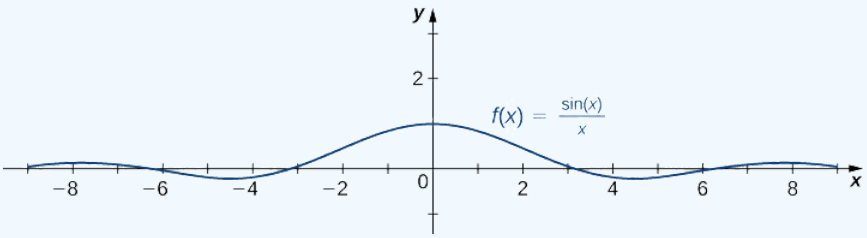

*Figure 2.4.7: This function crosses its horizontal asymptote multiple times.*

https://math.libretexts.org/@go/page/175433

## Infinite Limits at Infinity

Sometimes the values of a function $f$ become arbitrarily large as $x \to \infty$ (or as $x \to -\infty$). In this case, we write $\lim_{x\to\infty} f(x) = \infty$ (or $\lim_{x\to-\infty} f(x) = \infty$). On the other hand, if the values of $f$ are negative but become arbitrarily large in magnitude as $x \to \infty$ (or as $x \to -\infty$), we write $\lim_{x\to\infty} f(x) = -\infty$ (or $\lim_{x\to-\infty} f(x) = -\infty$).

For example, consider the function $f(x) = x^3$. As seen in Table **2.4.2** and Figure **2.4.8**, as $x \to \infty$ the values $f(x)$ become arbitrarily large. Therefore, $\lim_{x\to\infty} x^3 = \infty$. On the other hand, as $x \to -\infty$, the values of $f(x) = x^3$ are negative but become arbitrarily large in magnitude. Consequently, $\lim_{x\to-\infty} x^3 = -\infty$.

**Table 2.4.2: Values of a power function as $x \to \pm\infty$**

| $x$ | 10 | 20 | 50 | 100 | 1000 |
|---|---|---|---|---|---|
| $x^3$ | 1000 | 8000 | 125,000 | 1,000,000 | 1,000,000,000 |
| $x$ | −10 | −20 | −50 | −100 | −1000 |
| $x^3$ | −1000 | −8000 | −125,000 | −1,000,000 | −1,000,000,000 |

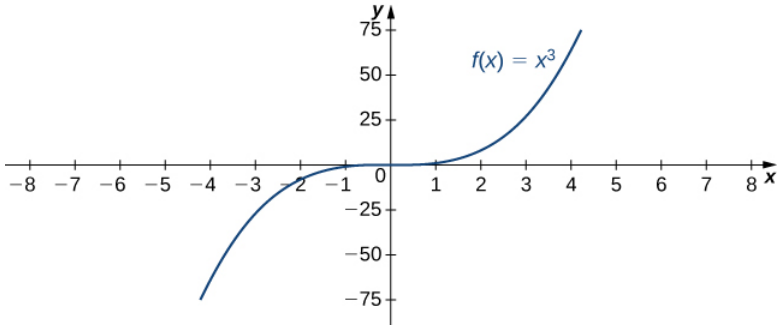

*Figure* **2.4.8***: For this function, the functional values approach ±infinity as $x \to \pm\infty$.*

**Definition: Infinite Limit at Infinity (Informal)**

We say a function $f$ has an infinite limit at infinity and write

$$\lim_{x\to\infty} f(x) = \infty.$$

if $f(x)$ becomes arbitrarily large for $x$ sufficiently large. We say a function has a negative infinite limit at infinity and write

$$\lim_{x\to\infty} f(x) = -\infty.$$

if $f(x) < 0$ and $|f(x)|$ becomes arbitrarily large for $x$ sufficiently large. Similarly, we can define infinite limits as $x \to -\infty$.

In general, infinite limits at infinity require fewer prerequisite manipulations to evaluate than other types of limits and require more conceptual investigation. The following theorem (which we will prove parts of in the next section) contains some common infinite limits at infinity.

**Theorem**

- $\lim_{x\to\infty} x = \infty$
- $\lim_{x\to-\infty} x = -\infty$
- If $p > 0$, $\lim_{x\to\infty} x^p = \infty$
- If $b > 1$, $\lim_{x\to\infty} b^x = \infty$.

### Example 2.4.5: Evaluating an Infinite Limit at Infinity

Evaluate the limit.

$$\lim_{x\to-\infty}\frac{3+x^6}{x^4+8}$$

**Solution**

$$\lim_{x\to-\infty}\frac{3+x^6}{x^4+8} = \lim_{x\to-\infty}\frac{\frac{3}{x^6}+1}{\frac{1}{x^2}+\frac{8}{x^6}} \qquad \text{(dividing numerator and denominator by } x^6\text{)}$$

Since $3/x^6 \to 0$ as $x \to -\infty$, we know the numerator is approaching $1$. Moreover, as $x \to -\infty$,

$$\frac{1}{x^2}+\frac{8}{x^6} \to 0^+ + 0^+ \to 0^+$$

Hence,

$$\lim_{x\to-\infty}\frac{3+x^6}{x^4+8} = \infty.$$

# 2.4E: EXERCISES

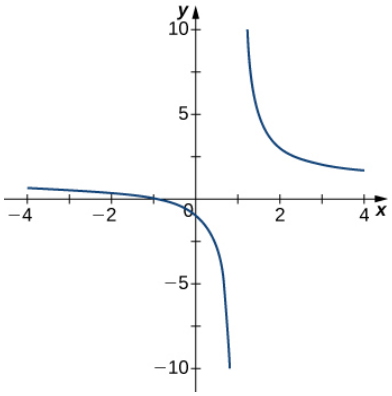
## READING QUESTIONS

1. What does it mean for a function $f(x)$ to have a finite limit $L$ as $x$ approaches infinity?
2. How is a horizontal asymptote $y = L$ defined in terms of limits at infinity?
3. Can a function's graph cross its horizontal asymptote? If so, provide an example or describe one from the text.
4. State the Product Law for Limits at Infinity. What conditions must be met for it to apply?
5. What is the value of $\lim_{x\to\infty} \frac{1}{x^p}$ if $p > 0$? Does this also hold for $x \to -\infty$? Are there any additional conditions for the $x \to -\infty$ case?
6. When evaluating the limit of a rational function at infinity, what is the common first algebraic step described in Example 2a?
7. In Example 2b, when simplifying $\lim_{x\to\infty} \frac{\sqrt{1-x+x^2}}{3-x}$, how is $\sqrt{x^2(\frac{1}{x^2} - \frac{1}{x} + 1)}$ simplified when $x \to \infty$?
8. How does the simplification in the previous question change if $x \to -\infty$, as in Example 2c? What does $\sqrt{x^2}$ become?
9. What indeterminate form is encountered in Example 2d, $\lim_{x\to-\infty} (\sqrt{1-x+9x^2} + 3x)$? What algebraic technique is used to resolve it?
10. What are the values of $\lim_{x\to\infty} \tan^{-1}(x)$ and $\lim_{x\to-\infty} \tan^{-1}(x)$?
11. State the Squeeze Theorem for Limits at Infinity.
12. What does it mean if $\lim_{x\to\infty} f(x) = \infty$?
13. When evaluating an infinite limit at infinity for a rational function, such as $\lim_{x\to-\infty} \frac{3+x^6}{x^4+8}$ in Example 1.5.5, what was the general strategy used after dividing by the highest power of $x$ from the original expression?

## HOMEWORK

**For exercises 1 - 5, examine the graphs. Identify where the vertical asymptotes are located and use limit notation in your answer.**

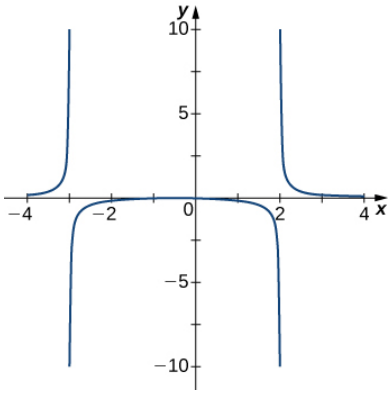
1)



**Answer**

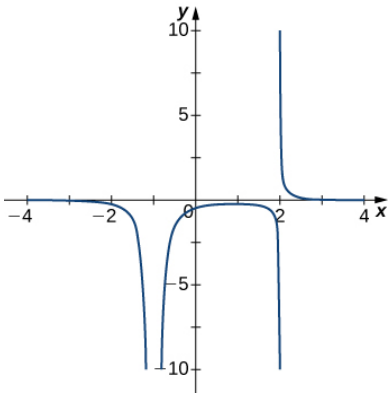
$x = 1$

2)



https://math.libretexts.org/@go/page/175434

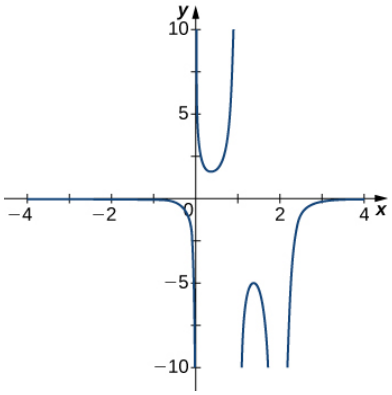
3)



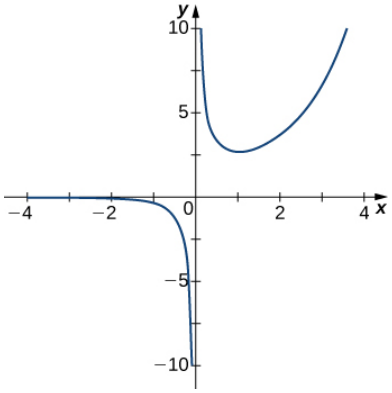
**Answer**

$x = -1,\ x = 2$

4)



5)



**Answer**

$x = 0$

**For the functions $f(x)$ in exercises 6 - 10, determine whether there is an asymptote at $x = a$. Justify your answer using limits and without using graphing technology.**

6) $f(x) = \dfrac{x+1}{x^2+5x+4},\quad a = -1$

7) $f(x) = \dfrac{x}{x-2},\quad a = 2$

**Answer**

Yes, there is a vertical asymptote at $x = 2$.

8) $f(x) = (x+2)^{3/2}, \quad a = -2$

9) $f(x) = (x-1)^{-1/3}, \quad a = 1$

**Answer**

Yes, there is vertical asymptote at $x = 1$.

10) $f(x) = 1 + x^{-2/5}, \quad a = 1$

**In exercises 11 - 20, evaluate the limit.**

11) $\lim\limits_{x\to\infty} \dfrac{1}{3x+6}$

**Answer**

$$\lim_{x\to\infty} \frac{1}{3x+6} = 0$$

12) $\lim\limits_{x\to\infty} \dfrac{2x-5}{4x}$

13) $\lim\limits_{x\to\infty} \dfrac{x^2-2x+5}{x+2}$

**Answer**

$$\lim_{x\to\infty} \frac{x^2-2x+5}{x+2} = \infty$$

14) $\lim\limits_{x\to-\infty} \dfrac{3x^3-2x}{x^2+2x+8}$

15) $\lim\limits_{x\to-\infty} \dfrac{x^4-4x^3+1}{2-2x^2-7x^4}$

**Answer**

$$\lim_{x\to-\infty} \frac{x^4-4x^3+1}{2-2x^2-7x^4} = -\frac{1}{7}$$

16) $\lim\limits_{x\to\infty} \dfrac{3x}{\sqrt{x^2+1}}$

17) $\lim\limits_{x\to-\infty} \dfrac{\sqrt{4x^2-1}}{x+2}$

**Answer**

$$\lim_{x\to-\infty} \frac{\sqrt{4x^2-1}}{x+2} = -2$$

18) $\lim\limits_{x\to\infty} \dfrac{4x}{\sqrt{x^2-1}}$

19) $\lim\limits_{x\to-\infty} \dfrac{4x}{\sqrt{x^2-1}}$

**Answer**

$$\lim_{x\to-\infty} \frac{4x}{\sqrt{x^2-1}} = -4$$

20) $\lim\limits_{x\to\infty} \dfrac{2\sqrt{x}}{x-\sqrt{x}+1}$

**For exercises 21 - 25, find the horizontal and vertical asymptotes.**

21) $f(x) = x - \dfrac{9}{x}$

**Answer**

Horizontal: none,

Vertical: $x = 0$

22) $f(x) = \dfrac{1}{1-x^2}$

23) $f(x) = \dfrac{x^3}{4 - x^2}$

**Answer**

Horizontal: none,
Vertical: $x = \pm 2$

24) $f(x) = \dfrac{x^2 + 3}{x^2 + 1}$

25) $f(x) = \sin(x)\sin(2x)$

**Answer**

Horizontal: none,
Vertical: none

26) $f(x) = \cos x + \cos(3x) + \cos(5x)$

27) $f(x) = \dfrac{x \sin(x)}{x^2 - 1}$

**Answer**

Horizontal: $y = 0$,
Vertical: $x = \pm 1$

28) $f(x) = \dfrac{x}{\sin(x)}$

29) $f(x) = \dfrac{1}{x^3 + x^2}$

**Answer**

Horizontal: $y = 0$,
Vertical: $x = 0$ and $x = -1$

30) $f(x) = \dfrac{1}{x - 1} - 2x$

31) $f(x) = \dfrac{x^3 + 1}{x^3 - 1}$

**Answer**

Horizontal: $y = 1$,
Vertical: $x = 1$

32) $f(x) = \dfrac{\sin x + \cos x}{\sin x - \cos x}$

33) $f(x) = x - \sin x$

**Answer**

Horizontal: none,
Vertical: none

34) $f(x) = \dfrac{1}{x} - \sqrt{x}$

**For exercises 35 - 38, construct a function $f(x)$ that has the given asymptotes.**

35) $x = 1$ and $y = 2$

**Answer**

Answers will vary, for example: $y = \dfrac{2x}{x - 1}$

36) $x = 1$ and $y = 0$

37) $y = 4,\ x = -1$

**Answer**

Answers will vary, for example: $y = \dfrac{4x}{x+1}$

38) $x = 0$

**In exercises 39 - 43, graph the function on a graphing calculator on the window $x = [-5, 5]$ and estimate the horizontal asymptote or limit. Then, calculate the actual horizontal asymptote or limit.**

39) $f(x) = \dfrac{1}{x+10}$

**Answer**

$\lim\limits_{x\to\infty} \dfrac{1}{x+10} = 0$ so $f$ has a horizontal asymptote of $y = 0$.

40) $f(x) = \dfrac{x+1}{x^2+7x+6}$

41) $\lim\limits_{x\to-\infty} x^2+10x+25$

**Answer**

$\lim\limits_{x\to-\infty} x^2+10x+25 = \infty$

42) $\lim\limits_{x\to-\infty} \dfrac{x+2}{x^2+7x+6}$

43) $\lim\limits_{x\to\infty} \dfrac{3x+2}{x+5}$

**Answer**

$\lim\limits_{x\to\infty} \dfrac{3x+2}{x+5} = 3$ so this function has a horizontal asymptote of $y = 3$.

# 2.5: The Precise Definition of a Finite Limit at a Finite Number

https://math.libretexts.org/@go/page/175435

**Note to the Instructor (click to expand)**

This is where the magic happens - you are likely going to spend around a week (at least) on this material. **It is NOT optional**. Use the digital manipulations in this section to help students visualize the $\epsilon - \delta$ proof. Additionally, students should be introduced to symbolic logic here (for use throughout the rest of Calculus).

---

To succeed in this section, you'll need to use some skills from previous courses. While you should already know them, this is the first time they've been required. You can review these skills in CRC's Corequisite Codex. If you have a support class, it might cover some, **but not all**, of these topics.

**Prerequisite Skills and Support Topics (click to expand)**

- **Simplifying Expressions**
  - Simplifying Radical Expressions: Needed when working with proofs involving square roots, such as in Example 8 ($\sqrt{x-4}$) or Checkpoint 8 ($\sqrt{1-x}$).
- **Solving Inequalities**
  - Solving Linear Inequalities: Manipulating inequalities is key in the scratch work to find $\delta$ in terms of $\epsilon$. For example, from $|5x-5|<\epsilon$ to $|x-1|<\epsilon/5$ in Example 3.
  - Solving Absolute Value Inequalities: The entire epsilon-delta definition is framed using absolute value inequalities and understanding how to manipulate them.
- **Absolute Value Functions**
  - The Concept of Absolute Value: The concept of what an absolute value represents (both from a piecewise function and a distance point of view) is critical to understanding how $\epsilon$-$\delta$ proofs work.
- **Logic and Proofs**
  - Quantifiers and Symbolic Logic: The precise definition uses universal ($\forall$, "for every") and existential ($\exists$, "there exists") quantifiers. Understanding these is key to interpreting the definition. The section explicitly defines these symbols.
  - Direct Proofs: The examples (3, 4, 6, and 8) are all direct proofs following the $\epsilon - \delta$ structure. The concept of "antecedent" and "consequent" is discussed.

---

The following is a list of learning objectives for this section.

**Learning Objectives (click to expand)**

- Describe the precise definition of a limit for finite limits at finite points.
- Apply the epsilon-delta definition to find the limit of a function.
- Prove finite limits using the precise definition of a limit.
- Describe the epsilon-delta definitions of one-sided limits.
- Use the epsilon-delta definition to prove the Limit Laws.

Hawk A.I. Section-Specific Tutor

To access the Hawk A.I. Tutor, you will need to be logged into your campus Gmail account.

By now, you have progressed from the very informal definition of a limit in the introduction of this chapter to the intuitive understanding of a limit. At this point, you should have a solid intuitive sense of what the limit of a function means and how you can find it. This section converts this intuitive idea of a limit into a formal definition using precise mathematical language. The formal definition of a limit is one of the most challenging definitions you will encounter in Calculus; however, it is well worth any effort you make to reconcile it with your intuitive notion of a limit. Understanding this definition is the key that opens the door to a better understanding of calculus.

## Foreword: A Lesson in Patience

I have written this section to step you *slowly* through the concept, visualization, and understanding of the precise definition of a finite limit at a finite number (in addition to the other limits presented at the end of this section). Reading everything presented here, in the order it is presented, might seem exhaustingly lengthy; however, the presentation in this section is meticulously crafted to get you to a level of understanding necessary to succeed in calculus.

## Quantifying Closeness

Before stating the formal definition of a limit, we must introduce a few preliminary ideas. Recall that the distance between two points $a$ and $b$ on a number line is given by $|a-b|$. From this point forward, we will constantly be using this interpretation.

- The statement $|f(x)-L|<\epsilon$ may be interpreted as: The distance between $f(x)$ and $L$ is less than $\epsilon$.
- The statement $0<|x-a|<\delta$ may be interpreted as: $x\neq a$ and the distance between $x$ and $a$ is less than $\delta$.

In calculus, $\delta$ and $\epsilon$ (the Greek lowercase letters delta and epsilon, respectively) are inevitably going to be *very* small positive numbers. In fact, in most cases, they will be infinitesimally small (i.e., both $\to 0^+$).

It is also essential to look at the following equivalences for absolute value:

- The statement $|f(x)-L|<\epsilon$ is equivalent to the statement $L-\epsilon<f(x)<L+\epsilon$.
- The statement $0<|x-a|<\delta$ is equivalent to the statement $a-\delta<x<a+\delta$, where $x\neq a$.

With these concepts of distances between values in hand, we need to introduce some language commonly used to discuss the precise definition of a limit.

**Definition: $\delta$-Neighborhood Centered at $a$**

A **$\delta$-neighborhood centered at $a$** is defined to be the interval $(a-\delta,a)\cup(a,a+\delta)$ on the $x$-axis.

**Definition: $\epsilon$-Neighborhood Centered at $L$**

An **$\epsilon$-neighborhood centered at $L$** is defined to be the interval $(L-\epsilon,L+\epsilon)$ on the $y$-axis.

Do you see a difference between these two definitions? A $\delta$-neighborhood *never* includes its center ($x=a$), while an $\epsilon$-neighborhood *always* includes its center ($y=L$). Some people (myself included) call a $\delta$-neighborhood a **punctured neighborhood**.

The next example illustrates how this idea of "closeness" might be linked to the idea of a limit.

**Example 2.5.1**

Using the concepts of "closeness" presented here (specifically, $\delta$- and $\epsilon$-neighborhoods), create a possible interpretation of

$$\lim_{x\to 1}(5x+1)=6.$$

**Solution**

**Building the logic:** Since $f(x)=5x+1$ is approaching $6$ as $x$ is approaching $1$, it *seems* like we are considering a group of $x$-values near $1$ whose corresponding values on the function $f(x)$ are approaching $6$.

**Tying this to intervals:** In terms of intervals, it *appears to be the case* that we are saying all of the $x$-values in an interval (neighborhood) around $x = 1$ lead to $y$-values in an interval (neighborhood) around $y = 6$.

**Tightening up the language:** *Perhaps* this means that all the $x$-values in a $\delta$-neighborhood centered at $x = 1$ lead to function values in an $\epsilon$-neighborhood centered at $y = 6$.

Take note of the imprecise language in the solution of Example 2.5.1 - this is purposeful. We have not yet developed a definition of the limit, so we are trying to guess our way to a strong, infallible definition.

## The $\epsilon$ Gauntlet

Our interpretation of the meaning of the limit from Example 2.5.1,

$$\lim_{x \to 1} (5x + 1) = 6,$$

was, "all $x$-values in a $\delta$-neighborhood centered at $x = 1$ lead to function values in an $\epsilon$-neighborhood centered at $y = 6$." Not only is this imprecise, but it is actually *backward* .[1] For now, let's focus on thinking of our interpretation *in the correct order*.

When handed the limit

$$\lim_{x \to 1} (5x + 1) = 6,$$

you are essentially being told that, no matter what sized $\epsilon$-neighborhood someone creates about $y = 6$, you *should* be able to find a small enough $\delta$-neighborhood about $x = 1$ so that the function, $f(x) = 5x + 1$, is very close to the supposed limit 6 whenever $x$ is close to 1. What do we mean by "close?" Hopefully, as long as our value of $x$ is within the $\delta$-neighborhood, then the corresponding value of $f(x)$ should be within the *given* $\epsilon$-neighborhood.

At this point, it's understandable if you had to read those last two paragraphs a few times. If you did, then good for you - you are practicing becoming a better critical thinker! Let's reward ourselves with a visualization that will help us grasp this idea of "$\epsilon$ before $\delta$."

The act of being handed a static $\epsilon$ and challenged to find a corresponding $\delta$ is called the $\epsilon$ **gauntlet**. I call it this because it's as if someone is throwing a gauntlet at your feet and challenging you to find an appropriate $\delta$-neighborhood - if you dare!

### Example 2.5.2: Finding $\delta$ Given $\epsilon$

Consider the limit

$$\lim_{x \to 1} (5x + 1) = 6.$$

Find an appropriate $\delta$ so that all the function values, $f(x) = 5x + 1$, lie within $\epsilon = 0.001$ units of $y = 6$ whenever $x$ is within $\delta$ units of $x = 1$.

**Solution**

The $\epsilon$ gauntlet has been thrown! Someone has issued the challenge and said that you could not find a $\delta$-neighborhood about $x = 1$ such that all of the values of the corresponding function land in their very small $\epsilon$-neighborhood about $y = 6$. The size of their given $\epsilon$ neighborhood is 0.001.

The given $\epsilon$-neighborhood rises from

$$y = 6 - \epsilon = 6 - 0.001 = 5.999$$

to

$$y = 6 + \epsilon = 6 + 0.001 = 6.001.$$

Solving $5.999 = 5x + 1$ and $6.001 = 5x + 1$, we get $x = 0.9998$ and $x = 1.0002$, respectively. This means that as long as $x \in (0.9998, 1) \cup (1, 1.0002)$, $f(x) \in (5.999, 6.001)$.

To compute the value of $\delta$, we consider the "length" of each subinterval on the $x$-axis. The first is $(0.9998, 1)$. This has a length of $0.0002$. Likewise, the subinterval $(1, 1.0002)$ has a length of $0.0002$. Thus, we choose $\delta = 0.0002$.[2]

Whenever $x$ is within $\delta = 0.0002$ units of $1$ on the $x$-axis, the corresponding function value, $f(x)$, must therefore be within $\epsilon = 0.001$ units of $y = 6$.

A visual to confirm this is in Figure $2.5.1$ below

## The Precise Definition of a Finite Limit at a Finite Number

With these clarifications, we can state the formal $\epsilon - \delta$ **definition of a finite limit at a finite number**.

**Definition: Finite Limit at a Finite Number (Precise Definition)**

Let $f(x)$ be defined for all $x \neq a$ over an open interval containing $a$, and let $L$ be a real number. We say

$$\lim_{x \to a} f(x) = L$$

if for every $\epsilon > 0$, there exists a $\delta > 0$, such that if $0 < |x - a| < \delta$, then $|f(x) - L| < \epsilon$.

Stated with symbolic logic,

$$\lim_{x \to a} f(x) = L$$

means

$$\forall \epsilon > 0, \quad \exists \delta > 0 \ni$$

$$0 < |x - a| < \delta \implies |f(x) - L| < \epsilon.$$

You are probably not used to symbolic logic, so let's define those symbols.

| Symbol | Meaning |
|---|---|
| $\forall$ | " for all" or "for each" or "for every" |
| $\exists$ | "there exists" or "there is" |
| $\implies$ | "implies" or "then" |
| $\ni$ | "such that" or "so that" |

**Caution**

The symbol $\ni$ is used frequently in symbolic logic for "such that"; however, many mathematicians do not use it for that purpose. Check with your instructor to see what logic symbol they prefer (many avoid the confusion entirely and use "s.t.").

### Critically Analyzing the Structure of the Precise Definition of a Finite Limit at a Finite Number

This definition may seem rather complex from a mathematical point of view. Still, it becomes easier to understand if we break it down phrase by phrase. The statement itself involves something called a **universal quantifier** (for every $\epsilon > 0$, or $\forall \epsilon > 0$), an **existential quantifier** (there exists a $\delta > 0$, or $\exists \delta > 0$), and, last, a **conditional statement** (if $0 < |x - a| < \delta$, then $|f(x) - L| < \epsilon$). Let's look at Table $2.5.1$, which breaks down the definition and translates each part.

**Table 2.5.1**

| Definition | Symbolic Logic | Translation |
|---|---|---|
| For every $\epsilon > 0$, | $\forall \epsilon > 0$ | For every positive distance $\epsilon$ from $L$, |
| there exists a $\delta > 0$, | $\exists \delta > 0$ | there is a positive distance $\delta$ from $a$, |
| such that | $\ni$ | such that |
| if $0 < \lvert x - a \rvert < \delta$, then $\lvert f(x) - L \rvert < \epsilon$. | $0 < \lvert x - a \rvert < \delta \implies \lvert f(x) - L \rvert < \epsilon$ | if $x$ is *within* $\delta$ units of $a$ and $x \neq a$, then $f(x)$ is *within* $\epsilon$ units of $L$. |

## Graphically Interpreting the Precise Definition of a Finite Limit at a Finite Number

We can get a better handle on this definition by looking at the definition geometrically. Figure **2.5.1** shows possible values of $\delta$ for various choices of $\epsilon > 0$ for a given function $f(x)$, a number $a$, and a limit $L$ at $a$. Notice that as we choose smaller values of $\epsilon$ (the distance between the function and the limit), we can always find a $\delta$ small enough so that if we have chosen an $x$ value within $\delta$ of $a$, then the value of $f(x)$ is within $\epsilon$ of the limit $L$.

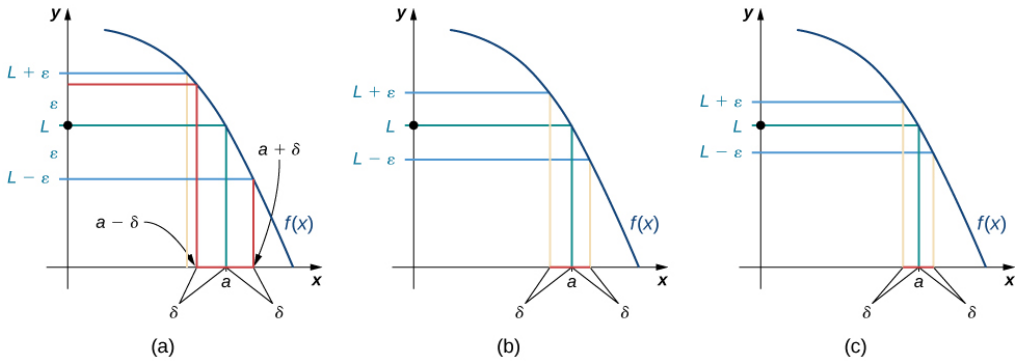


*Figure* **2.5.1***: These graphs show possible values of $\delta$, given successively smaller choices of $\epsilon$.*

## The Importance of Scratch Work

Your instructor has likely presented clean, concise, and well-polished proofs in class. Did she do so out of thin air? Is she just a genius that can throw together any logical argument without flaw? Nope!

Before delving into examples, it is *incredibly* important to understand that mathematicians (and, therefore, you) do not magically write clean proofs from step 1 to step 100 without doing a bit (or quite a bit) of scratch work. **Scratch work** is where the *real* magic happens. It is where you allow yourself to think creatively, experiment with options, and discover pathways to the proof without fear of judgment and nasty comments from someone looking over your shoulder. On the other hand, the proof is a cleaned-up version of the scratch work with logically deductive steps and *no flaws*.

To understand how scratch work is done (and *why* we need it), you need first to have a solid understanding of the structure of a theorem. Theorems come in many forms, but the form that is relevant to our current task is the "If..., then..." statement. An "If..., then..." statement is a theorem (or conjecture) that is either

a. written as "If $P$ is true, then $Q$ is true," where $P$ and $Q$ are simple statements, or
b. is written in a form that can be rewritten as the form above.

For an example of each, consider the following:

a. "If it's raining, then it's cloudy."
b. "It's only raining when it is cloudy."

These two conjectures are the same; however, in mathematics, it's often easier to rewrite conjectures (or theorems) in the first, "If..., then..." format.

The "If" part of a theorem is known as the **antecedent**, and the "then" part is called the **consequent**. In the example above, the antecedent is "it's raining," and the consequent is "it's cloudy." These parts of a theorem will be important as we move forward.

Once we have rewritten the theorem in "If..., then..." format, it can be visualized as a 1000-piece puzzle in a box. Conceptually, the theorem can be thought of as follows:

> ***If*** *you can fit all the pieces together correctly,* ***then*** *the result will look like the picture on the box.*

For reference, the antecedent is "you can fit all the pieces of the puzzle together correctly." The consequent is "the result will precisely match the picture on the box."

The scratch work in the puzzle-building process is constantly referencing the picture on the box (the consequent) to see what you want to end up with. You have a blue corner piece in your hand, and looking at the box, you see the only corner that is blue is the upper-right corner. So you place it there. You notice on the box that a creepy clown with red hair is not too far down from that corner (important: all clowns are creepy). Therefore, you start gathering all the puzzle pieces that look to have red hair. And on the process goes.

This is akin to working backward or reverse engineering, the puzzle-solving process, and this is precisely what we do in scratch work.

> *Scratch work often starts by assuming we have arrived at the consequent. We then work backward to see how we got to the consequent. We hope this will eventually, with some possible conditions, allow us to work back to the antecedent.*

We ask ourselves, "If I arrived at the picture on the box, what must be true about the last piece I fit into the puzzle? And what does that mean about the piece I fit in before that?" And so on.

In each proof throughout this section, I will demonstrate what good scratch work in mathematics looks like. Please pay close attention to that *and* the proof structure.

## Proving Finite Limits at Finite Numbers (symmetric $\delta$-neighborhood)

We will take our time going through this first example. Still, as we progress, the amount of "discussion" within examples will decrease.

### ✔ Example 2.5.3: Proving a Statement about the Limit of a Linear Function

Prove

$$\lim_{x\to 1}(5x+1)=6.$$

**Solution**

A crucial initial step is to rewrite this limit as the precise definition of a limit.

$$\lim_{x\to 1}(5x+1)=6$$

means that

$$\forall \epsilon>0, \quad \exists \delta>0 \quad \ni$$

$$0<|x-1|<\delta \implies |(5x+1)-6|<\epsilon.$$

Read alternatively: No matter what $\epsilon>0$ that someone hands us, it is our job to find a $\delta>0$ (that almost always relies on the value of $\epsilon$ we were given) so that

> ***If*** $0<|x-1|<\delta$, ***then*** *we can guarantee that* $|(5x+1)-6|<\epsilon$.

**SCRATCH WORK**

Just like we would reference the puzzle box to see where we want to arrive, we will look at the consequent of our "If..., then..." statement to see where we need our proof to finish.

In our proof, we want to arrive at

$$|(5x+1)-6|<\epsilon \quad \text{(consequent)}$$

given that

$$0<|x-1|<\delta. \quad \text{(antecedent)}$$

Working backward from the consequent and trying to arrive at the antecedent, we get

$$\begin{aligned} |(5x+1)-6|<\epsilon &\implies |5x-5|<\epsilon \\ &\implies |5(x-1)|<\epsilon \\ &\implies |5|\cdot|x-1|<\epsilon \\ &\implies 5\cdot|x-1|<\epsilon \\ &\implies |x-1|<\frac{\epsilon}{5} \end{aligned}$$

So we can see that if we want to arrive at the consequent ($|(5x+1)-6|<\epsilon$), a superb choice for $\delta$ in our antecedent ($0<|x-1|<\delta$) is $\epsilon/5$. We now know how to "correctly put this puzzle together."

Note that the proof structure should be closely aligned with the structure of the precise definition of the limit. That is, it should flow in the following direction:

$$\forall \epsilon>0, \quad \exists \delta>0 \quad \ni$$

$$0<|x-1|<\delta \implies |(5x+1)-6|<\epsilon.$$

**PROOF**

$\forall \epsilon>0$, choose $\delta=\frac{\epsilon}{5}$. Therefore, if $0<|x-1|<\delta$, then

$$\begin{aligned} |x-1| &< \frac{\epsilon}{5} \quad \text{(Substitution)} \\ \implies 5|x-1| &< \epsilon \\ \implies |5x-5| &< \epsilon \\ \implies |(5x+1)-6| &< \epsilon \\ \implies |f(x)-L| &< \epsilon \quad \text{(Substitution)} \end{aligned}$$

Thus, we have proved the limit

$$\lim_{x\to 1}(5x+1)=6.$$

Before moving on to the following example, let's take some lessons from Example 2.5.3.

1. We always need scratch work when attempting a proof. Not doing so is akin to not looking at the cover of the puzzle box before attempting to piece a puzzle together.
2. The scratch work starts with the consequent and works backward to (hopefully) arrive at the antecedent.
3. We have no control over what $\epsilon$ they hand us, but $\delta$ will almost always be a function of $\epsilon$ (the single exception is when proving the limit of a constant function).
4. The structure of our proof will be closely aligned with the language of the precise definition of a limit with the exception that we will not be saying, "there exists a $\delta>0$," but rather, "let $\delta=...$" because we found a workable $\delta$ in our scratch work.

We streamline our language and work as we progress into the next example. Additionally, we write our scratch work off to the side so that the reader can immediately see our proof (the scratch work is provided for you, the student, to demonstrate what proper scratch work looks like).

### Example 2.5.4: Proving a Statement about the Limit of a Nonlinear Function (symmetric $\delta$)

Prove

$$\lim_{x\to -2/3}(9x^2+12x-7)=-11.$$

**Solution**

**PROOF**

For any given positive value of $\epsilon$, let $\delta=\frac{\sqrt{\epsilon}}{3}$. If it is the case that $0<\left|x-\left(-\frac{2}{3}\right)\right|<\delta$, then

$$\begin{aligned}
&\left|x-\left(-\frac{2}{3}\right)\right| &&< \frac{\sqrt{\epsilon}}{3}\\
\Longrightarrow\quad &\left|3\left(x+\frac{2}{3}\right)\right| &&< \sqrt{\epsilon}\\
\Longrightarrow\quad &|3x+2| &&< \sqrt{\epsilon}\\
\Longrightarrow\quad &|(3x+2)^2| &&< \epsilon\\
\Longrightarrow\quad &|9x^2+12x+4| &&< \epsilon\\
\Longrightarrow\quad &|(9x^2+12x-7)-(-11)| &&< \epsilon\\
\Longrightarrow\quad &|f(x)-L| &&< \epsilon
\end{aligned}$$

Thus, we have proved the limit

$$\lim_{x\to -2/3}(9x^2+12x-7)=-11.$$

**SCRATCH WORK**

We want to arrive at

$$|(9x^2+12x-7)-(-11)|<\epsilon \quad \text{(consequent)}$$

given that

$$0<\left|x-\left(-\frac{2}{3}\right)\right|<\delta. \quad \text{(antecedent)}$$

Working backward from the consequent and trying to arrive at the antecedent, we get

$$\begin{aligned}
|(9x^2+12x-7)-(-11)|<\epsilon \quad &\Longrightarrow \quad |9x^2+12x+4|<\epsilon\\
&\Longrightarrow \quad |(3x+2)^2|<\epsilon\\
&\Longrightarrow \quad |3x+2|^2<\epsilon\\
&\Longrightarrow \quad |3x+2|<\sqrt{\epsilon}\\
&\Longrightarrow \quad \left|3\left(x+\frac{2}{3}\right)\right|<\sqrt{\epsilon}\\
&\Longrightarrow \quad 3\left|x+\frac{2}{3}\right|<\sqrt{\epsilon}\\
&\Longrightarrow \quad \left|x+\frac{2}{3}\right|<\frac{\sqrt{\epsilon}}{3}\\
&\Longrightarrow \quad \left|x-\left(-\frac{2}{3}\right)\right|<\frac{\sqrt{\epsilon}}{3}\\
&\Longrightarrow \quad \text{Let } \delta=\frac{\sqrt{\epsilon}}{3}
\end{aligned}$$

Let's add to our list of lessons by looking at the previous example.

5. We have *some* flexibility in the language used during the proof. You don't always have to write, "$\forall \epsilon>0$." Instead, you could use language.

### Checkpoint 2.5.4

Prove

$$\lim_{x\to 2}(3x-2)=4$$

**Hint**

You should eventually arrive at $\delta = \frac{\epsilon}{3}$.

## Proving Finite Limits at Finite Numbers (non-symmetric $\delta$-neighborhoods)

In Examples **2.5.3** and **2.5.4**, the proofs were fairly straightforward, since the $\delta$-neighborhoods were symmetric about $x = a$. However, what happens if the $\delta$-neighborhood is not symmetric about $x = a$? What does that question even mean?

Consider the function

$$f(x) = x^2$$

as $x \to 2$. From Figure **2.5.2**, we can see that, for a given $\epsilon > 0$, we create an interval of sufficient $x$-values on the $x$-axis whose function values land in the interval $(4-\epsilon, 4+\epsilon)$.

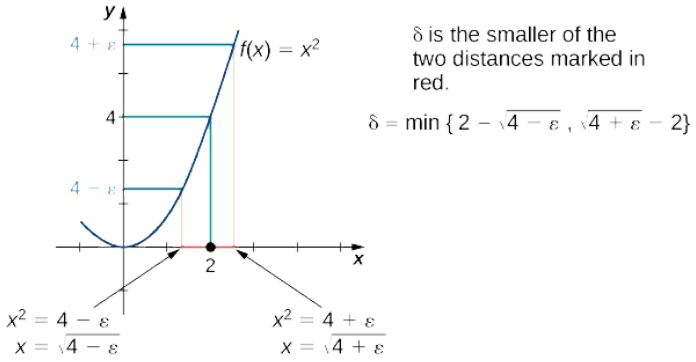

*Figure* **2.5.2**: *This graph shows how we find $\delta$ geometrically for a given $\epsilon$ given $f(x) = x^2$.*

The size of the interval of acceptable values *to the left* of $x = 2$ looks to be slightly greater than the size of the interval of acceptable values to the right of $x = 2$. If we let $\delta_L$ be the size of the interval to the left and $\delta_R$ be the size of the interval to the right, then as long as $x \in (2-\delta_L, 2) \cup (2, 2+\delta_R)$, we know $f(x) = x^2 \in (4-\epsilon, 4+\epsilon)$.

*However*, $\delta$- and $\epsilon$- neighborhoods are defined to be *symmetric* about their centers. We have an issue because it looks as though our $\delta$-neighborhood is not symmetric about $x = 2$ (as an aside, the $\epsilon$-neighborhoods will *always* be symmetric about their centers, so you don't have to worry about those). What do we do?

If given two choices for $\delta$, always take the smaller. For example, if we performed the computations given $\epsilon = 2$ (a gratuitously large $\epsilon$-neighborhood), we would find $\delta_L \approx 0.586$ and $\delta_R \approx 0.449$. This means that for $x \in (1.414, 2) \cup (2, 2.449)$, $f(x) \in (2, 6)$.

If all of the $x$-values in the interval $(1.414, 2) \cup (2, 2.449)$ have this property, then all of the $x$-values in a smaller subinterval of $(1.414, 2) \cup (2, 2.449)$ must also share this same property. Therefore, if we "tighten up" the interval to be symmetric about $x = 2$ using the minimum of $\delta_L$ and $\delta_R$, the resulting set of $x$-values should still map to function values within the given $\epsilon$-neighborhood about $y = 4$.

$$\delta_L \approx 2 - 1.414 = 0.586 \quad \text{and} \quad \delta_R \approx 2.449 - 2 = 0.449.$$

Hence, we choose $\delta$ to be

$$\min\{\delta_L, \delta_R\} \approx \min\{0.586, 0.449\} = 0.449.$$

### ✔ Example **2.5.5**: Determining an Appropriately-Sized $\delta$-Neighborhood Geometrically

While investigating the following limit, someone states that you couldn't possibly find an appropriate $\delta$-neighborhood given $\epsilon = 0.5$. With the use of graphing technology, prove them wrong.

$$\lim_{x \to -2} \left( e^{x+2} + 3\sin\left(\frac{\pi}{12}x\right) + 2 \right) = 1.5$$

**Solution**

This style of problem displays whether or not someone truly understands the *language translation* of the precise definition of a finite limit at a finite number. Remember, this limit is equivalent to saying,

$$\forall \epsilon > 0, \quad \exists \delta > 0 \ni$$

$$0 < |x+2| < \delta \implies \left| \left( e^{x+2} + 3\sin\left(\frac{\pi}{12}x\right) + 2 \right) - 1.5 \right| < \epsilon.$$

However, reading this in language and allowing $\epsilon = 0.5$, we can rephrase this as follows: Given $\epsilon = 0.5$, we should be able to find a positive distance, $\delta$, from $x = -2$, such that if $x$ is within $\delta$ units of $-2$, then $f(x)$ is within $0.5$ units of $1.5$.

Since we are allowed graphing technology, let's use Desmos to graph $f(x) = e^{x+2} + 3\sin\left(\frac{\pi}{12}x\right) + 2$, $y = 1.5$, and the edges of our provided $\epsilon$-neighborhood $y = 1.5 \pm 0.5$.

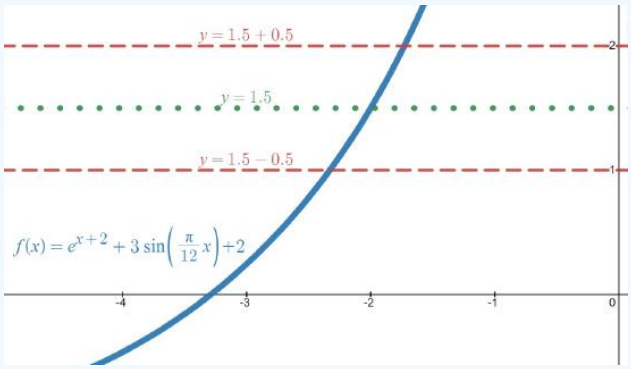

*Figure* 2.5.3

It is now our job to find an appropriately-sized $\delta$-neighborhood about $x = -2$ so that all $x$-values from this $\delta$-neighborhood lead to function values in the interval $(1.5 - 0.5, 1.5 + 0.5)$. Desmos automatically computes intersections for us, so all we need to do is click on the points where the function meets the upper and lower horizontal lines (the red-dashed lines).

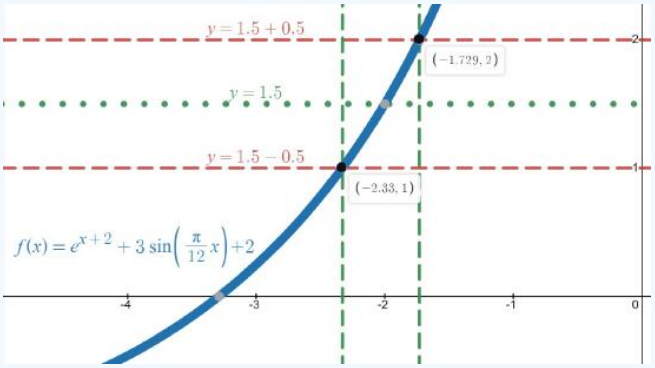

*Figure* 2.5.4

I also graph the vertical lines at these intersection points to help our visual further. Therefore, as long as $x \in (-2.33, -2) \cup (-2, -1.729)$, the function values look to satisfy the requirement by our challenger. That is, on the interval $(-2.33, -2) \cup (-2, -1.729)$, $|f(x) - 1.5| < 0.5$.

So how large should our $\delta$-neighborhood be?

The size of the interval to the left of $-2$ is approximately $-2 - (-2.33) = 0.33$, and the size of the interval to the right of $-2$ is approximately $-1.729 - (-2) = 0.271$. I say "approximately" because Desmos only returns a maximum of three digits on their graphs.

When given the option of two values for $\delta$, we always choose the smaller. Thus, we should choose $\delta = 0.271$ (due to rounding errors, we might want to choose $\delta$ *slightly* smaller - say, $0.270$).

The geometric investigation we just performed provides invaluable insight into the formal definition of the limit. However, an algebraic approach is the primary tool used to prove statements about limits. In Example **2.5.6**, we take on a purely algebraic approach to prove a limit involving non-symmetric values of $\delta$.

### Example 2.5.6: Proving a Statement about the Limit of a Nonlinear Function (non-symmetric $\delta$)

Prove that

$$\lim_{x \to -1} (x^2 - 2x + 3) = 6.$$

https://math.libretexts.org/@go/page/175435

**Solution**

**PROOF**

$\forall \epsilon > 0$, I will choose $\delta = \min\left\{1, \frac{\epsilon}{5}\right\}$. If $0 < |x-(-1)| < \delta$, then

$$|x+1| < 1 \text{ and } |x+1| < \frac{\epsilon}{5}$$

Since $|x+1| < 1$,

$$\begin{aligned} -2 < x < 0 &\implies -5 < x-3 < -3 \\ &\implies 5 > |x-3| > 3 \\ &\implies 5 > |x-3| \end{aligned}$$

Additionally, since $|x+1| < \frac{\epsilon}{5}$,

$$\begin{aligned} 5|x+1| < \epsilon &\implies |x-3| \cdot |x+1| < 5|x+1| < \epsilon \\ &\implies |x-3| \cdot |x+1| < \epsilon \\ &\implies |x^2-2x-3| < \epsilon \\ &\implies |(x^2-2x+3)-6| < \epsilon \\ &\implies |f(x)-L| < \epsilon \end{aligned}$$

Thus, we have proved the limit

$$\lim_{x \to -1} (x^2-2x+3) = 6.$$

**SCRATCH WORK**

We want to arrive at

$$|(x^2-2x+3)-6| < \epsilon \quad \text{(consequent)}$$

given that

$$0 < |x-(-1)| < \delta. \quad \text{(antecedent)}$$

Working backward from the consequent and trying to arrive at the antecedent, we get

$$\begin{aligned} |(x^2-2x+3)-6| < \epsilon &\implies |x^2-2x-3| < \epsilon \\ &\implies |(x-3)(x+1)| < \epsilon \end{aligned}$$

We want to keep $|x+1|$ because that is part of the antecedent; however, that $|x-3|$ needs to be replaced with (hopefully) a constant. We will need to judiciously **build a bound** for $|x-3|$.

**Building the Bound for $|x-3|$**

Since $x \to -1$, it's fair to say that $-2 < x < 0$. We are **assuming** here that $\delta_1 = 1$. That is, we are assuming $x$ is within 1 unit of $-1$. This means that, for the remainder of this argument (and for the proof), we will not allow our $\delta$-neighborhood to be larger than 1.

With this assumption, and subtracting 3 from all three sides of the inequality, we get

$$-5 < x-3 < -3.$$

Taking the absolute value of all three sides, we get

$$5 > |x-3| > 3.$$

Therefore, if $x \in (-2, 0)$, we know that $|x-3|$ can be, at maximum, 5. This will be our bound on $|x-3|$. That is,

$$|x-3| < 5.$$

**Using the Bound**

Going back to our work, we ended with

$$|(x-3)(x+1)| = |x-3| \cdot |x+1| < \epsilon;$$

however, we know that, in the very worst-case scenario, $|x-3|$ is still less than 5. Therefore,

$$\begin{aligned} |x-3| \cdot |x+1| &< 5 \cdot |x+1| \\ &= 5|x+1| \\ &< \epsilon \end{aligned}$$

Hence,

$$5|x+1| < \epsilon \implies |x+1| < \frac{\epsilon}{5}.$$

This shows us that $\delta_2 = \frac{\epsilon}{5}$. We can now begin the proof.

**Checkpoint 2.5.6**

Prove that $\lim_{x\to 1} x^2 = 1$.

**Answer**

$|\, x^2 - 1 \,| = |x-1| \cdot |x+1| < \epsilon/3 \cdot 3 = \epsilon$

You will find that, in general, the more complex a function, the more likely it is that the algebraic approach is the easiest to apply. The algebraic approach is also more useful in proving statements about limits.

## Proving Limit Laws

We now demonstrate how to use the $\epsilon - \delta$ definition of a limit to construct a rigorous proof of one of the Limit Laws. The **Triangle Inequality** is used at a key point of the proof, so we first review this key property of absolute value.

**Theorem: Triangle Inequality**

If $a$ and $b$ are any real numbers, then $|a+b| \leq |a| + |b|$.

**Proof of the Sum Law**

Recall: If $\lim_{x\to a} f(x) = L$ and $\lim_{x\to a} g(x) = M$, then $\lim_{x\to a} (f(x) + g(x)) = L + M$.

**Proof**

Let $\epsilon > 0$. Choose $\delta_1 > 0$ so that if $0 < |x-a| < \delta_1$, then $|f(x) - L| < \epsilon/2$, and choose $\delta_2 > 0$ so that if $0 < |x-a| < \delta_2$, then $|g(x) - M| < \epsilon/2$. Let $\delta = \min\{\delta_1, \delta_2\}$. If $0 < |x-a| < \delta$, then

$$0 < |x-a| < \delta_1 \text{ and } 0 < |x-a| < \delta_2.$$

Hence,

$$\begin{aligned} |(f(x)+g(x)) - (L+M)| &= |(f(x)-L) + (g(x)-M)| \\ &\leq |f(x)-L| + |g(x)-M| \\ &< \tfrac{\epsilon}{2} + \tfrac{\epsilon}{2} \\ &= \epsilon \end{aligned}$$

*Q.E.D.*

## Showing a Limit Does Not Exist

We now explore what it means for a limit not to exist. The limit $\lim_{x\to a} f(x)$ does not exist if there is no real number $L$ for which $\lim_{x\to a} f(x) = L$. Thus, for all real numbers $L$, $\lim_{x\to a} f(x) \neq L$. To understand what this means, we look at each part of the definition of $\lim_{x\to a} f(x) = L$ together with its opposite. A translation of the definition is given in Table 2.5.2.

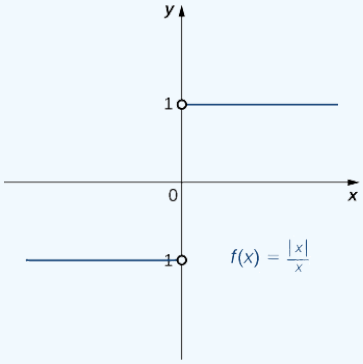
**Table 2.5.2. Translation of the Definition of $\lim_{x\to a} f(x) = L$ and its Opposite**

| Definition | Opposite |
|---|---|
| For every $\epsilon > 0$, | **There exists** $\epsilon > 0$ so that |
| there exists a $\delta > 0$, so that | **for every** $\delta > 0$, |
| if $0 < \|x-a\| < \delta$, then $\|f(x) - L\| < \epsilon$. | there is an $x$ satisfying $0 < \|x-a\| < \delta$ so that $\|f(x) - L\| \geq \epsilon$. |

Finally, we may state what it means for a limit not to exist. The limit $\lim_{x\to a} f(x)$ does not exist if for every real number $L$, there exists a real number $\epsilon > 0$ so that for all $\delta > 0$, there is an $x$ satisfying $0 < |x-a| < \delta$, so that $|f(x) - L| \geq \epsilon$. Let's apply this in Example 2.5.7 to show that a limit does not exist.

### Example 2.5.7: Showing That a Limit Does Not Exist

Show that $\lim\limits_{x\to 0}\dfrac{|x|}{x}$ does not exist. The graph of $f(x)=|x|/x$ is shown here:



**Solution**

Suppose that $L$ is a candidate for a limit. Choose $\epsilon = 1/2$.

Let $\delta > 0$. Either $L \geq 0$ or $L < 0$. If $L \geq 0$, then let $x = -\delta/2$.

Thus,

$$|x-0| = |-\frac{\delta}{2}-0| = \frac{\delta}{2} < \delta$$

and

$$\left|\frac{|-\frac{\delta}{2}|}{-\frac{\delta}{2}} - L\right| = |-1-L| = L+1 \geq 1 > \frac{1}{2} = \epsilon.$$

On the other hand, if $L < 0$, then let $x = \delta/2$. Thus,

$$|x-0| = |\frac{\delta}{2}-0| = \frac{\delta}{2} < \delta$$

and

$$\left|\frac{|\frac{\delta}{2}|}{\frac{\delta}{2}} - L\right| = |1-L| = |L|+1 \geq 1 > \frac{1}{2} = \epsilon.$$

Thus, for any value of $L$, $\lim\limits_{x\to 0}\dfrac{|x|}{x} \neq L$.

## One-Sided Limits

Just as we first gained an intuitive understanding of limits and then moved on to a more rigorous definition, we now revisit one-sided limits. To do this, we modify the $\epsilon - \delta$ definition of a limit to give formal $\epsilon - \delta$ definitions for limits from the right and left at a point. These definitions only require slight modifications from the definition of the limit. In the definition of the limit from the right, the inequality $0 < x - a < \delta$ replaces $0 < |x-a| < \delta$, which ensures that we only consider values of $x$ that are greater than (to the right of) $a$. Similarly, in the definition of the limit from the left, the inequality $-\delta < x - a < 0$ replaces $0 < |x-a| < \delta$, which ensures that we only consider values of $x$ that are less than (to the left of) $a$.

### Definition: One-Sided Finite Limits at Finite Numbers (Precise Definition)

**Limit from the Right**: Let $f(x)$ be defined over an open interval of the form $(a,b)$ where $a < b$. Then

$$\lim_{x\to a^+} f(x) = L$$

if for every $\epsilon > 0$, there exists a $\delta > 0$, such that if $0 < x - a < \delta$, then $|f(x) - L| < \epsilon$.

**Limit from the Left:** Let $f(x)$ be defined over an open interval of the form $(b, c)$ where $b < c$. Then,

$$\lim_{x \to c^-} f(x) = L$$

if for every $\epsilon > 0$,there exists a $\delta > 0$ such that if $-\delta < x - c < 0$, then $|f(x) - L| < \epsilon$.

### Example 2.5.8: Proving a Statement about a Limit From the Right

Prove that

$$\lim_{x \to 4^+} \sqrt{x-4} = 0.$$

**Solution**

**PROOF**

For $\epsilon > 0$, let $\delta = \epsilon^2$. If $0 < x - 4 < \delta$, then

$$\begin{aligned} \sqrt{x-4} &< \epsilon \\ \implies |\sqrt{x-4} - 0| &< \epsilon \\ \implies |f(x) - L| &< \epsilon \end{aligned}$$

Thus, we have proved the limit

$$\lim_{x \to 4^+} \sqrt{x-4} = 0.$$

**SCRATCH WORK**

We want to arrive at

$$|\sqrt{x-4} - 0| < \epsilon \quad \text{(consequent)}$$

given that

$$0 < x - 4 < \delta. \quad \text{(antecedent)}$$

(Remember, since $x \to 4^+$, $x > 4 \implies x - 4 > 0$)
Working backward from the consequent and trying to arrive at the antecedent, we get

$$\begin{aligned} |\sqrt{x-4} - 0| < \epsilon &\implies \sqrt{x-4} < \epsilon \\ &\implies x - 4 < \epsilon^2 \\ &\implies \text{Let } \delta = \epsilon^2 \end{aligned}$$

### Checkpoint 2.5.8

Find $\delta$ corresponding to $\epsilon$ for a proof that $\lim_{x \to 1^-} \sqrt{1-x} = 0$.

**Answer**

$\delta = \epsilon^2$

## Footnotes

[1] I will explain why in a few short paragraphs from now.

[2] The idea of the "length" of a subinterval is a bit loose. In reality, we measure the radii from the center, $x = 1$, to the edge of each subinterval. To find the "length" of the interval $(x_L, x_R)$ (I use the notation $L$ for the $x$-value at the left edge and $R$ for the $x$-value of the right edge), we compute

$$x_R - x_L.$$

This concept (right minus left) will become paramount when we learn about integrals and their applications.

# 2.5E: EXERCISES

This page is a draft and is under active development.

## READING QUESTIONS

1. What does the statement $|f(x)-L|<\epsilon$ mean in terms of distance?
2. What does the statement $0<|x-a|<\delta$ mean in terms of distance and the value of $x$ relative to $a$?
3. What is a $\delta$-neighborhood centered at $a$? Does it include $a$?
4. What is an $\epsilon$-neighborhood centered at $L$? Does it include $L$?
5. State the precise ($\epsilon-\delta$) definition of a finite limit at a finite number: $\lim\limits_{x\to a} f(x)=L$.
6. In the $\epsilon-\delta$ definition, which quantity is chosen first, $\epsilon$ or $\delta$? Which one typically depends on the other?
7. What is the role of "scratch work" in constructing an $\epsilon-\delta$ proof? Which part of the definition (antecedent or consequent) does scratch work typically start with?
8. When proving a limit for a non-linear function where the $\delta$-neighborhood might not be symmetric (e.g., $f(x)=x^2$ near $x=2$), if you find two possible values $\delta_L$ (from the left) and $\delta_R$ (from the right), how do you choose the final $\delta$?
9. How is the precise definition of a limit from the right, $\lim\limits_{x\to a^+} f(x)=L$, different from the definition of a two-sided limit? Specifically, how does the condition on $x-a$ change?
10. What is the Triangle Inequality?
11. When proving that a limit does not exist, what needs to be shown regarding $\epsilon$, $\delta$, and $L$?

## HOMEWORK

**In exercises 1 - 4, write the appropriate $\epsilon-\delta$ definition for each of the given statements.**

1) $\lim\limits_{x\to a} f(x)=N$

2) $\lim\limits_{t\to b} g(t)=M$

**Answer**

For every $\epsilon>0$, there exists a $\delta>0$, so that if $0<|t-b|<\delta$, then $|g(t)-M|<\epsilon$

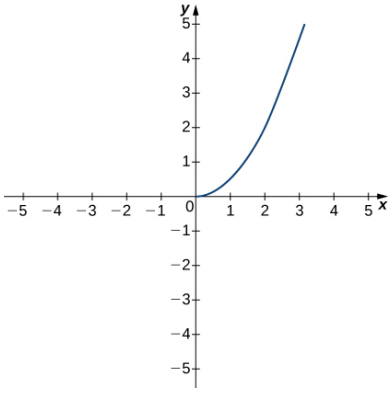
3) $\lim\limits_{x\to c} h(x)=L$

4) $\lim\limits_{x\to a} \phi(x)=A$

**Answer**

For every $\epsilon>0$, there exists a $\delta>0$, so that if $0<|x-a|<\delta$, then $|\phi(x)-A|<\epsilon$

**The following graph of the function $f$ satisfies $\lim\limits_{x\to 2} f(x)=2$. In the following exercises, determine a value of $\delta>0$ that satisfies each statement.**



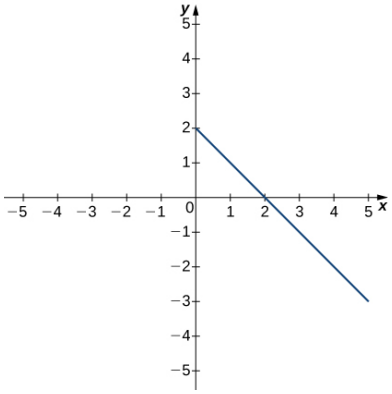
5) If $0<|x-2|<\delta$, then $|f(x)-2|<1$.

6) If $0<|x-2|<\delta$, then $|f(x)-2|<0.5$.

**Answer**

$\delta \leq 0.25$

**The following graph of the function $f$ satisfies $\lim_{x \to 3} f(x) = -1$. In the following exercises, determine a value of $\delta > 0$ that satisfies each statement.**



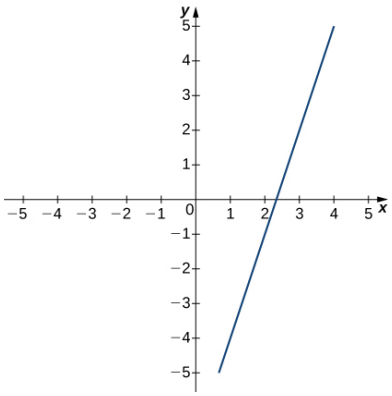
7) If $0 < |x - 3| < \delta$, then $|f(x) + 1| < 1$.

8) If $0 < |x - 3| < \delta$, then $|f(x) + 1| < 2$.

**Answer**

$\delta \leq 2$

**The following graph of the function $f$ satisfies $\lim_{x \to 3} f(x) = 2$. In the following exercises, for each value of $\epsilon$, find a value of $\delta > 0$ such that the precise definition of limit holds true.**



9) $\epsilon = 1.5$

10) $\epsilon = 3$

**Answer**

$\delta \leq 1$

**In exercises 11 - 12, use graphing technology to find a number $\delta$ such that the statements hold true.**

11) $\left|\sin(2x) - \frac{1}{2}\right| < 0.1$, whenever $\left|x - \frac{\pi}{12}\right| < \delta$

12) $\left|\sqrt{x - 4} - 2\right| < 0.1$, whenever $|x - 8| < \delta$

**Answer**

$\delta < 0.3900$

**In exercises 13 - 17, use the precise definition of limit to prove the given limits.**

13) $\lim_{x \to 2} (5x + 8) = 18$

14) $\lim_{x \to 3} \dfrac{x^2 - 9}{x - 3} = 6$

**Answer**

Let $\delta = \epsilon$. If $0 < |x-3| < \epsilon$, then $\left|\dfrac{x^2-9}{x-3} - 6\right| = \left|\dfrac{(x+3)(x-3)}{x-3} - 6\right| = |x+3-6| = |x-3| < \epsilon$.

15) $\lim\limits_{x\to 2} \dfrac{2x^2-3x-2}{x-2} = 5$

16) $\lim\limits_{x\to 0} x^4 = 0$

**Answer**

Let $\delta = \sqrt[4]{\epsilon}$. If $0 < |x| < \sqrt[4]{\epsilon}$, then $|x^4 - 0| = x^4 < \epsilon$.

17) $\lim\limits_{x\to 2} (x^2 + 2x) = 8$

**In exercises 18 - 20, use the precise definition of limit to prove the given one-sided limits.**

18) $\lim\limits_{x\to 5^-} \sqrt{5-x} = 0$

**Answer**

Let $\delta = \epsilon^2$. If $-\epsilon^2 < x - 5 < 0$, we can multiply through by $-1$ to get $0 < 5 - x < \epsilon^2$.
Then $\left|\sqrt{5-x} - 0\right| = \sqrt{5-x} < \sqrt{\epsilon^2} = \epsilon$.

19) $\lim\limits_{x\to 0^+} f(x) = -2$, where $f(x) = \begin{cases} 8x-3, & \text{if } x < 0 \\ 4x-2, & \text{if } x \geq 0 \end{cases}$.

20) $\lim\limits_{x\to 1^-} f(x) = 3$, where $f(x) = \begin{cases} 5x-2, & \text{if } x < 1 \\ 7x-1, & \text{if } x \geq 1 \end{cases}$.

**Answer**

Let $\delta = \epsilon/5$. If $-\epsilon/5 < x - 1 < 0$, we can multiply through by $-1$ to get $0 < 1 - x < \epsilon/5$.
Then $|f(x) - 3| = |5x - 2 - 3| = |5x - 5| = 5(1-x)$, since $x < 1$ here.
And $5(1-x) < 5(\epsilon/5) = \epsilon$.

21) An engineer is using a machine to cut a flat square of Aerogel of area $144\,\text{cm}^2$. If there is a maximum error tolerance in the area of $8\,\text{cm}^2$, how accurately must the engineer cut on the side, assuming all sides have the same length? How do these numbers relate to $\delta$, $\epsilon$, $a$, and $L$?

**Answer**

$0.033$ cm, $\epsilon = 8$, $\delta = 0.33$, $a = 12$, $L = 144$

22) Use the precise definition of limit to prove that the following limit does not exist: $\lim\limits_{x\to 1} \dfrac{|x-1|}{x-1}$.

23) Using precise definitions of limits, prove that $\lim\limits_{x\to 0} f(x)$ does not exist, given that $f(x)$ is the ceiling function. (Hint: Try any $\delta < 1$.)

**Answer**

Answers may very.

24) Using precise definitions of limits, prove that $\lim\limits_{x\to 0} f(x)$ does not exist: $f(x) = \begin{cases} 1, & \text{if } x \text{ is rational} \\ 0, & \text{if } x \text{ is irrational} \end{cases}$. (Hint: Think about how you can always choose a rational number $0 < r < d$, but $|f(r) - 0| = 1$.)

25) Using precise definitions of limits, determine $\lim\limits_{x\to 0} f(x)$ for $f(x) = \begin{cases} x, & \text{if } x \text{ is rational} \\ 0, & \text{if } x \text{ is irrational} \end{cases}$. (Hint: Break into two cases, $x$ rational and $x$ irrational.)

**Answer**

0

26) Using the function from the previous exercise, use the precise definition of limits to show that $\lim\limits_{x\to a} f(x)$ does not exist for $a \neq 0$

**For exercises 27 - 29, suppose that $\lim\limits_{x\to a} f(x) = L$ and $\lim\limits_{x\to a} g(x) = M$ both exist. Use the precise definition of limits to prove the following limit laws:**

27) $\lim\limits_{x\to a}(f(x) - g(x)) = L - M$

**Answer**

$$f(x) - g(x) = f(x) + (-1)g(x)$$

28) $\lim_{x \to a}[cf(x)] = cL$ for any real constant $c$ (Hint: Consider two cases: $c = 0$ and $c \neq 0$.)

29) $\lim_{x \to a}[f(x)g(x)] = LM$. (Hint: $|f(x)g(x) - LM| = |f(x)g(x) - f(x)M + f(x)M - LM| \leq |f(x)||g(x) - M| + |M||f(x) - L|$.)

**Answer**

Answers may vary.

# 2.6: The Precise Definitions of Infinite Limits and Limits at Infinity

**Note to the Instructor (click to expand)**

This section rounds out the precise definition of a limit by presenting the definitions involving infinities. As with the previous section, **this material is NOT optional**.

---

To succeed in this section, you'll need to use some skills from previous courses. While you should already know them, this is the first time they've been required. You can review these skills in CRC's Corequisite Codex. If you have a support class, it might cover some, **but not all**, of these topics.

**Prerequisite Skills and Support Topics (click to expand)**

- **Sets and Numbers**
  - Inequalities and Inequality Notation: Concepts like "much greater than" ($\gg$) and "much less than" ($\ll$) are used, and understanding the behavior of inequalities when multiplying/dividing by negatives or taking powers/roots is essential.
- **Solving Inequalities**
  - Solving Quadratic Inequalities: Required for scratch work, e.g., solving $(x-1)^2 < 1/N$ (Example 1).
  - Solving Exponential Inequalities: Necessary for proofs involving exponential functions, like $e^{-x} < \epsilon \Rightarrow -x < \ln(\epsilon)$.
  - Solving Logarithmic Inequalities: Necessary for proofs involving logarithmic functions, like $\ln(x+2) < N \Rightarrow x + 2 < e^N$ (Example 2).

---

The following is a list of learning objectives for this section.

**Learning Objectives (click to expand)**

- Describe the precise definition of a limit for infinite limits, at finite points and infinity.
- Prove finite and infinite limits using the precise definition of a limit.

Hawk A.I. Section-Specific Tutor

COSUMNES RIVER COLLEGE MATHEMATICS

To access the Hawk A.I. Tutor, you will need to be logged into your campus Gmail account.

The previous section walked us slowly through the theory of finite limits at finite numbers. Instead of *evaluating* limits, we *proved* limits using $\epsilon - \delta$ proofs. We now turn our attention to limits involving infinity. There are three such limits:

1. infinite limits at finite numbers,
2. finite limits at infinity, and
3. infinite limits at infinity.

We treat each of these separately and pull all limit proof styles into a unified theory at the end of the section.

## Infinite Limits at Finite Numbers

Previously, we learned how to *conceptually* investigate limits of the form

$$\lim_{x \to 1} \frac{1}{(x-1)^2}.$$

These types of limits are called **infinite limits at finite numbers** because their limits approach infinity as $x$ approaches a finite number.

To investigate this limit, we stated that $(x-1)^2 \to 0^+$ as $x \to 1$. Thus, $\frac{1}{(x-1)^2} \to \frac{1}{0^+} \to \infty$.

At the time, these arguments were sufficient, if not precise; however, we now turn our attention to *proving*

$$\lim_{x \to 1} \frac{1}{(x-1)^2} = \infty. \tag{2.6.1}$$

To understand the structure of the proof for infinite limits at finite numbers, we need to discuss the structure of the traditional $\epsilon - \delta$ proof.

Given $\lim_{x \to a} (f(x)) = L$, where $a$ and $L$ are finite, it should now make sense that we *require* an $\epsilon$-neighborhood about the *finite* number $L$, and a $\delta$-neighborhood about the *finite* number $a$; however, in the limit 2.6.1, $L = \infty$ is *not* finite. Therefore, creating a small $\epsilon$-neighborhood about $L$ makes no sense. We cannot bound $\infty$ in a small $\epsilon$-neighborhood. Thus, our precise definition needs some adjustment for this type of limit.

Figure 2.6.1 shows the graph of $f(x) = \frac{1}{(x-1)^2}$.

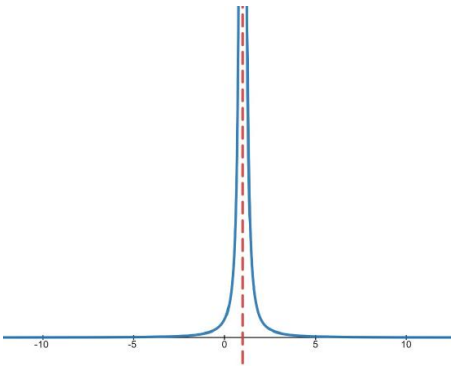


*Figure* 2.6.1: $f(x) = \frac{1}{(x-1)^2}$

While it's easy to *see* that the function values, $f(x)$, tend to $\infty$ as our $\delta$-neighborhood centered at $x = 1$ gets smaller and smaller, this is *not* a proof. What we need is for someone to challenge us (as they did with the $\epsilon$-gauntlet in the previous section) and say, "I bet you cannot find a small enough $\delta$-neighborhood centered at $x = 1$ so that all the corresponding function values are above... oh, let's say a billion!" **And this is the key to the structure of the precise definition of an infinite limit at a finite point.** Instead of "for any given $\epsilon > 0$," we are faced with "for any given $N \ggg 0$," where the notation $\ggg$ means "much greater than." And instead of a small $\epsilon$-neighborhood around $L$, we are challenged with getting the function values *above* (or below, if the limit is tending to $-\infty$) some massively large number $N$. Visually, it looks a bit like Figure 2.6.2.

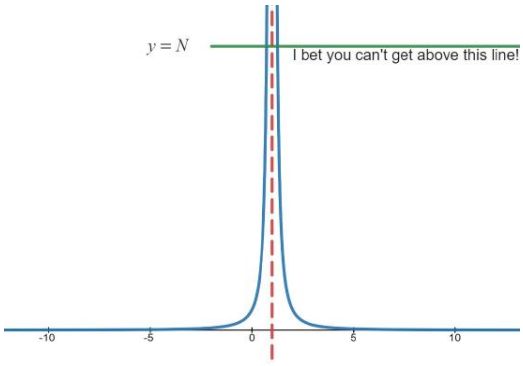

*Figure* 2.6.2

We can now formalize the precise definition of an infinite limit at a finite number.

### Definition: Infinite Limit at a Finite Number (Precise Definition)

Let $f(x)$ be defined for all $x \neq a$ over an open interval containing $a$. Then we say

$$\lim_{x \to a} f(x) = \infty$$

if for every $N \ggg 0$, there exists a $\delta > 0$, such that if $0 < |x - a| < \delta$, then $f(x) > N$.

Stated with symbolic logic,

$$\lim_{x \to a} f(x) = \infty$$

means

$$\forall N \ggg 0, \quad \exists \delta > 0 \ni$$

$$0 < |x - a| < \delta \implies f(x) > N.$$

Additionally, we say

$$\lim_{x \to a} f(x) = -\infty$$

if for every $N \lll 0$, there exists a $\delta > 0$, such that if $0 < |x - a| < \delta$, then $f(x) < N$.

Stated with symbolic logic,

$$\lim_{x \to a} f(x) = -\infty$$

means

$$\forall N \lll 0, \quad \exists \delta > 0 \ni$$

$$0 < |x - a| < \delta \implies f(x) < N.$$

Let's see this in an example.

### Example 2.6.1

Prove

$$\lim_{x \to 1} \frac{1}{(x-1)^2} = \infty.$$

**Solution**

**PROOF**

For $N \ggg 0$, let $\delta = \frac{1}{\sqrt{N}}$. If $0 < |x-1| < \delta$, then

$$\begin{aligned} |x-1| &< \frac{1}{\sqrt{N}} \\ \Longrightarrow \quad (x-1)^2 &< \frac{1}{N} \\ \Longrightarrow \quad \frac{1}{(x-1)^2} &> N \\ \Longrightarrow \quad f(x) &> N \end{aligned}$$

Thus, we have proved the limit

$$\lim_{x\to 1} \frac{1}{(x-1)^2} = \infty.$$

**SCRATCH WORK**

We want to arrive at

$$\frac{1}{(x-1)^2} > N \quad \text{(consequent)}$$

given that

$$0 < |x-1| < \delta. \quad \text{(antecedent)}$$

Working backward from the consequent and trying to arrive at the antecedent, we get

$$\begin{aligned} \frac{1}{(x-1)^2} > N \quad &\Longrightarrow \quad (x-1)^2 < \frac{1}{N} \\ &\Longrightarrow \quad |x-1| < \frac{1}{\sqrt{N}} \\ &\Longrightarrow \quad \text{Let } \delta = \frac{1}{\sqrt{N}} \end{aligned}$$

A few tripping points commonly arise while working with this material. It's important to remember the following from your prerequisite courses:

1. An inequality switches directions if you multiply or divide by a negative.
2. Applying an even power to an expression results in a positive value (this can be seen between the first and second steps of the proof in Example **2.6.1**).
3. $\sqrt{(\blacksquare)^2} = |\blacksquare|$. This fact is used in the second-to-last step of the Scratch Work.

We will add to this list as we move forward, but if you have solid prerequisites, you have nothing to worry about.

## Vertical Asymptotes

You have encountered vertical asymptotes in your algebra courses as part of the rational and logarithmic functions material. Moreover, you worked with them in Trigonometry. We now formalize their definition using Calculus.

**Definition: Vertical Asymptote**

The vertical line $x = a$ is called a **vertical asymptote** of the function $f(x)$ if at least one of the following is true:

$$\lim_{x\to a} f(x) = \infty \qquad \lim_{x\to a^-} f(x) = \infty \qquad \lim_{x\to a^+} f(x) = \infty$$
$$\lim_{x\to a} f(x) = -\infty \qquad \lim_{x\to a^-} f(x) = -\infty \qquad \lim_{x\to a^+} f(x) = -\infty$$

**Example 2.6.2**

Prove that $x = -2$ is a vertical asymptote of $f(x) = \ln(x+2)$.

**Solution**

From algebra, we know the domain of $f(x) = \ln(x+2)$ is $(-2, \infty)$. Therefore, to prove $x = -2$ is a vertical asymptote, we only need to concern ourselves with the one-sided limit

$$\lim_{x\to -2^+} \ln(x+2).$$

We know that the graph of $\ln(x+2)$ tends to $-\infty$ as $x$ approaches $-2$. Now we are asked to *prove* it. That is, we want to prove

$$\lim_{x\to -2^+} \ln(x+2) = -\infty.$$

**PROOF**

For $N \ll 0$, let $\delta = e^N$. If $0 < x-(-2) < \delta$, then

$$\begin{aligned} & x+2 < e^N \\ \implies & \ln(x+2) < N \\ \implies & f(x) < N \end{aligned}$$

Thus, we have proved the limit

$$\lim_{x\to -2} \ln(x+2) = -\infty.$$

Therefore, $x=-2$ is a vertical asymptote of $f(x) = \ln(x+2)$.

**SCRATCH WORK**

We want to arrive at

$$\ln(x+2) < N \quad \text{(consequent)}$$

given that

$$0 < x-(-2) = x+2 < \delta. \quad \text{(antecedent)}$$

(Since $x \to -2^+$, $x > -2 \implies x+2 > 0$.)
Working backward from the consequent and trying to arrive at the antecedent, we get

$$\begin{aligned} \ln(x+2) < N \quad & \implies \quad x+2 < e^N \\ & \implies \quad \text{Let } \delta = e^N \end{aligned}$$

Adding to that list of tripping points:

4. If $x < y$, then $e^x < e^y$ (this is a direct result of the fact that $y = e^x$ is an increasing function). This allows us to rewrite inequalities like $\ln(x+2) < N$ as $e^{\ln(x+2)} < e^N \implies x+2 < e^N$.
5. Stating that $\delta = e^N$ might *seem* wrong to you because $\delta$ is typically *very* small; however, pay close attention to the value of $N$. In Example **2.6.2**, $N \ll 0$. Therefore, $e^N$ *is* very small.

## Finite Limits at Infinity

Consider

$$\lim_{x\to\infty} \frac{e^x - e^{-x}}{e^x + e^{-x}}.$$

Some algebraic manipulation is necessary to see how this limit behaves.

$$\begin{aligned} \lim_{x\to\infty} \frac{e^x - e^{-x}}{e^x + e^{-x}} &= \lim_{x\to\infty} \frac{1 - e^{-2x}}{1 + e^{-2x}} && \left(\text{multiplying by } \frac{1/e^x}{1/e^x}\right) \\ &= \lim_{x\to\infty} \frac{1 - \frac{1}{e^{2x}}}{1 + \frac{1}{e^{2x}}} \\ &= \frac{1-0}{1+0} && \left(\frac{1}{e^{2x}} \to 0 \text{ as } x \to \infty\right) \\ &= 1 \end{aligned}$$

The second-to-last step in this derivation relied on *assumptions* that $\frac{1}{e^{2x}} \to 0$ as $x \to \infty$. In previous sections, we bolstered this assumption with a "hand-waving" argument, saying, "Well, it's *obvious* that the denominator of $\frac{1}{e^{2x}}$ goes to infinity as $x$ goes to infinity. Therefore, **1** over something going to infinity will shrink to **0**." However, this is not a rigorous mathematical justification.

So, how can we *prove*

$$\lim_{x\to\infty} \frac{1}{e^{kx}} = 0 \ \text{(for } k > 0), \tag{2.6.2}$$

which in turn will *prove*

$$\lim_{x\to\infty} \frac{e^x - e^{-x}}{e^x + e^{-x}} = 1? \tag{2.6.3}$$

Limits like 2.6.2 and 2.6.3 are called **finite limits at infinity** because the limits become finite (**0** in 2.6.2 and **1** in 2.6.3) as $x$ approaches infinity.

To understand the proof structure for finite limits at infinity, we again need to modify the traditional $\epsilon - \delta$ proof. In 2.6.2, $L = 0$ is finite, but $a = \infty$ is *not* finite. Therefore, creating a small $\delta$-neighborhood about $a$ makes no sense. Just as before, we cannot bound $\infty$ in a small $\delta$-neighborhood.

Figure 2.6.3 shows the graph of $f(x) = \frac{1}{e^{2x}}$ (we will worry about $\frac{1}{e^{kx}}$ later).

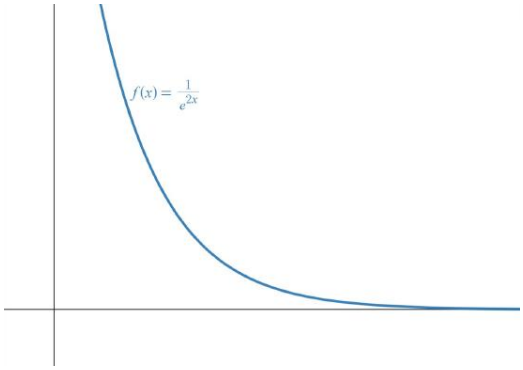

*Figure* 2.6.3: $f(x) = \frac{1}{e^{2x}}$

If the claim is that

$$\lim_{x \to \infty} \frac{1}{e^{2x}} = 0,$$

then someone is going to throw the $\epsilon$-gauntlet to challenge us to force the function to be bounded within the interval $(0 - \epsilon, 0 + \epsilon)$, as in Figure 2.6.4.

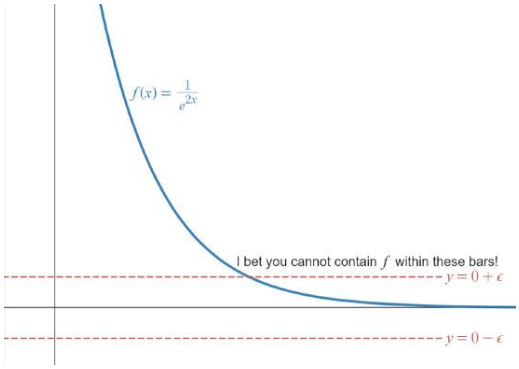

*Figure* 2.6.4

It's apparent from Figure 2.6.4 that, as long as $x$ is large enough, $-\epsilon < f(x) < \epsilon$. In fact, we see in Figure 2.6.5, as long as $x > M$, $|f(x) - 0| < \epsilon$.

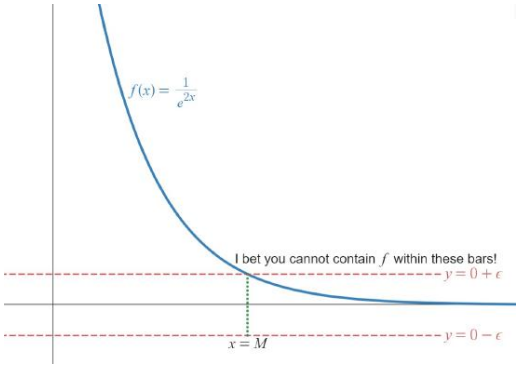

*Figure* 2.6.5

This gives us great insight into the formal definition of finite limits at infinity.

### Definition: Finite Limit at Infinity (Precise Definition)

Let $f(x)$ be defined for all $x > a$. Then we say

$$\lim_{x\to\infty} f(x) = L$$

if for every $\epsilon > 0$, there exists a number $M > 0$, such that if $x > M$, then $|f(x) - L| < \epsilon$.

Stated with symbolic logic,

$$\lim_{x\to\infty} f(x) = L$$

means

$$\forall \epsilon > 0, \quad \exists M > 0 \ni$$

$$x > M \implies |f(x) - L| < \epsilon.$$

Additionally, we say

$$\lim_{x\to-\infty} f(x) = L$$

if for every $\epsilon > 0$, there exists a number $M < 0$, such that if $x < M$, then $|f(x) - L| < \epsilon$.

Stated with symbolic logic,

$$\lim_{x\to-\infty} f(x) = L$$

means

$$\forall \epsilon > 0, \quad \exists M < 0 \ni$$

$$x < M \implies |f(x) - L| < \epsilon.$$

We now introduce two very powerful theorems. The proofs of each of these theorems showcase how to use the precise definition of a finite limit at infinity.

### Theorem

$$\lim_{x\to\infty} e^{-x} = 0$$

**Proof**

**PROOF**

For $\epsilon > 0$, let $M = -\ln(\epsilon)$. If $x > M$, then

$$\begin{aligned} & x > -\ln(\epsilon) \\ \implies & -x < \ln(\epsilon) \\ \implies & e^{-x} < \epsilon \\ \implies & |e^{-x} - 0| < \epsilon \\ \implies & |f(x) - L| < \epsilon \end{aligned}$$

Thus, we have proved the limit

$$\lim_{x\to\infty} e^{-x} = 0.$$

**SCRATCH WORK**

We want to arrive at

$$|e^{-x} - 0| < \epsilon \quad \text{(consequent)}$$

given that

$$x > M. \quad \text{(antecedent)}$$

(Since $x \to \infty$, $x > M$.)
Working backward from the consequent and trying to arrive at the antecedent, we get

$$\begin{aligned} |e^{-x} - 0| < \epsilon \implies & e^{-x} < \epsilon \\ \implies & -x < \ln(\epsilon) \\ \implies & x > -\ln(\epsilon) \\ \implies & \text{Let } M = -\ln(\epsilon) \end{aligned}$$

Again, adding to our list of tripping points:

6. $|e^{-x}| = e^{-x}$ because $e^{-x} > 0$.
7. In the proof of Theorem **2.6.1**, we found $M = -\ln(\epsilon)$; however, we also stated that $M > 0$. How can this be?
   Don't be fooled into thinking an "opposite sign" $(-)$ means that you're dealing with a negative number. In reality, $\epsilon$ is a *very* small positive number. Therefore, $\ln(\epsilon)$ is negative. Hence, $M = -\ln(\epsilon)$ is positive.

The previous theorem begets a simple corollary.

**Corollary**

If $k > 0$,

$$\lim_{x \to \infty} e^{-kx} = 0$$

**Proof**

$$\begin{aligned} \lim_{x \to \infty} e^{-kx} &= \lim_{x \to \infty} \left(e^{-x}\right)^k \\ &= \left(\lim_{x \to \infty} e^{-x}\right)^k \qquad \text{(Power Law of Limits)} \\ &= (0)^k \\ &= 0 \end{aligned}$$

The following theorem will be used throughout Calculus.

**Theorem**

If $p > 0$ is a rational number, then

$$\lim_{x \to \infty} \frac{1}{x^p} = 0.$$

If $p > 0$ is a rational number such that $x^p$ is defined for all $x$, then

$$\lim_{x \to -\infty} \frac{1}{x^p} = 0.$$

**Proof**

**PROOF (for $\lim_{x\to\infty}\frac{1}{x^p}=0$)**

For $\epsilon>0$, let $M=\frac{1}{\epsilon^{1/p}}$. If $x>M$, then

$$\begin{aligned} x &> \frac{1}{\epsilon^{1/p}} \\ \Longrightarrow \quad x^p &> \frac{1}{\epsilon} \\ \Longrightarrow \quad \frac{1}{x^p} &< \epsilon \\ \Longrightarrow \quad \left|\frac{1}{x^p}-0\right| &< \epsilon \\ \Longrightarrow \quad |f(x)-L| &< \epsilon \end{aligned}$$

Thus, we have proved the limit

$$\lim_{x\to\infty}\frac{1}{x^p}=0.$$

**SCRATCH WORK (for $\lim_{x\to\infty}\frac{1}{x^p}=0$)**

We want to arrive at

$$\left|\frac{1}{x^p}-0\right|<\epsilon \quad \text{(consequent)}$$

given that

$$x>M. \quad \text{(antecedent)}$$

Working backward from the consequent, and trying to arrive at the antecedent, we get

$$\begin{aligned} \left|\frac{1}{x^p}-0\right|<\epsilon \quad &\Longrightarrow \quad \frac{1}{x^p}<\epsilon \\ &\Longrightarrow \quad x^p>\frac{1}{\epsilon} \\ &\Longrightarrow \quad x>\frac{1}{\epsilon^{1/p}} \\ &\Longrightarrow \quad \text{Let } M=\frac{1}{\epsilon^{1/p}} \end{aligned}$$

The proof of the second half of this theorem is left as a homework exercise.

As before, the proof of this theorem adds to our list of tripping points.

8. If $x>0$, then $\left|\frac{1}{x^p}-0\right|=\frac{1}{x^p}$.

## Horizontal Asymptotes

We have already introduced the definition of a horizontal asymptote; however, we repeat it here due to the connection with the finite limit at infinity.

**Definition: Horizontal Asymptote**

The vertical line $y=L$ is called a **horizontal asymptote** of the function $f(x)$ if at least one of the following is true:

$$\lim_{x\to\infty}f(x)=L \qquad \text{or} \qquad \lim_{x\to-\infty}f(x)=L$$

## Infinite Limits at Infinity

Up to this point, we have allowed ourselves the luxury of *assuming*

$$\lim_{x\to\infty}3^x=\infty; \tag{2.6.4}$$

however, it is at this moment that we need to *prove* this assumption is true. Limits of the form 2.6.4 are called **infinite limits at infinity** because the function tends to infinity (or negative infinity) and $x$ tends to infinity (or negative infinity).

As with all our work in this section, developing the precise definition of an infinite limit at infinity requires adjusting the traditional $\epsilon-\delta$ definition of a limit.

Since both $x$ and the function are approaching infinity in 2.6.4, it is impossible for us to say, "For any given $\epsilon>0$, there exists a $\delta>0$," because there is no way for us to contain infinity in a small interval (whether an $\epsilon$- or $\delta$-neighborhood).

So, how do we adjust the definition? Consider the following figure.

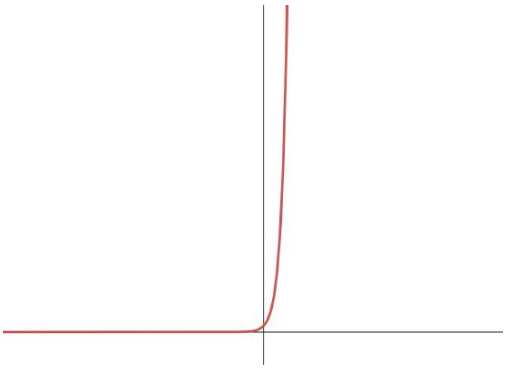

*Figure* **2.6.6**: $f(x) = 3^x$

Instead of someone challenging us by throwing down an $\epsilon$-gauntlet, they are going to challenge us to get our function values *above* a colossal number (see Figure **2.6.7**.

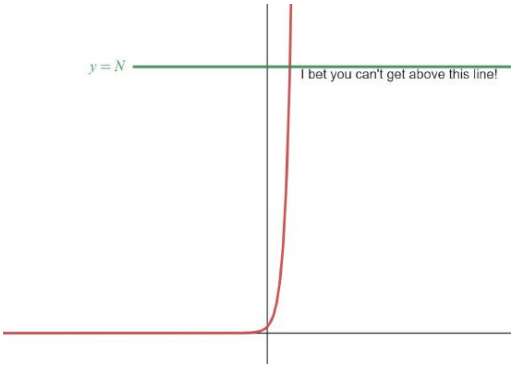

*Figure* **2.6.7**

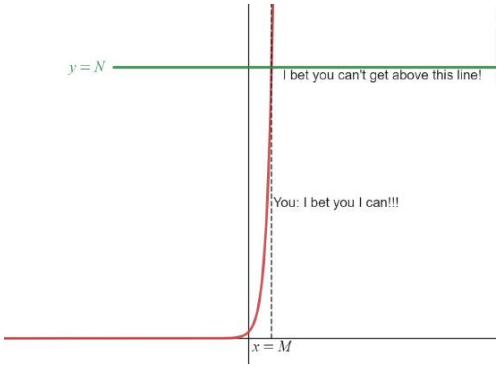
That is, someone is going to hand us $N \ggg 0$. Our job is to somehow find $x$-values whose function values are *above* the line $y = N$. Figure **2.6.8***a* shows graphically how this is done.



*Figures* **2.6.8***a*

Figure **2.6.8***b* shows a zoomed-in view of Figure **2.6.8***a*. As long as $x > M$, it looks as though $3^x > N$.

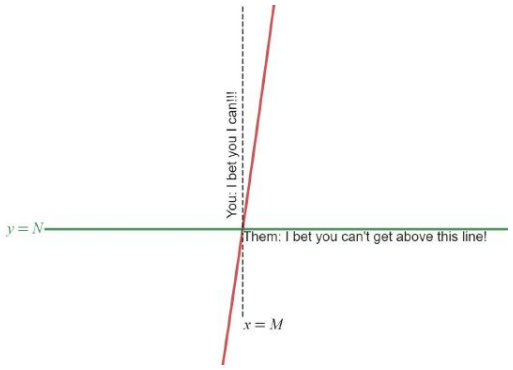


*Figure* **2.6.8***b*

Using this same idea, let's write our final set of precise definitions for limits.

**Definition: Infinite Limit at Infinity (Precise Definition)**

**As $x \to \infty$...**

Let $f(x)$ be defined for all $x > a$. Then we say

$$\lim_{x\to\infty} f(x) = \infty$$

if for every $N \ggg 0$, there exists a number $M > 0$, such that if $x > M$, then $f(x) > N$.
Stated with symbolic logic,

$$\lim_{x\to\infty} f(x) = \infty$$

means

$$\forall N \ggg 0, \quad \exists M > 0 \ni$$

$$x > M \implies f(x) > N.$$

Additionally, we say

$$\lim_{x\to\infty} f(x) = -\infty$$

if for every $N \lll 0$, there exists a number $M > 0$, such that if $x > M$, then $f(x) < N$.
Stated with symbolic logic,

$$\lim_{x\to\infty} f(x) = -\infty$$

means

$$\forall N \lll 0, \quad \exists M > 0 \ni$$

$$x > M \implies f(x) < N.$$

**As $x \to -\infty$...**

Let $f(x)$ be defined for all $x < a$. Then we say

$$\lim_{x\to-\infty} f(x) = \infty$$

if for every $N \ggg 0$, there exists a number $M < 0$, such that if $x < M$, then $f(x) > N$.
Stated with symbolic logic,

$$\lim_{x\to-\infty} f(x) = \infty$$

means

$$\forall N \ggg 0, \quad \exists M < 0 \ni$$

$$x < M \implies f(x) > N.$$

Additionally, we say

$$\lim_{x\to-\infty} f(x) = -\infty$$

if for every $N \lll 0$, there exists a number $M < 0$, such that if $x < M$, then $f(x) < N$.
Stated with symbolic logic,

$$\lim_{x\to-\infty} f(x) = -\infty$$

means

$$\forall N \lll 0, \quad \exists M < 0 \ni$$

$$x < M \implies f(x) < N.$$

**Example 2.6.3**

Prove

$$\lim_{x\to-\infty} x^3 = -\infty.$$

**Solution**

**PROOF**

For $N \ll 0$, let $M = \sqrt[3]{N}$. If $x < M$, then

$$\begin{aligned} & x < \sqrt[3]{N} \\ \implies & x^3 < N \\ \implies & f(x) < N \end{aligned}$$

Thus, we have proved the limit

$$\lim_{x \to -\infty} x^3 = -\infty.$$

**SCRATCH WORK**

We want to arrive at

$$x^3 < N \quad \text{(consequent)}$$

given that

$$x < M. \quad \text{(antecedent)}$$

Working backward from the consequent, and trying to arrive at the antecedent, we get

$$\begin{aligned} x^3 < N & \implies x < \sqrt[3]{N} \\ & \implies \text{Let } \delta = \sqrt[3]{N} \end{aligned}$$

**Checkpoint 2.6.3**

Use the formal definition of infinite limit at infinity to prove that $\lim_{x \to \infty} 3x^2 = \infty$.

**Answer**

Let $M > 0$. Let $N = \sqrt{\frac{M}{3}}$. Then, for all $x > N$, we have

$$3x^2 > 3N^2 = 3\left(\sqrt{\frac{M}{3}}\right)^2 = \frac{3M}{3} = M.$$

## Unifying the Precise Definitions of Limits

The following table *might* help you understand when to use $\epsilon$, $\delta$, $N$, or $M$ in your proofs.

| | Finite Limit at a Finite Number | Finite Limit at Infinity | Infinite Limit at a Finite Number | Infinite Limit at Infinity |
|---|---|---|---|---|
| **Limit** | $\lim_{x \to a} f(x) = L$ | $\lim_{x \to \pm\infty} f(x) = L$ | $\lim_{x \to a} f(x) = \pm\infty$ | $\lim_{x \to \pm\infty} f(x) = \pm\infty$ |
| **Universal Quantifier** | $\forall \epsilon > 0$ | $\forall \epsilon > 0$ | $f(x) \to +\infty \implies \forall N \gg 0$<br>$f(x) \to -\infty \implies \forall N \ll 0$ | $f(x) \to +\infty \implies \forall N \gg 0$<br>$f(x) \to -\infty \implies \forall N \ll 0$ |
| **Existential Quantifier** | $\exists \delta > 0$ | $x \to +\infty \implies \exists M > 0$<br>$x \to -\infty \implies \exists M < 0$ | $\exists \delta > 0$ | $x \to +\infty \implies \exists M > 0$<br>$x \to -\infty \implies \exists M < 0$ |

I did not include the conditional statements in this list because each statement depends heavily on the type of limit in consideration. They each have the *basic* form

$$\text{[Universal Quantifier Statement], [Existential Quantifier Statement]} \ni$$

$$\text{[inequality involving } x \text{ and either } \delta \text{ or } M\text{]} \implies \text{[inequality involving } y \text{ and either } \epsilon \text{ or } N\text{]}$$

# 2.6E: Exercises

## Reading Questions

1. What is the key difference in the precise definition of an infinite limit at a finite point (e.g., $\lim_{x\to a} f(x) = \infty$) compared to a finite limit at a finite point, in terms of the "challenge" value ($N$ vs. $\epsilon$) and the condition on $f(x)$?
2. In the precise definition $\lim_{x\to a} f(x) = \infty$, what does $N \gg 0$ signify?
3. How is the definition of a vertical asymptote related to infinite limits at finite numbers?
4. When defining a finite limit at infinity (e.g., $\lim_{x\to\infty} f(x) = L$), what replaces the $\delta$-neighborhood around $a$? What is the condition on $x$?
5. State the precise definition for $\lim_{x\to\infty} f(x) = L$.
6. State the precise definition for $\lim_{x\to-\infty} f(x) = L$.
7. How is the definition of a horizontal asymptote related to finite limits at infinity?
8. In the precise definition of an infinite limit at infinity (e.g., $\lim_{x\to\infty} f(x) = \infty$), what two quantities are we relating using $N$ and $M$?
9. State the precise definition for $\lim_{x\to\infty} f(x) = \infty$.
10. State the precise definition for $\lim_{x\to-\infty} f(x) = -\infty$.
11. What does the theorem regarding $\lim_{x\to\infty} \frac{1}{x^p}$ state for $p > 0$?
12. When proving $\lim_{x\to-2^+} \ln(x+2) = -\infty$, why is a one-sided limit considered?

## Homework

**In exercises 1 - 10, use the precise definitions to prove the given limits.**

1) $\lim_{x\to 0} \frac{1}{x^2} = \infty$

2) $\lim_{x\to -1} \frac{3}{(x+1)^2} = \infty$

**Answer**

Let $\delta = \sqrt{\frac{3}{N}}$. If $0 < |x+1| < \sqrt{\frac{3}{N}}$, then $f(x) = \frac{3}{(x+1)^2} > N$.

3) $\lim_{x\to 2} -\frac{1}{(x-2)^2} = -\infty$

4) $\lim_{x\to \pi^+} \ln(x-\pi) = -\infty$

5) $\lim_{x\to\infty} \frac{2}{x^6} = 0$

6) $\lim_{x\to-\infty} -\frac{5}{x^3} = 0$

7) $\lim_{x\to\infty} ax^6 = \infty$, where $a > 0$

8) $\lim_{x\to-\infty} (-10 + 2x^5) = -\infty$

9) $\lim_{x\to-\infty} e^{-x} = \infty$

10) $\lim_{x\to-\infty} e^x = 0$

# 2.7: Continuity

**Note to the Instructor (click to expand)**

Before we get to derivatives, we have one last limit-related concept - continuity. For students at this level, the most important result in this section is that, as long as we have a function that is continuous at $x = a$, we can simply substitute $a$ when evaluating the limit of the function as $x$ is approaching $a$. Don't skip over the Intermediate Value Theorem - it appears throughout the rest of the course!

---

To succeed in this section, you'll need to use some skills from previous courses. While you should already know them, this is the first time they've been required. You can review these skills in CRC's Corequisite Codex. If you have a support class, it might cover some, **but not all**, of these topics.

**Prerequisite Skills and Support Topics (click to expand)**

- **An Overview of Functions**
  - Function Composition and Domain: The Composite Function Theorem for limits (and thus continuity) is introduced.
- **Trigonometry**
  - Trigonometric Identities - Sum and Difference of Angles Identities: Used in the proof of the continuity of $\cos x$.

---

The following is a list of learning objectives for this section.

**Learning Objectives (click to expand)**

- Explain the three conditions for continuity at a point.
- Describe three kinds of discontinuities.
- Define continuity on an interval.
- Evaluate limits using the Generalized Direct Substitution Property.
- State the theorem for limits of composite functions.
- Understand and investigate uses of the Intermediate Value Theorem.

We begin our investigation of continuity by exploring what it means for a function to have *continuity at a point*. Intuitively, a function is continuous at a particular point if there is no break in its graph at that point; however, as often is the case, intuition has its flaws.

## Continuity at a Point

Before we formally define what it means to be continuous at a point, let's consider various functions that fail to meet our intuitive notion of what it means to be continuous at a point. We then create a list of conditions that prevent such failures.

Our first function of interest is shown in Figure **2.7.1**. We see that the graph of $f(x)$ has a hole at $a$. In fact, $f(a)$ is undefined. At the very least, for $f(x)$ to be continuous at $a$, we need the following condition:

i. $f(a)$ is defined

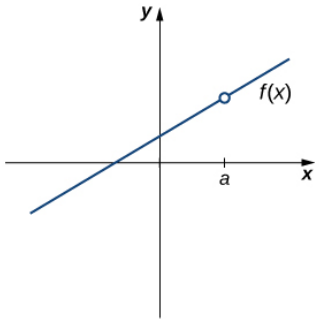

*Figure* **2.7.1***: The function* $f(x)$ *is not continuous at* $a$ *because* $f(a)$ *is undefined.*

However, as we see in Figure **2.7.2**, this condition alone is insufficient to guarantee continuity at the point $a$. Although $f(a)$ is defined, the function has a gap at $a$. In this example, the gap exists because $\lim_{x \to a} f(x)$ does not exist. We must add another condition for continuity at $a$ - namely,

ii. $\lim_{x \to a} f(x)$ exists

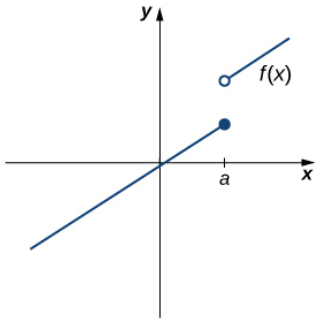

*Figure* **2.7.2***: The function* $f(x)$ *is not continuous at* $a$ *because* $\lim_{x \to a} f(x)$ *does not exist.*

However, as we see in Figure **2.7.3**, these two conditions by themselves do not guarantee continuity at a point. The function in this figure satisfies both of our first two conditions but is still not continuous at $a$. We must add a third condition to our list:

iii. $\lim_{x \to a} f(x) = f(a)$

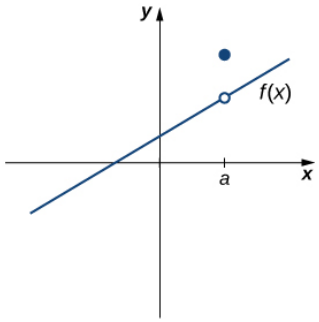

*Figure* **2.7.3***: The function* $f(x)$ *is not continuous at* $a$ *because* $\lim_{x \to a} f(x) \neq f(a)$.

Now, we put our list of conditions together and form a definition of continuity at a point.

**Definition: Continuous at a Point**

A function $f(x)$ is said to be **continuous at a point** $a$ if each of the following three conditions is satisfied:

i. $f(a)$ is defined
ii. $\lim_{x \to a} f(x)$ exists
iii. $\lim_{x \to a} f(x) = f(a)$

A function is **discontinuous at a point** $a$ if it fails to be continuous at $a$.

The next three examples demonstrate how to apply this definition to determine whether a function is continuous at a given point. These examples illustrate situations in which each of the conditions for continuity in the definition succeeds or fails.

### Example 2.7.1A: Determining Continuity at a Point, Condition 1

Using the definition, determine whether the function $f(x) = \frac{x^2-4}{x-2}$ is continuous at $x = 2$. Justify the conclusion.

**Solution**

Let's begin by trying to calculate $f(2)$. We can see that $f(2) = \frac{4-4}{2-2}$, which is undefined. Therefore, $f(x) = \frac{x^2-4}{x-2}$ is discontinuous at $2$ because $f(2)$ is undefined. The graph of $f(x)$ is shown in Figure 2.7.4.

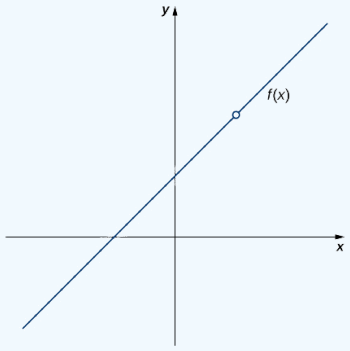

*Figure 2.7.4: The function $f(x)$ is discontinuous at $2$ because $f(2)$ is undefined.*

### Example 2.7.1B: Determining Continuity at a Point, Condition 2

Using the definition, determine whether the function

$$f(x) = \begin{cases} -x^2 + 4, & \text{if } x \leq 3 \\ 4x - 8, & \text{if } x > 3 \end{cases}$$

is continuous at $x = 3$. Justify the conclusion.

**Solution**

Let's begin by trying to calculate $f(3)$.

$$f(3) = -(3^2) + 4 = -5.$$

Thus, $f(3)$ is defined. Next, we calculate $\lim_{x\to 3} f(x)$. To do this, we must compute $\lim_{x\to 3^-} f(x)$ and $\lim_{x\to 3^+} f(x)$:

$$\lim_{x\to 3^-} f(x) = -(3^2) + 4 = -5$$

and

$$\lim_{x\to 3^+} f(x) = 4(3) - 8 = 4.$$

Therefore, $\lim_{x\to 3} f(x)$ does not exist. Thus, $f(x)$ is not continuous at 3. The graph of $f(x)$ is shown in Figure 2.7.5.

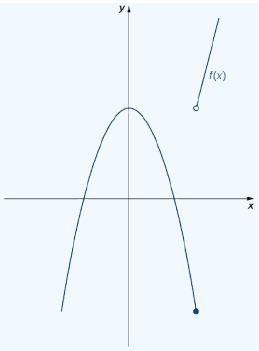

*Figure 2.7.5: The function $f(x)$ is not continuous at 3 because $\lim_{x\to 3} f(x)$ does not exist.*

### Example 2.7.1C: Determining Continuity at a Point, Condition 3

Using the definition, determine whether the function

$$f(x) = \begin{cases} \frac{\sin x}{x}, & \text{if } x \neq 0 \\ 1, & \text{if } x = 0 \end{cases}$$

is continuous at $x = 0$.

**Solution**

First, observe that

$$f(0) = 1.$$

Next,

$$\lim_{x\to 0} f(x) = \lim_{x\to 0} \frac{\sin x}{x} = 1.$$

Last, compare $f(0)$ and $\lim_{x\to 0} f(x)$. We see that

$$f(0) = 1 = \lim_{x\to 0} f(x).$$

Since all three of the conditions in the definition of continuity are satisfied, $f(x)$ is continuous at $x = 0$.

### Checkpoint 2.7.1

Using the definition, determine whether the function

$$f(x) = \begin{cases} 2x + 1, & \text{if } x < 1 \\ 2, & \text{if } x = 1 \\ -x + 4, & \text{if } x > 1 \end{cases}$$

is continuous at $x = 1$. If the function is not continuous at 1, indicate the condition for continuity at a point that fails to hold.

**Answer**

$f$ is not continuous at 1 because $f(1) = 2 \neq 3 = \lim_{x\to 1} f(x)$.

By applying the definition of continuity and previously established theorems concerning the evaluation of limits, we can state the following theorem.

### Theorem: Continuity of Polynomials and Rational Functions

Polynomials and rational functions are continuous at every point in their domains.

**Proof**

Previously, we showed that if $p(x)$ and $q(x)$ are polynomials, $\lim_{x\to a} p(x) = p(a)$ for every polynomial $p(x)$ and $\lim_{x\to a} \frac{p(x)}{q(x)} = \frac{p(a)}{q(a)}$ as long as $q(a) \neq 0$. Therefore, polynomials and rational functions are continuous on their domains.

*Q.E.D.*

We now apply this theorem to determine the points at which a given rational function is continuous.

### Example 2.7.2: Continuity of a Rational Function

For what values of $x$ is $f(x) = \frac{x+1}{x-5}$ continuous?

**Solution**

The rational function $f(x) = \frac{x+1}{x-5}$ is continuous for every value of $x$ except $x = 5$.

### Checkpoint 2.7.2

For what values of $x$ is $f(x) = 3x^4 - 4x^2$ continuous?

**Answer**

$f(x)$ is continuous at every real number.

## Types of Discontinuities

As we have seen in Example 2.7.1*A* and Example 2.7.1*B*, discontinuities take on several different appearances. We classify the types of discontinuities we have seen thus far as removable, infinite, or jump discontinuities. Intuitively, a **removable discontinuity** is a discontinuity in which the graph has a hole. A **jump discontinuity** is a noninfinite discontinuity for which the sections of the function do not meet up. Finally, an **infinite discontinuity** is a discontinuity located at a vertical asymptote. Figure 2.7.6 illustrates the differences in these types of discontinuities. Although these terms provide a handy way of describing three common types of discontinuities, remember that not all discontinuities fit neatly into these categories.

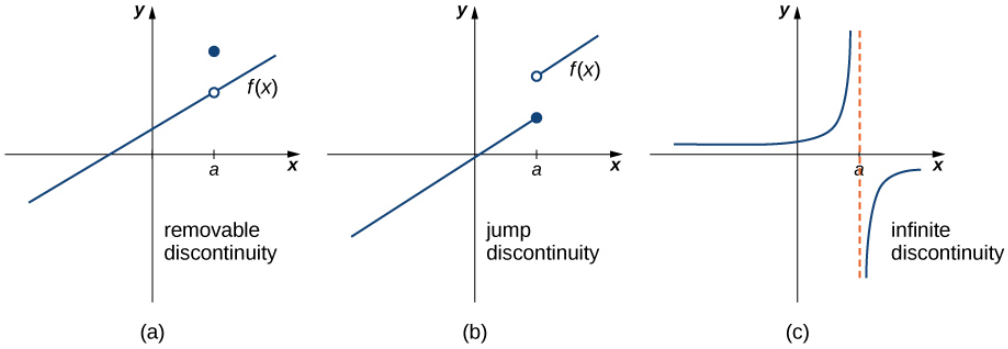

*Figure 2.7.6: Discontinuities are classified as (a) removable, (b) jump, or (c) infinite.*

These three discontinuities are formally defined as follows:

### Definition: Types of Discontinuities

If $f(x)$ is discontinuous at $a$, then

i. $f$ has a **removable discontinuity** at $a$ if $\lim_{x\to a} f(x)$ exists. (Note: When we state that $\lim_{x\to a} f(x)$ exists, we mean that $\lim_{x\to a} f(x) = L$, where $L$ is a real number.)

ii. $f$ has a **jump discontinuity** at $a$ if $\lim_{x\to a^-} f(x)$ and $\lim_{x\to a^+} f(x)$ both exist, but $\lim_{x\to a^-} f(x) \neq \lim_{x\to a^+} f(x)$. (Note: When we state that $\lim_{x\to a^-} f(x)$ and $\lim_{x\to a^+} f(x)$ both exist, we mean that both are real-valued and that neither takes on the values $\pm\infty$.)

iii. $f$ has an **infinite discontinuity** at $a$ if $\lim_{x\to a^-} f(x) = \pm\infty$ or $\lim_{x\to a^+} f(x) = \pm\infty$.

### Example 2.7.3: Classifying a Discontinuity

In Example 2.7.1A, we showed that $f(x) = \frac{x^2-4}{x-2}$ is discontinuous at $x = 2$. Classify this discontinuity as removable, jump, or infinite.

**Solution**

To classify the discontinuity at 2 we must evaluate $\lim_{x\to 2} f(x)$:

$$\begin{aligned}\lim_{x\to 2} f(x) &= \lim_{x\to 2} \frac{x^2-4}{x-2} \\ &= \lim_{x\to 2} \frac{(x-2)(x+2)}{x-2} \\ &= \lim_{x\to 2} (x+2) \\ &= 4\end{aligned}$$

Since $f$ is discontinuous at 2 and $\lim_{x\to 2} f(x)$ exists, $f$ has a removable discontinuity at $x = 2$.

### Example 2.7.4: Classifying a Discontinuity

In Example 2.7.1B, we showed that

$$f(x) = \begin{cases} -x^2+4, & \text{if } x \le 3 \\ 4x-8, & \text{if } x > 3 \end{cases}$$

is discontinuous at $x = 3$. Classify this discontinuity as removable, jump, or infinite.

**Solution**

Earlier, we showed that $f$ is discontinuous at 3 because $\lim_{x\to 3} f(x)$ does not exist. However, since $\lim_{x\to 3^-} f(x) = -5$ and $\lim_{x\to 3^+} f(x) = 4$ both exist, we conclude that the function has a jump discontinuity at 3.

### Example 2.7.5: Classifying a Discontinuity

Determine whether $f(x) = \frac{x+2}{x+1}$ is continuous at $-1$. If the function is discontinuous at $-1$, classify the discontinuity as removable, jump, or infinite.

**Solution**

The function value $f(-1)$ is undefined. Therefore, the function is not continuous at $-1$. To determine the type of discontinuity, we must determine the limit at $-1$. We see that $\lim_{x\to -1^-} \frac{x+2}{x+1} = -\infty$ and $\lim_{x\to -1^+} \frac{x+2}{x+1} = +\infty$. Therefore, the function has an infinite discontinuity at $-1$.

### Checkpoint 2.7.5

For

$$f(x) = \begin{cases} x^2, & \text{if } x \ne 1 \\ 3, & \text{if } x = 1 \end{cases}$$

decide whether $f$ is continuous at 1. If $f$ is not continuous at 1, classify the discontinuity as removable, jump, or infinite.

**Answer**

Discontinuous at 1; removable

## Continuity over an Interval

Now that we have explored the concept of continuity at a point, we extend that idea to **continuity over an interval**. As we develop this idea for different types of intervals, it may be useful to keep in mind the intuitive (but flawed) idea that a function is continuous over an

interval if we can use a pencil to trace the function between any two points in the interval without lifting the pencil from the paper. In preparation for defining continuity on an interval, we begin by defining what it means for a function to be continuous from the right at a point and continuous from the left at a point.

**Definition: Continuity from the Right and from the Left**

A function $f(x)$ is said to be **continuous from the right** at $a$ if $\lim_{x\to a^+} f(x) = f(a)$.

A function $f(x)$ is said to be **continuous from the left** at $a$ if $\lim_{x\to a^-} f(x) = f(a)$.

**Definition: Continuity over Intervals**

A function is **continuous over an open interval** if it is continuous at every point in the interval. A function $f(x)$ is **continuous over a closed interval** of the form $[a, b]$ if it is continuous at every point in $(a, b)$ and is continuous from the right at $a$ and is continuous from the left at $b$. Analogously, a function $f(x)$ is continuous over an interval of the form $(a, b]$ if it is continuous over $(a, b)$ and is continuous from the left at $b$. Continuity over other types of intervals is defined similarly.

Requiring that $\lim_{x\to a^+} f(x) = f(a)$ and $\lim_{x\to b^-} f(x) = f(b)$ ensures that we can trace the graph of the function from the point $(a, f(a))$ to the point $(b, f(b))$ without lifting the pencil. If, for example, $\lim_{x\to a^+} f(x) \neq f(a)$, we would need to lift our pencil to jump from $f(a)$ to the graph of the rest of the function over $(a, b]$.

**Example 2.7.6: Continuity on an Interval**

State the interval(s) over which the function $f(x) = \frac{x-1}{x^2+2x}$ is continuous.

**Solution**

Since $f(x) = \frac{x-1}{x^2+2x}$ is a rational function, it is continuous at every point in its domain. The domain of $f(x)$ is the set $(-\infty, -2) \cup (-2, 0) \cup (0, +\infty)$. Thus, $f(x)$ is continuous over each of the intervals $(-\infty, -2), (-2, 0)$, and $(0, +\infty)$.

**Example 2.7.7: Continuity over an Interval**

State the interval(s) over which the function $f(x) = \sqrt{4 - x^2}$ is continuous.

**Solution**

From the Limit Laws, we know that $\lim_{x\to a} \sqrt{4 - x^2} = \sqrt{4 - a^2}$ for all values of $a$ in $(-2, 2)$. We also know that $\lim_{x\to -2^+} \sqrt{4 - x^2} = 0$ exists and $\lim_{x\to 2^-} \sqrt{4 - x^2} = 0$ exists. Therefore, $f(x)$ is continuous over the interval $[-2, 2]$.

**Checkpoint 2.7.7**

State the interval(s) over which the function $f(x) = \sqrt{x + 3}$ is continuous.

**Answer**

$[-3, +\infty)$

## Continuity and Compositions

**Theorem: Composite Function Theorem**

If $f(x)$ is continuous at $L$ and $\lim_{x\to a} g(x) = L$, then

$$\lim_{x\to a} f\big(g(x)\big) = f\Big(\lim_{x\to a} g(x)\Big) = f(L).$$

The Composite Function Theorem allows us to expand our ability to compute limits. In particular, this theorem ultimately allows us to demonstrate that trigonometric functions are continuous over their domains.

Before we move on to Example 2.7.8, recall that earlier, in the section on Limit Laws, we showed $\lim_{x\to 0}\cos x = 1 = \cos(0)$. Consequently, we know that $f(x) = \cos x$ is continuous at $0$. In Example 2.7.8, we see how to combine this result with the Composite Function Theorem.

### Example 2.7.8: Limit of a Composite Cosine Function

Evaluate $\lim_{x\to\pi/2}\cos\left(x-\frac{\pi}{2}\right)$.

**Solution**

The given function is a composite of $\cos x$ and $x-\frac{\pi}{2}$. Since $\lim_{x\to\pi/2}\left(x-\frac{\pi}{2}\right)=0$ and $\cos x$ is continuous at $0$, we may apply the Composite Function Theorem. Thus,

$$\lim_{x\to\pi/2}\cos\left(x-\frac{\pi}{2}\right)=\cos\left(\lim_{x\to\pi/2}\left(x-\frac{\pi}{2}\right)\right)=\cos(0)=1.$$

### Checkpoint 2.7.8

Evaluate $\lim_{x\to\pi}\sin(x-\pi)$.

**Answer**

$0$

The proof of the next theorem uses the Composite Function Theorem as well as the continuity of $f(x)=\sin x$ and $g(x)=\cos x$ at the point $0$ to show that trigonometric functions are continuous over their entire domains.

### Theorem: Continuity of Trigonometric Functions

Trigonometric functions are continuous over their entire domains.

**Proof**

We begin by demonstrating that $\cos x$ is continuous at every real number. To do this, we must show that $\lim_{x\to a}\cos x=\cos a$ for all values of $a$.

$$\begin{aligned}
\lim_{x\to a}\cos x &= \lim_{x\to a}\cos((x-a)+a) && \text{(rewrite } x=x-a+a\text{)}\\
&= \lim_{x\to a}(\cos(x-a)\cos a-\sin(x-a)\sin a) && \text{(Sum and Difference of Angles Identities)}\\
&= \cos(\lim_{x\to a}(x-a))\cos a-\sin(\lim_{x\to a}(x-a))\sin a && \text{(since } \lim_{x\to a}(x-a)=0,\ \sin x \text{ and } \cos x \text{ are continuous at } 0\text{)}\\
&= \cos(0)\cos a-\sin(0)\sin a\\
&= 1\cdot\cos a-0\cdot\sin a\\
&= \cos a
\end{aligned}$$

The proof that $\sin x$ is continuous at every real number is analogous. Because the remaining trigonometric functions may be expressed in terms of $\sin x$ and $\cos x$, their continuity follows from the quotient limit law.

*Q.E.D.*

As you can see, the Composite Function Theorem is invaluable in demonstrating the continuity of trigonometric functions. As we continue our study of calculus, we revisit this theorem many times.

## The Intermediate Value Theorem

Functions that are continuous over intervals of the form $[a,b]$, where $a$ and $b$ are real numbers, exhibit many useful properties. Throughout our study of calculus, we will encounter many powerful theorems concerning such functions. The first of these theorems is the **Intermediate Value Theorem.**

**Theorem: Intermediate Value Theorem (IVT)**

Let $f$ be continuous over a closed, bounded interval $[a, b]$. If $z$ is any real number between $f(a)$ and $f(b)$, then there is a number $c$ in $[a, b]$ satisfying $f(c) = z$.

See Figure 2.7.7 for a visualization of the IVT.

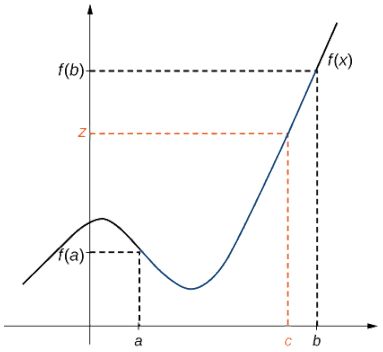

*Figure 2.7.7: There is a number $c \in [a, b]$ that satisfies $f(c) = z$.*

**Example 2.7.9: Application of the Intermediate Value Theorem**

Show that $f(x) = x - \cos x$ has at least one zero.

**Solution**

Since $f(x) = x - \cos x$ is continuous over $(-\infty, +\infty)$, it is continuous over any closed interval of the form $[a, b]$. If you can find an interval $[a, b]$ such that $f(a)$ and $f(b)$ have opposite signs, you can use the Intermediate Value Theorem to conclude there must be a real number $c$ in $(a, b)$ that satisfies $f(c) = 0$. Note that

$$f(0) = 0 - \cos(0) = -1 < 0$$

and

$$f\left(\frac{\pi}{2}\right) = \frac{\pi}{2} - \cos\frac{\pi}{2} = \frac{\pi}{2} > 0.$$

Using the Intermediate Value Theorem, we can see that there must be a real number $c$ in $[0, \pi/2]$ that satisfies $f(c) = 0$. Therefore, $f(x) = x - \cos x$ has at least one zero.

**Example 2.7.10: When Can You Apply the Intermediate Value Theorem?**

If $f(x)$ is continuous over $[0, 2], f(0) > 0$ and $f(2) > 0$, can we use the Intermediate Value Theorem to conclude that $f(x)$ has no zeros in the interval $[0, 2]$? Explain.

**Solution**

No. The Intermediate Value Theorem only allows us to conclude that we can find a value between $f(0)$ and $f(2)$; it doesn't allow us to conclude that we can't find other values. To see this more clearly, consider the function $f(x) = (x-1)^2$. It satisfies $f(0) = 1 > 0, f(2) = 1 > 0$, and $f(1) = 0$.

**Example 2.7.11: When Can You Apply the Intermediate Value Theorem?**

For $f(x) = 1/x, f(-1) = -1 < 0$ and $f(1) = 1 > 0$. Can we conclude that $f(x)$ has a zero in the interval $[-1, 1]$?

**Solution**

No. The function is not continuous over $[-1, 1]$. The Intermediate Value Theorem does not apply here.

**Checkpoint 2.7.11**

Show that $f(x) = x^3 - x^2 - 3x + 1$ has a zero over the interval $[0, 1]$.

**Answer**

$f(0) = 1 > 0,\ f(1) = -2 < 0;\ f(x)$ is continuous over $[0, 1]$. It must have a zero on this interval.

# 2.7E: EXERCISES

## READING QUESTIONS

1. What are the three conditions that must be satisfied for a function $f(x)$ to be continuous at a point $a$?
2. If $\lim_{x \to a} f(x)$ exists but is not equal to $f(a)$ (assuming $f(a)$ is defined), what type of discontinuity does $f$ have at $a$?
3. Describe a jump discontinuity in terms of one-sided limits.
4. What characterizes an infinite discontinuity at $x = a$ in terms of limits?
5. What does it mean for a function to be continuous from the left at a point $a$?
6. How is continuity over a closed interval $[a, b]$ defined, including the conditions at the endpoints $a$ and $b$?
7. At what points are polynomial functions continuous?
8. At what points are rational functions continuous? What condition must be met for their denominators?
9. State the Composite Function Theorem as it applies to limits.
10. Are trigonometric functions like $\sin x$ and $\cos x$ continuous over their entire domains?
11. What are the conditions required to apply the Intermediate Value Theorem to a function $f$ on an interval $[a, b]$?
12. If the conditions for the Intermediate Value Theorem are met, and $z$ is a number between $f(a)$ and $f(b)$, what does the theorem guarantee?
13. If a function $f$ is continuous on $[a, b]$ and $f(a)$ and $f(b)$ have opposite signs, what specific conclusion can be drawn from the IVT?

## HOMEWORK

**For exercises 1 - 8, determine the point(s), if any, at which each function is discontinuous. Classify any discontinuity as *jump*, *removable*, *infinite*, or *other*.**

1) $f(x) = \dfrac{1}{\sqrt{x}}$

**Answer**

The function is defined for all $x$ in the interval $(0, \infty)$.

2) $f(x) = \dfrac{2}{x^2 + 1}$

3) $f(x) = \dfrac{x}{x^2 - x}$

**Answer**

Removable discontinuity at $x = 0$; infinite discontinuity at $x = 1$.

4) $g(t) = t^{-1} + 1$

5) $f(x) = \dfrac{5}{e^x - 2}$

**Answer**

Infinite discontinuity at $x = \ln 2$

6) $f(x) = \dfrac{|x - 2|}{x - 2}$

7) $H(x) = \tan 2x$

**Answer**

Infinite discontinuities at $x = \dfrac{(2k + 1)\pi}{4}$, for $k = 0, \pm 1, \pm 2, \pm 3, \ldots$

8) $f(t) = \dfrac{t + 3}{t^2 + 5t + 6}$

**For exercises 9 - 14, decide if the function continuous at the given point. If it is discontinuous, what type of discontinuity is it?**

9) $\dfrac{2x^2 - 5x + 3}{x - 1}$ at $x = 1$

**Answer**

No. It is a removable discontinuity.

10) $h(\theta)=\dfrac{\sin\theta-\cos\theta}{\tan\theta}$ at $\theta=\pi$

11) $g(u)=\begin{cases}\dfrac{6u^2+u-2}{2u-1}, & \text{if } u\neq\frac{1}{2}\\ \frac{7}{2}, & \text{if } u=\frac{1}{2}\end{cases}$, at $u=\frac{1}{2}$

**Answer**

Yes. It is continuous.

12) $f(y)=\dfrac{\sin(\pi y)}{\tan(\pi y)}$, at $y=1$

13) $f(x)=\begin{cases}x^2-e^x, & \text{if } x<0\\ x-1, & \text{if } x\geq 0\end{cases}$, at $x=0$

**Answer**

Yes. It is continuous.

14) $f(x)=\begin{cases}x\sin(x), & \text{if } x\leq\pi\\ x\tan(x), & \text{if } x>\pi\end{cases}$, at $x=\pi$

**In exercises 15 - 19, find the value(s) of $k$ that makes each function continuous over the given interval.**

15) $f(x)=\begin{cases}3x+2, & \text{if } x<k\\ 2x-3, & \text{if } k\leq x\leq 8\end{cases}$

**Answer**

$k=-5$

16) $f(\theta)=\begin{cases}\sin\theta, & \text{if } 0\leq\theta<\frac{\pi}{2}\\ \cos(\theta+k), & \text{if } \frac{\pi}{2}\leq\theta\leq\pi\end{cases}$

17) $f(x)=\begin{cases}\dfrac{x^2+3x+2}{x+2}, & \text{if } x\neq -2\\ k, & \text{if } x=-2\end{cases}$

**Answer**

$k=-1$

18) $f(x)=\begin{cases}e^{kx}, & \text{if } 0\leq x<4\\ x+3, & \text{if } 4\leq x\leq 8\end{cases}$

19) $f(x)=\begin{cases}\sqrt{kx}, & \text{if } 0\leq x\leq 3\\ x+1, & \text{if } 3<x\leq 10\end{cases}$

**Answer**

$k=\frac{16}{3}$

**In exercises 20 - 21, use the Intermediate Value Theorem (IVT).**

20) Let $h(x)=\begin{cases}3x^2-4, & \text{if } x\leq 2\\ 5+4x, & \text{if } x>2\end{cases}$ Over the interval $[0,4]$, there is no value of $x$ such that $h(x)=10$, although $h(0)<10$ and $h(4)>10$. Explain why this does not contradict the IVT.

21) A particle moving along a line for time $t$ has a position function $s(t)$, which is continuous. Assume $s(2)=5$ and $s(5)=2$. Another particle moves such that its position is given by $h(t)=s(t)-t$. Explain why there must be a value $c$ for $2<c<5$ such that $h(c)=0$.

**Answer**

Since both $s$ and $y=t$ are continuous everywhere, then $h(t)=s(t)-t$ is continuous everywhere and, in particular, it is continuous over the closed interval $[2,5]$. Also, $h(2)=3>0$ and $h(5)=-3<0$. Therefore, by the IVT, there is a value $x=c$ such that $h(c)=0$.

22) Use the statement "The cosine of $t$ is equal to $t$ cubed."

a. Write a mathematical equation of the statement.

b. Prove that the equation in part a. has at least one real solution.

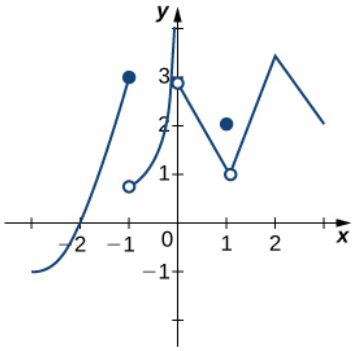
c. Use a calculator to find an interval of length $0.01$ that contains a solution.

23) Apply the IVT to determine whether $2^x=x^3$ has a solution in one of the intervals $[1.25,1.375]$ or $[1.375,1.5]$. Briefly explain your response for each interval.

**Answer**

The function $f(x) = 2^x - x^3$ is continuous over the interval $[1.25, 1.375]$ and has opposite signs at the endpoints.

24) Consider the graph of the function $y = f(x)$ shown in the following graph.



a. Find all values for which the function is discontinuous.

b. For each value in part a., state why the formal definition of continuity does not apply.

c. Classify each discontinuity as either jump, removable, or infinite.

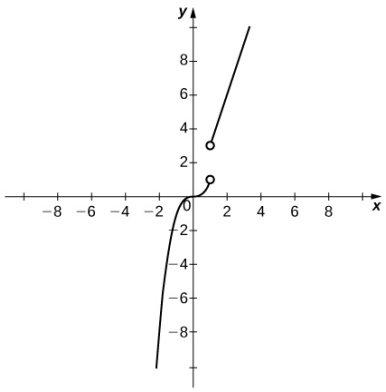
25) Let $f(x) = \begin{cases} 3x, & \text{if } x > 1 \\ x^3, & \text{if } x < 1 \end{cases}$.

a. Sketch the graph of $f$.

b. Is it possible to find a value $k$ such that $f(1) = k$, which makes $f(x)$ continuous for all real numbers? Briefly explain.

**Answer**

a.



b. It is not possible to redefine $f(1)$ since the discontinuity is a jump discontinuity.

26) Let $f(x) = \dfrac{x^4 - 1}{x^2 - 1}$ for $x \neq -1, 1$.

a. Sketch the graph of $f$.

b. Is it possible to find values $k_1$ and $k_2$ such that $f(-1) = k$ and $f(1) = k_2$, and that makes $f(x)$ continuous for all real numbers? Briefly explain.

27) Sketch the graph of the function $y = f(x)$ with properties i. through vii.

i. The domain of $f$ is $(-\infty, +\infty)$.

ii. $f$ has an infinite discontinuity at $x = -6$.

iii. $f(-6) = 3$

iv. $\lim\limits_{x \to -3^-} f(x) = \lim\limits_{x \to -3^+} f(x) = 2$

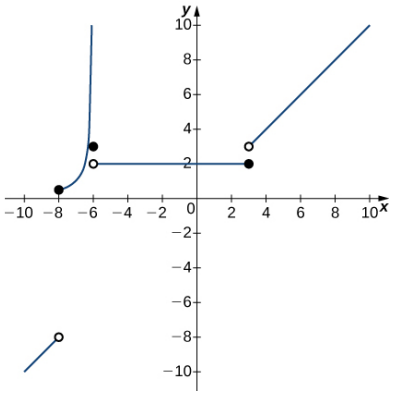
v. $f(-3) = 3$

vi. $f$ is left continuous but not right continuous at $x = 3$.

vii. $\lim_{x\to-\infty} f(x) = -\infty$ and $\lim_{x\to+\infty} f(x) = +\infty$

**Answer**

Answers may vary; see the following example:



28) Sketch the graph of the function $y = f(x)$ with properties i. through iv.

i. The domain of $f$ is $[0, 5]$.

ii. $\lim_{x\to1^+} f(x)$ and $\lim_{x\to1^-} f(x)$ exist and are equal.

iii. $f(x)$ is left continuous but not continuous at $x = 2$, and right continuous but not continuous at $x = 3$.

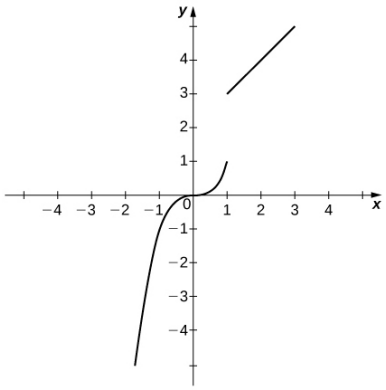
iv. $f(x)$ has a removable discontinuity at $x = 1$, a jump discontinuity at $x = 2$, and the following limits hold: $\lim_{x\to3^-} f(x) = -\infty$ and $\lim_{x\to3^+} f(x) = 2$.

**In exercises 29 - 30, suppose $y = f(x)$ is defined for all $x$. For each description, sketch a graph with the indicated property.**

29) Discontinuous at $x = 1$ with $\lim_{x\to-1} f(x) = -1$ and $\lim_{x\to2} f(x) = 4$

**Answer**

Answers may vary; see the following example:



30) Discontinuous at $x = 2$ but continuous elsewhere with $\lim_{x\to0} f(x) = \frac{1}{2}$

**Determine whether each of the given statements is true. Justify your response with an explanation or counterexample.**

31) $f(t) = \frac{2}{e^t - e^{-t}}$ is continuous everywhere.

**Answer**

False. It is continuous over $(-\infty, 0)$ \cup $(0, \infty)$.

32) If the left- and right-hand limits of $f(x)$ as $x \to a$ exist and are equal, then $f$ cannot be discontinuous at $x = a$.

33) If a function is not continuous at a point, then it is not defined at that point.

**Answer**

False. Consider $f(x) = \begin{cases} x, & \text{if } x \neq 0 \\ 4, & \text{if } x = 0 \end{cases}$.

34) According to the IVT, $\cos x - \sin x - x = 2$ has a solution over the interval $[-1, 1]$.

35) If $f(x)$ is continuous such that $f(a)$ and $f(b)$ have opposite signs, then $f(x) = 0$ has exactly one solution in $[a, b]$.

**Answer**

False. Consider $f(x) = \cos(x)$ on $[-\pi, 2\pi]$.

36) The function $f(x) = \dfrac{x^2 - 4x + 3}{x^2 - 1}$ is continuous over the interval $[0, 3]$.

37) If $f(x)$ is continuous everywhere and $f(a), f(b) > 0$, then there is no root of $f(x)$ in the interval $[a, b]$.

**Answer**

False. The IVT does not work in reverse! Consider $(x-1)^2$ over the interval $[-2, 2]$.

**The following problems consider the scalar form of Coulomb's law, which describes the electrostatic force between two point charges, such as electrons. It is given by the equation $F(r) = k_e \dfrac{|q_1 q_2|}{r^2}$, where $k_e$ is Coulomb's constant, $q_i$ are the magnitudes of the charges of the two particles, and $r$ is the distance between the two particles.**

38) To simplify the calculation of a model with many interacting particles, after some threshold value $r = R$, we approximate $F$ as zero.

a. Explain the physical reasoning behind this assumption.

b. What is the force equation?

c. Evaluate the force $F$ using both Coulomb's law and our approximation, assuming two protons with a charge magnitude of $1.6022 \times 10^{-19}$ **coulombs (C)**, and the Coulomb constant $k_e = 8.988 \times 10^9 Nm^2/C^2$ are 1 m apart. Also, assume $R < 1$ m. How much inaccuracy does our approximation generate? Is our approximation reasonable?

d. Is there any finite value of R for which this system remains continuous at R?

39) Instead of making the force 0 at $R$, we let the force be $10 - 20$ for $r \geq R$. Assume two protons, which have a magnitude of charge $1.6022 \times 10^{-19}$ $C$, and the Coulomb constant $k_e = 8.988 \times 10^9$ $Nm^2/C^2$. Is there a value $R$ that can make this system continuous? If so, find it.

**Answer**

$R = 0.0001519$ m

**Recall the discussion on spacecraft from the chapter opener. The following problems consider a rocket launch from Earth's surface. The force of gravity on the rocket is given by $F(d) = -mk/d^2$, where m is the mass of the rocket, $d$ is the distance of the rocket from the center of Earth, and $k$ is a constant.**

40) Determine the value and units of $k$ given that the mass of the rocket on Earth is 3 million kg. (Hint: The distance from the center of Earth to its surface is 6378 km.)

41) After a certain distance $D$ has passed, the gravitational effect of Earth becomes quite negligible, so we can approximate the force function by $F(d) = \begin{cases} -\dfrac{mk}{d^2}, & \text{if } d < D \\ 10,000, & \text{if } d \geq D \end{cases}$. Find the necessary condition $D$ such that the force function remains continuous.

**Answer**

$D = 63.78$ km

42) As the rocket travels away from Earth's surface, there is a distance D where the rocket sheds some of its mass, since it no longer needs the excess fuel storage. We can write this function as $F(d) = \begin{cases} -\dfrac{m_1 k}{d^2}, & \text{if } d < D \\ -\dfrac{m_2 k}{d^2}, & \text{if } d \geq D \end{cases}$. Is there a value of $D$ such that this function is continuous, assuming $m_1 \neq m_2$?

**In Exercises 43 - 44, prove each function is continuous everywhere.**

43) $f(\theta) = \sin\theta$

**Answer**

For all values of $a$, $f(a)$ is defined, $\lim_{\theta \to a} f(\theta)$ exists, and $\lim_{\theta \to a} f(\theta) = f(a)$. Therefore, $f(\theta)$ is continuous everywhere.

44) $g(x) = |x|$

45) Where is $f(x) = \begin{cases} 0, & \text{if } x \text{ is irrational} \\ 1, & \text{if } x \text{ is rational} \end{cases}$ continuous?

**Answer**

Nowhere

# 2.8: Defining the Derivative

**Note to the Instructor (click to expand)**

This section focuses on tangent lines, their slopes, and the limit definition of a derivative at a number. Some instructors prefer to lump this (and the next) section in with the derivative material (Chapter 2); however, Chapter 2 is long enough as is and this material still focuses on limits, so it is included in Chapter 1.

---

To succeed in this section, you'll need to use some skills from previous courses. While you should already know them, this is the first time they've been required. You can review these skills in CRC's Corequisite Codex. If you have a support class, it might cover some, **but not all**, of these topics.

**Prerequisite Skills and Support Topics (click to expand)**

- **An Overview of Functions**
  - The Difference Quotient: This topic is necessary to compute the derivative of a function at a point.
- **Linear Functions**
  - Slope and Average Rate of Change: The difference quotient is explicitly defined as the slope of a secant line, which represents an average rate of change.
  - Equations of Lines: The point-slope form is used to find the equation of a tangent line once its slope (the derivative) and a point on the line are known (Examples 1 and 3).

---

The following is a list of learning objectives for this section.

**Learning Objectives (click to expand)**

- Identify the derivative as the limit of a difference quotient.
- Recognize the meaning of the tangent to a curve at a point.
- Calculate the slope and equation of a tangent line.
- Calculate the derivative of a given function at a point.
- Describe the velocity as a rate of change.
- Explain the difference between average velocity and instantaneous velocity.
- Estimate the derivative from a table of values.

To access the Hawk A.I. Tutor, you will need to be logged into your campus Gmail account.

Now that we have both a conceptual understanding of a limit and the practical ability to compute limits, we have established the foundation for our study of Calculus, the branch of mathematics in which we compute derivatives and integrals. Most mathematicians and historians agree that calculus was developed independently by the Englishman Isaac **Newton (1643–1727)** and the German Gottfried **Leibniz (1646–1716)**, whose images appear in Figure **2.8.1**. When we credit Newton and Leibniz with developing calculus, we are referring to the fact that Newton and Leibniz were the first to understand the relationship between the derivative and the integral. Both mathematicians benefited from the work of predecessors, such as Barrow, Fermat, and Cavalieri. The initial relationship between the two mathematicians appears to have been amicable; however, a bitter controversy erupted over whose work took precedence in later years. Although it seems likely that Newton did arrive at the ideas behind calculus first, we are indebted to Leibniz for the notation that we commonly use today.

*Figure* **2.8.1***: Newton and Leibniz are credited with developing calculus independently.*

## Tangent Lines

We begin our study of differential calculus by revisiting the notion of secant and tangent lines. Recall that we used the slope of a secant line to a function at a point $(a, f(a))$ to estimate the rate of change (which is the rate at which one variable changes in relation to another variable). We can obtain the slope of the secant by choosing a value of $x$ near $a$ and drawing a line through the points $(a, f(a))$ and $(x, f(x))$, as shown in Figure **2.8.2**. The slope of this line is given by an equation in the form of a difference quotient:

$$m_{sec} = \frac{f(x) - f(a)}{x - a}$$

We can also calculate the slope of a secant line to a function at a value $a$ by using this equation and replacing $x$ with $a + h$, where $h$ is a value close to $a$. We can then calculate the slope of the line through the points $(a, f(a))$ and $(a + h, f(a + h))$. In this case, we find the secant line has a slope given by the following difference quotient with increment $h$:

$$m_{sec} = \frac{f(a + h) - f(a)}{a + h - a} = \frac{f(a + h) - f(a)}{h}$$

**Definition: Difference Quotient**

Let $f$ be a function defined on an interval $I$ containing $a$. If $x \neq a$ is in $I$, then

$$Q = \frac{f(x) - f(a)}{x - a}$$

is a **difference quotient**.

Also, if $h \neq 0$ is chosen so that $a + h$ is in $I$, then

$$Q = \frac{f(a + h) - f(a)}{h}$$

is a difference quotient with increment $h$.

These two expressions for calculating the slope of a secant line are illustrated in Figure **2.8.2**. We will see that each of these two methods for finding the slope of a secant line is of value. Depending on the setting, we can choose one or the other. The primary consideration in our choice depends on the ease of calculation.

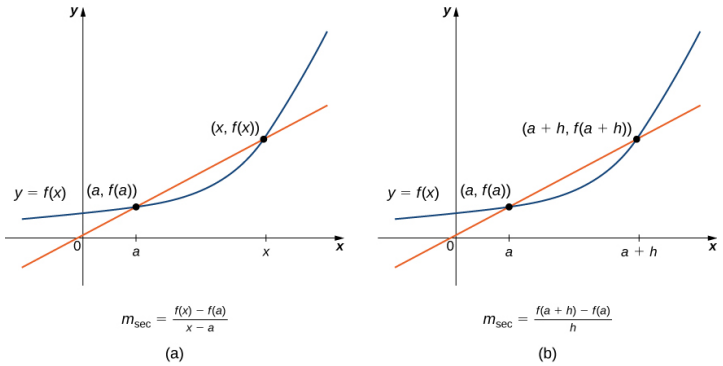

*Figure* **2.8.2***: We can calculate the slope of a secant line in either of two ways.*

In Figure **2.8.3***a*, we see that, as the values of $x$ approach $a$, the slopes of the secant lines provide better estimates of the rate of change of the function at $a$. Furthermore, the secant lines approach the tangent line to the function at $a$, representing the limit of the secant lines. Similarly, Figure **2.8.3***b* shows that as the values of $h$ get closer to 0, the secant lines also approach the tangent line. The slope of the tangent line at $a$ is the rate of change of the function at $a$, as shown in Figure **2.8.3***c*.

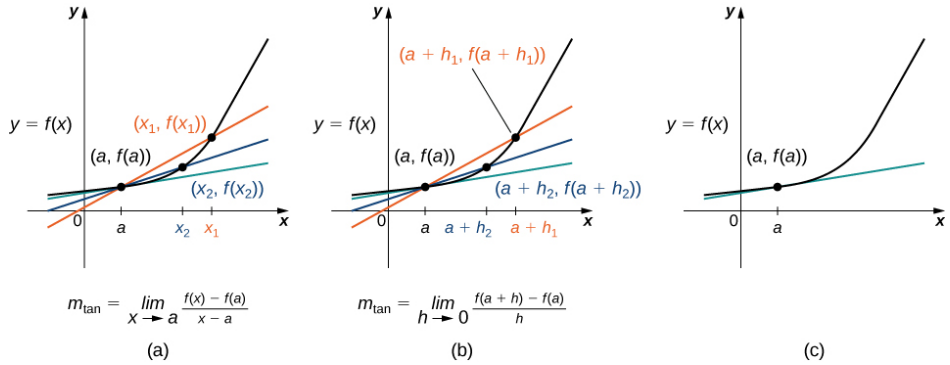

*Figure* **2.8.3***: The secant lines approach the tangent line (shown in green) as the second point approaches the first.*

In Figure **2.8.4**, we show the graph of $f(x) = \sqrt{x}$ and its tangent line at $(1, 1)$ in a series of tighter intervals about $x = 1$. As the intervals become narrower, the graph of the function and its tangent line appear to coincide, making the values on the tangent line a good approximation to the values of the function for choices of $x$ close to 1. In fact, the graph of $f(x)$ itself appears to be **locally linear** near $x = 1$.

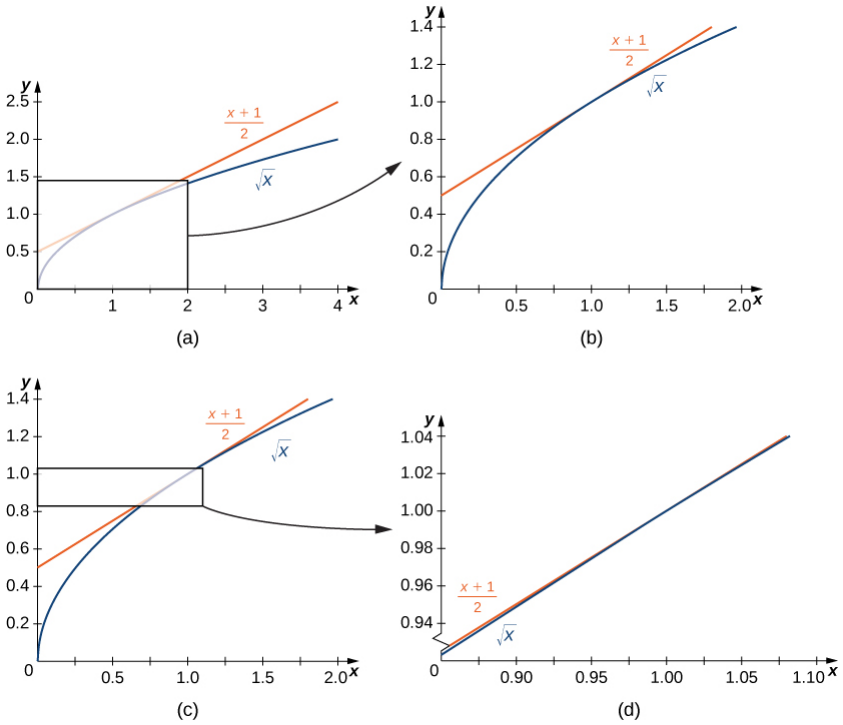

*Figure* **2.8.4**: *For values of* $x$ *close to* $1$, *the graph of* $f(x) = \sqrt{x}$ *and its tangent line appear to coincide.*

Formally, we may define the tangent line to the graph of a function as follows.

**Definition: Tangent Line**

Let $f(x)$ be a function defined in an open interval containing $a$. The **tangent line** to $f(x)$ at $a$ is the line passing through the point $(a, f(a))$ having slope

$$m_{tan} = \lim_{x \to a} \frac{f(x) - f(a)}{x - a} \tag{2.8.1}$$

provided this limit exists.

Equivalently, we may define the tangent line to $f(x)$ at $a$ to be the line passing through the point $(a, f(a))$ having slope

$$m_{tan} = \lim_{h \to 0} \frac{f(a+h) - f(a)}{h} \tag{2.8.2}$$

provided this limit exists.

Just as we have used two different expressions to define the slope of a secant line, we use two different forms to define the slope of the tangent line. In this text, we use both definitions. As before, the choice of definition will depend on the setting. Now that we have formally defined a tangent line to a function at a point, we can use this definition to find equations of tangent lines.

**Example 2.8.1: Finding a Tangent Line**

Find the equation of the line tangent to the graph of $f(x) = x^2$ at $x = 3$.

**Solution**

First, find the slope of the tangent line. In this example, use Equation 2.8.1.

$$
\begin{aligned}
m_{tan} &= \lim_{x\to 3}\frac{f(x)-f(3)}{x-3} && \text{(definition of tangent slope)}\\
&= \lim_{x\to 3}\frac{x^2-9}{x-3} && \text{(substitute } f(x)=x^2 \text{ and } f(3)=9\text{)}\\
&= \lim_{x\to 3}\frac{(x-3)(x+3)}{x-3}\\
&= \lim_{x\to 3}\frac{\cancel{(x-3)}\,(x+3)}{\cancel{(x-3)}^{1}}\\
&= \lim_{x\to 3}(x+3)\\
&\overset{\text{D.S.}}{=} 6
\end{aligned}
$$

Next, find a point on the tangent line. Since the line is tangent to the graph of $f(x)$ at $x=3$, it passes through the point $(3, f(3))$. We have $f(3)=9$, so the tangent line passes through the point $(3,9)$.

Using the point-slope equation of the line with the slope $m=6$ and the point $(3,9)$, we obtain the line $y-9=6(x-3)$. Simplifying, we have $y=6x-9$. The graph of $f(x)=x^2$ and its tangent line at 3 are shown in Figure 2.8.5.

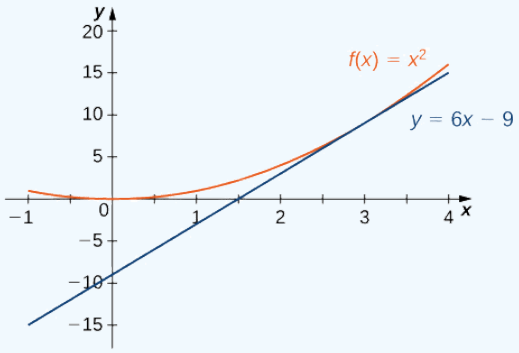

*Figure 2.8.5: The tangent line to $f(x)$ at $x=3$.*

## Example 2.8.2: The Slope of a Tangent Line Revisited

Use Equation 2.8.2 to find the slope of the line tangent to the graph of $f(x)=x^2$ at $x=3$.

**Solution**

The steps are very similar to Example 2.8.1. See Equation 2.8.2 for the definition.

$$
\begin{aligned}
m_{tan} &= \lim_{h\to 0}\frac{f(3+h)-f(3)}{h} && \text{(definition of tangent slope)}\\
&= \lim_{h\to 0}\frac{(3+h)^2-9}{h} && \text{(substitute } f(3+h)=(3+h)^2 \text{ and } f(3)=9\text{)}\\
&= \lim_{h\to 0}\frac{9+6h+h^2-9}{h}\\
&= \lim_{h\to 0}\frac{h(6+h)}{h}\\
&= \lim_{h\to 0}\frac{\cancel{h}(6+h)}{\cancel{h}^{1}}\\
&= \lim_{h\to 0}(6+h)\\
&\overset{\text{D.S.}}{=} 6
\end{aligned}
$$

We obtained the same value for the slope of the tangent line by using the other definition, demonstrating that the formulas can be interchanged.

### Example 2.8.3: Finding the Equation of a Tangent Line

Find the equation of the line tangent to the graph of $f(x)=1/x$ at $x=2$.

**Solution**

We can use Equation 2.8.1, but as we have seen, the results are the same if we use Equation 2.8.2.

$$
\begin{aligned}
m_{tan} &= \lim_{x\to 2}\frac{f(x)-f(2)}{x-2}\\
&= \lim_{x\to 2}\frac{\frac{1}{x}-\frac{1}{2}}{x-2}\\
&= \lim_{x\to 2}\frac{\frac{1}{x}-\frac{1}{2}}{x-2}\cdot\frac{2x}{2x}\\
&= \lim_{x\to 2}\frac{(2-x)}{(x-2)(2x)}\\
&= \lim_{x\to 2}\frac{-1}{2x}\\
&= -\frac{1}{4}
\end{aligned}
$$

We now know that the slope of the tangent line is $-\frac{1}{4}$. To find the equation of the tangent line, we also need a point on the line. We know that $f(2)=\frac{1}{2}$. Since the tangent line passes through the point $(2,\frac{1}{2})$, we can use the point-slope equation of a line to find the equation of the tangent line. Thus, the tangent line has the equation $y=-\frac{1}{4}x+1$. The graphs of $f(x)=\frac{1}{x}$ and $y=-\frac{1}{4}x+1$ are shown in Figure 2.8.6.

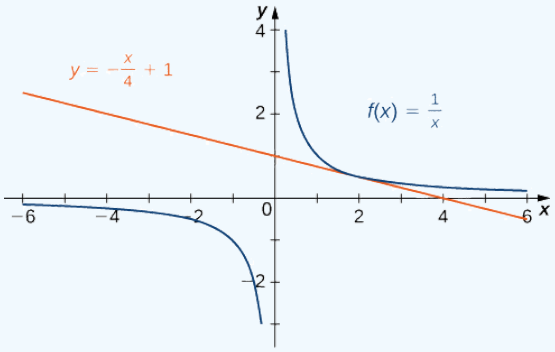

*Figure* **2.8.6***:The line is tangent to* $f(x)$ *at* $x = 2$.

**? Checkpoint 2.8.3**

Find the slope of the line tangent to the graph of $f(x) = \sqrt{x}$ at $x = 4$.

**Answer**

$\frac{1}{4}$

## The Derivative of a Function at a Point

The type of limit we compute to find the slope of the line tangent to a function at a point occurs in many applications across many disciplines. These applications include velocity and acceleration in physics, marginal profit functions in business, and growth rates in biology. This limit occurs so frequently that we give this value a special name: the **derivative.** The process of finding a derivative is called **differentiation**.

**Definition: Derivative**

Let $f(x)$ be a function defined in an open interval containing $a$. The **derivative** of the function $f(x)$ at $a$, denoted by $f'(a)$, is defined by

$$f'(a) = \lim_{x \to a} \frac{f(x) - f(a)}{x - a} \tag{2.8.3}$$

provided this limit exists.

Alternatively, we may also define the derivative of $f(x)$ at $a$ as

$$f'(a) = \lim_{h \to 0} \frac{f(a + h) - f(a)}{h}. \tag{2.8.4}$$

**Example 2.8.4: Finding a Derivative**

For $f(x) = 3x^2 - 4x + 1$, find $f'(2)$ by using Equation 2.8.3.

**Solution**

Substitute the given function and value directly into the equation.

$$
\begin{aligned}
f'(2) &= \lim_{x\to 2}\frac{f(x)-f(2)}{x-2} && \text{(definition of the derivative)}\\
&= \lim_{x\to 2}\frac{(3x^2-4x+1)-5}{x-2} && \text{(substitute } f(x)=3x^2-4x+1 \text{ and } f(2)=5\text{)}\\
&= \lim_{x\to 2}\frac{(x-2)(3x+2)}{x-2}\\
&= \lim_{x\to 2}(3x+2)\\
&= 8
\end{aligned}
$$

### Example 2.8.5: Revisiting the Derivative

For $f(x)=3x^2-4x+1$, find $f'(2)$ by using Equation 2.8.4.

**Solution**

Using this equation, we can substitute two values of the function into the equation, and we should get the same value as in Example 2.8.4.

$$
\begin{aligned}
f'(2) &= \lim_{h\to 0}\frac{f(2+h)-f(2)}{h} && \text{(definition of the derivative)}\\
&= \lim_{h\to 0}\frac{(3(2+h)^2-4(2+h)+1)-5}{h} && \text{(substituting } f(2)=5 \text{ and } f(2+h)=3(2+h)^2-4(2+h)+1\text{)}\\
&= \lim_{h\to 0}\frac{3(4+4h+h^2)-8-4h+1-5}{h} && \text{(expanding the numerator)}\\
&= \lim_{h\to 0}\frac{12+12h+3h^2-12-4h}{h}\\
&= \lim_{h\to 0}\frac{3h^2+8h}{h}\\
&= \lim_{h\to 0}\frac{h(3h+8)}{h} && \text{(factoring)}\\
&= \lim_{h\to 0}(3h+8) && \text{(canceling)}\\
&= 8
\end{aligned}
$$

The results are the same whether we use Equation 2.8.3 or Equation 2.8.4.

### Checkpoint 2.8.5

For $f(x)=x^2+3x+2$, find $f'(1)$.

**Answer**

$f'(1)=5$

## Velocities and Rates of Change

Now that we can evaluate a derivative, we can use it in velocity applications. Recall that if $s(t)$ is the position of an object moving along a coordinate axis, the **average velocity** of the object over a time interval $[a, t]$ if $t > a$ or $[t, a]$ if $t < a$ is given by the difference quotient

$$v_{avg} = \frac{s(t) - s(a)}{t - a}. \tag{2.8.5}$$

As the values of $t$ approach $a$, the values of $v_{avg}$ approach the value we call the **instantaneous velocity** at $a$. That is, instantaneous velocity at $a$, denoted $v(a)$, is given by

$$v(a) = s'(a) = \lim_{t \to a} \frac{s(t) - s(a)}{t - a}. \tag{2.8.6}$$

To better understand the relationship between average velocity and instantaneous velocity, see Figure 2.8.7. In this figure, the slope of the tangent line (shown in red) is the instantaneous velocity of the object at time $t = a$ whose position at time $t$ is given by the function $s(t)$. The slope of the secant line (shown in green) is the average velocity of the object over the time interval $[a, t]$.

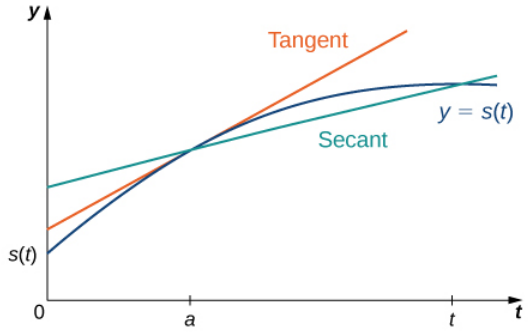

*Figure 2.8.7: The slope of the secant line is the average velocity over the interval $[a, t]$. The slope of the tangent line is the instantaneous velocity.*

We can use Equation 2.8.6 to calculate the instantaneous velocity, or we can estimate the velocity of a moving object by using a table of values. We can then confirm the estimate by using Equation 2.8.5.

### Example 2.8.6: Estimating Velocity

A lead weight on a spring is oscillating up and down. Its position at time $t$ with respect to a fixed horizontal line is given by $s(t) = \sin t$ (Figure 2.8.8). Use a table of values to estimate $v(0)$. Check the estimate by using Equation 2.8.6.

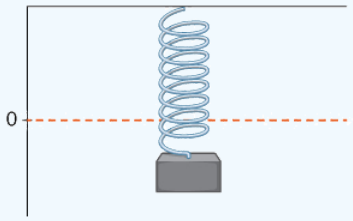

*Figure 2.8.8: A lead weight suspended from a spring in vertical oscillatory motion.*

**Solution**

We can estimate the instantaneous velocity at $t = 0$ by computing a table of average velocities using values of $t$ approaching 0, as shown in Table 2.8.1.

**Table 2.8.1: Average velocities using values of $t$ approaching 0**

| $t$ | $\frac{\sin t - \sin 0}{t-0} = \frac{\sin t}{t}$ |
|---|---|
| −0.1 | 0.998334166 |
| −0.01 | 0.9999833333 |
| −0.001 | 0.999999833 |
| 0.001 | 0.999999833 |
| 0.01 | 0.9999833333 |
| 0.1 | 0.998334166 |

From the table, we see that the average velocity over the time interval $[-0.1, 0]$ is $0.998334166$, the average velocity over the time interval $[-0.01, 0]$ is $0.9999833333$, and so forth. Using this table of values, it appears that a reasonable estimate is $v(0) = 1$.

By using Equation 2.8.6, we can see that

$$v(0) = s'(0) = \lim_{t \to 0} \frac{\sin t - \sin 0}{t - 0} = \lim_{t \to 0} \frac{\sin t}{t} = 1.$$

Thus, in fact, $v(0) = 1$.

**Checkpoint 2.8.6**

A rock is dropped from a height of $64$ feet. Its height above ground at time $t$ seconds later is given by $s(t) = -16t^2 + 64,\ 0 \le t \le 2$. Find its instantaneous velocity $1$ second after it is dropped, using Equation 2.8.6.

**Answer**

−32 ft/s

As we have seen throughout this section, the slope of a tangent line to a function and instantaneous velocity are related concepts. Each is calculated by computing a derivative, and each measures the instantaneous rate of change of a function or the rate of change of a function at any point along the function.

**Definition: Instantaneous Rate of Change**

The **instantaneous rate of change** of a function $f(x)$ at a value $a$ is its derivative $f'(a)$.

**Example 2.8.7: Estimating Rate of Change of Velocity**

Reaching a top speed of $270.49$ mph, the Hennessey Venom GT is one of the fastest cars in the world. In tests it went from $0$ to $60$ mph in $3.05$ seconds, from $0$ to $100$ mph in $5.88$ seconds, from $0$ to $200$ mph in $14.51$ seconds, and from $0$ to $229.9$ mph in $19.96$ seconds. Use this data to conclude the rate of change of velocity (that is, its **acceleration**) as it approaches $229.9$ mph. Does the rate at which the car accelerates appear to be increasing, decreasing, or constant?

*Figure 2.8.9: (credit: modification of work by Codex41, Flickr)*

**Solution**

First observe that $60$ mph = $88$ ft/s, $100$ mph $\approx 146.67$ ft/s, $200$ mph $\approx 293.33$ ft/s, and $229.9$ mph $\approx 337.19$ ft/s. We can summarize the information in a table.

**Table 2.8.2: $v(t)$ at different values of $t$**

| $t$ | $v(t)$ |
|---|---|
| 0 | 0 |
| 3.05 | 88 |
| 5.88 | 147.67 |
| 14.51 | 293.33 |
| 19.96 | 337.19 |

Now compute the average acceleration of the car in feet per second on intervals of the form $[t, 19.96]$ as $t$ approaches $19.96$, as shown in the following table.

**Table 2.8.3: Average acceleration**

| $t$ | $\frac{v(t)-v(19.96)}{t-19.96} = \frac{v(t)-337.19}{t-19.96}$ |
|---|---|
| 0.0 | 16.89 |
| 3.05 | 14.74 |
| 5.88 | 13.46 |
| 14.51 | 8.05 |

The rate at which the car is accelerating is decreasing as its velocity approaches $229.9$ mph ($337.19$ ft/s).

### Example 2.8.8: Rate of Change of Temperature

A homeowner sets the thermostat so that the temperature in the house begins to drop from $70°F$ at $9$ p.m., reaches a low of $60°$ during the night, and rises back to $70°$ by $7$ a.m. the next morning. Suppose that the temperature in the house is given by $T(t) = 0.4t^2 - 4t + 70$ for $0 \le t \le 10$, where $t$ is the number of hours past $9$ p.m. Find the instantaneous rate of change of the temperature at midnight.

**Solution**

Since midnight is $3$ hours past $9$ p.m., we want to compute $T'(3)$. Refer to Equation 2.8.3.

$$
\begin{aligned}
T'(3) &= \lim_{t\to 3}\frac{T(t)-T(3)}{t-3} && \text{(definition of the derivative)}\\
&= \lim_{t\to 3}\frac{0.4t^2-4t+70-61.6}{t-3} && \text{(substituting } T(t)=0.4t^2-4t+70 \text{ and } T(3)=61.6\text{)}\\
&= \lim_{t\to 3}\frac{0.4t^2-4t+8.4}{t-3}\\
&= \lim_{t\to 3}\frac{0.4(t-3)(t-7)}{t-3}\\
&= \lim_{t\to 3}0.4(t-7)\\
&= -1.6
\end{aligned}
$$

The instantaneous rate of change of the temperature at midnight is $-1.6^\circ F$ per hour.

### Example 2.8.9: Rate of Change of Profit

A toy company can sell $x$ electronic gaming systems at a price of $p=-0.01x+400$ dollars per gaming system. The cost of manufacturing $x$ systems is given by $C(x)=100x+10,000$ dollars. Find the rate of change of profit when $10,000$ games are produced. Should the toy company increase or decrease production?

**Solution**

The profit $P(x)$ earned by producing $x$ gaming systems is $R(x)-C(x)$, where $R(x)$ is the revenue obtained from the sale of $x$ games. Since the company can sell $x$ games at $p=-0.01x+400$ per game,

$$R(x)=xp=x(-0.01x+400)=-0.01x^2+400x.$$

Consequently,

$$P(x)=-0.01x^2+300x-10,000.$$

Therefore, evaluating the rate of change of profit gives

$$
\begin{aligned}
P'(10000) &= \lim_{x\to 10000}\frac{P(x)-P(10000)}{x-10000}\\
&= \lim_{x\to 10000}\frac{-0.01x^2+300x-10000-1990000}{x-10000}\\
&= \lim_{x\to 10000}\frac{-0.01x^2+300x-2000000}{x-10000}\\
&= 100
\end{aligned}
$$

Since the rate of change of profit $P'(10,000)>0$ and $P(10,000)>0$, the company should increase production.

### Checkpoint 2.8.9

A coffee shop determines that the daily profit on scones obtained by charging s dollars per scone is $P(s)=-20s^2+150s-10$. The coffee shop currently charges $\$3.25$ per scone. Find $P'(3.25)$, the rate of change of profit when the price is $\$3.25$, and decide whether or not the coffee shop should consider raising or lowering its prices on scones.

**Answer**

$P'(3.25)=20>0$; raise prices

# 2.8E: EXERCISES

## READING QUESTIONS

1. What are the two common forms of the difference quotient used to calculate the slope of a secant line?
2. How is the slope of a tangent line at a point $(a, f(a))$ defined using a limit? Provide both forms.
3. What is the definition of the derivative of a function $f(x)$ at a point $a$, denoted $f'(a)$? Provide both limit forms.
4. What does it mean if a function $f(x)$ is "locally linear" near $x = a$?
5. If $s(t)$ represents the position of an object at time $t$, how is the average velocity over the interval $[a, t]$ calculated?
6. How is the instantaneous velocity $v(a)$ at time $a$ defined in terms of a derivative?
7. What does the derivative $f'(a)$ represent in terms of the instantaneous rate of change of the function $f$ at $a$?
8. In Example 1, why was it necessary to factor $x^2 - 9$ before evaluating the limit for $m_{tan}$?
9. When calculating $f'(a)$ using the definition $\lim_{h \to 0} \frac{f(a+h) - f(a)}{h}$, what is the typical algebraic goal before substituting $h = 0$?
10. How can a table of values for average velocities be used to estimate instantaneous velocity?

## HOMEWORK

**For exercises 1 - 10, use the equation $m_{sec} = \frac{f(x) - f(a)}{x - a}$ to find the slope of the secant line between the values $x_1$ and $x_2$ for each function $y = f(x)$.**

1) $f(x) = 4x + 7; \quad x_1 = 2, \quad x_2 = 5$

**Answer**

$m_{sec} = 4$

2) $f(x) = 8x - 3; \quad x_1 = -1, \quad x_2 = 3$

3) $f(x) = x^2 + 2x + 1; \quad x_1 = 3, \quad x_2 = 3.5$

**Answer**

$m_{sec} = 8.5$

4) $f(x) = -x^2 + x + 2; \quad x_1 = 0.5, \quad x_2 = 1.5$

5) $f(x) = \frac{4}{3x - 1}; \quad x_1 = 1, \quad x_2 = 3$

**Answer**

$m_{sec} = -\frac{3}{4}$

6) $f(x) = \frac{x - 7}{2x + 1}; \quad x_1 = -2, \quad x_2 = 0$

7) $f(x) = \sqrt{x}; \quad x_1 = 1, \quad x_2 = 16$

**Answer**

$m_{sec} = 0.2$

8) $f(x) = \sqrt{x - 9}; \quad x_1 = 10, \quad x_2 = 13$

9) $f(x) = x^{1/3} + 1; \quad x_1 = 0, \quad x_2 = 8$

**Answer**

$m_{sec} = 0.25$

10) $f(x) = 6x^{2/3} + 2x^{1/3}; \quad x_1 = 1, \quad x_2 = 27$

**For the functions in exercises 11 - 20,**

**a. use the equation $m_{tan} = \lim_{h \to 0} \frac{f(a+h) - f(a)}{h}$ to find the slope of the tangent line $m_{tan} = f'(a)$, and**

**b. find the equation of the tangent line to $f$ at $x = a$.**

11) $f(x) = 3 - 4x, \quad a = 2$

**Answer**

a. $m_{tan} = -4$

b. $y = -4x + 3$

12) $f(x) = \frac{x}{5} + 6, \quad a = -1$

13) $f(x) = x^2 + x, \quad a = 1$

**Answer**

a. $m_{\tan} = 3$
b. $y = 3x - 1$

14) $f(x) = 1 - x - x^2, \quad a = 0$

15) $f(x) = \frac{7}{x}, \quad a = 3$

**Answer**

a. $m_{\tan} = \frac{-7}{9}$
b. $y = \frac{-7}{9}x + \frac{14}{3}$

16) $f(x) = \sqrt{x+8}, \quad a = 1$

17) $f(x) = 2 - 3x^2, \quad a = -2$

**Answer**

a. $m_{\tan} = 12$
b. $y = 12x + 14$

18) $f(x) = \frac{-3}{x-1}, \quad a = 4$

19) $f(x) = \frac{2}{x+3}, \quad a = -4$

**Answer**

a. $m_{\tan} = -2$
b. $y = -2x - 10$

20) $f(x) = \frac{3}{x^2}, \quad a = 3$

**For the functions $y = f(x)$ in exercises 21 - 30, find $f'(a)$ using the equation $f'(a) = \lim_{x \to a} \frac{f(x) - f(a)}{x - a}$.**

21) $f(x) = 5x + 4, \quad a = -1$

**Answer**

$f'(-1) = 5$

22) $f(x) = -7x + 1, \quad a = 3$

23) $f(x) = x^2 + 9x, \quad a = 2$

**Answer**

$f'(2) = 13$

24) $f(x) = 3x^2 - x + 2, \quad a = 1$

25) $f(x) = \sqrt{x}, \quad a = 4$

**Answer**

$f'(4) = \frac{1}{4}$

26) $f(x) = \sqrt{x-2}, \quad a = 6$

27) $f(x) = \frac{1}{x}, \quad a = 2$

**Answer**

$f'(2) = -\frac{1}{4}$

28) $f(x) = \frac{1}{x-3}, \quad a = -1$

29) $f(x) = \frac{1}{x^3}, \quad a = 1$

**Answer**

$f'(1) = -3$

30) $f(x) = \frac{1}{\sqrt{x}}, \quad a = 4$

**For the following exercises, given the function $y = f(x)$,**

**a. find the slope of the secant line $PQ$ for each point $Q(x, f(x))$ with $x$ value given in the table.**

**b. Use the answers from a. to estimate the value of the slope of the tangent line at $P$.**

**c. Use the answer from b. to find the equation of the tangent line to $f$ at point $P$.**

31) [Technology Required] $f(x) = x^2 + 3x + 4, \quad P(1, 8)$ (Round to 6 decimal places.)

| $x$ | Slope $m_{PQ}$ | $x$ | Slope $m_{PQ}$ |
|---|---|---|---|
| 1.1 | (i) | 0.9 | (vii) |
| 1.01 | (ii) | 0.99 | (viii) |
| 1.001 | (iii) | 0.999 | (ix) |
| 1.0001 | (iv) | 0.9999 | (x) |
| 1.00001 | (v) | 0.99999 | (xi) |
| 1.000001 | (vi) | 0.999999 | (xii) |

**Answer**

$a.(i)5.100000, (ii)5.010000, (iii)5.001000, (iv)5.000100, (v)5.000010, (vi)5.000001, (vii)4.900000, (viii)4.990000, (ix)4.999000, (x)4.999900, (xi)4.999990, (x)4.999999$

b. $m_{\tan} = 5$

c. $y = 5x + 3$

32) [Technology Required] $f(x) = \dfrac{x+1}{x^2-1}, \quad P(0, -1)$

| $x$ | Slope $m_{PQ}$ | $x$ | Slope $m_{PQ}$ |
|---|---|---|---|
| 0.1 | (i) | −0.1 | (vii) |

| 3.141592 | (vi) |

[Technology Required] For the following position functions $y = s(t)$, an object is moving along a straight line, where $t$ is in seconds and $s$ is in meters. Find

a. the simplified expression for the average velocity from $t = 2$ to $t = 2 + h$;

b. the average velocity between $t = 2$ and $t = 2 + h$, where $(i)\ h = 0.1,\ (ii)\ h = 0.01,\ (iii)\ h = 0.001$, and $(iv)\ h = 0.0001$; and

c. use the answer from a. to estimate the instantaneous velocity at $t = 2$ second.

35) $s(t) = \frac{1}{3}t + 5$

**Answer**

a. $\frac{1}{3}$;

b. $(i)\ \frac{1}{3}$ m/s, $(ii)\ \frac{1}{3}$ m/s, $(iii)\ \frac{1}{3}$ m/s, $(iv)\ \frac{1}{3}$ m/s;

c. $\frac{1}{3}$ m/s

36) $s(t) = t^2 - 2t$

37) $s(t) = 2t^3 + 3$

**Answer**

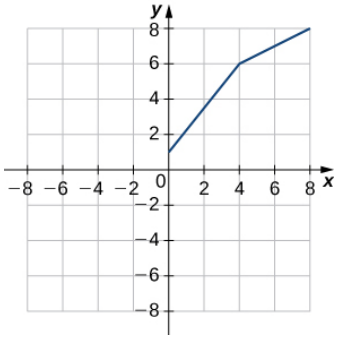
a. $2(h^2 + 6h + 12)$;

b. $(i)$ $25.22$ m/s, $(ii)$ $24.12$ m/s, $(iii)$ $24.01$ m/s, $(iv)$ $24$ m/s;

c. $24$ m/s

38) $s(t) = \frac{16}{t^2} - \frac{4}{t}$

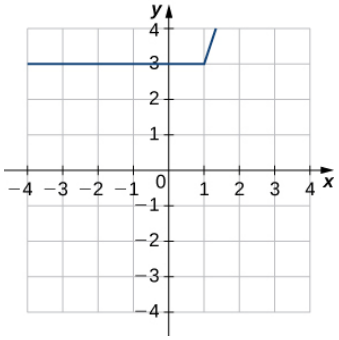
39) Use the following graph to evaluate a. $f'(1)$ and b. $f'(6)$.



**Answer**

a. $1.25$; b. $0.5$

40) Use the following graph to evaluate a. $f'(-3)$ and b. $f'(1.5)$.



**For the following exercises, use the limit definition of derivative to show that the derivative does not exist at $x = a$ for each of the given functions.**

41) $f(x) = x^{1/3}, \quad x = 0$

**Answer**

$$\lim_{x \to 0^-} \frac{x^{1/3} - 0}{x - 0} = \lim_{x \to 0^-} \frac{1}{x^{2/3}} = \infty$$

42) $f(x) = x^{2/3}, \quad x = 0$

43) $f(x) = \begin{cases} 1, & \text{if } x < 1 \\ x, & \text{if } x \geq 1 \end{cases}, \quad x = 1$

**Answer**

$$\lim_{x \to 1^-} \frac{1 - 1}{x - 1} = 0 \neq 1 = \lim_{x \to 1^+} \frac{x - 1}{x - 1}$$

44) $f(x) = \frac{|x|}{x}, \quad x = 0$

45) [Technology Required] The position in feet of a race car along a straight track after $t$ seconds is modeled by the function $s(t) = 8t^2 - \frac{1}{16}t^3$.

a. Find the average velocity of the vehicle over the following time intervals to four decimal places:

i. $[4, 4.1]$

ii. $[4, 4.01]$

iii. $[4, 4.001]$

iv. $[4, 4.0001]$

b. Use a. to draw a conclusion about the instantaneous velocity of the vehicle at $t = 4$ seconds.

**Answer**

a. $(i) 61.7244 ft/s,\ (ii) 61.0725 ft/s,\ (iii) 61.0072 ft/s,\ (iv) 61.0007 ft/s$

b. At $4$ seconds the race car is traveling at a rate/velocity of $61$ ft/s.

46) [Technology Required] The distance in feet that a ball rolls down an incline is modeled by the function $s(t) = 14t^2$,

where t is seconds after the ball begins rolling.

a. Find the average velocity of the ball over the following time intervals:

i. [5, 5.1]

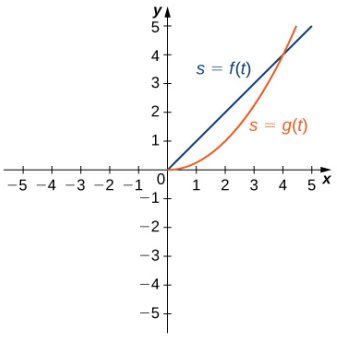
ii. [5, 5.01]

iii. [5, 5.001]

iv. [5, 5.0001]

b. Use the answers from a. to draw a conclusion about the instantaneous velocity of the ball at $t = 5$ seconds.

47) Two vehicles start out traveling side by side along a straight road. Their position functions, shown in the following graph, are given by $s = f(t)$ and $s = g(t)$, where s is measured in feet and t is measured in seconds.



a. Which vehicle has traveled farther at $t = 2$ seconds?

b. What is the approximate velocity of each vehicle at $t = 3$ seconds?

c. Which vehicle is traveling faster at $t = 4$ seconds?

d. What is true about the positions of the vehicles at $t = 4$ seconds?

**Answer**

a. The vehicle represented by $f(t)$, because it has traveled $2$ feet, whereas $g(t)$ has traveled $1$ foot.

b. The velocity of $f(t)$ is constant at $1$ ft/s, while the velocity of $g(t)$ is approximately $2$ ft/s.

c. The vehicle represented by $g(t)$, with a velocity of approximately $4$ ft/s.

d. Both have traveled $4$ feet in $4$ seconds.

48) [Technology Required] The total cost $C(x)$, in hundreds of dollars, to produce $x$ jars of mayonnaise is given by $C(x) = 0.000003x^3 + 4x + 300$.

a. Calculate the average cost per jar over the following intervals:

i. [100, 100.1]

ii. [100, 100.01]

iii. [100, 100.001]

iv. [100, 100.0001]

b. Use the answers from a. to estimate the average cost to produce $100$ jars of mayonnaise.

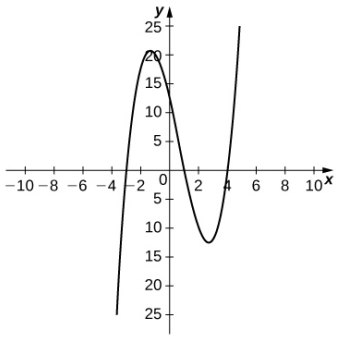
49) [Technology Required] For the function $f(x) = x^3 - 2x^2 - 11x + 12$, do the following.

a. Use a graphing calculator to graph $f$ in an appropriate viewing window.

b. Use the ZOOM feature on the calculator to approximate the two values of $x = a$ for which $m_{tan} = f'(a) = 0$.

**Answer**

a.



b. $a \approx -1.361,\ 2.694$

50) [Technology Required] For the function $f(x) = \dfrac{x}{1+x^2}$, do the following.

a. Use a graphing calculator to graph $f$ in an appropriate viewing window.

b. Use the ZOOM feature on the calculator to approximate the values of $x = a$ for which $m_{\tan} = f'(a) = 0$.

51) Suppose that $N(x)$ computes the number of gallons of gas used by a vehicle traveling $x$ miles. Suppose the vehicle gets $30$ mpg.

a. Find a mathematical expression for $N(x)$.

b. What is $N(100)$? Explain the physical meaning.

c. What is $N'(100)$? Explain the physical meaning.

**Answer**

a. $N(x) = \dfrac{x}{30}$

b. $\sim 3.3$ gallons. When the vehicle travels $100$ miles, it has used $3.3$ gallons of gas.

c. $\frac{1}{30}$. The rate of gas consumption in gallons per mile that the vehicle is achieving after having traveled $100$ miles.

52) [Technology Required] For the function $f(x) = x^4 - 5x^2 + 4$, do the following.

a. Use a graphing calculator to graph $f$ in an appropriate viewing window.

b. Use the *nDeriv* function, which numerically finds the derivative, on a graphing calculator to estimate $f'(-2),\ f'(-0.5),\ f'(1.7)$, and $f'(2.718)$.

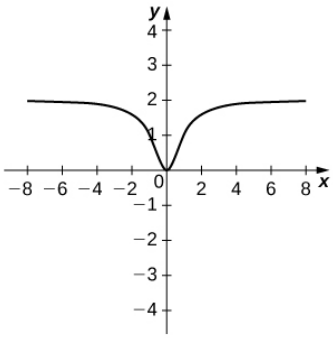
53) [Technology Required] For the function $f(x) = \dfrac{x^2}{x^2+1}$, do the following.

a. Use a graphing calculator to graph $f$ in an appropriate viewing window.

b. Use the *nDeriv* function on a graphing calculator to find $f'(-4),\ f'(-2),\ f'(2)$, and $f'(4)$.

**Answer**

a.



b. $-0.028, -0.16, 0.16, 0.028$

# 2.9: The Derivative as a Function

**Note to the Instructor (click to expand)**

In this section, focus on the limit definition of the derivative as a function (as opposed to at a number). Make sure that students learn how to graph the derivative given the graph of the original function and that they know (at the very least) Lagrange and Leibniz notations. Connect derivatives and continuity (differentiability implies continuity - not the other way around). Finally, introduce higher-order derivatives. **Derivative tricks and shortcuts are not to be used in this section!**

---

To succeed in this section, you'll need to use some skills from previous courses. While you should already know them, this is the first time they've been required. You can review these skills in CRC's Corequisite Codex. If you have a support class, it might cover some, **but not all**, of these topics.

**Prerequisite Skills and Support Topics (click to expand)**

- **Graphing Functions**
  - Symmetry: The concept that the derivative of an even function is an odd function (and vice-versa) is explored.
  - Intervals of Increase and Decrease: The sign of the derivative $f'(x)$ corresponds to intervals where $f(x)$ is increasing ($f'(x) > 0$) or decreasing ($f'(x) < 0$). (Figure 3 and surrounding discussion).
  - Local and Absolute Extrema: Where a function has a horizontal tangent (often at local extrema), its derivative is zero. (Figure 3 and surrounding discussion).

---

The following is a list of learning objectives for this section.

**Learning Objectives (click to expand)**

- Define the derivative function of a given function.
- Graph a derivative function from the graph of a given function.
- State the connection between derivatives and continuity.
- Describe three conditions when a function has no derivative.
- Explain the meaning of a higher-order derivative.

As we have seen, the derivative of a function at a given point gives us the rate of change or slope of the tangent line to the function at that point. We obtain the velocity if we differentiate a position function at a given time. Knowing the function's derivative at every point produces valuable information about the function's behavior. However, finding the derivative at even a handful of values using the techniques of the preceding section would quickly become quite tedious. In this section, we define the derivative function and learn a process for finding it.

## Derivative Functions

The derivative function gives the derivative of a function at each point in the domain of the original function for which the derivative is defined. We can formally define a derivative function as follows.

**Definition: Derivative Function**

Let $f$ be a function. The **derivative function**, denoted by $f'$, is the function whose domain consists of those values of $x$ such that the following limit exists:

$$f'(x) = \lim_{h \to 0} \frac{f(x+h) - f(x)}{h}. \tag{2.9.1}$$

A function $f(x)$ is said to be **differentiable** at $a$ if $f'(a)$ exists. More generally, a function is said to be **differentiable on** $S$ if it is differentiable at every point in an open set $S$, and a differentiable function is one in which $f'(x)$ exists on its domain.

In the next few examples we use Equation 2.9.1 to find the derivative of a function.

**Example 2.9.1: Finding the Derivative of a Square-Root Function**

Find the derivative of $f(x) = \sqrt{x}$.

**Solution**

Start directly with the definition of the derivative function.

Substitute $f(x+h) = \sqrt{x+h}$ and $f(x) = \sqrt{x}$ into $f'(x) = \lim_{h \to 0} \frac{f(x+h) - f(x)}{h}$.

$$\begin{aligned} f'(x) &= \lim_{h \to 0} \frac{\sqrt{x+h} - \sqrt{x}}{h} \\ &= \lim_{h \to 0} \frac{\left(\sqrt{x+h} - \sqrt{x}\right)}{h} \cdot \frac{\left(\sqrt{x+h} + \sqrt{x}\right)}{\left(\sqrt{x+h} + \sqrt{x}\right)} \\ &= \lim_{h \to 0} \frac{h}{h\left(\sqrt{x+h} + \sqrt{x}\right)} \\ &= \lim_{h \to 0} \frac{\cancel{h}^{1}}{\cancel{h}\left(\sqrt{x+h} + \sqrt{x}\right)} \\ &= \lim_{h \to 0} \frac{1}{\sqrt{x+h} + \sqrt{x}} \\ &\overset{\text{D.S.}}{=} \frac{1}{2\sqrt{x}} \end{aligned}$$

**Example 2.9.2: Finding the Derivative of a Quadratic Function**

Find the derivative of the function $f(x) = x^2 - 2x$.

**Solution**

Follow the same procedure, but without multiplying by the conjugate.

Substitute $f(x+h) = (x+h)^2 - 2(x+h)$ and $f(x) = x^2 - 2x$ into $f'(x) = \lim_{h \to 0} \frac{f(x+h) - f(x)}{h}$.

$$
\begin{aligned}
f'(x) &= \lim_{h\to 0}\frac{((x+h)^2-2(x+h))-(x^2-2x)}{h}\\
&= \lim_{h\to 0}\frac{x^2+2xh+h^2-2x-2h-x^2+2x}{h}\\
&= \lim_{h\to 0}\frac{2xh-2h+h^2}{h}\\
&= \lim_{h\to 0}\frac{h(2x-2+h)}{h}\\
&= \lim_{h\to 0}\frac{\cancel{h}^{1}(2x-2+h)}{\cancel{h}^{1}}\\
&= \lim_{h\to 0}(2x-2+h)\\
&\overset{\text{D.S.}}{=} 2x-2
\end{aligned}
$$

**? Checkpoint 2.9.2**

Find the derivative of $f(x)=x^2$.

**Answer**

$f'(x)=2x$

## Notations for the Derivative

There is no single uniform notation for differentiation. Instead, various notations for the derivative of a function or variable have been proposed by various mathematicians. The usefulness of each notation varies with the context, and it is sometimes advantageous to use more than one notation in a given context.

### Lagrange's Notation: $f'(x)$

One of the most common modern notations for differentiation is named after Joseph Louis Lagrange, even though Euler invented it and Lagrange just popularized it. In Lagrange's notation, a prime mark denotes a derivative. If $y=f(x)$ is a function, then its derivative evaluated at $x$ is written

$$f'(x) \quad (\text{a common alternative form is } y')$$

Lagrange's notation first appeared in print in 1749.

If the derivative is evaluated at $x=a$, then the value is written as $f'(a)$ or $y'(a)$.

### Leibniz's Notation: $\frac{dy}{dx}$

The original notation employed by Gottfried Leibniz is still frequently used throughout mathematics. It is prevalent when the equation $y=f(x)$ is regarded as a functional relationship between dependent and independent variables $y$ and $x$. Leibniz's notation makes this relationship explicit by writing the derivative as

$$\frac{dy}{dx} \quad \left(\text{common alternative forms are } \frac{df(x)}{dx}, \frac{df}{dx}(x), \text{ and } \frac{d}{dx}f(x)\right)$$

In Example 2.9.2, we could have expressed the derivative as $\frac{dy}{dx}=2x-2$. We could have conveyed the same information by writing $\frac{d}{dx}\left(x^2-2x\right)=2x-2$.

To understand this notation better, recall that the derivative of a function at a point is the limit of the slopes of secant lines as the secant lines approach the tangent line. The slopes of these secant lines are often expressed in the form $\frac{\Delta y}{\Delta x}$ where $\Delta y$ is the difference in the $y$ values corresponding to the difference in the $x$ values, which are expressed as $\Delta x$ (Figure 2.9.1). Thus the derivative, which can be thought of as the instantaneous rate of change of $y$ with respect to $x$, is expressed as

$$\frac{dy}{dx} = \lim_{\Delta x \to 0} \frac{\Delta y}{\Delta x}.$$

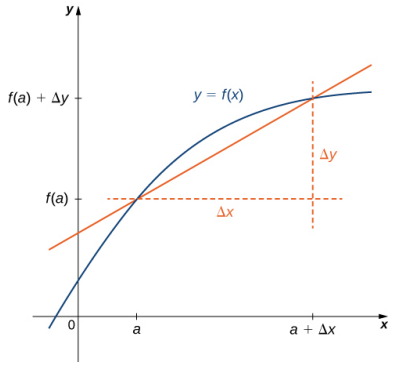

*Figure* 2.9.1*: The derivative is expressed as* $\frac{dy}{dx} = \lim_{\Delta x \to 0} \frac{\Delta y}{\Delta x}$.

If the derivative is evaluated at $x = a$, then the value is written as $\left.\frac{dy}{dx}\right|_{x=a}$ or $\left.\frac{df}{dx}\right|_{x=a}$.

**Caution: Careful Use of Leibniz's Notation**

When using Leibniz's notation to find the derivative of $y = f(x)$ at $x = a$, it is incorrect to write $\frac{df(a)}{dx}$. The reason for this will be explored in the next chapter.

### Euler's Notation: $D$

Leonhard Euler's notation uses a differential operator suggested by Louis François Antoine Arbogast, denoted as $D$. When applied to a function $f(x)$, it is defined by

$$(Df)(x)$$

Euler's notation is useful in a subject called differential equations; however, we will not be using it in this text.

### Newton's Notation: $\dot{y}$

Isaac Newton's notation for differentiation (also called the dot notation, fluxions, or sometimes, crudely, the flyspeck notation for differentiation) places a dot over the dependent variable. That is if $y$ is a function of $t$, then the derivative of $y$ with respect to $t$ is

$$\dot{y}$$

This notation is popular in physics and mathematical physics. It also appears in areas of mathematics connected with physics, such as differential equations. As with Euler's notation, we will not be using Newton's notation in this text.

## Graphing a Derivative

We have already discussed how to graph a function, so given the equation of a function or the equation of a derivative function, we could graph it. Given both, we would expect to see a correspondence between the graphs of these two functions since $f'(x)$ gives the rate of change of a function $f(x)$ (or slope of the tangent line to $f(x)$).

In Example 2.9.1, we found that for $f(x) = \sqrt{x}$, $f'(x) = \frac{1}{2\sqrt{x}}$. If we graph these functions on the same axes, as in Figure 2.9.2, we can use the graphs to understand the relationship between these two functions. First, we notice that $f(x)$ is increasing over its entire domain, which means that the slopes of its tangent lines at all points are positive. Consequently, we expect $f'(x) > 0$ for all values of $x$ in its domain. Furthermore, as $x$ increases, the slopes of the tangent lines to $f(x)$ are decreasing. We expect to see a

corresponding decrease in $f'(x)$. We also observe that $f(0)$ is undefined and that $\lim_{x \to 0^+} f'(x) = +\infty$, corresponding to a vertical tangent to $f(x)$ at $0$.

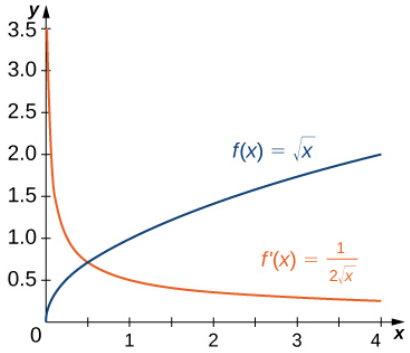

*Figure 2.9.2: The derivative $f'(x)$ is positive everywhere because the function $f(x)$ is increasing.*

In Example 2.9.2, we found that for $f(x) = x^2 - 2x$, $f'(x) = 2x - 2$. The graphs of these functions are shown in Figure 2.9.3. Observe that $f(x)$ is decreasing for $x < 1$. For these same values of $x$, $f'(x) < 0$. For values of $x > 1$, $f(x)$ is increasing and $f'(x) > 0$. Also, $f(x)$ has a horizontal tangent at $x = 1$ and $f'(1) = 0$.

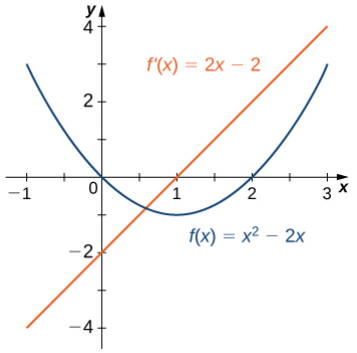

*Figure 2.9.3: The derivative $f'(x) < 0$ where the function $f(x)$ is decreasing and $f'(x) > 0$ where $f(x)$ is increasing. The derivative is zero where the function has a horizontal tangent*

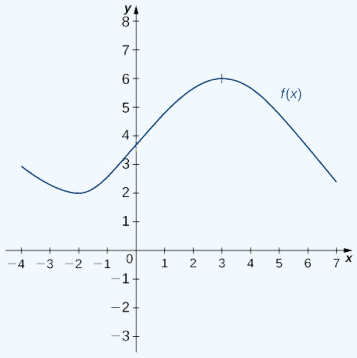
### Example 2.9.3: Sketching a Derivative Using a Function

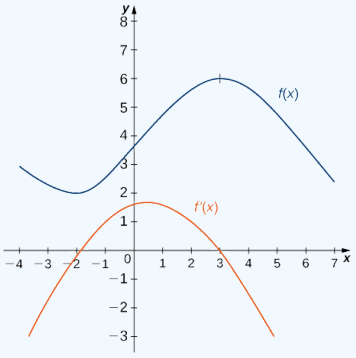
Use the following graph of $f(x)$ to sketch a graph of $f'(x)$.



**Solution**

The solution is shown in the following graph. Observe that $f(x)$ is increasing and $f'(x) > 0$ on $(-2, 3)$. Also, $f(x)$ is decreasing and $f'(x) < 0$ on $(-\infty, -2)$ and on $(3, +\infty)$. Also note that $f(x)$ has horizontal tangents at $-2$ and $3$, and $f'(-2) = 0$ and $f'(3) = 0$.

https://math.libretexts.org/@go/page/175443



**Checkpoint 2.9.3**

Sketch the graph of $f(x) = x^2 - 4$. On what interval is the graph of $f'(x)$ above the $x$-axis?

**Answer**

$(0, +\infty)$

## Derivatives and Continuity

Now that we can graph a derivative let's examine the behavior of the graphs. First, we consider the relationship between differentiability and continuity. We will see that if a function is differentiable at a point, it must be continuous there; however, a continuous function need not be differentiable at that point. A function may be continuous at a point and fail to be differentiable at the point for one of several reasons.

**Theorem: Differentiability Implies Continuity**

Let $f(x)$ be a function and $a$ be in its domain. If $f(x)$ is differentiable at $a$, then $f$ is continuous at $a$.

**Proof**

If $f(x)$ is differentiable at $a$, then $f'(a)$ exists and, if we let $h = x - a$, we have $x = a + h$, and as $h = x - a \to 0$, we can see that $x \to a$.

Then

$$f'(a) = \lim_{h \to 0} \frac{f(a+h) - f(a)}{h}$$

can be rewritten as

$$f'(a) = \lim_{x \to a} \frac{f(x) - f(a)}{x - a}.$$

We want to show that $f(x)$ is continuous at $a$ by showing that $\lim_{x \to a} f(x) = f(a)$. Thus,

$$\begin{aligned}\lim_{x\to a} f(x) &= \lim_{x\to a}\big(f(x)-f(a)+f(a)\big)\\ &= \lim_{x\to a}\left(\frac{f(x)-f(a)}{x-a}\cdot(x-a)+f(a)\right)\\ &= \left(\lim_{x\to a}\frac{f(x)-f(a)}{x-a}\right)\cdot\left(\lim_{x\to a}(x-a)\right)+\lim_{x\to a} f(a)\\ &= f'(a)\cdot 0+f(a)\\ &= f(a).\end{aligned}$$

Therefore, since $f(a)$ is defined and $\lim_{x\to a} f(x) = f(a)$, we conclude that $f$ is continuous at $a$.

*Q.E.D.*

We have just proven that differentiability implies continuity, but now we consider whether continuity implies differentiability. To determine an answer to this question, we examine the function $f(x) = |x|$. This function is continuous everywhere; however, $f'(0)$ is undefined. This observation leads us to believe that continuity does not imply differentiability. Let's explore further. For $f(x) = |x|$,

$$f'(0) = \lim_{x\to 0}\frac{f(x)-f(0)}{x-0} = \lim_{x\to 0}\frac{|x|-|0|}{x-0} = \lim_{x\to 0}\frac{|x|}{x}.$$

This limit does not exist because

$$\lim_{x\to 0^-}\frac{|x|}{x} = -1 \quad \text{and} \quad \lim_{x\to 0^+}\frac{|x|}{x} = 1.$$

See Figure 2.9.4.

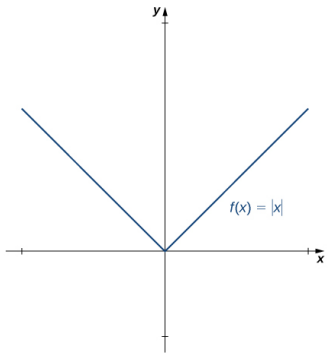


*Figure* 2.9.4: *The function* $f(x) = |x|$ *is continuous at* $0$ *but is not differentiable at* $0$.

Let's consider some additional situations in which a continuous function fails to be differentiable. Consider the function $f(x) = \sqrt[3]{x}$:

$$f'(0) = \lim_{x\to 0}\frac{\sqrt[3]{x}-0}{x-0} = \lim_{x\to 0}\frac{1}{\sqrt[3]{x^2}} = +\infty.$$

Thus $f'(0)$ does not exist. A quick look at the graph of $f(x) = \sqrt[3]{x}$ clarifies the situation. The function has a vertical tangent line at $0$ (Figure 2.9.5).

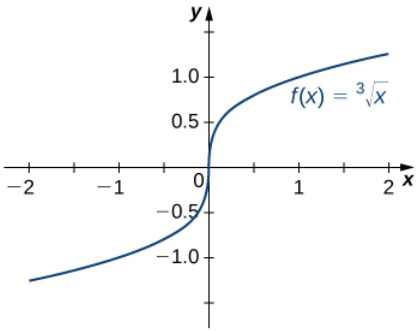

*Figure* **2.9.5**: *The function* $f(x) = \sqrt[3]{x}$ *has a vertical tangent at* $x = 0$. *It is continuous at* $0$ *but is not differentiable at* $0$.

The function $f(x) = \begin{cases} x \sin\left(\frac{1}{x}\right), & \text{if } x \neq 0 \\ 0, & \text{if } x = 0 \end{cases}$ also has a derivative that exhibits interesting behavior at $0$.

We see that

$$f'(0) = \lim_{x \to 0} \frac{x \sin(1/x) - 0}{x - 0} = \lim_{x \to 0} \sin\left(\frac{1}{x}\right).$$

This limit does not exist, essentially because the slopes of the secant lines continuously change direction as they approach zero (Figure **2.9.6**).

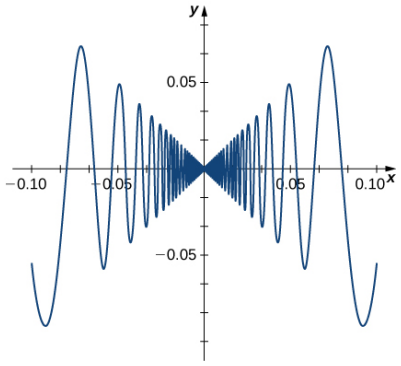

*Figure* **2.9.6**: *The function* $f(x) = \begin{cases} x \sin\left(\frac{1}{x}\right), & \text{if } x \neq 0 \\ 0, & \text{if } x = 0 \end{cases}$ *is not differentiable at* $0$.

In summary:

- We observe that if a function is not continuous, it cannot be differentiable since every differentiable function must be continuous. However, if a function is continuous, it may still fail to be differentiable.
- We saw that $f(x) = |x|$ failed to be differentiable at $0$ because the limits of the slopes of the tangent lines on the left and right were not the same. Visually, this resulted in a sharp corner on the function's graph at $0$.. From this, we conclude that to be differentiable at a point, a function must be "smooth" at that point.
- As we saw in the example of $f(x) = \sqrt[3]{x}$, a function fails to be differentiable at a point where there is a vertical tangent line.
- As we saw with $f(x) = \begin{cases} x \sin\left(\frac{1}{x}\right), & \text{if } x \neq 0 \\ 0, & \text{if } x = 0 \end{cases}$ a function may fail to be differentiable at a point in more complicated ways as well.

### ✔ Example 2.9.4: A Piecewise Function that is Continuous and Differentiable

A toy company wants to design a track for a toy car that starts along a parabolic curve and then converts to a straight line (Figure **2.9.7**). The function that describes the track is to have the form $f(x) = \begin{cases} \frac{1}{10}x^2 + bx + c, & \text{if } x < -10 \\ -\frac{1}{4}x + \frac{5}{2}, & \text{if } x \geq -10 \end{cases}$ where $x$ and $f(x)$ are in inches. For the car to move smoothly along the track, the function $f(x)$ must be both continuous and differentiable at $-10$. Find values of $b$ and $c$ that make $f(x)$ both continuous and differentiable.

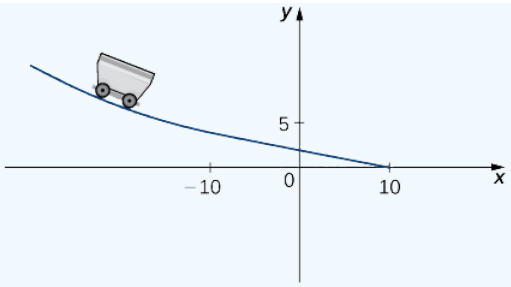

*Figure* **2.9.7***: The function must be continuous and differentiable for the car to move smoothly along the track.*

**Solution**

For the function to be continuous at $x = -10$, $\lim_{x \to 10^-} f(x) = f(-10)$. Thus, since

$$\lim_{x \to -10^-} f(x) = \frac{1}{10}(-10)^2 - 10b + c = 10 - 10b + c$$

and $f(-10) = 5$, we must have $10 - 10b + c = 5$. Equivalently, we have $c = 10b - 5$.

For the function to be differentiable at $-10$,

$$f'(10) = \lim_{x \to -10} \frac{f(x) - f(-10)}{x + 10}$$

must exist. Since $f(x)$ is defined using different rules on the right and the left, we must evaluate this limit from the right and the left and then set them equal to each other:

$$\begin{aligned}
\lim_{x \to -10^-} \frac{f(x) - f(-10)}{x + 10} &= \lim_{x \to -10^-} \frac{\frac{1}{10}x^2 + bx + c - 5}{x + 10} \\
&= \lim_{x \to -10^-} \frac{\frac{1}{10}x^2 + bx + (10b - 5) - 5}{x + 10} \\
&= \lim_{x \to -10^-} \frac{x^2 - 100 + 10bx + 100b}{10(x + 10)} \\
&= \lim_{x \to -10^-} \frac{(x + 10)(x - 10 + 10b)}{10(x + 10)} \\
&= b - 2
\end{aligned}$$

We also have

$$\begin{aligned}
\lim_{x \to -10^+} \frac{f(x) - f(-10)}{x + 10} &= \lim_{x \to -10^+} \frac{-\frac{1}{4}x + \frac{5}{2} - 5}{x + 10} \\
&= \lim_{x \to -10^+} \frac{-(x + 10)}{4(x + 10)} \\
&= -\frac{1}{4}
\end{aligned}$$

This gives us $b - 2 = -\frac{1}{4}$. Thus $b = \frac{7}{4}$ and $c = 10(\frac{7}{4}) - 5 = \frac{25}{2}$.

**? Checkpoint 2.9.4**

Find values of a and b that make $f(x) = \begin{cases} ax+b, & \text{if } x < 3 \\ x^2, & \text{if } x \geq 3 \end{cases}$ both continuous and differentiable at 3.

**Answer**

$a = 6$ and $b = -9$

## Higher-Order Derivatives

The derivative of a function is itself a function, so we can find the derivative of a derivative. For example, the derivative of a position function is the rate of change of position or velocity. The derivative of velocity is the rate of change of velocity, which is acceleration. The new function obtained by differentiating the derivative is called the second derivative. Furthermore, we can continue taking derivatives to obtain the third, fourth, and so on. Collectively, these are referred to as **higher-order derivatives**. The notation for the higher-order derivatives of $y = f(x)$ can be expressed in any of the following forms:

$$\begin{gathered} f''(x),\ f'''(x),\ f^{(4)}(x),\ \ldots,\ f^{(n)}(x) \\ y''(x),\ y'''(x),\ y^{(4)}(x),\ \ldots,\ y^{(n)}(x) \\ \frac{d^2y}{dx^2},\ \frac{d^3y}{dy^3},\ \frac{d^4y}{dy^4},\ \ldots,\ \frac{d^ny}{dy^n}. \end{gathered}$$

It is interesting to note that the notation for $\frac{d^2y}{dx^2}$ may be viewed as an attempt to express $\frac{d}{dx}\left(\frac{dy}{dx}\right)$ more compactly.

Analogously, $\frac{d}{dx}\left(\frac{d}{dx}\left(\frac{dy}{dx}\right)\right) = \frac{d}{dx}\left(\frac{d^2y}{dx^2}\right) = \frac{d^3y}{dx^3}$.

**✓ Example 2.9.5: Finding a Second Derivative**

For $f(x) = 2x^2 - 3x + 1$, find $f''(x)$.

**Solution**

First find $f'(x)$.

Substitute $f(x) = 2x^2 - 3x + 1$ and $f(x+h) = 2(x+h)^2 - 3(x+h) + 1$ into $f'(x) = \lim\limits_{h\to 0} \dfrac{f(x+h) - f(x)}{h}$.

$$\begin{aligned} f'(x) &= \lim_{h\to 0} \frac{(2(x+h)^2 - 3(x+h) + 1) - (2x^2 - 3x + 1)}{h} \\ &= \lim_{h\to 0} \frac{4xh + 2h^2 - 3h}{h} \\ &= \lim_{h\to 0} (4x + 2h - 3) \\ &\overset{\text{D.S.}}{=} 4x - 3 \end{aligned}$$

Next, find $f''(x)$ by taking the derivative of $f'(x) = 4x - 3$.

$$\begin{aligned} f''(x) &= \lim_{h\to 0} \frac{f'(x+h) - f'(x)}{h} \\ &= \lim_{h\to 0} \frac{(4(x+h) - 3) - (4x - 3)}{h} \\ &= \lim_{h\to 0} 4 \\ &\overset{\text{D.S.}}{=} 4 \end{aligned}$$

**Checkpoint 2.9.5**

Find $f''(x)$ for $f(x) = x^2$.

**Answer**

$f''(x) = 2$

**Example 2.9.6: Finding Acceleration**

The position of a particle along a coordinate axis at time $t$ (in seconds) is given by $s(t) = 3t^2 - 4t + 1$ (in meters). Find the function that describes its acceleration at time $t$.

**Solution**

Since $v(t) = s'(t)$ and $a(t) = v'(t) = s''(t)$, we begin by finding the derivative of $s(t)$:

$$\begin{aligned} s'(t) &= \lim_{h \to 0} \frac{s(t+h) - s(t)}{h} \\ &= \lim_{h \to 0} \frac{3(t+h)^2 - 4(t+h) + 1 - (3t^2 - 4t + 1)}{h} \\ &= 6t - 4 \end{aligned}$$

Next,

$$\begin{aligned} s''(t) &= \lim_{h \to 0} \frac{s'(t+h) - s'(t)}{h} \\ &= \lim_{h \to 0} \frac{6(t+h) - 4 - (6t - 4)}{h} \\ &= 6 \end{aligned}$$

Thus, $a = 6 \text{ m/s}^2$.

**Checkpoint 2.9.6**

For $s(t) = t^3$, find $a(t)$.

**Answer**

$a(t) = 6t$

# 2.9E: EXERCISES

## READING QUESTIONS

1. How is the derivative function $f'(x)$ defined using a limit?
2. What does it mean for a function to be "differentiable at a point $a$"?
3. Name two common notations for the derivative of $y = f(x)$ besides $f'(x)$.
4. If $f(x) = \sqrt{x}$, what is $f'(x)$ according to Example 1?
5. What is the relationship between the sign of $f'(x)$ and whether $f(x)$ is increasing or decreasing?
6. If $f(x)$ has a horizontal tangent line at $x = a$, what is the value of $f'(a)$?
7. Does differentiability at a point imply continuity at that point? Explain the theorem.
8. Does continuity at a point imply differentiability at that point? Give an example of a function that is continuous at a point but not differentiable there.
9. List three reasons why a function might fail to be differentiable at a point where it is continuous.
10. What is a higher-order derivative? Give an example of notation for the second derivative.
11. If $s(t)$ is a position function, what do $s'(t)$ and $s''(t)$ represent physically?

## HOMEWORK

**For exercises 1 - 10, use the definition of a derivative to find $f'(x)$.**

1) $f(x) = 6$

2) $f(x) = 2 - 3x$

**Answer**

$f'(x) = -3$

3) $f(x) = \frac{2x}{7} + 1$

4) $f(x) = 4x^2$

**Answer**

$f'(x) = 8x$

5) $f(x) = 5x - x^2$

6) $f(x) = \sqrt{2x}$

**Answer**

$f'(x) = \frac{1}{\sqrt{2x}}$

7) $f(x) = \sqrt{x - 6}$

8) $f(x) = \frac{9}{x}$

**Answer**

$f'(x) = \frac{-9}{x^2}$

9) $f(x) = x + \frac{1}{x}$

10) $f(x) = \frac{1}{\sqrt{x}}$

**Answer**

$f'(x) = \frac{-1}{2x^{3/2}}$

**For the exercises 11 - 14, use the graph of $y = f(x)$ to sketch the graph of its derivative $f'(x)$.**

**For exercises 15 - 20, the given limit represents the derivative of a function $y = f(x)$ at $x = a$. Find $f(x)$ and $a$.**

15) $\lim\limits_{h \to 0} \dfrac{(1+h)^{2/3} - 1}{h}$

16) $\lim\limits_{h \to 0} \dfrac{[3(2+h)^2 + 2] - 14}{h}$

**Answer**

$f(x) = 3x^2 + 2, \quad a = 2$

17) $\lim\limits_{h \to 0} \dfrac{\cos(\pi + h) + 1}{h}$

18) $\lim\limits_{h \to 0} \dfrac{(2+h)^4 - 16}{h}$

**Answer**

$f(x) = x^4, \quad a = 2$

19) $\lim\limits_{h \to 0} \dfrac{[2(3+h)^2 - (3+h)] - 15}{h}$

20) $\lim\limits_{h \to 0} \dfrac{e^h - 1}{h}$

**Answer**

$f(x) = e^x, \quad a = 0$

**For the functions in exercises 21 - 24,**

**a. sketch the graph and**

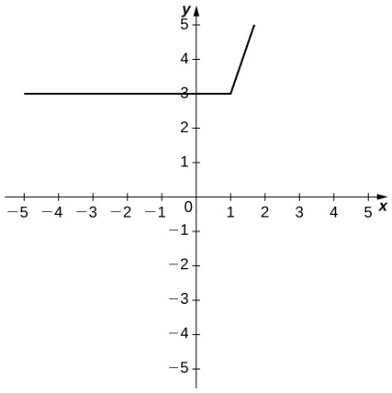
**b. use the definition of a derivative to show that the function is not differentiable at $x = 1$.**

21) $f(x)=\begin{cases}2\sqrt{x}, & \text{if } 0\le x\le 1\\ 3x-1, & \text{if } x>1\end{cases}$

22) $f(x)=\begin{cases}3, & \text{if } x<1\\ 3x, & \text{if } x\ge 1\end{cases}$

**Answer**

a.



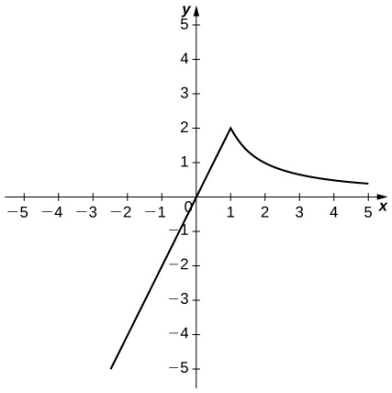
b. $\lim\limits_{h\to 1^-}\dfrac{3-3}{h}\neq\lim\limits_{h\to 1^+}\dfrac{3h}{h}$

23) $f(x)=\begin{cases}-x^2+2, & \text{if } x\le 1\\ x, & \text{if } x>1\end{cases}$

24) $f(x)=\begin{cases}2x, & \text{if } x\le 1\\ \frac{2}{x}, & \text{if } x>1\end{cases}$

**Answer**

a.



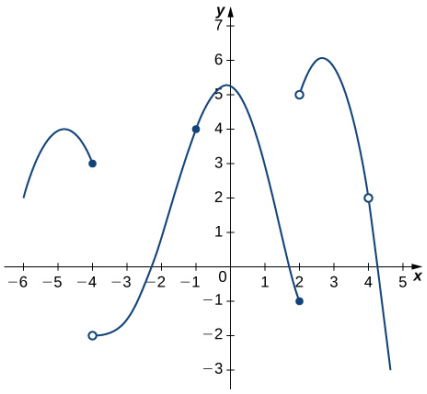
b. $\lim\limits_{h\to 1^-}\dfrac{2h}{h}\neq\lim\limits_{h\to 1^+}\dfrac{\frac{2}{x+h}-2x}{h}$.

**For the graphs in exercises 25 - 26,**

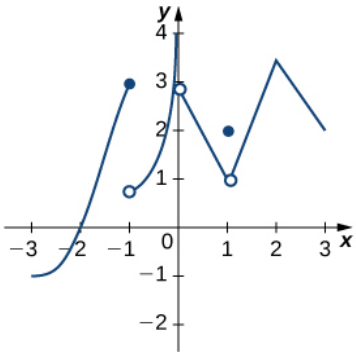
**a. determine for which values of $x=a$ the $\lim\limits_{x\to a}f(x)$ exists but $f$ is not continuous at $x=a$, and**

**b. determine for which values of $x=a$ the function is continuous but not differentiable at $x=a$.**

25)



26)

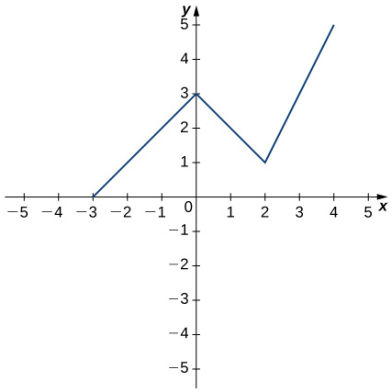


**Answer**

a. $x = 1$,

b. $x = 2$

27) Use the graph to evaluate a. $f'(-0.5)$, b. $f'(0)$, c. $f'(1)$, d. $f'(2)$, and e. $f'(3)$, if it exists.



**For the functions in exercises 28 - 30, use $f''(x) = \lim_{h \to 0} \frac{f'(x+h) - f'(x)}{h}$ to find $f''(x)$.**

28) $f(x) = 2 - 3x$

**Answer**

$f''(x) = 0$

29) $f(x) = 4x^2$

30) $f(x) = x + \frac{1}{x}$

**Answer**

$$f''(x) = \frac{2}{x^3}$$

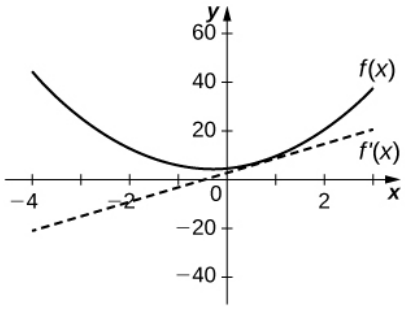
**For exercises 31 - 36, use a calculator to graph $f(x)$. Determine the function $f'(x)$, then use a calculator to graph $f'(x)$.**

31) [Technology Required] $f(x) = -\frac{5}{x}$

32) [Technology Required] $f(x) = 3x^2 + 2x + 4$.

**Answer**

$f'(x) = 6x + 2$

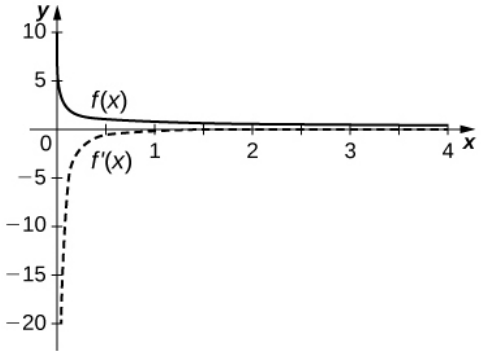


33) [Technology Required] $f(x) = \sqrt{x} + 3x$

34) [Technology Required] $f(x) = \frac{1}{\sqrt{2x}}$

**Answer**

$f'(x) = -\frac{1}{(2x)^{3/2}}$

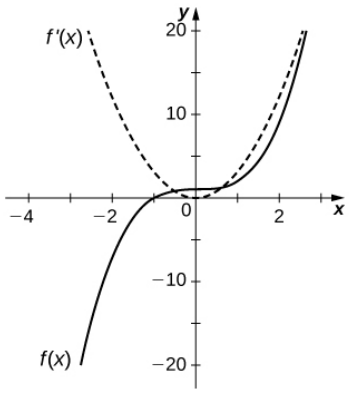


35) [Technology Required] $f(x) = 1 + x + \frac{1}{x}$

36) [Technology Required] $f(x) = x^3 + 1$

**Answer**

$f'(x) = 3x^2$



**For exercises 37 - 42, describe what the two expressions represent in terms of each of the given situations. Be sure to include units.**

**a.** $\dfrac{f(x+h)-f(x)}{h}$

**b.** $f'(x)=\lim\limits_{h\to 0}\dfrac{f(x+h)-f(x)}{h}$

37) $P(x)$ denotes the population of a city at time $x$ in years.

38) $C(x)$ denotes the total amount of money (in thousands of dollars) spent on concessions by $x$ customers at an amusement park.

**Answer**

a. Average rate at which customers spent on concessions in thousands per customer.

b. Rate (in thousands per customer) at which $x$ customers spent money on concessions in thousands per customer.

39) $R(x)$ denotes the total cost (in thousands of dollars) of manufacturing $x$ clock radios

40) $g(x)$ denotes the grade (in percentage points) received on a test, given $x$ hours of studying.

**Answer**

a. Average grade received on the test with an average study time between two values.

b. Rate (in percentage points per hour) at which the grade on the test increased or decreased for a given average study time of $x$ hours.

41) $B(x)$denotes the cost (in dollars) of a sociology textbook at university bookstores in the United States in $x$ years since $1990$.

42) $p(x)$ denotes atmospheric pressure at an altitude of $x$ feet.

**Answer**

a. Average change of atmospheric pressure between two different altitudes.

b. Rate (torr per foot) at which atmospheric pressure is increasing or decreasing at $x$ feet.

43) Sketch the graph of a function $y=f(x)$ with all of the following properties:

a. $f'(x)>0$ for $-2\le x<1$

b. $f'(2)=0$

c. $f'(x)>0$ for $x>2$

d. $f(2)=2$ and $f(0)=1$

e. $\lim\limits_{x\to-\infty}f(x)=0$ and $\lim\limits_{x\to\infty}f(x)=\infty$

f. $f'(1)$ does not exist.

44) Suppose temperature $T$ in degrees Fahrenheit at a height $x$ in feet above the ground is given by $y=T(x)$.

a. Give a physical interpretation, with units, of $T'(x)$.

b. If we know that $T'(1000)=-0.1$, explain the physical meaning.

**Answer**

a. The rate (in degrees per foot) at which temperature is increasing or decreasing for a given height $x$.

b. The rate of change of temperature as altitude changes at $1000$ feet is $-0.1$ degrees per foot.

45) Suppose the total profit of a company is $y = P(x)$ thousand dollars when $x$ units of an item are sold.

a. What does $\frac{P(b) - P(a)}{b - a}$ for $0 < a < b$ measure, and what are the units?

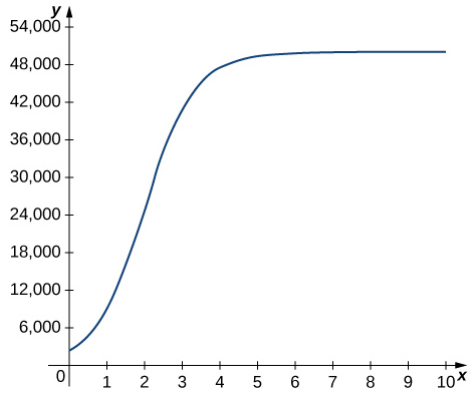
b. What does $P'(x)$ measure, and what are the units?

c. Suppose that $P'(30) = 5$, what is the approximate change in profit if the number of items sold increases from $30$ to $31$?

46) The graph in the following figure models the number of people $N(t)$ who have come down with the flu t weeks after its initial outbreak in a town with a population of 50,000 citizens.

a. Describe what $N'(t)$ represents and how it behaves as $t$ increases.

b. What does the derivative tell us about how this town is affected by the flu outbreak?



**Answer**

a. The rate at which the number of people who have come down with the flu is changing $t$ weeks after the initial outbreak.

b. The rate is increasing sharply up to the third week, at which point it slows down and then becomes constant.

**For exercises 47 - 52, use the following table, which shows the height $h$ of the Saturn V rocket for the Apollo 11 mission $t$ seconds after launch.**

| Time (seconds) | Height (meters) |
|---|---|
| 0 | 0 |
| 1 | 2 |
| 2 | 4 |
| 3 | 13 |
| 4 | 25 |
| 5 | 32 |

47) What is the physical meaning of $h'(t)$? What are the units?

48) [Technology Required] Construct a table of values for $h'(t)$ and graph both $h(t)$ and $h'(t)$ on the same graph. (Hint: for interior points, estimate both the left limit and right limit and average them.)

**Answer**

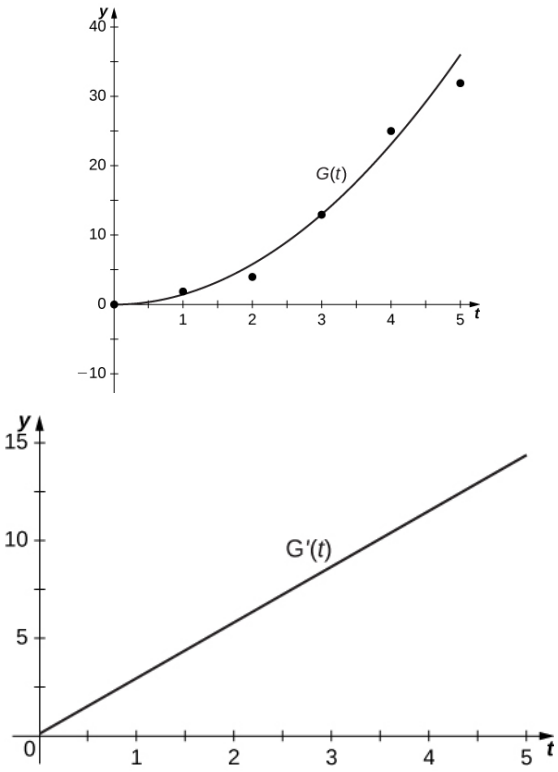
| Time (seconds) | $h'(t)$ (m/s) |
|---|---|
| 0 | 2 |
| 1 | 2 |
| 2 | 5.5 |
| 3 | 10.5 |
| 4 | 9.5 |
| 5 | 7 |

49) [Technology Required] The best linear fit to the data is given by $H(t) = 7.229t - 4.905$, where $H$ is the height of the rocket (in meters) and t is the time elapsed since takeoff. From this equation, determine $H'(t)$. Graph $H(t$ with the given data and, on a separate coordinate plane, graph $H'(t)$.

50) [Technology Required] The best quadratic fit to the data is given by $G(t) = 1.429t^2 + 0.0857t - 0.1429$, where $G$ is the height of the rocket (in meters) and $t$ is the time elapsed since takeoff. From this equation, determine $G'(t)$. Graph $G(t)$ with the given data and, on a separate coordinate plane, graph $G'(t)$.

**Answer**

$G'(t) = 2.858t + 0.0857$



51) [Technology Required] The best cubic fit to the data is given by $F(t) = 0.2037t^3 + 2.956t^2 - 2.705t + 0.4683$, where $F$ is the height of the rocket (in m) and $t$ is the time elapsed since take off. From this equation, determine $F'(t)$. Graph $F(t)$ with the given data and, on a separate coordinate plane, graph $F'(t)$. Does the linear, quadratic, or cubic function fit the data best?

52) Using the best linear, quadratic, and cubic fits to the data, determine what $H''(t)$, $G''(t)$ and $F''(t)$ are. What are the physical meanings of $H''(t)$, $G''(t)$ and $F''(t)$, and what are their units?

**Answer**

$H''(t) = 0$, $G''(t) = 2.858$ and $f''(t) = 1.222t + 5.912$ represent the acceleration of the rocket, with units of meters per second squared $(\mathrm{m/s^2})$.

# CHAPTER OVERVIEW

## 3: Discovering Derivatives

> This page is a draft and is under active development.

Calculating velocity and changes in velocity are important uses of calculus, but it is far more widespread than that. Calculus is important in all branches of mathematics, science, and engineering, and it is critical to analysis in business and health as well. In this chapter, we explore one of the main tools of calculus, the derivative, and show convenient ways to calculate derivatives. We apply these rules to a variety of functions in this chapter so that we can then explore applications of these techniques.

# 3.1: Derivatives of Polynomial Functions

https://math.libretexts.org/@go/page/175447

**Note to the Instructor (click to expand)**

The purpose of this section is to introduce the student to the Power Rule and the other general rules of differentiation (e.g., the Sum Rule). You should make sure to cover examples requiring equations of tangent lines, as well as some Physics examples.

---

To succeed in this section, you'll need to use some skills from previous courses. While you should already know them, this is the first time they've been required. You can review these skills in CRC's Corequisite Codex. If you have a support class, it might cover some, **but not all**, of these topics.

**Prerequisite Skills and Support Topics (click to expand)**

- **Arithmetic**
  - Factorials: Multiple derivatives of power functions often lead to factorials.
- **Solving Equations**
  - Solving Quadratic Equations: Needed to find where a function has horizontal tangents, which involves setting the derivative (often a quadratic) equal to zero (Example 11).
- **Linear Functions**
  - Parallel and Perpendicular Lines: From this point forward, you will be expected to find when the tangent line to a curve is parallel or perpendicular to another line. Therefore, understanding what this means is required.
- **Systems**
  - Solving 2x2 Systems of Linear Equations: Synthesis questions (especially those involving solutions to differential equations) from this point forward often result in the need to solve a system of linear equations.
  - Solving 3x3 Systems of Linear Equations: Synthesis questions (especially those involving solutions to differential equations) from this point forward often result in the need to solve a system of linear equations.

---

The following is a list of learning objectives for this section.

**Learning Objectives (click to expand)**

- State the constant, constant multiple, and Power Rules.
- Apply the Sum and Difference Rules to combine derivatives.
- Extend the Power Rule to functions with negative and rational exponents.
- Combine the differentiation rules to find the derivative of a polynomial or rational function.
- Use derivatives of polynomials for applications in the sciences, engineering, and business.

Hawk A.I. Section-Specific Tutor

To access the Hawk A.I. Tutor, you will need to be logged into your campus Gmail account.

- Combine previous knowledge of tangent lines with derivatives of polynomials.

Finding derivatives of functions by using the definition of the derivative can be a lengthy and, for certain functions, a rather challenging process. For example, previously we found that

$$\frac{d}{dx}\left(\sqrt{x}\right) = \frac{1}{2\sqrt{x}}$$

by using a process that involved multiplying an expression by a conjugate before evaluating a limit.

The process that we could use to evaluate $\frac{d}{dx}\left(\sqrt[3]{x}\right)$ using the definition, while similar, is more complicated.

In this section, we develop rules for finding derivatives that allow us to bypass this process. We begin with the basics.

## The Basic Rules

The functions $f(x) = c$ and $g(x) = x^n$ where $n$ is a positive integer are the building blocks from which all polynomials and rational functions are constructed. To find derivatives of polynomials and rational functions efficiently without resorting to the limit definition of the derivative, we must first develop formulas for differentiating these basic functions.

### The Constant Rule

We first apply the limit definition of the derivative to find the derivative of the constant function, $f(x) = c$. For this function, both $f(x) = c$ and $f(x+h) = c$, so we obtain the following result:

$$\begin{aligned} f'(x) &= \lim_{h\to 0} \frac{f(x+h) - f(x)}{h} \\ &= \lim_{h\to 0} \frac{c-c}{h} \\ &= \lim_{h\to 0} \frac{0}{h} \\ &= \lim_{h\to 0} 0 \qquad \text{(Before evaluating the limit, perform any simple arithmetic. Zero over something nonzero is zero.)} \\ &= 0. \end{aligned}$$

The rule for differentiating constant functions is called the **Constant Rule**. It states that the derivative of a constant function is zero; that is, since a constant function is a horizontal line, the slope, or the rate of change, of a constant function is $0$. We restate this rule in the following theorem.

**Theorem: The Constant Rule**

Let $c$ be a constant. If $f(x) = c$, then $f'(x) = 0$.

Alternatively, we may express this rule as

$$\frac{d}{dx}(c) = 0.$$

**Example 3.1.1: Applying the Constant Rule**

Find the derivative of $f(x) = 8$.

**Solution**

This is just a one-step application of the rule: $f'(x) = 0$.

**Checkpoint 3.1.1**

Find the derivative of $g(x) = -3$.

**Answer**

0

## The Power Rule

During our exploration of the limit definition of the derivative, we showed that

$$\frac{d}{dx}\left(x^2\right) = 2x \quad \text{and} \quad \frac{d}{dx}\left(x^{1/2}\right) = \frac{1}{2}x^{-1/2}.$$

At this point, you might see a pattern beginning to develop for derivatives of the form $\frac{d}{dx}\left(x^n\right)$. We continue our examination of derivative formulas by differentiating power functions of the form $f(x) = x^n$ where $n$ is a positive integer. We develop formulas for derivatives of this type of function in stages, beginning with positive integer powers. Before stating and proving the general rule for derivatives of functions of this form, we take a look at a specific case, $\frac{d}{dx}(x^3)$, as the technique used in this case is essentially the same as the technique used to prove the general case.

**Example 3.1.2: Differentiating $x^3$**

Find $\frac{d}{dx}\left(x^3\right)$.

**Solution**

$$\begin{aligned}
\frac{d}{dx}\left(x^3\right) &= \lim_{h\to 0}\frac{(x+h)^3 - x^3}{h} \\
&= \lim_{h\to 0}\frac{x^3 + 3x^2h + 3xh^2 + h^3 - x^3}{h} && \text{(distributing)} \\
&= \lim_{h\to 0}\frac{3x^2h + 3xh^2 + h^3}{h} && \text{(combining like terms)} \\
&= \lim_{h\to 0}\frac{h(3x^2 + 3xh + h^2)}{h} && \text{(factoring)} \\
&= \lim_{h\to 0}\frac{\cancel{h}(3x^2 + 3xh + h^2)}{\cancel{h}^1} && \text{(canceling like factors)} \\
&= \lim_{h\to 0}(3x^2 + 3xh + h^2) \\
&\overset{\text{D.S.}}{=} 3x^2
\end{aligned}$$

**Checkpoint 3.1.2**

Find $\frac{d}{dx}\left(x^4\right)$.

**Answer**

$\frac{d}{dx}\left(x^4\right) = 4x^3$

As we shall see, the procedure for finding the derivative of the general form $f(x) = x^n$ is very similar. Although it is often unwise to draw general conclusions from specific examples, we note that when we differentiate $f(x) = x^3$, the derivative becomes the product of the original power and $x$ to a power one less than it was before. A lot of students think of it as follows:

> When you take the derivative of $x^n$, you move the power to the front and subtract **1** from the exponent.

The following theorem states that the **Power Rule** holds for all positive integer powers of $x$.

**Theorem: The Power Rule (positive integer exponents only)**

Let $n$ be a positive integer. If $f(x) = x^n$, then

$$f'(x) = nx^{n-1}.$$

Alternatively, we may express this rule as

$$\frac{d}{dx}(x^n) = nx^{n-1}.$$

**Proof**

For $f(x) = x^n$ where $n$ is a positive integer, we have

$$f'(x) = \lim_{h\to 0} \frac{(x+h)^n - x^n}{h}.$$

Since

$$(x+h)^n = x^n + nx^{n-1}h + \binom{n}{2}x^{n-2}h^2 + \binom{n}{3}x^{n-3}h^3 + \ldots + nxh^{n-1} + h^n,$$

we see that

$$(x+h)^n - x^n = nx^{n-1}h + \binom{n}{2}x^{n-2}h^2 + \binom{n}{3}x^{n-3}h^3 + \ldots + nxh^{n-1} + h^n.$$

Next, divide both sides by h:

$$\frac{(x+h)^n - x^n}{h} = \frac{nx^{n-1}h + \binom{n}{2}x^{n-2}h^2 + \binom{n}{3}x^{n-3}h^3 + \ldots + nxh^{n-1} + h^n}{h}.$$

Thus,

$$\frac{(x+h)^n - x^n}{h} = nx^{n-1} + \binom{n}{2}x^{n-2}h + \binom{n}{3}x^{n-3}h^2 + \ldots + nxh^{n-2} + h^{n-1}.$$

Finally,

$$\begin{aligned} f'(x) &= \lim_{h\to 0}\left(nx^{n-1} + \binom{n}{2}x^{n-2}h + \binom{n}{3}x^{n-3}h^2 + \ldots + nxh^{n-2} + h^{n-1}\right) \\ &= nx^{n-1}. \end{aligned}$$

*Q.E.D.*

**Example 3.1.3: Applying the Power Rule**

Find the derivative of the function $f(x) = x^{10}$ by applying the Power Rule.

**Solution**

Using the Power Rule with $n = 10$, we obtain

$$f'(x) = 10x^{10-1} = 10x^9.$$

**Checkpoint 3.1.3**

Find the derivative of $f(x) = x^7$.

**Answer**

$f'(x) = 7x^6$

This theorem holds for *all* powers (not just positive integers). Despite being unable to prove it at this point in the course, we allow ourselves the luxury of using it.

**Theorem: The Power Rule (General Version)**

Let $n \in \mathbb{R}$. If $f(x) = x^n$,then

$$\frac{d}{dx}(x^n) = nx^{n-1}.$$

**Caution**

As a reminder, we have yet to prove the previous theorem. We are allowing ourselves the ability to use it for now. Still, I promise this fact will be proved rigorously when we have better mathematical "technology."

**Example 3.1.4: Using the Extended Power Rule**

Find $\frac{d}{dx}(x^{-4})$.

**Solution**

By applying the extended Power Rule with $k = -4$, we obtain

$$\frac{d}{dx}(x^{-4}) = -4x^{-4-1} = -4x^{-5}.$$

**Example 3.1.5: Using the Extended Power Rule and the Constant Multiple Rule**

Use the extended Power Rule and the Constant Multiple Rule to find $f(x) = \frac{6}{x^2}$.

**Solution**

It may seem tempting to use the Quotient Rule to find this derivative, and it would undoubtedly be correct. However, it is far easier to differentiate this function by first rewriting it as $f(x) = 6x^{-2}$.

$$\begin{aligned} f'(x) &= \frac{d}{dx}\left(\frac{6}{x^2}\right) \\ &= \frac{d}{dx}(6x^{-2}) && \text{(Laws of Exponents)} \\ &= 6\frac{d}{dx}(x^{-2}) && \text{(Constant Multiple Rule)} \\ &= 6(-2x^{-3}) && \text{(Power Rule)} \\ &= -12x^{-3} && \text{(simplifying)} \end{aligned}$$

**Checkpoint 3.1.5**

Find the derivative of $g(x) = \frac{1}{x^7}$ using the extended Power Rule.

**Answer**

$g'(x) = -7x^{-8}$.

**Example 3.1.6: Applying the General Power Rule**

Differentiate each of the following functions.

a. $f(x) = \frac{1}{x^{18}}$
b. $g(x) = \sqrt[5]{x^3}$

**Solutions**

a. Following the Mathematical Mantra, we handle any Algebra before performing Calculus. This function can be rewritten as $f(x) = x^{-18}$. Applying the General Power Rule, we get

$$\frac{d}{dx}[f(x)] = -18x^{-18-1} = -18x^{-19}$$

b. Again, following the Mathematical Mantra, we simplify this function first.

$$\frac{d}{dx}\left(\sqrt[5]{x^3}\right) = \frac{d}{dx}\left(x^{3/5}\right) = \frac{3}{5}x^{3/5-1} = \frac{3}{5}x^{-2/5}$$

Before stepping into the next subsection, a critical warning needs to be issued.

**Caution**

The Power Rule only applies to algebraic functions of the form $y = x^n$. It does not apply to functions that raise a constant to a variable power, such as $f(x) = 3^x$. That is,

$$\frac{d}{dx}(3^x) \neq x3^{x-1}.$$

## The Sum, Difference, and Constant Multiple Rules

We find our next differentiation rules by looking at derivatives of sums, differences, and constant multiples of functions. Just as when we work with functions, there are rules that make it easier to find derivatives of functions that we add, subtract, or multiply by a constant. These rules are summarized in the following theorem.

**Theorem: Sum, Difference, and Constant Multiple Rules**

Let $f(x)$ and $g(x)$ be differentiable functions and $k$ be a constant. Then, each of the following equations holds.

**Sum Rule**. The derivative of the sum of a function $f$ and a function $g$ is the same as the sum of the derivative of $f$ and the derivative of $g$.

$$\frac{d}{dx}\big(f(x) + g(x)\big) = \frac{d}{dx}\big(f(x)\big) + \frac{d}{dx}\big(g(x)\big);$$

that is,

$$\text{for } s(x) = f(x) + g(x), \quad s'(x) = f'(x) + g'(x).$$

**Difference Rule**. The derivative of the difference of a function $f$ and a function $g$ is the same as the difference of the derivative of $f$ and the derivative of $g$ :

$$\frac{d}{dx}(f(x)-g(x))=\frac{d}{dx}(f(x))-\frac{d}{dx}(g(x));$$

that is,

$$\text{for } d(x)=f(x)-g(x), \quad d'(x)=f'(x)-g'(x).$$

**Constant Multiple Rule.** The derivative of a constant $k$ multiplied by a function $f$ is the same as the constant multiplied by the derivative:

$$\frac{d}{dx}\big(kf(x)\big)=k\frac{d}{dx}\big(f(x)\big);$$

that is,

$$\text{for } m(x)=kf(x), \quad m'(x)=kf'(x).$$

**Proof**

We provide only the proof of the Sum Rule here. The rest follow similarly.

For differentiable functions $f(x)$ and $g(x)$, we set $s(x)=f(x)+g(x)$. Using the limit definition of the derivative we have

$$s'(x)=\lim_{h\to 0}\frac{s(x+h)-s(x)}{h}.$$

By substituting $s(x+h)=f(x+h)+g(x+h)$ and $s(x)=f(x)+g(x)$, we obtain

$$s'(x)=\lim_{h\to 0}\frac{\big(f(x+h)+g(x+h)\big)-\big(f(x)+g(x)\big)}{h}.$$

Rearranging and regrouping the terms, we have

$$s'(x)=\lim_{h\to 0}\left(\frac{f(x+h)-f(x)}{h}+\frac{g(x+h)-g(x)}{h}\right).$$

We now apply the Sum Law for limits and the definition of the derivative to obtain

$$s'(x)=\lim_{h\to 0}\frac{f(x+h)-f(x)}{h}+\lim_{h\to 0}\frac{g(x+h)-g(x)}{h}=f'(x)+g'(x).$$

*Q.E.D.*

### Example 3.1.7: Applying the Constant Multiple Rule

Find the derivative of $g(x)=3x^2$ and compare it to the derivative of $f(x)=x^2$.

**Solution**

We use the Power Rule directly:

$$g'(x)=\frac{d}{dx}(3x^2)=3\frac{d}{dx}(x^2)=3(2x)=6x.$$

Since $f(x)=x^2$ has derivative $f'(x)=2x$, we see that the derivative of $g(x)$ is 3 times the derivative of $f(x)$. This relationship is illustrated in Figure 3.1.1.

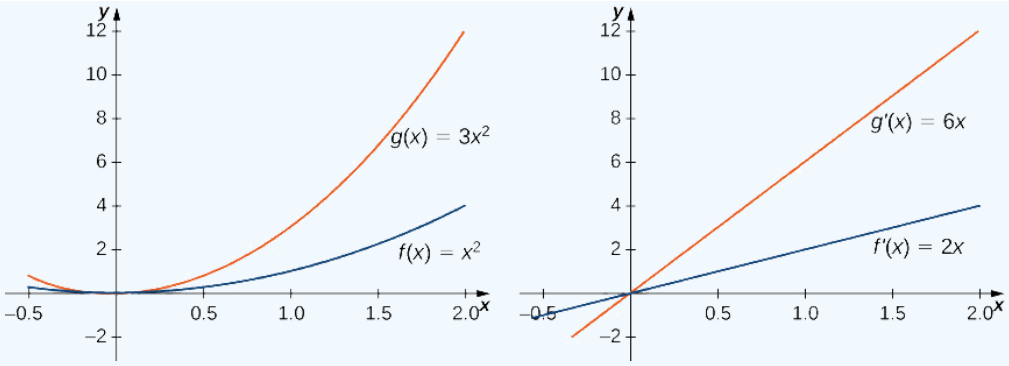

*Figure* **3.1.1***: The derivative of* $g(x)$ *is 3 times the derivative of* $f(x)$.

### ✔ Example 3.1.8: Applying Basic Derivative Rules

Find the derivative of $f(x) = 2x^5 + 7$.

**Solution**

We begin by applying the rule for differentiating the sum of two functions, followed by the rules for differentiating constant multiples of functions and the rule for differentiating powers. To better understand the sequence in which the differentiation rules are applied, we use Leibniz notation throughout the solution:

$$\begin{aligned} f'(x) &= \frac{d}{dx}\left(2x^5 + 7\right) \\ &= \frac{d}{dx}(2x^5) + \frac{d}{dx}(7) && \text{(Sum Rule)} \\ &= 2\frac{d}{dx}(x^5) + \frac{d}{dx}(7) && \text{(Constant Multiple Rule)} \\ &= 2(5x^4) + 0 && \text{(Power and Constant Rules)} \\ &= 10x^4 && \text{(simplifying)} \end{aligned}$$

### ? Checkpoint 3.1.8

Find the derivative of $f(x) = 2x^3 - 6x^2 + 3$.

**Answer**

$f'(x) = 6x^2 - 12x$.

The following example illustrates that we can use several rules within a single problem. It also emphasizes the need to pay attention to the Mathematical Mantra.

### ✔ Example 3.1.9

Compute the derivative of $g(x) = x^2 + \frac{3x^3 - 4x + \sqrt{x}}{x} + x\left(x^2 - 1\right)^2$.

**Solution**

$$\begin{aligned}\frac{d}{dx}\left(x^2+\frac{3x^3-4x+\sqrt{x}}{x}+x\left(x^2-1\right)^2\right) &= \frac{d}{dx}\left(x^2+3x^2-4+\frac{1}{\sqrt{x}}+x\left(x^4-2x^2+1\right)\right)\\ &= \frac{d}{dx}\left(x^2+3x^2-4+\frac{1}{\sqrt{x}}+x^5-2x^3+x\right)\\ &= \frac{d}{dx}\left(x^5-2x^3+4x^2+x+x^{-1/2}-4\right)\\ &= 5x^4-6x^2+8x+1-\frac{1}{2}x^{-3/2}\end{aligned}$$

## Synthesis Topic: Tangent Lines and Their Equations

### Example 3.1.10: Finding the Equation of a Tangent Line

Find the equation of the line tangent to the graph of $f(x)=x^2-4x+6$ at $x=1$.

**Solution**

To find the equation of the tangent line, we need a point and a slope. To find the point, compute

$$f(1)=1^2-4(1)+6=3.$$

This gives us the point $(1,3)$. Since the slope of the tangent line at 1 is $f'(1)$, we must first find $f'(x)$. Using the definition of a derivative, we have

$$f'(x)=2x-4$$

so the slope of the tangent line is $f'(1)=-2$. Using the point-slope formula, we see that the equation of the tangent line is

$$y-3=-2(x-1).$$

Putting the equation of the line in slope-intercept form, we obtain

$$y=-2x+5.$$

### Checkpoint 3.1.10

Find the equation of the line tangent to the graph of $f(x)=3x^2-11$ at $x=2$. Use the point-slope form.

**Answer**

$y=12x-23$

### Example 3.1.11: Determining Where a Function Has a Horizontal Tangent

Find the $x$-value(s) where the graph of $f(x)=2x^3+6x^2-90x+21$ has horizontal tangents.

**Solution**

To find the values of $x$ for which $f(x)$ has a horizontal tangent line, we must solve $f'(x)=0$.

$$\begin{aligned}f'(x) &= 6x^2+12x-90\\ &= 6\left(x^2+2x-15\right)\\ &= 6(x-3)(x+5)\end{aligned}$$

Hence, $f$ has horizontal tangent lines at $x = 3$ and $x = -5$.

**Checkpoint 3.1.11**

Find the values of $x$ for which the line tangent to the graph of $f(x) = 4x^2 - 3x + 2$ has a tangent line parallel to the line $y = 2x + 3$.

**Answer**

$\frac{5}{8}$

**Example 3.1.12**

For what values $a$ and $b$ is the line $4x + y = b$ tangent to the curve $y = ax^2$ when $x = -4$?

**Solution**

Careful reading is important in Calculus. We know that, for some special values of $a$ and $b$, the line $4x + y = b$ will be tangent to $y = ax^2$ at $x = -4$. This fact implies **two** important pieces of information:

1. the slope of the line and the slope of the tangent line to the quadratic function will match at $x = -4$, and
2. the line and the parabola will share a common point at $x = -4$.

**Matching Slopes**

To find the slope of the line, we place it in slope-intercept form.

$$y = -4x + b$$

Thus, the slope of the line is $-4$.To find the slope of the tangent line to $y = ax^2$, we first compute the derivative.

$$y' = 2ax$$

Evaluating this at $x = -4$, we get

$$y'(-4) = -8a.$$

Since the slope of the tangent line to the quadratic and the slope of the line are supposed to match at $x = -4$,

$$-4 = -8a \implies a = \frac{1}{2}.$$

**Common Point**

Since the line and the quadratic meet at $x = -4$, their $y$-values will be the same. That is, at $x = -4$, $-4x + b = ax^2$. Therefore,

$$\begin{aligned} -4(-4) + b &= a(-4)^2 \implies 16 + b = \frac{1}{2}(16) \\ &\implies 16 + b = 8 \\ &\implies b = -8 \end{aligned}$$

Thus, for the line and quadratic to meet and be tangent at $x = -4$, we require $a = \frac{1}{2}$ and $b = -8$.

## Applications of Differentiation: Physics

As we have mentioned previously, if $s(t)$ is the position of a particle at time $t$, then its velocity is

$$v(t) = \frac{ds}{dt}$$

and its acceleration is

$$a(t) = \frac{dv}{dt} = \frac{ds^2}{dt^2}.$$

**Example 3.1.13: Ballistic Motion**

A rocket is fired vertically upward. Its height in meters above the ground $t$ seconds after launch is given by

$$h(t) = -4.9t^2 + 154t + 388.$$

a. How high was the rocket when it was launched?
b. How high is the rocket after 6 seconds?
c. What is the velocity of the rocket after 6 seconds?
d. What is the acceleration of the rocket after 6 seconds?

**Solutions**

a. The initial height is given by $h(0) = 388$. Therefore, the initial height of the rocket is $388$ meters.
b. $h(6) = 1,135.6$. Therefore, the height of the rocket $6$ seconds after launch is $1,135.6$ meters.
c. To compute the velocity, we need to find the derivative of $h(t)$.

$$v(t) = h'(t) = -9.8t + 154$$

Evaluating $h'$ at $6$, we get

$$v(6) = h'(6) = -9.8(6) + 154 = 95.2.$$

This means that the velocity of the rocket exactly $6$ seconds after launch is $95.2$ meters per second. Since this velocity is positive, the rocket is still climbing upward.

d. To compute the acceleration, we need to find the derivative of the velocity.

$$a(t) = v'(t) = -9.8$$

Hence, the acceleration is *always* $-9.8$ meters per second squared. That is, the rocket is *decelerating*at 9.8 meters per second squared the entire time. While this idea of "slowing down" makes sense on the rise, how can we make sense of it as the rocket begins to fall? Well, the negative acceleration implies the rocket's velocity is decreasing as the rocket rises. At some point, the velocity would have to hit $0$. At that moment, the rocket begins its descent back to Earth. The velocity becomes negative as the distance between the rocket and the Earth decreases, and the rate of this descent increases (in the negative direction) until the rocket crashes into the ground. The negative acceleration acted to slow the ascent and speed the descent.

## Applications of Differentiation: Business

Most individuals taking this course are moving into a STEM field - not business; however, it is always nice to know what the news channels imply when they mention revenue, cost, profit, marginal cost, etc. To simplify the conversation, I have decided to forgo any lengthy discussion and jump right to the point.

- Revenue is the product of the price of the item and the number of items sold. Mathematically, $R(n) = p(n) \cdot n$, where $p(n)$ is the price-demand function (the price the company charges when the market demands $n$ items) and $n$ is the number of items sold.
- Profit is the difference between the revenue from sales and the cost of producing an item. Mathematically, $P(n) = R(n) - C(n)$, where $R(n)$ is the revenue function and $C(n)$ is the cost function.
- Marginal cost is the change in the total cost that arises when the quantity produced is incremented. That is, it is the change in cost with respect to the number of items produced. Mathematically, $M_C(n) = \frac{dC}{dn}$, where $C(n)$ is the cost function (i.e., the cost of producing $n$ items).
- Marginal profit is the change in the total profit that arises when the quantity produced is incremented. That is, it is the change in profit with respect to the number of items produced. Mathematically, $M_P(n) = \frac{dP}{dn}$, where $P(n)$ is the profit function.

- Marginal revenue is the change in the total revenue that arises when the quantity produced is incremented. That is, it is the change in revenue with respect to the number of items produced. Mathematically, $M_R(n) = \frac{dR}{dn}$, where $R(n)$ is the revenue function.

Thus, when you hear "marginal [insert business phrasing here]," it means that you need to take the derivative of that "business phrasing." The result will represent the cost, profit, revenue, etcetera associated with one additional item being produced.

### Example 3.1.14

Suppose a product's revenue function is given by $R(q) = -2q^2 + 800q$ , where $R(q)$ is in dollars and $q$ is units sold. Also, its cost function is given by $C(q) = 153q + 40,000$, where $C$ is in dollars and $q$ is units produced. Find an expression for the item's marginal profit function ($MP(q)$) and use it to determine and interpret $MP(220)$.

**Solution**

Marginal profit is the derivative of the profit function, which they did not *explicitly* hand us; however, we know that profit is revenue minus cost. Thus,

$$P(q) = R(q) - C(q) = -2q^2 + 800q - (153q + 40,000) = -2q^2 + 647q - 40,000.$$

Therefore, the marginal profit function is

$$MP(q) = P'(q) = -4q + 647.$$

Hence,

$$MP(220) = -233.$$

This means that if the company produces and sells 220 units, its profit will drop by \$233 if it sells another unit. This is usually tough for students to understand at first, so let's take a moment to dive a little deeper. The derivative, $\frac{dP}{dq}$, is the rate of change of profit with respect to the number of units produced (and sold). Since $\frac{dP}{dq}(220) = -233 = \frac{-233}{1}$, we can interpret this as *losing* \$233 in profit per 1 unit produced and sold when we have produced and sold *exactly* 220 units.

It's important to note that marginal profit is *not* the profit. In fact, the profit if the company produces and sells 220 units is $P(220) = 5540$. That is, the company is *still* making a profit of \$5,540 at that moment, but producing more units will eat into those profits.

## Your Turn

### Formula One Grandstands

Formula One car races can be exhilarating to watch and attract a lot of spectators. Formula One track designers must ensure sufficient grandstand space around the track to accommodate these viewers. However, car racing can be dangerous, and safety considerations are paramount. The grandstands must be placed where spectators will not be in danger should a driver lose control of a car (Figure **3.1.2**).

Figure **3.1.2**: The grandstand next to a straightaway of the Circuit de Barcelona-Catalunya race track, where the spectators are not in danger.

Safety is especially a concern on turns. If a driver does not slow down enough before entering the turn, the car may slide off the racetrack. Normally, this results in a wider turn, which slows the driver down. But if the driver loses control completely, the car may fly off the track entirely, on a path tangent to the curve of the racetrack.

Suppose you are designing a new Formula One track. One section of the track can be modeled by the function $f(x) = x^3 + 3x^2 + x$ (Figure **3.1.3**). The current plan calls for grandstands to be built along the first straightaway and around a portion of the first curve. The plans call for the front corner of the grandstand to be located at the point $(-1.9, 2.8)$. We want to determine whether this location puts the spectators in danger if a driver loses control of the car.

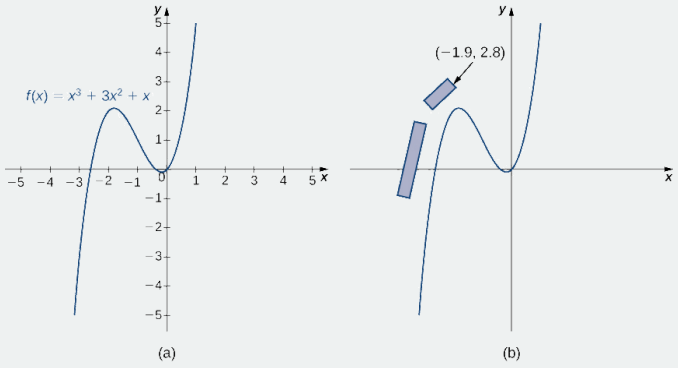

*Figure* **3.1.3***a: One section of the racetrack can be modeled by the function* $f(x) = x^3 + 3x^2 + x$.
*Figure* **3.1.3***b: The front corner of the grandstand is located at* $(-1.9, 2.8)$.

a. Physicists have determined that drivers are most likely to lose control of their cars as they are coming into a turn at the point where the slope of the tangent line is 1. Find the $(x, y)$ coordinates of this point near the turn.
b. Find the equation of the tangent line to the curve at this point.
c. To determine whether the spectators are in danger in this scenario, find the $x$-coordinate of the point where the tangent line crosses the line $y = 2.8$. Is this point safely to the right of the grandstand? Or are the spectators in danger?
d. What if a driver loses control earlier than the physicists project? Suppose a driver loses control at the point $(-2.5, 0.625)$. What is the slope of the tangent line at this point?
e. If a driver loses control as described in part d, are the spectators safe?
f. Should you proceed with the current design for the grandstand, or should the grandstands be moved?

# 3.1E: EXERCISES

This page is a draft and is under active development.

## READING QUESTIONS

1. What is the derivative of a constant function, $f(x) = c$?
2. State the Power Rule for differentiating $f(x) = x^n$. Does this rule apply only to positive integer exponents $n$, or is it more general?
3. What is the derivative of $f(x) = x^5$?
4. What is the derivative of $g(x) = \frac{1}{x^3}$ using the Power Rule?
5. State the Sum Rule for derivatives. If you know the derivatives of $f(x)$ and $g(x)$, how do you find the derivative of $f(x) + g(x)$?
6. State the Difference Rule for derivatives.
7. State the Constant Multiple Rule. If you know the derivative of $f(x)$, how do you find the derivative of $k \cdot f(x)$, where $k$ is a constant?
8. How would you find the derivative of $f(x) = 3x^4 - 7x^2 + 2x - 5$? Which rules would you apply?
9. If a function has a horizontal tangent line at a point, what is the value of its derivative at that point?
10. In business applications, what does "marginal cost" (or "marginal profit," "marginal revenue") generally refer to in terms of Calculus?
11. If $s(t)$ is the position of a particle at time $t$, what do $v(t) = s'(t)$ and $a(t) = v'(t) = s''(t)$ represent?

## HOMEWORK

**In exercises 1 - 10, find $f'(x)$ for each function.**

1) $f(x) = x^7 + 10$

2) $f(x) = 5x^3 - x + 1$

**Answer**

$f'(x) = 15x^2 - 1$

3) $f(x) = 4x^2 - 7x$

4) $f(x) = 8x^4 + 9x^2 - 1$

**Answer**

$f'(x) = 32x^3 + 18x$

5) $f(x) = x^4 + 2x$

7) $f(x) = (x + 2)(2x^2 - 3)$

8) $f(x) = x^2\left(\frac{2}{x^2} + \frac{5}{x^3}\right)$

**Answer**

$f'(x) = \frac{-5}{x^2}$

9) $f(x) = \frac{x^3+2x^2-4}{3}$

10) $f(x) = \frac{4x^3-2x+1}{x^2}$

**Answer**

$f'(x) = \dfrac{4x^4 + 2x^2 - 2x}{x^4}$

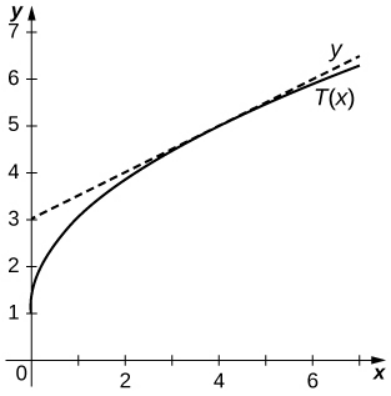
**[Technology Required] In exercises 11 - 13, find the equation of the tangent line $T(x)$ to the graph of the given function at the indicated point. Use graphing technology to graph the function and the tangent line.**

11) $y = 3x^2 + 4x + 1$ at $(0, 1)$

12) $y = 2\sqrt{x} + 1$ at $(4, 5)$

**Answer**

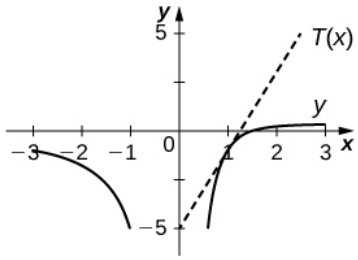
$T(x) = \frac{1}{2}x + 3$



13) $y = \frac{2}{x} - \frac{3}{x^2}$ at $(1, -1)$

**Answer**

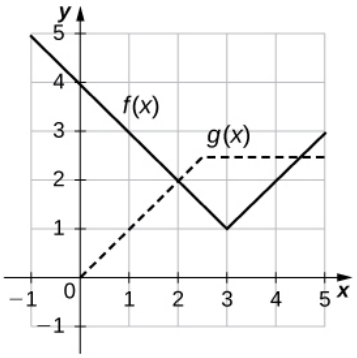
$T(x) = 4x - 5$



**In exercise 14, assume that $f(x)$ and $g(x)$ are both differentiable functions for all $x$. Find the derivative of the function $h(x)$.**

14) $h(x) = 4f(x) + \frac{g(x)}{7}$

**In exercise 15, use the following figure to find the indicated derivatives, if they exist.**



15) Let $h(x) = f(x) + g(x)$. Find

a) $h'(1)$,

b) $h'(3)$, and

c) $h'(4)$.

**[Technology Required] In exercises 16 - 19,**

**a) evaluate $f'(a)$, and**

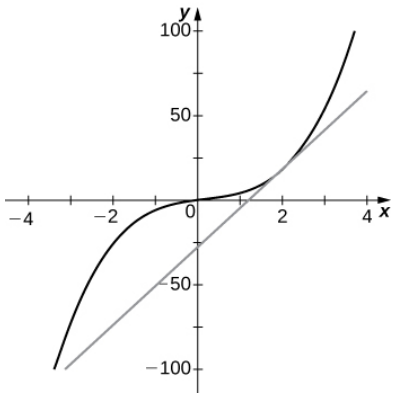
**b) graph the function $f(x)$ and the tangent line at $x = a$.**

16) $f(x) = 2x^3 + 3x - x^2, \quad a = 2$

**Answer**

a. 23

b. $y = 23x - 28$



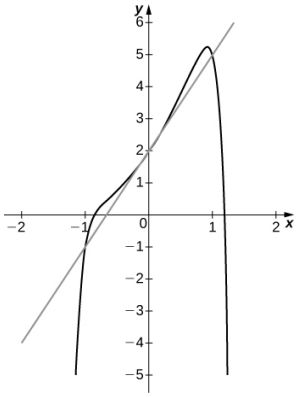
17) $f(x) = \frac{1}{x} - x^2, \quad a = 1$

18) $f(x) = x^2 - x^{12} + 3x + 2, \quad a = 0$

**Answer**

a. $3$

b. $y = 3x + 2$



19) $f(x) = \frac{1}{x} - x^{2/3}, \quad a = -1$

**In exercises 20 - 22, find the equation of the tangent line to the graph of the function at the given point.**

20) $f(x) = 2x^3 + 4x^2 - 5x - 3$ at $x = -1$.

**Answer**

$y = -7x - 3$

21) $f(x) = x^2 + \frac{4}{x} - 10$ at $x = 8$.

22) $f(x) = (3x - x^2)(3 - x - x^2)$ at $x = 1$.

**Answer**

$y = -5x + 7$

23) Find the point on the graph of $f(x) = x^3$ such that the tangent line at that point has an $x$-intercept of $(6, 0)$.

24) Determine all points on the graph of $f(x) = x^3 + x^2 - x - 1$ for which the slope of the tangent line is

a. horizontal

b. $-1$.

25) Find a quadratic polynomial such that $f(1) = 5,\ f'(1) = 3$ and $f''(1) = -6$.

**Answer**

$y = -3x^2 + 9x - 1$

## APPLICATIONS OF THE DERIVATIVE: PHYSICS

NOTE

- Velocity is the change in position with respect to time. That is, $v(t) = \frac{ds}{dt}$, where $s(t)$ is the position function.
- Acceleration is the change in velocity with respect to time. That is, $a(t) = \frac{dv}{dt} = \frac{ds^2}{dt^2}$.

**In exercises 26 - 27, the given functions represent the position of a particle traveling along a horizontal line.**

**a. Find the velocity and acceleration functions.**

**b. Determine the time intervals when the object is slowing down or speeding up.**

26) $s(t) = 2t^3 - 3t^2 - 12t + 8$

27) $s(t) = 2t^3 - 15t^2 + 36t - 10$

**Answer**

a. $v(t) = 6t^2 - 30t + 36, \quad a(t) = 12t - 30$;
b. speeds up for $(2, 2.5) \cup (3, \infty)$, slows down for $(0, 2) \cup (2.5, 3)$

28) A rocket is fired vertically upward from the ground. The distance $s$ in feet that the rocket travels from the ground after $t$ seconds is given by $s(t) = -16t^2 + 560t$.

a. Find the velocity of the rocket 3 seconds after being fired.

b. Find the acceleration of the rocket 3 seconds after being fired.

29) A ball is thrown downward with a speed of 8 ft/s from the top of a 64-foot-tall building. After $t$ seconds, its height above the ground is given by $s(t) = -16t^2 - 8t + 64$.

a. Determine how long it takes for the ball to hit the ground.

b. Determine the velocity of the ball when it hits the ground.

30) The position function $s(t) = t^2 - 3t - 4$ represents the position of the back of a car backing out of a driveway and then driving in a straight line, where $s$ is in feet and $t$ is in seconds. In this case, $s(t) = 0$ represents the time at which the back of the car is at the garage door, so $s(0) = -4$ is the starting position of the car, 4 feet inside the garage.

a. Determine the velocity of the car when $s(t) = 0$.

b. Determine the velocity of the car when $s(t) = 14$.

31) The position of a hummingbird flying along a straight line in $t$ seconds is given by $s(t) = 3t^3 - 7t$ meters.

a. Determine the velocity of the bird at $t = 1$ sec.

b. Determine the acceleration of the bird at $t = 1$ sec.

c. Determine the acceleration of the bird when the velocity equals 0.

32) A potato is launched vertically upward with an initial velocity of 100 ft/s from a potato gun at the top of an 85-foot-tall building. The distance in feet that the potato travels from the ground after $t$ seconds is given by $s(t) = -16t^2 + 100t + 85$.

a. Find the velocity of the potato after $0.5$ s and $5.75$ s.

b. Find the speed of the potato at $0.5$ s and $5.75$ s.

c. Determine when the potato reaches its maximum height.

d. Find the acceleration of the potato at $0.5$ s and $1.5$ s.

e. Determine how long the potato is in the air.

f. Determine the velocity of the potato upon hitting the ground.

**Answer**

a. 84 ft/s, −84 ft/s
b. 84 ft/s
c. $\frac{25}{8}$ s
d. $-32\ \text{ft/s}^2$ in both cases

e. $\frac{1}{8}(25+\sqrt{965})$ s

f. $-4\sqrt{965}$ ft/s

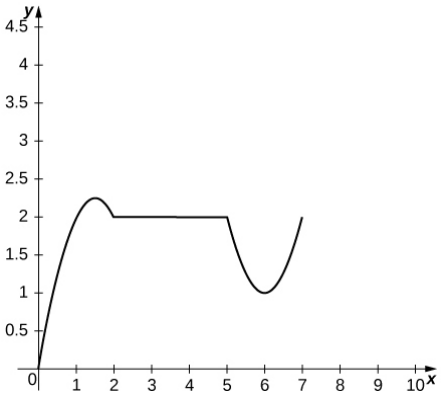
33) The position function $s(t)=t^3-8t$ gives the position in miles of a freight train where east is the positive direction and $t$ is measured in hours.

a. Determine the direction the train is traveling when $s(t)=0$.

b. Determine the direction the train is traveling when $a(t)=0$.

c. Determine the time intervals when the train is slowing down or speeding up.

34) The following graph shows the position $y=s(t)$ of an object moving along a straight line.



a. Use the graph of the position function to determine the time intervals when the velocity is positive, negative, or zero.

b. Sketch the graph of the velocity function.

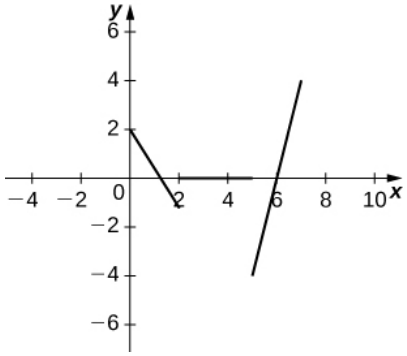
c. Use the graph of the velocity function to determine the time intervals when the acceleration is positive, negative, or zero.

d. Determine the time intervals when the object is speeding up or slowing down.

**Answer**

a. Velocity is positive on $(0,1.5)\cup(6,7)$, negative on $(1.5,2)\cup(5,6)$, and zero on $(2,5)$.

b.



c. Acceleration is positive on $(5,7)$, negative on $(0,2)$, and zero on $(2,5)$.

d. The object is speeding up on $(6,7)\cup(1.5,2)$ and slowing down on $(0,1.5)\cup(5,6)$.

35) A car driving along a freeway with traffic has traveled $s(t)=t^3-6t^2+9t$ meters in $t$ seconds.

a. Determine the time in seconds when the velocity of the car is 0.

b. Determine the acceleration of the car when the velocity is 0.

36) [Technology Required] According to Newton's law of universal gravitation, the force $F$ between two bodies of constant mass $m_1$ and $m_2$ is given by the formula $F=\frac{Gm_1m_2}{d^2}$, where $G$ is the gravitational constant and $d$ is the distance between the bodies.

a. Suppose that $G, m_1$, and $m_2$ are constants. Find the rate of change of force $F$ with respect to distance $d$.

b. Find the rate of change of force $F$ with gravitational constant $G = 6.67 \times 10^{-11} \text{Nm}^2/\text{kg}^2$, on two bodies 10 meters apart, each with a mass of 1000 kilograms.

**Answer**

a. $F'(d) = \dfrac{-2Gm_1m_2}{d_3}$

b. $-1.33 \times 10^{-7}$ N/m

37) The centripetal force of an object of mass m is given by $F(r) = \frac{mv^2}{r}$, where $v$ is the speed of rotation and $r$ is the distance from the center of rotation.

a. Find the rate of change of centripetal force with respect to the distance from the center of rotation.

b. Find the rate of change of centripetal force of an object with mass 1000 kilograms, velocity of 13.89 m/s, and a distance from the center of rotation of 200 meters.

38) [Technology Required] Consider an astronaut on a large planet in another galaxy. To learn more about the composition of this planet, the astronaut drops an electronic sensor into a deep trench. The sensor transmits its vertical position every second in relation to the astronaut's position. The summary of the falling sensor data is displayed in the following table.

| Time after dropping (s) | Position (m) |
|---|---|
| 0 | 0 |
| 1 | −1 |
| 2 | −2 |
| 3 | −5 |
| 4 | −7 |
| 5 | −14 |

a. Using a calculator or computer program, find the best-fit quadratic curve to the data.

b. Find the derivative of the position function and explain its physical meaning.

c. Find the second derivative of the position function and explain its physical meaning.

**Answer**

a. $p(t) = -0.6071x^2 + 0.4357x - 0.3571$

b. $p'(t) = -1.214x + 0.4357$. This is the velocity of the sensor.

c. $p''(t) = -1.214$. This is the acceleration of the sensor; it is a constant acceleration downward.

## APPLICATIONS OF THE DERIVATIVE: BUSINESS

NOTE

- Revenue is the product of the price of the item and the number of items sold. Mathematically, $R(n) = p(n) \cdot n$, where $p(n)$ is the price-demand function (the price the company charges when the market demands $n$ items) and $n$ is the number of items sold.
- Profit is the difference between the revenue from sales and the cost of producing an item. Mathematically, $P(n) = R(n) - C(n)$, where $R(n)$ is the revenue function and $C(n)$ is the cost function.
- Marginal cost is the change in the total cost that arises when the quantity produced is incremented. That is, it is the change in cost with respect to the number of items produced. Mathematically, $M_C(n) = \frac{dC}{dn}$, where $C(n)$ is the cost function (i.e., the cost of producing $n$ items).
- Marginal profit is the change in the total profit that arises when the quantity produced is incremented. That is, it is the change in profit with respect to the number of items produced. Mathematically, $M_P(n) = \frac{dP}{dn}$, where $P(n)$ is the profit function.
- Marginal revenue is the change in the total revenue that arises when the quantity produced is incremented. That is, it is the change in revenue with respect to the number of items produced. Mathematically, $M_R(n) = \frac{dR}{dn}$, where $R(n)$ is the revenue function.

39) A book publisher has a cost function given by $C(x) = \frac{x^3+2x+3}{x^2}$, where $x$ is the number of copies of a book in thousands and $C$ is the cost, per book, measured in dollars. Evaluate $C'(2)$ and explain its meaning.

40) The cost function, in dollars, of a company that manufactures food processors is given by $C(x) = 200 + \frac{7}{x} + \frac{x}{27}$, where $x$ is the number of food processors manufactured.

a. Find the marginal cost function.

b. Find the marginal cost of manufacturing 12 food processors.

c. Find the actual cost of manufacturing the thirteenth food processor.

41) The price p (in dollars) and the demand $x$ for a certain digital clock radio is given by the price–demand function $p = 10 - 0.001x$.

a. Find the revenue function $R(x)$

b. Find the marginal revenue function.

c. Find the marginal revenue at $x = 2000$ and $5000$.

**Answer**

a. $R(x) = 10x - 0.001x^2$
b. $R'(x) = 10 - 0.002x$
c. \$6 per item, \$0 per item

42) [Technology Required] A profit is earned when revenue exceeds cost. Suppose the profit function for a skateboard manufacturer is given by $P(x) = 30x - 0.3x^2 - 250$, where $x$ is the number of skateboards sold.

a. Find the exact profit from the sale of the thirtieth skateboard.

b. Find the marginal profit function and use it to estimate the profit from the sale of the thirtieth skateboard.

43) [Technology Required] In general, the profit function is the difference between the revenue and cost functions: $P(x) = R(x) - C(x)$.

Suppose the price-demand and cost functions for the production of cordless drills is given respectively by $p = 143 - 0.03x$ and $C(x) = 75,000 + 65x$, where $x$ is the number of cordless drills that are sold at a price of $p$ dollars per drill and $C(x)$ is the cost of producing $x$ cordless drills.

a. Find the marginal cost function.

b. Find the revenue and marginal revenue functions.

c. Find $R'(1000)$ and $R'(4000)$. Interpret the results.

d. Find the profit and marginal profit functions.

e. Find $P'(1000)$ and $P'(4000)$. Interpret the results.

**Answer**

a. $C'(x) = 65$
b. $R(x) = 143x - 0.03x^2, R'(x) = 143 - 0.06x$
c. $R'(1000) = 83, \quad R'(4000) = -97$. At a production level of 1000 cordless drills, revenue is increasing at a rate of \$83 per drill; at a production level of 4000 cordless drills, revenue is decreasing at a rate of \$97 per drill.
d. $P(x) = -0.03x^2 + 78x - 75000, \quad P'(x) = -0.06x + 78$
e. $P'(1000) = 18, \quad P'(4000) = -162$. At a production level of 1000 cordless drills, profit is increasing at a rate of \$18 per drill; at a production level of 4000 cordless drills, profit is decreasing at a rate of \$162 per drill.

---

## APPLICATIONS OF THE DERIVATIVE: POPULATION MODELS

44) A small town in Ohio commissioned an actuarial firm to conduct a study that modeled the rate of change of the town's population. The study found that the town's population (measured in thousands of people) can be modeled by the function $P(t) = -\frac{1}{3}t^3 + 64t + 3000$, where $t$ is measured in years.

a. Find the rate of change function $P'(t)$ of the population function.

b. Find $P'(1), P'(2), P'(3)$, and $P'(4)$. Interpret what the results mean for the town.

c. Find $P''(1), P''(2), P''(3)$, and $P''(4)$. Interpret what the results mean for the town's population.

**[Technology Required] In Exercises 45 - 46, use the following table concerning the population (in millions) of London by decade in the 19th century.**

| Year Since 1800 | Population (millions) |
|---|---|
| 1 | 0.8975 |
| 11 | 1.040 |
| 21 | 1.264 |
| 31 | 1.516 |
| 41 | 1.661 |
| 51 | 2.000 |
| 61 | 2.634 |
| 71 | 3.272 |
| 81 | 3.911 |
| 91 | 4.422 |

Population of London Source: http://en.Wikipedia.org/wiki/Demographics_of_London

45)

a. Using a calculator or a computer program, find the best-fit linear function to measure the population.

b. Find the derivative of the equation in a. and explain its physical meaning.

c. Find the second derivative of the equation and explain its physical meaning.

**Answer**

a. $P(t) = 0.03983t + 0.4280$

b. $P'(t) = 0.03983$. The population is increasing.

c. $P''(t) = 0$. The rate at which the population is increasing is constant.

46)

a. Using a calculator or a computer program, find the best-fit quadratic curve through the data.

b. Find the derivative of the equation and explain its physical meaning.

c. Find the second derivative of the equation and explain its physical meaning.

# 3.2: Differentiation Techniques - The Product and Quotient Rules

**Note to the Instructor (click to expand)**

Since the students will only know how to take derivatives of polynomials and expressions with rational exponents, this is a fast section. A good chunk of your time here (other than going through examples with the class) should be spent on proving the Product Rule.

---

To succeed in this section, you'll need to use some skills from previous courses. While you should already know them, this is the first time they've been required. You can review these skills in CRC's Corequisite Codex. If you have a support class, it might cover some, **but not all**, of these topics.

**Prerequisite Skills and Support Topics (click to expand)**

- **Simplifying Expressions**
  - Simplifying Expressions Involving Negative Rational Exponents: The Product Rule often results in expressions involving negative rational exponents. As such, you must be able to simplify these expressions.
- **Factoring Techniques**
  - Factoring Expressions Involving Negative Rational Exponents: The Quotient Rule often results in ratios of expressions involving negative rational exponents. As such, you must be able to simplify these expressions.

---

The following is a list of learning objectives for this section.

**Learning Objectives (click to expand)**

- Use the Product Rule for finding the derivative of a product of functions.
- Use the Quotient Rule for finding the derivative of a quotient of functions.
- Combine the differentiation rules to find the derivative of a polynomial or rational function.

## The Product Rule

Now that we have examined the basic rules, we can look at some of the more advanced ones. The first one examines the derivative of the product of two functions. Although it might be tempting to assume that the derivative of the product is the product of the derivatives, similar to the Sum and Difference Rules, the **Product Rule** does not follow this pattern. To see why we cannot use this pattern, consider the function $f(x) = x^2$, whose derivative is $f'(x) = 2x$ and not $\frac{d}{dx}(x) \cdot \frac{d}{dx}(x) = 1 \cdot 1 = 1$.

**Theorem: The Product Rule**

Let $f(x)$ and $g(x)$ be differentiable functions. Then

$$\frac{d}{dx}(f(x)g(x)) = \frac{d}{dx}(f(x)) \cdot g(x) + \frac{d}{dx}(g(x)) \cdot f(x).$$

That is,

$$\text{if } p(x) = f(x)g(x), \quad \text{then } p'(x) = f'(x)g(x) + g'(x)f(x).$$

This means that the derivative of a product of two functions is the derivative of the first function times the second function plus the derivative of the second function times the first function.

**Proof**

We begin by assuming that $f(x)$ and $g(x)$ are differentiable functions. At a key point in this proof, we need to use the fact that since $g(x)$ is differentiable, it is also continuous. In particular, we use the fact that since $g(x)$ is continuous, $\lim_{h \to 0} g(x+h) = g(x)$.

By applying the limit definition of the derivative to $p(x) = f(x)g(x)$, we obtain

$$p'(x) = \lim_{h \to 0} \frac{f(x+h)g(x+h) - f(x)g(x)}{h}.$$

By adding and subtracting $f(x)g(x+h)$ in the numerator, we have

$$p'(x) = \lim_{h \to 0} \frac{f(x+h)g(x+h) - f(x)g(x+h) + f(x)g(x+h) - f(x)g(x)}{h}.$$

After breaking apart this quotient and applying the Sum Law for limits, the derivative becomes

$$p'(x) = \lim_{h \to 0} \frac{f(x+h)g(x+h) - f(x)g(x+h)}{h} + \lim_{h \to 0} \frac{f(x)g(x+h) - f(x)g(x)}{h}.$$

Rearranging, we obtain

$$\begin{aligned} p'(x) &= \lim_{h \to 0} \left( \frac{f(x+h) - f(x)}{h} \cdot g(x+h) \right) + \lim_{h \to 0} \left( \frac{g(x+h) - g(x)}{h} \cdot f(x) \right) \\ &= \left( \lim_{h \to 0} \frac{f(x+h) - f(x)}{h} \right) \cdot \left( \lim_{h \to 0} g(x+h) \right) + \left( \lim_{h \to 0} \frac{g(x+h) - g(x)}{h} \right) \cdot f(x) \end{aligned}$$

By using the continuity of $g(x)$, the definition of the derivatives of $f(x)$ and $g(x)$, and applying the Limit Laws, we arrive at the Product Rule,

$$p'(x) = f'(x)g(x) + g'(x)f(x).$$

*Q.E.D.*

### Example 3.2.1: Applying the Product Rule to Constant Functions

For $p(x) = f(x)g(x)$, use the Product Rule to find $p'(2)$ if $f(2) = 3$, $f'(2) = -4$, $g(2) = 1$, and $g'(2) = 6$.

**Solution**

Since $p(x) = f(x)g(x)$, $p'(x) = f'(x)g(x) + g'(x)f(x)$, and hence

$$p'(2) = f'(2)g(2) + g'(2)f(2) = (-4)(1) + (6)(3) = 14.$$

### Example 3.2.2: Applying the Product Rule to Binomials

For $p(x) = (x^2 + 2)(3x^3 - 5x)$, find $p'(x)$ by applying the Product Rule. Check the result by first finding the product and then differentiating.

**Solution**

If we set $f(x) = x^2 + 2$ and $g(x) = 3x^3 - 5x$, then $f'(x) = 2x$ and $g'(x) = 9x^2 - 5$. Thus,

$$p'(x) = f'(x)g(x) + g'(x)f(x) = (2x)(3x^3 - 5x) + (9x^2 - 5)(x^2 + 2).$$

Simplifying, we have

$$p'(x) = 15x^4 + 3x^2 - 10.$$

To check, we see that $p(x) = 3x^5 + x^3 - 10x$ and, consequently, $p'(x) = 15x^4 + 3x^2 - 10$.

**Checkpoint 3.2.2**

Use the Product Rule to obtain the derivative of $p(x) = 2x^5(4x^2 + x)$.

**Answer**

$p'(x) = 10x^4(4x^2 + x) + (8x + 1)(2x^5) = 56x^6 + 12x^5$.

Before we move on, it is important to repeat a previous warning.

**Caution: The Product Rule is NOT the Product of Derivatives!**

$$\frac{d}{dx}\left(f(x) \cdot g(x)\right) \neq \frac{d}{dx}\left(f(x)\right) \cdot \frac{d}{dx}\left(g(x)\right)$$

## The Quotient Rule

Having developed and practiced the Product Rule, we now consider differentiating quotients of functions. As we see in the following theorem, the derivative of the quotient is not the quotient of the derivatives; rather, it is the derivative of the function in the numerator times the function in the denominator minus the derivative of the function in the denominator times the function in the numerator, all divided by the square of the function in the denominator. To better grasp why we cannot simply take the quotient of the derivatives, keep in mind that

$$\frac{d}{dx}(x^2) = 2x, \text{ not } \frac{\frac{d}{dx}(x^3)}{\frac{d}{dx}(x)} = \frac{3x^2}{1} = 3x^2.$$

**Theorem: The Quotient Rule**

Let $f(x)$ and $g(x)$ be differentiable functions. Then

$$\frac{d}{dx}\left(\frac{f(x)}{g(x)}\right) = \frac{\frac{d}{dx}(f(x)) \cdot g(x) - \frac{d}{dx}(g(x)) \cdot f(x)}{\left(g(x)\right)^2}.$$

That is, if

$$q(x) = \frac{f(x)}{g(x)}$$

then

$$q'(x) = \frac{f'(x)g(x) - g'(x)f(x)}{\left(g(x)\right)^2}.$$

The proof of the Quotient Rule is very similar to the proof of the Product Rule, so it is omitted here. Instead, we apply this new rule to find derivatives in the next example.

**Example 3.2.3: Applying the Quotient Rule**

Find the derivative of each function.

a. $q(x) = \frac{5x^2}{4x+3}$
b. $s(t) = \frac{\sqrt[3]{t}}{t-5}$

**Solutions**

a. Let $f(x) = 5x^2$ and $g(x) = 4x + 3$. Thus, $f'(x) = 10x$ and $g'(x) = 4$. Substituting into the Quotient Rule, we have

$$q'(x) = \frac{f'(x)g(x) - g'(x)f(x)}{(g(x))^2} = \frac{10x(4x+3) - 4(5x^2)}{(4x+3)^2}.$$

Simplifying, we obtain

$$q'(x) = \frac{20x^2 + 30x}{(4x+3)^2}$$

b. It's best to rewrite $s$ using rational exponents, where possible.

$$s(t) = \frac{t^{1/3}}{t-5}$$

Now we can start to take the derivative of this quotient using the Quotient Rule. For reference, if we let $N(t)$ and $D(t)$ be the numerator and denominator, respectively, then

$$N(t) = t^{1/3} \quad \text{and} \quad D(t) = t - 5$$

$$N'(t) = \frac{1}{3}t^{-2/3} \quad \text{and} \quad D'(t) = 1$$

Therefore,

$$\begin{aligned}
\frac{d}{dt}(s(t)) &= \frac{d}{dt}\left(\frac{N(t)}{D(t)}\right) \\
&= \frac{N'(t)D(t) - N(t)D'(t)}{[D(t)]^2} \qquad \text{(Quotient Rule)} \\
&= \frac{\left(\frac{1}{3}t^{-2/3}\right)(t-5) - \left(t^{1/3}\right)(1)}{(t-5)^2} \\
&= \frac{(t-5) - 3t}{3t^{2/3}(t-5)^2} \\
&= \frac{-2t-5}{3t^{2/3}(t-5)^2}
\end{aligned}$$

The previous example demonstrates the need to use our prerequisite algebra skills often when using the Quotient Rule. We will commonly have to factor, simplify, and multiply by fractions equivalent to 1 when using this rule.

**? Checkpoint 3.2.3**

Find the derivative of $h(x) = \frac{3x+1}{4x-3}$.

**Answer**

$h'(x) = -\frac{13}{(4x-3)^2}$.

As with the last topic, caution is merited here.

**Caution: The Quotient Rule is NOT the Quotient of Derivatives!**

$$\frac{d}{dx}\left(\frac{N(x)}{D(x)}\right) \neq \frac{\frac{d}{dx}(N(x))}{\frac{d}{dx}(D(x))}$$

## Revisiting the Power Rule

Using the Quotient Rule to prove most of the General Power Rule is now possible. In the previous section, recall that we proved the Power Rule for *positive integers*. Still, we stated that we had to wait until later in the course to prove the Power Rule for the general case when the exponent is any real number. At this point, we can also add to our previous proof by extending the Power Rule to negative integers. This proof is provided for completeness.

**Proof**

Let $f(x) = x^k$. If $k$ is a negative integer, we may set $n = -k$, so that $n$ is a positive integer with $k = -n$. Since for each positive integer $n$,$x^{-n} = \frac{1}{x^n}$, we may now apply the Quotient Rule by setting $f(x) = 1$ and $g(x) = x^n$. In this case, $f'(x) = 0$ and $g'(x) = nx^{n-1}$. Thus,

$$\frac{d}{dx}(x^{-n}) = \frac{0(x^n) - 1(nx^{n-1})}{(x^n)^2}.$$

Simplifying, we see that

$$\begin{aligned}\frac{d}{dx}(x^{-n}) &= \frac{-nx^{n-1}}{x^{2n}} \\ &= -nx^{(n-1)-2n} \\ &= -nx^{-n-1}.\end{aligned}$$

Finally, observe that since $k = -n$, by substituting we have

$$\frac{d}{dx}(x^k) = kx^{k-1}.$$

*Q.E.D.*

## Combining Differentiation Rules

As we have seen throughout the examples in this section, it seldom happens that we are called on to apply just one differentiation rule to find the derivative of a given function. By combining the differentiation rules, we may find the derivatives of any polynomial or rational function. Later on, we will encounter more complex combinations of differentiation rules. A good rule of thumb to use when applying several rules is to apply the rules in reverse of the order in which we would evaluate the function.

**Example 3.2.4: Combining Differentiation Rules**

For $k(x) = 3h(x) + x^2g(x)$, find $k'(x)$.

**Solution**

Finding this derivative requires the Sum Rule, the Constant Multiple Rule, and the Product Rule.

$$
\begin{aligned}
k'(x) &= \frac{d}{dx}\big(3h(x)+x^2g(x)\big) \\
&= \frac{d}{dx}\big(3h(x)\big)+\frac{d}{dx}\big(x^2g(x)\big) && \text{(Sum Rule)} \\
&= 3\frac{d}{dx}\big(h(x)\big)+\Big(\frac{d}{dx}(x^2)g(x)+\frac{d}{dx}(g(x))x^2\Big) && \text{(Constant Multiple and Product Rules)} \\
&= 3h'(x)+2xg(x)+g'(x)x^2
\end{aligned}
$$

### Example 3.2.5: Extending the Product Rule

For $k(x)=f(x)g(x)h(x)$, express $k'(x)$ in terms of $f(x), g(x), h(x)$, and their derivatives.

**Solution**

We can think of the function $k(x)$ as the product of the function $f(x)g(x)$ and the function $h(x)$. That is, $k(x)=(f(x)g(x))\cdot h(x)$. Thus,

$$
\begin{aligned}
k'(x) &= \frac{d}{dx}\big(f(x)g(x)\big)\cdot h(x)+\frac{d}{dx}\big(h(x)\big)\cdot\big(f(x)g(x)\big) && \text{(Product Rule)} \\
&= \big(f'(x)g(x)+g'(x)f(x)\big)h(x)+h'(x)f(x)g(x) && \text{(Product Rule)} \\
&= f'(x)g(x)h(x)+f(x)g'(x)h(x)+f(x)g(x)h'(x)
\end{aligned}
$$

### Example 3.2.6: Combining the Quotient Rule and the Product Rule

For $h(x)=\frac{2x^3k(x)}{3x+2}$, find $h'(x)$.

**Solution**

This procedure is typical for finding the derivative of a rational function.

$$
\begin{aligned}
h'(x) &= \frac{\frac{d}{dx}(2x^3k(x))\cdot(3x+2)-\frac{d}{dx}(3x+2)\cdot(2x^3k(x))}{(3x+2)^2} && \text{(Quotient Rule)} \\
&= \frac{(6x^2k(x)+k'(x)\cdot 2x^3)(3x+2)-3(2x^3k(x))}{(3x+2)^2} && \text{(Product Rule)} \\
&= \frac{-6x^3k(x)+18x^3k(x)+12x^2k(x)+6x^4k'(x)+4x^3k'(x)}{(3x+2)^2}
\end{aligned}
$$

# 3.2E: EXERCISES

This page is a draft and is under active development.

## READING QUESTIONS

1. State the Product Rule for finding the derivative of $p(x) = f(x)g(x)$.
2. Is the derivative of a product of two functions equal to the product of their derivatives? Explain.
3. State the Quotient Rule for finding the derivative of $q(x) = \frac{f(x)}{g(x)}$.
4. Is the derivative of a quotient of two functions equal to the quotient of their derivatives? Explain.
5. When applying the Quotient Rule to a function like $s(t) = \frac{\sqrt[3]{t}}{t-5}$, what algebraic step is often helpful before starting the differentiation?
6. How can the Quotient Rule be used to prove the Power Rule for negative integer exponents, assuming the Power Rule for positive integers is known?
7. When finding the derivative of a function that involves sums, products, and quotients, what is a good rule of thumb for the order in which to apply the differentiation rules?
8. Given $k(x) = f(x)g(x)h(x)$, how can the Product Rule be extended or applied iteratively to find $k'(x)$?

## HOMEWORK

**In exercises 1 - 5, find $f'(x)$ for each function.**

1) $f(x) = 3x\left(18x^4 + \frac{13}{x+1}\right)$

**Answer**

$$f'(x) = 270x^4 + \frac{39}{(x+1)^2}$$

2) $f(x) = (x+2)(2x^2-3)$

3) $f(x) = \frac{4x^3 - 2x + 1}{x^2}$

**Answer**

$$f'(x) = \frac{4x^4 + 2x^2 - 2x}{x^4}$$

4) $f(x) = \frac{x^2+4}{x^2-4}$

5) $f(x) = \frac{x+9}{x^2-7x+1}$

**Answer**

$$f'(x) = \frac{-x^2 - 18x + 64}{(x^2-7x+1)^2}$$

**In exercise 6, find the equation of the tangent line $T(x)$ to the graph of the given function at the indicated point. Use a graphing calculator to graph the function and the tangent line.**

6) [Technology Required] $y = \frac{2x}{x-1}$ at $(-1, 1)$

**In exercises 7 - 10, assume that $f(x)$ and $g(x)$ are both differentiable functions for all $x$. Find the derivative of each of the functions $h(x)$.**

7) $h(x) = 4f(x) + \frac{g(x)}{7}$

8) $h(x) = x^3 f(x)$

**Answer**

$$h'(x) = 3x^2 f(x) + x^3 f'(x)$$

9) $h(x) = \frac{f(x)g(x)}{2}$

10) $h(x) = \dfrac{3f(x)}{g(x)+2}$

**Answer**

$h'(x) = \dfrac{3f'(x)(g(x)+2) - 3f(x)g'(x)}{(g(x)+2)^2}$

**For exercises 11 - 14, assume that $f(x)$ and $g(x)$ are both differentiable functions with values as given in the following table. Use the following table to calculate the following derivatives.**

| $x$ | 1 | 2 | 3 | 4 |
|---|---|---|---|---|
| $f(x)$ | 3 | 5 | −2 | 0 |
| $g(x)$ | 2 | 3 | −4 | 6 |
| $f'(x)$ | −1 | 7 | 8 | −3 |
| $g'(x)$ | 4 | 1 | 2 | 9 |

11) Find $h'(1)$ if $h(x) = xf(x) + 4g(x)$.

12) Find $h'(2)$ if $h(x) = \dfrac{f(x)}{g(x)}$.

**Answer**

$h'(2) = \frac{16}{9}$

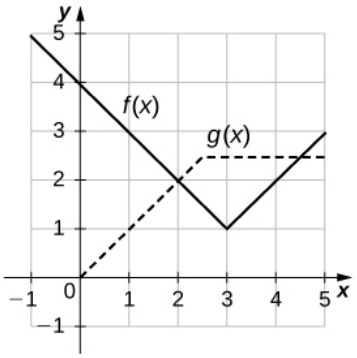
13) Find $h'(3)$ if $h(x) = 2x + f(x)g(x)$.

14) Find $h'(4)$ if $h(x) = \dfrac{1}{x} + \dfrac{g(x)}{f(x)}$.

**Answer**

$h'(4)$ is undefined.

**In exercises 15 - 16, use the following figure to find the indicated derivatives, if they exist.**



15) Let $h(x) = f(x)g(x)$. Find

a) $h'(1)$,

b) $h'(3)$, and

c) $h'(4)$.

**Answer**

a. $h'(1) = 2$,

b. $h'(3)$ does not exist,

c. $h'(4) = 2.5$

16) Let $h(x) = \dfrac{f(x)}{g(x)}$. Find

a) $h'(1)$,

b) $h'(3)$, and

c) $h'(4)$.

17) Find the equation of the tangent line to the graph of $f(x) = (3x - x^2)(3 - x - x^2)$ at $x = 1$.

**Answer**

$y = -5x + 7$

18) Find the equation of the line passing through the point $P(3, 3)$ and tangent to the graph of $f(x) = \dfrac{6}{x - 1}$.

**Answer**

$y = -\frac{3}{2}x + \frac{15}{2}$

19) [Technology Required] A herring swimming along a straight line has traveled $s(t) = \dfrac{t^2}{t^2 + 2}$ feet in $t$ seconds. Determine the velocity of the herring when it has traveled 3 seconds.

**Answer**

$\frac{12}{121}$ or 0.0992 ft/s

20) The population in millions of arctic flounder in the Atlantic Ocean is modeled by the function $P(t) = \dfrac{8t + 3}{0.2t^2 + 1}$, where $t$ is measured in years.

a. Determine the initial flounder population.

b. Determine $P'(10)$ and briefly interpret the result.

21) [Technology Required] The concentration of antibiotic in the bloodstream $t$ hours after being injected is given by the function $C(t) = \dfrac{2t^2 + t}{t^3 + 50}$, where $C$ is measured in milligrams per liter of blood.

a. Find the rate of change of $C(t)$.

b. Determine the rate of change for $t = 8, 12, 24$,and $36$.

c. Briefly describe what seems to be occurring as the number of hours increases.

**Answer**

a. $\dfrac{-2t^4 - 2t^3 + 200t + 50}{(t^3 + 50)^2}$

b. $-0.02395$ mg/L-hr, $-0.01344$ mg/L-hr, $-0.003566$ mg/L-hr, $-0.001579$ mg/L-hr

c. The rate at which the concentration of drug in the bloodstream decreases is slowing to 0 as time increases.

**In exercise 22, the given function represents the position of a particle traveling along a horizontal line.**

**a. Find the velocity and acceleration functions.**

**b. Determine the time intervals when the object is slowing down or speeding up.**

22) $s(t) = \dfrac{t}{1 + t^2}$

23) [Technology Required] A culture of bacteria grows in number according to the function $N(t) = 3000(1 + \dfrac{4t}{t^2 + 100})$, where $t$ is measured in hours.

a. Find the rate of change of the number of bacteria.

b. Find $N'(0)$, $N'(10)$, $N'(20)$, and $N'(30)$.

c. Interpret the results in (b).

d. Find $N''(0)$, $N''(10)$, $N''(20)$, and $N''(30)$. Interpret what the answers imply about the bacteria population growth.

**Answer**

a. $N'(t) = 3000\left(\dfrac{-4t^2 + 400}{(t^2 + 100)^2}\right)$

b. $120, 0, -14.4, -9.6$

c. The bacteria population increases from time 0 to 10 hours; afterwards, the bacteria population decreases.

d. $0, -6, 0.384, 0.432$. The rate at which the bacteria is increasing is decreasing during the first 10 hours. Afterwards, the bacteria population is decreasing at a decreasing rate.

The following problems deal with the Holling type I, II, and III equations. These equations describe the ecological event of growth of a predator population given the amount of prey available for consumption.

24) [Technology Required] The **Holling type I equation** is described by $f(x) = ax$, where $x$ is the amount of prey available and $a > 0$ is the rate at which the predator meets the prey for consumption.

a. Graph the Holling type I equation, given $a = 0.5$.

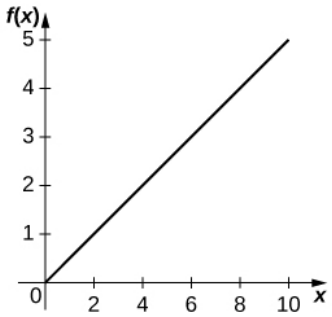
b. Determine the first derivative of the Holling type I equation and explain physically what the derivative implies.

c. Determine the second derivative of the Holling type I equation and explain physically what the derivative implies.

d. Using the interpretations from b. and c. explain why the Holling type I equation may not be realistic.

**Answer**

a.



b. $f'(x) = a$. The more increase in prey, the more growth for predators.

c. $f''(x) = 0$. As the amount of prey increases, the rate at which the predator population growth increases is constant.

d. This equation assumes that if there is more prey, the predator is able to increase consumption linearly. This assumption is unphysical because we would expect there to be some saturation point at which there is too much prey for the predator to consume adequately.

25) [Technology Required] The Holling type II equation is described by $f(x) = \frac{ax}{n+x}$, where $x$ is the amount of prey available and $a > 0$ is the maximum consumption rate of the predator.

a. Graph the Holling type II equation given $a = 0.5$ and $n = 5$. What are the differences between the Holling type I and II equations?

b. Take the first derivative of the Holling type II equation and interpret the physical meaning of the derivative.

c. Show that $f(n) = \frac{1}{2}a$ and interpret the meaning of the parameter n.

d. Find and interpret the meaning of the second derivative. What makes the Holling type II function more realistic than the Holling type I function?

26) [Technology Required] The Holling type III equation is described by $f(x) = \frac{ax^2}{n^2+x^2}$, where x is the amount of prey available and $a > 0$ is the maximum consumption rate of the predator.

a. Graph the Holling type III equation given $a = 0.5$ and $n = 5$. What are the differences between the Holling type II and III equations?

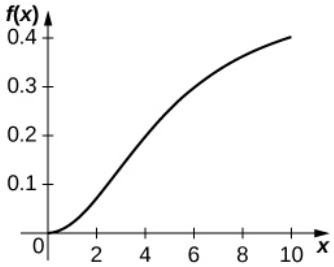
b. Take the first derivative of the Holling type III equation and interpret the physical meaning of the derivative.

c. Find and interpret the meaning of the second derivative (it may help to graph the second derivative).

d. What additional ecological phenomena does the Holling type III function describe compared with the Holling type II function?

**Answer**

a.



b. $f'(x) = \frac{2axn^2}{(n^2+x^2)^2}$. When the amount of prey increases, the predator growth increases.

c. $f''(x) = \frac{2an^2(n^2-3x^2)}{(n^2+x^2)^3}$. When the amount of prey is extremely small, the rate at which predator growth is increasing is increasing, but when the amount of prey reaches above a certain threshold, the rate at which predator growth is increasing begins to decrease.

d. At lower levels of prey, the prey is more easily able to avoid detection by the predator, so fewer prey individuals are consumed, resulting in less predator growth.

27) [Technology Required] The populations of the snowshoe hare (in thousands) and the lynx (in hundreds) collected over 7 years from 1937 to 1943 are shown in the following table. The snowshoe hare is the primary prey of the lynx.

| Population of snowshoe hare (thousands) | Population of lynx (hundreds) |
|---|---|
| 20 | 10 |
| 5 | 15 |
| 65 | 55 |
| 95 | 60 |

Snowshoe Hare and Lynx Populations Source: http://www.biotopics.co.uk/newgcse/predatorprey.html.

a. Graph the data points and determine which Holling-type function fits the data best.

b. Using the meanings of the parameters $a$ and $n$, determine values for those parameters by examining a graph of the data. Recall that $n$ measures what prey value results in the half-maximum of the predator value.

c. Plot the resulting Holling-type I, II, and III functions on top of the data. Was the result from part a. correct?

# 3.3: Derivatives of Trigonometric Functions

**Note to the Instructor (click to expand)**

This section introduces the student to the derivatives of all the trigonometric functions (and you should prove the derivative of either the sine or the cosine). This is a great opportunity to use the Product and Quotient Rules with new functions. Moreover, this is a *wonderful* opportunity to solve some trig equations when working with tangent lines.

---

To succeed in this section, you'll need to use some skills from previous courses. While you should already know them, this is the first time they've been required. You can review these skills in CRC's Corequisite Codex. If you have a support class, it might cover some, **but not all**, of these topics.

**Prerequisite Skills and Support Topics (click to expand)**

- **Geometry**
  - Special Triangles: When working with trigonometric functions in Calculus, it is assumed you know the special triangles (and, therefore, the special angles).
- **Trigonometry**
  - Trigonometric Identities - The Ratio, Reciprocal, Symmetry, and Cofunction Identities: Reciprocal identities like $\sec x = 1/\cos x$ are used in deriving derivatives (e.g., end of Example 4). Ratio identities like $\tan x = \sin x/\cos x$ are fundamental for deriving the derivative of $\tan x$ (Example 4).
  - Reference Angles: Knowledge of reference angles (and knowing how to find them) is required when finding, for example, when a trigonometric function has a horizontal tangent.
  - Solving Trigonometric Equations Involving Multiple Angles: If given a function involving trigonometric expressions and asked to find when the slope of the tangent line is equal to a given constant, you must solve a trigonometric equation. This might require solving an equation involving multiple angles.
  - Solving Trigonometric Equations Using Identities: If given a function involving trigonometric expressions and asked to find when the slope of the tangent line is equal to a given constant, you must solve a trigonometric equation. This often requires using trigonometric identities during the solution process.

---

The following is a list of learning objectives for this section.

**Learning Objectives (click to expand)**

- Compute the derivatives of the standard trigonometric functions.
- Calculate the higher-order derivatives of the sine and cosine.

Hawk A.I. Section-Specific Tutor

COSUMNES RIVER COLLEGE MATHEMATICS

One of the most important types of motion in physics is simple harmonic motion, which is associated with such systems as an object with mass oscillating on a spring. Simple harmonic motion can be described by using either sine or cosine functions. In this section, we expand our knowledge of derivative formulas to include derivatives of these and other trigonometric functions. We begin with the derivatives of the sine and cosine functions and then use them to obtain formulas for the derivatives of the remaining four trigonometric functions. Calculating the derivatives of the sine and cosine functions will enable us to find the velocity and acceleration of simple harmonic motion.

## Derivatives of the Sine and Cosine Functions

We begin our exploration of the derivative for the sine function by using the formula to make a reasonable guess at its derivative. Recall that for a function $f(x)$,

$$f'(x) = \lim_{h \to 0} \frac{f(x+h) - f(x)}{h}.$$

Consequently, for values of $h$ very close to 0,

$$f'(x) \approx \frac{f(x+h) - f(x)}{h}.$$

We see that by using $h = 0.01$,

$$\frac{d}{dx}(\sin x) \approx \frac{\sin(x + 0.01) - \sin x}{0.01}$$

By setting

$$D(x) = \frac{\sin(x + 0.01) - \sin x}{0.01}$$

and using a graphing utility, we can get a graph of an approximation to the derivative of $\sin x$ (Figure 3.3.1).

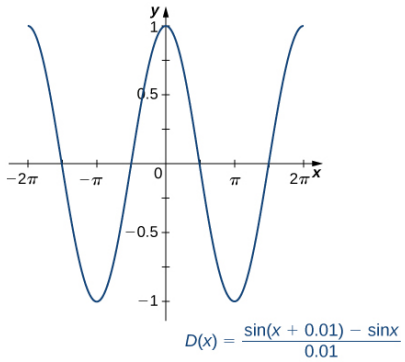

*Figure 3.3.1: The graph of the function $D(x)$ looks a lot like a cosine curve.*

Upon inspection, the graph of $D(x)$ appears to be very close to the graph of the cosine function. Indeed, we will show that

$$\frac{d}{dx}(\sin x) = \cos x.$$

If we were to follow the same steps to approximate the derivative of the cosine function, we would find that

$$\frac{d}{dx}(\cos x) = -\sin x.$$

**Theorem: The Derivatives of $\sin(x)$ and $\cos(x)$**

The derivative of the sine function is the cosine, and the derivative of the cosine function is the negative sine.

$$\frac{d}{dx}(\sin(x)) = \cos(x)$$

$$\frac{d}{dx}(\cos(x)) = -\sin(x)$$

**Proof**

Because the proofs for $\frac{d}{dx}(\sin x) = \cos x$ and $\frac{d}{dx}(\cos x) = -\sin x$ use similar techniques, we provide only the proof for $\frac{d}{dx}(\sin x) = \cos x$. Before beginning, recall two important trigonometric limits:

$$\lim_{h\to 0}\frac{\sin h}{h} = 1 \quad \text{and} \quad \lim_{h\to 0}\frac{\cos h - 1}{h} = 0.$$

Before we get too far in the proof, it is important to remind ourselves that these limits were only proved using radian measure. As such, the remainder of this proof assumes radian measure! If we wish to work in degrees, we must adjust a lot of our work (as such, we will *not* work in degrees). The graphs of $y = \frac{\sin h}{h}$ and $y = \frac{\cos h - 1}{h}$ are shown in Figure **3.3.2**.

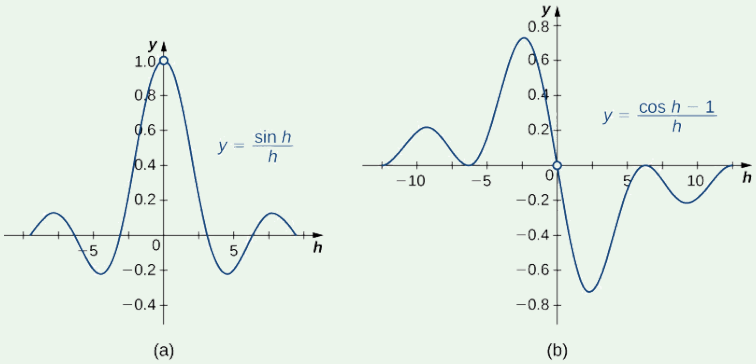

*Figure* **3.3.2***: These graphs show two important limits needed to establish the derivative formulas for the sine and cosine functions.*

We also recall the following trigonometric identity for the sine of the sum of two angles:

$$\sin(x+h) = \sin x \cos h + \cos x \sin h.$$

Now that we have gathered all the necessary equations and identities, we proceed with the proof.

$$\begin{aligned}
\frac{d}{dx}(\sin x) &= \lim_{h\to 0}\frac{\sin(x+h)-\sin x}{h} && \text{(definition of the derivative)}\\
&= \lim_{h\to 0}\frac{\sin x\cos h + \cos x \sin h - \sin x}{h} && \text{(Sum of Angles Identity)}\\
&= \lim_{h\to 0}\left(\frac{\sin x\cos h - \sin x}{h} + \frac{\cos x \sin h}{h}\right) && \text{(regrouping)}\\
&= \lim_{h\to 0}\left(\sin x\left(\frac{\cos h - 1}{h}\right) + (\cos x)\left(\frac{\sin h}{h}\right)\right) && \text{(factoring)}\\
&= (\sin x)\lim_{h\to 0}\left(\frac{\cos h - 1}{h}\right) + (\cos x)\lim_{h\to 0}\left(\frac{\sin h}{h}\right) && \text{(factoring)}\\
&= (\sin x)(0) + (\cos x)(1)\\
&= \cos x
\end{aligned}$$

*Q.E.D.*

Figure **3.3.3** shows the relationship between the graph of $f(x) = \sin x$ and its derivative $f'(x) = \cos x$. Notice that at the points where $f(x) = \sin x$ has a horizontal tangent, its derivative $f'(x) = \cos x$ takes on the value zero. We also see that where f$(x) = \sin x$ is increasing, $f'(x) = \cos x > 0$ and where $f(x) = \sin x$ is decreasing, $f'(x) = \cos x < 0$.

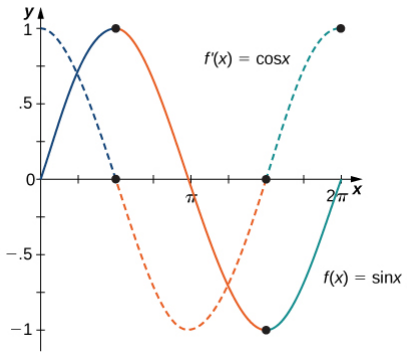

*Figure* **3.3.3***: Where* $f(x)$ *has a maximum or a minimum,* $f'(x) = 0$ *that is,* $f'(x) = 0$ *where* $f(x)$ *has a horizontal tangent. These points are noted with dots on the graphs*

### ✔ Example 3.3.1: Differentiating a Function Containing $\sin x$

Find the derivative of $f(x) = 5x^3 \sin x$.

**Solution**

Using the Product Rule, we have

$$\begin{aligned} f'(x) &= \frac{d}{dx}(5x^3) \cdot \sin x + \frac{d}{dx}(\sin x) \cdot 5x^3 \\ &= 15x^2 \cdot \sin x + \cos x \cdot 5x^3. \end{aligned}$$

After simplifying, we obtain

$$f'(x) = 15x^2 \sin x + 5x^3 \cos x.$$

### ? Checkpoint 3.3.1

Find the derivative of $f(x) = \sin x \cos x$.

**Answer**

$$f'(x) = \cos^2 x - \sin^2 x$$

### ✔ Example 3.3.2: Finding the Derivative of a Function Containing cos x

Find the derivative of $g(x) = \frac{\cos x}{4x^2}$.

**Solution**

By applying the Quotient Rule, we have

$$g'(x) = \frac{(-\sin x)4x^2 - 8x(\cos x)}{(4x^2)^2}.$$

Simplifying, we obtain

$$g'(x) = \frac{-4x^2 \sin x - 8x \cos x}{16x^4} = \frac{-x \sin x - 2 \cos x}{4x^3}.$$

**? Checkpoint 3.3.2**

Find the derivative of $f(x) = \frac{x}{\cos x}$.

**Answer**

$f'(x) = \frac{\cos x + x \sin x}{\cos^2 x}$

**✓ Example 3.3.3: An Application to Velocity**

A particle moves along a coordinate axis in such a way that its position at time $t$ is given by $s(t) = 2 \sin t - t$ for $0 \leq t \leq 2\pi$. At what times is the particle at rest?

**Solution**

To determine when the particle is at rest, set $s'(t) = v(t) = 0$. Begin by finding $s'(t)$. We obtain

$$s'(t) = 2 \cos t - 1,$$

so we must solve

$$2 \cos t - 1 = 0 \text{ for } 0 \leq t \leq 2\pi.$$

The solutions to this equation are $t = \frac{\pi}{3}$ and $t = \frac{5\pi}{3}$. Thus the particle is at rest at times $t = \frac{\pi}{3}$ and $t = \frac{5\pi}{3}$.

**? Checkpoint 3.3.3**

A particle moves along a coordinate axis. Its position at time $t$ is given by $s(t) = \sqrt{3}t + 2 \cos t$ for $0 \leq t \leq 2\pi$. At what times is the particle at rest?

**Answer**

$t = \frac{\pi}{3}, \quad t = \frac{2\pi}{3}$

## Derivatives of Other Trigonometric Functions

Since the remaining four trigonometric functions may be expressed as quotients involving sine, cosine, or both, we can use the Quotient Rule to find formulas for their derivatives.

**✓ Example 3.3.4: The Derivative of the Tangent Function**

Find the derivative of $f(x) = \tan x$.

**Solution**

Start by expressing $\tan x$ as the quotient of $\sin x$ and $\cos x$:

$$f(x) = \tan x = \frac{\sin x}{\cos x}.$$

Now apply the Quotient Rule to obtain

$$f'(x) = \frac{\cos x \cos x - (-\sin x) \sin x}{(\cos x)^2}.$$

Simplifying, we obtain

$$f'(x) = \frac{\cos^2 x + \sin^2 x}{\cos^2 x}.$$

Recognizing that $\cos^2 x + \sin^2 x = 1$, by the Pythagorean Identity, we now have

$$f'(x) = \frac{1}{\cos^2 x}.$$

Finally, use the identity $\sec x = \frac{1}{\cos x}$ to obtain

$$f'(x) = \sec^2 x.$$

**? Checkpoint 3.3.4**

Find the derivative of $f(x) = \cot x$.

**Answer**

$f'(x) = -\csc^2 x$

The derivatives of the remaining trigonometric functions may be obtained by using similar techniques. We provide these formulas in the following theorem.

**Theorem: Derivatives of $\tan(x)$, $\cot(x)$, $\sec(x)$, and $\csc(x)$**

The derivatives of the remaining trigonometric functions (along with the sine and cosine) are as follows:

$$\frac{d}{dx}(\sin(x)) = \cos(x) \qquad \frac{d}{dx}(\csc(x)) = -\csc(x)\cot(x)$$

$$\frac{d}{dx}(\cos(x)) = -\sin(x) \qquad \frac{d}{dx}(\sec(x)) = \sec(x)\tan(x)$$

$$\frac{d}{dx}(\tan(x)) = \sec^2(x) \qquad \frac{d}{dx}(\cot(x)) = -\csc^2(x)$$

Getting these formulas cemented in your memory as quickly and efficiently as possible is critical. The following might help a little:

**A Trick to Remember**

The derivatives of the **co**sine, **co**secant, and **co**tangent have a negative sign in their formulas (not to be construed as "they are always negative," which is not true).

**✓ Example 3.3.5: Finding the Equation of a Tangent Line**

Find the equation of a line tangent to the graph of $f(x) = \cot x$ at $x = \frac{\pi}{4}$.

**Solution**

To find the equation of the tangent line, we need a point and a slope at that point. To find the point, compute

$$f\left(\frac{\pi}{4}\right) = \cot\frac{\pi}{4} = 1.$$

Thus the tangent line passes through the point $\left(\frac{\pi}{4}, 1\right)$. Next, find the slope by finding the derivative of $f(x) = \cot x$ and evaluating it at $\frac{\pi}{4}$:

$$f'(x) = -\csc^2 x \quad \text{and} \quad f'\left(\frac{\pi}{4}\right) = -\csc^2\left(\frac{\pi}{4}\right) = -2.$$

Using the point-slope equation of the line, we obtain

$$y - 1 = -2\left(x - \frac{\pi}{4}\right)$$

or equivalently,

$$y = -2x + 1 + \frac{\pi}{2}.$$

### Example 3.3.6: Finding the Derivative of Trigonometric Functions

Find the derivative of $f(x) = \csc x + x \tan x$.

**Solution**

To find this derivative, we must use both the Sum Rule and the Product Rule. Using the Sum Rule, we find

$$f'(x) = \frac{d}{dx}(\csc x) + \frac{d}{dx}(x \tan x).$$

In the first term, $\frac{d}{dx}(\csc x) = -\csc x \cot x$, and by applying the Product Rule to the second term we obtain

$$\frac{d}{dx}(x \tan x) = (1)(\tan x) + (\sec^2 x)(x).$$

Therefore, we have

$$f'(x) = -\csc x \cot x + \tan x + x \sec^2 x.$$

### Checkpoint 3.3.6

Find the derivative of $f(x) = 2 \tan x - 3 \cot x$.

**Answer**

$f'(x) = 2 \sec^2 x + 3 \csc^2 x$

### Example 3.3.7

Evaluate.

$$\frac{d}{dx}\left(\frac{\tan(x)}{1+\cos(x)}\right)$$

**Solution**

$$\frac{d}{dx}\left(\frac{\tan(x)}{1+\cos(x)}\right) = \frac{\frac{d}{dx}(\tan(x))[1+\cos(x)] - \tan(x)\frac{d}{dx}(1+\cos(x))}{[1+\cos(x)]^2} \quad \text{(Quotient Rule)}$$

$$= \frac{\sec^2(x)[1+\cos(x)] - \tan(x)[-\sin(x)]}{[1+\cos(x)]^2}$$

$$= \frac{\sec^2(x)[1+\cos(x)] + \sin(x)\tan(x)}{[1+\cos(x)]^2}$$

The tricky thing about trigonometric functions is the number of identities and the ultimate desire to simplify answers. It's often best to perform a few extra steps to see if any algebra or Trigonometry could simplify this result further.

$$\begin{aligned}
\frac{\sec^2(x)\,[1+\cos(x)]+\sin(x)\tan(x)}{[1+\cos(x)]^2} &= \frac{[1+\cos(x)]+\cos(x)\sin^2(x)}{\cos^2(x)\,[1+\cos(x)]^2} && \left(\text{multiplying by } \frac{\cos^2(x)}{\cos^2(x)}\right)\\
&= \frac{[1+\cos(x)]+\cos(x)\,[1-\cos^2(x)]}{\cos^2(x)\,[1+\cos(x)]^2} && \text{(Pythagorean Identity)}\\
&= \frac{[1+\cos(x)]+\cos(x)\,[1-\cos(x)]\,[1+\cos(x)]}{\cos^2(x)\,[1+\cos(x)]^2} && \text{(Difference of Squares)}\\
&= \frac{[1+\cos(x)]\,(1+\cos(x)\,[1-\cos(x)])}{\cos^2(x)\,[1+\cos(x)]^2} && \text{(factoring)}\\
&= \frac{\cancel{[1+\cos(x)]}\,(1+\cos(x)\,[1-\cos(x)])}{\cos^2(x)\,[1+\cos(x)]^{\cancel{2}^{1}}} && \text{(canceling)}\\
&= \frac{1+\cos(x)-\cos^2(x)}{\cos^2(x)\,[1+\cos(x)]} && \text{(distributing)}
\end{aligned}$$

As you can see, our efforts to arrive at a more "simplified" form have not paid off. Any of these answers are equivalent, and none are really "simpler" than others; however, it is *always* advisable to perform a few extra steps like this to see if your results simplify (they often will).

**? Checkpoint 3.3.7**

Find the slope of the line tangent to the graph of $f(x)=\tan x$ at $x=\frac{\pi}{6}$.

**Answer**

$\frac{4}{3}$

## Higher-Order Derivatives

The higher-order derivatives of $\sin x$ and $\cos x$ follow a repeating pattern. By following the pattern, we can find any higher-order derivative of $\sin x$ and $\cos x$.

**✓ Example 3.3.8: Finding Higher-Order Derivatives of $y=\sin x$**

Find the first four derivatives of $y=\sin x$.

**Solution**

Each step in the chain is straightforward:

$$\begin{aligned} y &= \sin x \\ \frac{dy}{dx} &= \cos x \\ \frac{d^2y}{dx^2} &= -\sin x \\ \frac{d^3y}{dx^3} &= -\cos x \\ \frac{d^4y}{dx^4} &= \sin x \end{aligned}$$

**Analysis**

Once we recognize the pattern of derivatives, we can find any higher-order derivative by determining the step in the pattern to which it corresponds. For example, every fourth derivative of $\sin x$ equals $\sin x$, so

$$\frac{d^4}{dx^4}(\sin x) = \frac{d^8}{dx^8}(\sin x) = \frac{d^{12}}{dx^{12}}(\sin x) = \ldots = \frac{d^{4n}}{dx^{4n}}(\sin x) = \sin x$$

$$\frac{d^5}{dx^5}(\sin x) = \frac{d^9}{dx^9}(\sin x) = \frac{d^{13}}{dx^{13}}(\sin x) = \ldots = \frac{d^{4n+1}}{dx^{4n+1}}(\sin x) = \cos x.$$

**? Checkpoint 3.3.8**

For $y = \cos x$, find $\frac{d^4y}{dx^4}$.

**Answer**

$\cos x$

**✓ Example 3.3.9: Using the Pattern for Higher-Order Derivatives of $y = \sin x$**

Find $\frac{d^{74}}{dx^{74}}(\sin x)$.

**Solution**

We can see right away that for the 74th derivative of $\sin x$, $74 = 4(18) + 2$, so

$$\frac{d^{74}}{dx^{74}}(\sin x) = \frac{d^{72+2}}{dx^{72+2}}(\sin x) = \frac{d^2}{dx^2}(\sin x) = -\sin x.$$

**? Checkpoint 3.3.9**

For $y = \sin x$, find $\frac{d^{59}}{dx^{59}}(\sin x)$.

**Answer**

$-\cos x$

**✓ Example 3.3.10: An Application to Acceleration**

A particle moves along a coordinate axis in such a way that its position at time $t$ is given by $s(t) = 2 - \sin t$. Find $v(\pi/4)$ and $a(\pi/4)$. Compare these values and decide whether the particle is speeding up or slowing down.

**Solution**

First find $v(t) = s'(t)$.

$$v(t) = s'(t) = -\cos t.$$

Thus,

$$v\left(\frac{\pi}{4}\right) = -\frac{1}{\sqrt{2}} = -\frac{\sqrt{2}}{2}.$$

Next, find $a(t) = v'(t)$. Thus, $a(t) = v'(t) = \sin t$ and we have

$$a\left(\frac{\pi}{4}\right) = \frac{1}{\sqrt{2}} = \frac{\sqrt{2}}{2}.$$

Since $v\left(\frac{\pi}{4}\right) = -\frac{\sqrt{2}}{2} < 0$ and $a\left(\frac{\pi}{4}\right) = \frac{\sqrt{2}}{2} > 0$, we see that velocity and acceleration are acting in opposite directions; that is, the object is being accelerated in the direction opposite to the direction in which it is traveling. Consequently, the particle is slowing down.

**? Checkpoint 3.3.10**

A block attached to a spring is moving vertically. Its position at time t is given by $s(t) = 2\sin t$. Find $v\left(\frac{5\pi}{6}\right)$ and $a\left(\frac{5\pi}{6}\right)$. Compare these values and decide whether the block is speeding up or slowing down.

**Answer**

$v\left(\frac{5\pi}{6}\right) = -\sqrt{3} < 0$ and $a\left(\frac{5\pi}{6}\right) = -1 < 0$. The block is speeding up.

# 3.3E: EXERCISES

This page is a draft and is under active development.

## READING QUESTIONS

1. What is the derivative of $f(x) = \sin x$?
2. What is the derivative of $f(x) = \cos x$?
3. Which two trigonometric limits are crucial for proving the derivative of $\sin x$?
4. How is the Quotient Rule used to find the derivative of $f(x) = \tan x$?
5. What is the derivative of $f(x) = \tan x$?
6. What is the derivative of $f(x) = \cot x$?
7. What is the derivative of $f(x) = \sec x$?
8. What is the derivative of $f(x) = \csc x$?
9. Which three standard trigonometric functions have derivatives that include a negative sign?
10. If a particle's position is given by $s(t) = 2\sin t - t$, how would you find the times when the particle is at rest?
11. Describe the pattern of higher-order derivatives for $y = \sin x$. What is the fourth derivative of $\sin x$?
12. If a particle's velocity is $v(t)$ and its acceleration is $a(t)$, what does it mean if $v(t)$ and $a(t)$ have opposite signs at a particular time?

## HOMEWORK

**In exercises 1 - 10, find $\frac{dy}{dx}$ for the given functions.**

1) $y = x^2 - \sec x + 1$

**Answer**

$$\frac{dy}{dx} = 2x - \sec x \tan x$$

2) $y = 3\csc x + \frac{5}{x}$

3) $y = x^2 \cot x$

**Answer**

$$\frac{dy}{dx} = 2x \cot x - x^2 \csc^2 x$$

4) $y = x - x^3 \sin x$

5) $y = \frac{\sec x}{x}$

**Answer**

$$\frac{dy}{dx} = \frac{x \sec x \tan x - \sec x}{x^2}$$

6) $y = \sin x \tan x$

7) $y = (x + \cos x)(1 - \sin x)$

**Answer**

$$\frac{dy}{dx} = (1 - \sin x)(1 - \sin x) - \cos x(x + \cos x)$$

8) $y = \frac{\tan x}{1 - \sec x}$

9) $y = \frac{1 - \cot x}{1 + \cot x}$

**Answer**

$$\frac{dy}{dx} = \frac{2\csc^2 x}{(1 + \cot x)^2}$$

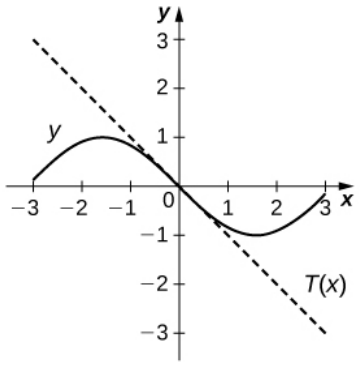
10) $y = (\cos x)(1 + \csc x)$

**In exercises 11 - 16, find the equation of the tangent line to each of the given functions at the indicated values of $x$. Then use graphing technology to graph both the function and the tangent line to ensure the equation for the tangent line is correct.**

11) $f(x) = -\sin x, \quad x = 0$

**Answer**

$y = -x$

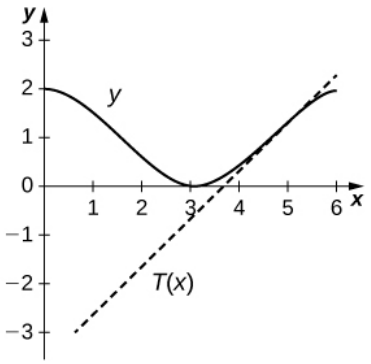


12) $f(x) = \csc x, \quad x = \frac{\pi}{2}$

13) $f(x) = 1 + \cos x, \quad x = \frac{3\pi}{2}$

**Answer**

$y = x + \frac{2-3\pi}{2}$

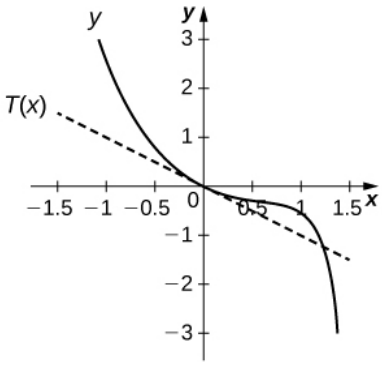


14) $f(x) = \sec x, \quad x = \frac{\pi}{4}$

15) $f(x) = x^2 - \tan x, \quad x = 0$

**Answer**

$y = -x$



16) $f(x) = 5\cot x, \quad x = \frac{\pi}{4}$

**In exercises 17 - 22, find $\frac{d^2y}{dx^2}$ for the given functions.**

17) $y = x\sin x - \cos x$

**Answer**

$\frac{d^2y}{dx^2} = 3\cos x - x\sin x$

18) $y = \sin x \cos x$

19) $y = x - \frac{1}{2}\sin x$

**Answer**

$\frac{d^2y}{dx^2} = \frac{1}{2}\sin x$

20) $y = \frac{1}{x} + \tan x$

21) $y = 2\csc x$

**Answer**

$\frac{d^2y}{dx^2} = 2\csc(x)\left(\csc^2(x) + \cot^2(x)\right)$

22) $y = \sec^2 x$

23) Find all $x$ values on the graph of $f(x) = -3\sin x \cos x$ where the tangent line is horizontal.

**Answer**

$x = \frac{(2n+1)\pi}{4}$,where $n$ is an integer

24) Find all $x$ values on the graph of $f(x) = x - 2\cos x$ for $0 < x < 2\pi$ where the tangent line has slope 2.

25) Let $f(x) = \cot x$. Determine the points on the graph of $f$ for $0 < x < 2\pi$ where the tangent line(s) is (are) parallel to the line $y = -2x$.

**Answer**

$\left(\frac{\pi}{4}, 1\right), \quad \left(\frac{3\pi}{4}, -1\right), \quad \left(\frac{5\pi}{4}, 1\right), \quad \left(\frac{7\pi}{4}, -1\right)$

26) [Technology Required] A mass on a spring bounces up and down in simple harmonic motion, modeled by the function $s(t) = -6\cos t$ where s is measured in inches and $t$ is measured in seconds. Find the rate at which the spring is oscillating at $t = 5$ s.

27) Let the position of a swinging pendulum in simple harmonic motion be given by $s(t) = a\cos t + b\sin t$. Find the constants $a$ and $b$ such that when the velocity is 3 cm/s, $s = 0$ and $t = 0$.

**Answer**

$a = 0, \quad b = 3$

28) After a diver jumps off a diving board, the edge of the board oscillates with position given by $s(t) = -5\cos t$ cm at $t$ seconds after the jump.

a. Sketch one period of the position function for $t \geq 0$.

b. Find the velocity function.

c. Sketch one period of the velocity function for $t \geq 0$.

d. Determine the times when the velocity is 0 over one period.

e. Find the acceleration function.

f. Sketch one period of the acceleration function for $t \geq 0$.

29) The number of hamburgers sold at a fast-food restaurant in Pasadena, California, is given by $y = 10 + 5\sin x$ where $y$ is the number of hamburgers sold and $x$ represents the number of hours after the restaurant opened at 11 a.m. until 11 p.m., when the store closes. Find $y'$ and determine the intervals where the number of burgers being sold is increasing.

**Answer**

$y' = 5\cos(x)$, increasing on $(0, \frac{\pi}{2})$, $(\frac{3\pi}{2}, \frac{5\pi}{2})$, and $(\frac{7\pi}{2}, 12)$

30) [Technology Required] The amount of rainfall per month in Phoenix, Arizona, can be approximated by $y(t) = 0.5 + 0.3\cos t$, where $t$ is months since January. Find $y'$and use a calculator to determine the intervals where the amount of rain falling is decreasing.

**For exercises 31 - 33, use the quotient rule to derive the given equations.**

31) $\frac{d}{dx}(\cot x) = -\csc^2 x$

32) $\frac{d}{dx}(\sec x) = \sec x \tan x$

33) $\frac{d}{dx}(\csc x) = -\csc x \cot x$

34) Use the definition of derivative and the identity $\cos(x + h) = \cos x \cos h - \sin x \sin h$ to prove that $\frac{d}{dx}(\cos x) = -\sin x$.

**For exercises 35 - 39, find the requested higher-order derivative for the given functions.**

35) $\frac{d^3y}{dx^3}$ of $y = 3\cos x$

**Answer**

$\frac{d^3y}{dx^3} = 3\sin x$

36) $\frac{d^2y}{dx^2}$ of $y = 3\sin x + x^2\cos x$

37) $\frac{d^4y}{dx^4}$ of $y = 5\cos x$

**Answer**

$\frac{d^4y}{dx^4} = 5\cos x$

38) $\frac{d^2y}{dx^2}$ of $y = \sec x + \cot x$

39) $\frac{d^3y}{dx^3}$ of $y = x^{10} - \sec x$

**Answer**

$\frac{d^3y}{dx^3} = 720x^7 - 5\tan(x)\sec^3(x) - \tan^3(x)\sec(x)$

# 3.4: Differentiation Techniques - The Chain Rule

**Learning Objectives**

- State the Chain Rule using both Lagrange and Leibniz notations.
- Use the Chain Rule combined with the Power Rule.
- Apply the Chain Rule and the Product/Quotient Rules correctly when necessary.
- Describe the proof of the Chain Rule.

Hawk A.I. Section-Specific Tutor

Please note that, to access the Hawk A.I. Tutor, you will need a (free) OpenAI account.

We have seen the techniques for differentiating basic functions ($x^n, \sin x, \cos x$, etc.) as well as sums, differences, products, quotients, and constant multiples of these functions. However, these techniques do not allow us to differentiate compositions of functions, such as $h(x) = \sin(x^3)$ or $k(x) = \sqrt{3x^2 + 1}$. In this section, we study the rule for finding the derivative of the composition of two or more functions.

## Deriving the Chain Rule

When we have a function composed of two or more functions, we can use all the techniques we have already learned to differentiate it. However, using all those techniques to break down a function into simpler parts that we can differentiate can be challenging. Instead, we use the **Chain Rule**, which states that the derivative of a composite function is the derivative of the outer function evaluated at the inner function times the derivative of the inner function.

To put this rule into context, let's take a look at an example: $h(x) = \sin(x^3)$. We can think of the derivative of this function with respect to $x$ as the rate of change of $\sin(x^3)$ relative to the change in $x$. Consequently, we want to know how $\sin(x^3)$ changes as $x$ changes. We can think of this event as a chain reaction: As $x$ changes, $x^3$ changes, which leads to a change in $\sin(x^3)$. This chain reaction hints at what is involved in computing the derivative of $\sin(x^3)$. First of all, a change in $x$ forcing a change in $x^3$ suggests that somehow the derivative of $x^3$ is involved. In addition, the change in $x^3$ forcing a change in $\sin(x^3)$ suggests that the derivative of $\sin(u)$ with respect to $u$, where $u = x^3$, is also part of the final derivative.

We can take a more formal look at the derivative of $h(x) = \sin(x^3)$ by setting up the limit that would give us the derivative at a specific value $a$ in the domain of $h(x) = \sin(x^3)$.

$$h'(a) = \lim_{x \to a} \frac{\sin(x^3) - \sin(a^3)}{x - a}$$

This expression does not seem particularly helpful; however, we can modify it by multiplying and dividing by the expression $x^3 - a^3$ to obtain

$$h'(a) = \lim_{x \to a} \frac{\sin(x^3) - \sin(a^3)}{x^3 - a^3} \cdot \frac{x^3 - a^3}{x - a}.$$

From the definition of the derivative, we can see that the second factor is the derivative of $x^3$ at $x = a$. That is,

$$\lim_{x \to a} \frac{x^3 - a^3}{x - a} = \frac{d}{dx}(x^3)\Big|_{x=a} = 3a^2.$$

However, recognizing that the first term is also a derivative might be a little more challenging. We can see this by letting $u = x^3$ and observing that as $x \to a, u \to a^3$:

$$\lim_{x\to a}\frac{\sin(x^3)-\sin(a^3)}{x^3-a^3} = \lim_{u\to a^3}\frac{\sin u-\sin(a^3)}{u-a^3}$$

$$= \frac{d}{du}(\sin u)\Big|_{u=a^3}$$

$$= \cos(a^3)$$

Thus, $h'(a)=\cos(a^3)\cdot 3a^2$.

In other words, if $h(x)=\sin(x^3)$, then $h'(x)=\cos(x^3)\cdot 3x^2$. Thus, if we think of $h(x)=\sin(x^3)$ as the composition $(f\circ g)(x)=f(g(x))$ where $f(x)=\sin x$ and $g(x)=x^3$, then the derivative of $h(x)=\sin(x^3)$ is the product of the derivative of $g(x)=x^3$ and the derivative of the function $f(x)=\sin x$ evaluated at the function $g(x)=x^3$. At this point, we anticipate that for $h(x)=\sin(g(x))$, it is quite likely that $h'(x)=\cos(g(x))g'(x)$. As we determined above, this is the case for $h(x)=\sin(x^3)$.

Now that we have derived a special case of the Chain Rule, we state the general case and then apply it in a general form to other composite functions.

### Theorem: The Chain Rule (Lagrange's Notation)

Let $f$ and $g$ be functions. For all $x$ in the domain of $g$ for which $g$ is differentiable at $x$ and $f$ is differentiable at $g(x)$, the derivative of the composite function

$$h(x)=(f\circ g)(x)=f(g(x))$$

is given by

$$h'(x)=f'(g(x))\cdot g'(x).$$

Alternatively, if $y$ is a function of $u$, and $u$ is a function of $x$, then

$$\frac{dy}{dx}=\frac{dy}{du}\cdot\frac{du}{dx}.$$

**Proof (informal)**

At this point, we present a very informal proof of the Chain Rule. For simplicity's sake, we ignore certain issues: For example, we assume that $g(x)\neq g(a)$ for $x\neq a$ in some open interval containing $a$. We begin by applying the limit definition of the derivative to the function $h(x)$ to obtain $h'(a)$:

$$h'(a)=\lim_{x\to a}\frac{f(g(x))-f(g(a))}{x-a}.$$

Rewriting, we obtain

$$h'(a)=\lim_{x\to a}\frac{f(g(x))-f(g(a))}{g(x)-g(a)}\cdot\frac{g(x)-g(a)}{x-a}.$$

Although it is clear that

$$\lim_{x\to a}\frac{g(x)-g(a)}{x-a}=g'(a),$$

it is not obvious that

$$\lim_{x\to a}\frac{f(g(x))-f(g(a))}{g(x)-g(a)}=f'(g(a)).$$

To see that this is true, first recall that since $g$ is differentiable at $a$, $g$ is also continuous at $a$. Thus,

$$\lim_{x\to a}g(x)=g(a).$$

Next, make the substitution $y=g(x)$and $b=g(a)$ and use change of variables in the limit to obtain

$$\lim_{x\to a}\frac{f(g(x))-f(g(a))}{g(x)-g(a)}=\lim_{y\to b}\frac{f(y)-f(b)}{y-b}=f'(b)=f'(g(a)).$$

Finally,

$$h'(a)=\lim_{x\to a}\frac{f(g(x))-f(g(a))}{g(x)-g(a)}\cdot\frac{g(x)-g(a)}{x-a}=f'(g(a))\cdot g'(a).$$

*Q.E.D.*

## The Chain and Power Rules Combined

We can now apply the Chain Rule to composite functions, but note that we often need to use it with other rules. For example, to find derivatives of functions of the form $h(x)=(g(x))^n$, we need to use the Chain Rule combined with the Power Rule. To do so, we can think of $h(x)=(g(x))^n$ as $f(g(x))$ where $f(x)=x^n$. Then $f'(x)=nx^{n-1}$. Thus, $f'(g(x))=n(g(x))^{n-1}$. This leads us to the derivative of a power function using the Chain Rule,

$$h'(x)=n(g(x))^{n-1}\cdot g'(x)$$

**Theorem: Power Rule for Composition of Functions (General Power Rule)**

For all values of $x$ for which the derivative is defined, if

$$h(x)=(g(x))^n,$$

Then

$$h'(x)=n(g(x))^{n-1}\cdot g'(x). \tag{3.4.1}$$

**Example 3.4.1: Using the Chain and Power Rules**

Find the derivative of $h(x)=\frac{1}{(3x^2+1)^2}$.

**Solution**

First, rewrite $h(x)=\frac{1}{(3x^2+1)^2}=(3x^2+1)^{-2}$. Applying the Power Rule with $g(x)=3x^2+1$, we have

$$h'(x)=-2(3x^2+1)^{-3}\cdot 6x.$$

Rewriting back to the original form gives us

$$h'(x)=\frac{-12x}{(3x^2+1)^3}.$$

**Checkpoint 3.4.1**

Find the derivative of $h(x)=(2x^3+2x-1)^4$.

**Answer**

$h'(x)=4(2x^3+2x-1)^3(6x^2+2)=8(3x^2+1)(2x^3+2x-1)^3$

**Example 3.4.2: Using the Chain and Power Rules with a Trigonometric Function**

Find the derivative of $h(x)=\sin^3 x$.

**Solution**

First recall that $\sin^3 x=(\sin x)^3$, so we can rewrite $h(x)=\sin^3 x$ as $h(x)=(\sin x)^3$.

Applying the Power Rule with $g(x)=\sin x$, we obtain

$$h'(x) = 3(\sin x)^2 \cos x = 3\sin^2 x \cos x.$$

### Example 3.4.3: Finding the Equation of a Tangent Line

Find the equation of a line tangent to the graph of $h(x) = \frac{1}{(3x-5)^2}$ at $x = 2$.

**Solution**

Because we are finding an equation of a line, we need a point. The $x$-coordinate of the point is $2$. To find the $y$-coordinate, substitute $2$ into $h(x)$. Since $h(2) = \frac{1}{(3(2)-5)^2} = 1$, the point is $(2, 1)$.

For the slope, we need $h'(2)$. To find $h'(x)$, first we rewrite $h(x) = (3x-5)^{-2}$ and apply the Power Rule to obtain

$$h'(x) = -2(3x-5)^{-3}(3) = -6(3x-5)^{-3}.$$

By substituting, we have $h'(2) = -6(3(2)-5)^{-3} = -6$.

Therefore, the line has equation $y - 1 = -6(x-2)$. Rewriting, the equation of the line is $y = -6x + 13$.

### Checkpoint 3.4.3

Find the equation of the line tangent to the graph of $f(x) = (x^2-2)^3$ at $x = -2$.

**Answer**

$y = -48x - 88$

## Combining the Chain Rule with Other Rules

Now that we can combine the Chain Rule and the Power Rule, we examine how to combine the Chain Rule with the other rules we have learned. In particular, we can use it with the formulas for the derivatives of trigonometric functions or with the Product Rule.

### Example 3.4.4: Using the Chain Rule on a General Cosine Function

Find the derivative of $h(x) = \cos(g(x))$.

**Solution**

Think of $h(x) = \cos(g(x))$ as $f(g(x))$ where $f(x) = \cos x$. Since $f'(x) = -\sin x$, we have $f'(g(x)) = -\sin(g(x))$. Then we do the following calculation.

$$\begin{aligned} h'(x) &= f'(g(x)) \cdot g'(x) && \text{(Chain Rule)} \\ &= -\sin(g(x)) \cdot g'(x) && \text{(substituting } f'(g(x)) = -\sin(g(x))\text{)} \end{aligned}$$

Thus, the derivative of $h(x) = \cos(g(x))$ is given by $h'(x) = -\sin(g(x)) \cdot g'(x)$.

In the following example, we apply the rule that we have just derived.

### Example 3.4.5: Using the Chain Rule on a Cosine Function

Find the derivative of $h(x) = \cos(5x^2)$.

**Solution**

Let $g(x) = 5x^2$. Then $g'(x) = 10x$. Using the result from the previous example,

$$h'(x) = -\sin(5x^2) \cdot 10x = -10x\sin(5x^2).$$

### Example 3.4.6: Using the Chain Rule on Another Trigonometric Function

Find the derivative of $h(x) = \sec(4x^5 + 2x)$.

**Solution**

Apply the Chain Rule to $h(x) = \sec(g(x))$ to obtain

$$h'(x) = \sec(g(x))\tan(g(x)) \cdot g'(x).$$

In this problem, $g(x) = 4x^5 + 2x$, so we have $g'(x) = 20x^4 + 2$. Therefore, we obtain

$$h'(x) = \sec(4x^5 + 2x)\tan(4x^5 + 2x)(20x^4 + 2) = (20x^4 + 2)\sec(4x^5 + 2x)\tan(4x^5 + 2x).$$

### Checkpoint 3.4.6

Find the derivative of $h(x) = \sin(7x + 2)$.

**Answer**

$h'(x) = 7\cos(7x + 2)$

### Example 3.4.7: Combining the Chain Rule with the Product Rule

Find the derivative of $h(x) = (2x + 1)^5(3x - 2)^7$.

**Solution**

First apply the Product Rule, then apply the Chain Rule to each term of the product.

$$\begin{aligned} h'(x) &= \frac{d}{dx}\left((2x+1)^5\right)\cdot(3x-2)^7 + \frac{d}{dx}\left((3x-2)^7\right)\cdot(2x+1)^5 && \text{(Product Rule)} \\ &= 5(2x+1)^4\cdot 2\cdot(3x-2)^7 + 7(3x-2)^6\cdot 3\cdot(2x+1)^5 && \text{(Chain Rule)} \\ &= 10(2x+1)^4(3x-2)^7 + 21(3x-2)^6(2x+1)^5 && \text{(simplifying)} \\ &= (2x+1)^4(3x-2)^6(10(3x-2) + 21(2x+1)) && \text{(factoring)} \\ &= (2x+1)^4(3x-2)^6(72x+1) && \text{(simplifying)} \end{aligned}$$

### Checkpoint 3.4.7

Find the derivative of $h(x) = \frac{x}{(2x+3)^3}$.

**Answer**

$h'(x) = \frac{3-4x}{(2x+3)^4}$

## Composites of Three or More Functions

We can now combine the Chain Rule with other rules for differentiating functions, but when differentiating the composition of three or more functions, we need to apply the Chain Rule more than once. Let's look at this situation in general terms. We can generate a formula without remembering it, as we can apply the Chain Rule multiple times.

In general terms, first we let

$$k(x) = h(f(g(x))).$$

Then, applying the Chain Rule once we obtain

$$k'(x) = \frac{d}{dx}\left(h\left(f\left(g(x)\right)\right)\right) = h'\left(f\left(g(x)\right)\right) \cdot \frac{d}{dx}\left(f\left(g(x)\right)\right).$$

Applying the Chain Rule again, we obtain

$$k'(x) = h'\left(f\left(g(x)\right)\right) \cdot f'\left(g(x)\right) \cdot g'(x).$$

### Corollary: Chain Rule for a Composition of Three Functions

For all values of $x$ for which the function is differentiable, if

$$k(x) = h\left(f\left(g(x)\right)\right),$$

then

$$k'(x) = h'\left(f\left(g(x)\right)\right) \cdot f'\left(g(x)\right) \cdot g'(x).$$

In other words, we are applying the Chain Rule twice.

Notice that the derivative of the composition of three functions has three parts. (Similarly, the derivative of the composition of four functions has four parts, and so on.) Also, *remember, we can always work from the outside in, taking one derivative at a time.*

### Example 3.4.8: Differentiating a Composite of Three Functions

Find the derivative of $k(x) = \cos^4(7x^2 + 1)$.

**Solution**

First, rewrite $k(x)$ as

$$k(x) = \left(\cos(7x^2 + 1)\right)^4.$$

Then apply the Chain Rule several times.

$$\begin{aligned} k'(x) &= 4(\cos(7x^2+1))^3 \cdot \frac{d}{dx}\left(\cos(7x^2+1)\right) && \text{(Chain Rule)} \\ &= 4(\cos(7x^2+1))^3(-\sin(7x^2+1)) \cdot \frac{d}{dx}\left(7x^2+1\right) && \text{(Chain Rule)} \\ &= 4(\cos(7x^2+1))^3(-\sin(7x^2+1))(14x) && \text{(Chain Rule)} \\ &= -56x\sin(7x^2+1)\cos^3(7x^2+1) && \text{(simplifying)} \end{aligned}$$

### Checkpoint 3.4.8

Find the derivative of $h(x) = \sin^6(x^3)$.

**Answer**

$h'(x) = 18x^2\sin^5(x^3)\cos(x^3)$

### Example 3.4.9: Using the Chain Rule in a Velocity Problem

A particle moves along a coordinate axis. Its position at time t is given by $s(t) = \sin(2t) + \cos(3t)$. What is the velocity of the particle at time $t = \frac{\pi}{6}$?

**Solution**

To find $v(t)$, the velocity of the particle at time $t$, we must differentiate $s(t)$. Thus,

$$v(t) = s'(t) = 2\cos(2t) - 3\sin(3t).$$

**Example 3.4.10: Using the Chain Rule with Functional Values**

Let $h(x) = f(g(x))$. If $g(1) = 4, g'(1) = 3$, and $f'(4) = 7$, find $h'(1)$.

**Solution**

Use the Chain Rule, then substitute.

$$\begin{aligned} h'(1) &= f'(g(1)) \cdot g'(1) && \text{(Chain Rule)} \\ &= f'(4) \cdot 3 && \text{(substituting } g(1) = 4 \text{ and } g'(1) = 3\text{)} \\ &= 7 \cdot 3 && \text{(substituting } f'(4) = 7\text{)} \\ &= 21 && \text{(simplifying)} \end{aligned}$$

**Checkpoint 3.4.10**

Given $h(x) = f(g(x))$. If $g(2) = -3, g'(2) = 4$, and $f'(-3) = 7$, find $h'(2)$.

**Answer**

28

## The Chain Rule Using Leibniz's Notation

As with other derivatives that we have seen, we can express the Chain Rule using Leibniz's notation. This notation for the Chain Rule is used heavily in physics applications.

For $h(x) = f(g(x))$, let $u = g(x)$ and $y = h(x) = f(u)$. Thus,

$$h'(x) = \frac{dy}{dx}$$

$$f'(g(x)) = f'(u) = \frac{dy}{du}$$

and

$$g'(x) = \frac{du}{dx}.$$

Consequently,

$$\frac{dy}{dx} = h'(x) = f'(g(x)) \cdot g'(x) = \frac{dy}{du} \cdot \frac{du}{dx}.$$

**Theorem: Chain Rule (Leibniz's Notation)**

If $y$ is a function of $u$, and $u$ is a function of $x$, then

$$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx}.$$

**Example 3.4.11: Taking a Derivative Using Leibniz's Notation I**

Find the derivative of $y = \left(\frac{x}{3x+2}\right)^5$.

**Solution**

First, let $u = \frac{x}{3x+2}$. Thus, $y = u^5$. Next, find $\frac{du}{dx}$ and $\frac{dy}{du}$. Using the Quotient Rule,

$$\frac{du}{dx} = \frac{2}{(3x+2)^2}$$

and

$$\frac{dy}{du} = 5u^4,$$

Finally, we put it all together.

$$\begin{aligned}
\frac{dy}{dx} &= \frac{dy}{du} \cdot \frac{du}{dx} && \text{(Chain Rule)} \\
&= 5u^4 \cdot \frac{2}{(3x+2)^2} && \left(\text{substituting } \frac{dy}{du} = 5u^4 \text{ and } \frac{du}{dx} = \frac{2}{(3x+2)^2}\right) \\
&= 5\left(\frac{x}{3x+2}\right)^4 \cdot \frac{2}{(3x+2)^2} && \left(\text{substituting } u = \frac{x}{3x+2}\right) \\
&= \frac{10x^4}{(3x+2)^6} && \text{(simplifying)}
\end{aligned}$$

It is important to remember that when using the Leibniz form of the Chain Rule, the final answer must be expressed entirely in terms of the original variable given in the problem.

### Example 3.4.12: Taking a Derivative Using Leibniz's Notation II

Find the derivative of $y = \tan(4x^2 - 3x + 1)$.

**Solution**

First, let $u = 4x^2 - 3x + 1$. Then $y = \tan u$. Next, find $\frac{du}{dx}$ and $\frac{dy}{du}$:

$$\frac{du}{dx} = 8x - 3 \quad \text{and} \quad \frac{dy}{du} = \sec^2 u.$$

Finally, we put it all together.

$$\begin{aligned}
\frac{dy}{dx} &= \frac{dy}{du} \cdot \frac{du}{dx} && \text{(Chain Rule)} \\
&= \sec^2 u \cdot (8x - 3) && \left(\frac{du}{dx} = 8x - 3 \text{ and } \frac{dy}{du} = \sec^2 u\right) \\
&= \sec^2 (4x^2 - 3x + 1) \cdot (8x - 3) && \text{(substituting } u = 4x^2 - 3x + 1.)
\end{aligned}$$

### Checkpoint 3.4.12

Use Leibniz's notation to find the derivative of $y = \cos(x^3)$. Ensure that the final answer is expressed entirely in terms of the variable $x$.

**Answer**

$\frac{dy}{dx} = -3x^2 \sin(x^3)$.

## READING QUESTIONS

1. State the Chain Rule using Lagrange's notation for a composite function $h(x) = f(g(x))$.
2. State the Chain Rule using Leibniz's notation if $y$ is a function of $u$ and $u$ is a function of $x$.
3. What is the General Power Rule (Power Rule for Composition of Functions) for differentiating $h(x) = (g(x))^n$?
4. If $h(x) = \sin(x^3)$, identify the "outer" function $f(u)$ and the "inner" function $u = g(x)$. Then find $h'(x)$.
5. How is the Chain Rule applied to find the derivative of a composition of three functions, say $k(x) = h(f(g(x)))$?
6. When differentiating a function like $h(x) = \frac{1}{(3x^2+1)^2}$, what algebraic step is recommended before applying the General Power Rule?
7. In Example 7, $h(x) = (2x+1)^5(3x-2)^7$, which differentiation rule is applied first, and which rule is then applied to the terms resulting from the first rule?
8. When using Leibniz notation for the Chain Rule, like $\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx}$, what must be done to the term $\frac{dy}{du}$ to express the final answer in terms of $x$?

## HOMEWORK

**In exercises 1 - 6, given $y = f(u)$ and $u = g(x)$, find $\frac{dy}{dx}$ by using Leibniz's notation for the chain rule: $\frac{dy}{dx} = \frac{dy}{du}\frac{du}{dx}$.**

1) $y = 3u - 6, \quad u = 2x^2$

2) $y = 6u^3, \quad u = 7x - 4$

**Answer**

$$\frac{dy}{dx} = 18u^2 \cdot 7 = 18(7x-4)^2 \cdot 7 = 126(7x-4)^2$$

3) $y = \sin u, \quad u = 5x - 1$

4) $y = \cos u, \quad u = -\frac{x}{8}$

**Answer**

$$\frac{dy}{dx} = -\sin u \cdot \left(-\tfrac{1}{8}\right) = \tfrac{1}{8}\sin\left(-\tfrac{x}{8}\right)$$

5) $y = \tan u, \quad u = 9x + 2$

6) $y = \sqrt{4u+3}, \quad u = x^2 - 6x$

**Answer**

$$\frac{dy}{dx} = \frac{8x-24}{2\sqrt{4u+3}} = \frac{4x-12}{\sqrt{4x^2-24x+3}}$$

**For each of the following exercises,**

**a. decompose each function in the form $y = f(u)$ and $u = g(x)$, and**

**b. find $\frac{dy}{dx}$ as a function of $x$.**

7) $y = (3x-2)^6$

8) $y = (3x^2+1)^3$

**Answer**

a. $f(u) = u^3, \quad u = 3x^2 + 1;$

b. $\frac{dy}{dx} = 18x(3x^2+1)^2$

9) $y = \sin^5(x)$

10) $y = \left(\frac{x}{7} + \frac{7}{x}\right)^7$

**Answer**

a. $f(u) = u^7, \quad u = \dfrac{x}{7} + \dfrac{7}{x};$

b. $\dfrac{dy}{dx} = 7\left(\dfrac{x}{7} + \dfrac{7}{x}\right)^6 \cdot \left(\dfrac{1}{7} - \dfrac{7}{x^2}\right)$

11) $y = \tan(\sec x)$

12) $y = \csc(\pi x + 1)$

**Answer**

a. $f(u) = \csc u, \quad u = \pi x + 1;$

b. $\dfrac{dy}{dx} = -\pi \csc(\pi x + 1) \cdot \cot(\pi x + 1)$

13) $y = \cot^2 x$

14) $y = -6 \sin^{-3} x$

**Answer**

a. $f(u) = -6u^{-3}, \quad u = \sin x;$

b. $\dfrac{dy}{dx} = 18 \sin^{-4} x \cdot \cos x$

**In exercises 15 - 24, find $\dfrac{dy}{dx}$ for each function.**

15) $y = (3x^2 + 3x - 1)^4$

16) $y = (5 - 2x)^{-2}$

**Answer**

$\dfrac{dy}{dx} = \dfrac{4}{(5 - 2x)^3}$

17) $y = \cos^3(\pi x)$

18) $y = (2x^3 - x^2 + 6x + 1)^3$

**Answer**

$\dfrac{dy}{dx} = 6(2x^3 - x^2 + 6x + 1)^2 \cdot (3x^2 - x + 3)$

19) $y = \dfrac{1}{\sin^2(x)}$

20) $y = \left(\tan x + \sin x\right)^{-3}$

**Answer**

$\dfrac{dy}{dx} = -3\left(\tan x + \sin x\right)^{-4} \cdot (\sec^2 x + \cos x)$

21) $y = x^2 \cos^4 x$

22) $y = \sin(\cos 7x)$

**Answer**

$\dfrac{dy}{dx} = -7 \cos(\cos 7x) \cdot \sin 7x$

23) $y = \sqrt{6 + \sec \pi x^2}$

24) $y = \cot^3(4x + 1)$

**Answer**

$\dfrac{dy}{dx} = -12 \cot^2(4x + 1) \cdot \csc^2(4x + 1)$

25) Let $y = [f(x)]^3$ and suppose that $f'(1) = 4$ and $\frac{dy}{dx} = 10$ for $x = 1$. Find $f(1)$.

26) Let $y = \left(f(x) + 5x^2\right)^4$ and suppose that $f(-1) = -4$ and $\frac{dy}{dx} = 3$ when $x = -1$. Find $f'(-1)$

**Answer**

$f'(-1) = 10\frac{3}{4}$

27) Let $y = (f(u) + 3x)^2$ and $u = x^3 - 2x$. If $f(4) = 6$ and $\frac{dy}{dx} = 18$ when $x = 2$, find $f'(4)$.

28) [Technology Required] Find the equation of the tangent line to $y = -\sin(\frac{x}{2})$ at the origin. Use a calculator to graph the function and the tangent line together.

**Answer**

$y = -\frac{1}{2}x$

29) [Technology Required] Find the equation of the tangent line to $y = \left(3x + \frac{1}{x}\right)^2$ at the point $(1, 16)$. Use a calculator to graph the function and the tangent line together.

30) Find the $x$ -coordinates at which the tangent line to $y = \left(x - \frac{6}{x}\right)^8$ is horizontal.

**Answer**

$x = \pm\sqrt{6}$

31) [Technology Required] Find an equation of the line that is normal to $g(\theta) = \sin^2(\pi\theta)$ at the point $\left(\frac{1}{4}, \frac{1}{2}\right)$. Use a calculator to graph the function and the normal line together.

**For exercises 32 - 39, use the information in the following table to find $h'(a)$ at the given value for $a$.**

| $x$ | $f(x)$ | $f'(x)$ | $g(x)$ | $g'(x)$ |
|---|---|---|---|---|
| 0 | 2 | 5 | 0 | 2 |
| 1 | 1 | −2 | 3 | 0 |
| 2 | 4 | 4 | 1 | −1 |
| 3 | 3 | −3 | 2 | 3 |

32) $h(x) = f\big(g(x)\big); \quad a = 0$

**Answer**

$h'(0) = 10$

33) $h(x) = g\big(f(x)\big); \quad a = 0$

34) $h(x) = \left(x^4 + g(x)\right)^{-2}; \quad a = 1$

**Answer**

$h'(1) = -\frac{1}{8}$

35) $h(x) = \left(\frac{f(x)}{g(x)}\right)^2; \quad a = 3$

36) $h(x) = f\big(x + f(x)\big); \quad a = 1$

**Answer**

$h'(1) = -4$

37) $h(x) = \left(1 + g(x)\right)^3; \quad a = 2$

38) $h(x) = g\big(2 + f(x^2)\big); \quad a = 1$

**Answer**

$h'(1) = -12$

39) $h(x) = f\big(g(\sin x)\big); \quad a = 0$

40) [Technology Required] The position function of a freight train is given by $s(t) = 100(t+1)^{-2}$, with $s$ in meters and $t$ in seconds. At time $t = 6$ s, find the train's

a. velocity and

b. acceleration.

c. Considering your results in parts a. and b., is the train speeding up or slowing down?

**Answer**

a. $v(6) = -\frac{200}{343}$ m/s,

b. $a(6) = \frac{600}{2401}$ m/s$^2$,

c. The train is slowing down since velocity and acceleration have opposite signs.

41) [Technology Required] A mass hanging from a vertical spring is in simple harmonic motion as given by the following position function, where $t$ is measured in seconds and $s$ is in inches:

$$s(t) = -3\cos\left(\pi t + \frac{\pi}{4}\right).$$

a. Determine the position of the spring at $t = 1.5$ s.

b. Find the velocity of the spring at $t = 1.5$ s.

42) [Technology Required] The total cost to produce $x$ boxes of Thin Mint Girl Scout cookies is $C$ dollars, where $C = 0.0001x^3 - 0.02x^2 + 3x + 300$. In $t$ weeks production is estimated to be $x = 1600 + 100t$ boxes.

a. Find the marginal cost $C'(x)$.

b. Use Leibniz's notation for the chain rule, $\frac{dC}{dt} = \frac{dC}{dx} \cdot \frac{dx}{dt}$, to find the rate with respect to time $t$ that the cost is changing.

c. Use your result in part b. to determine how fast costs are increasing when $t = 2$ weeks. Include units with the answer.

**Answer**

a. $C'(x) = 0.0003x^2 - 0.04x + 3$

b. $\frac{dC}{dt} = 100 \cdot (0.0003x^2 - 0.04x + 3) = 100 \cdot (0.0003(1600 + 100t)^2 - 0.04(1600 + 100t) + 3) = 300t^2 + 9200t + 70700$

c. Approximately $90,300 per week

43) [Technology Required] The formula for the area of a circle is $A = \pi r^2$, where $r$ is the radius of the circle. Suppose a circle is expanding, meaning that both the area $A$ and the radius $r$ (in inches) are expanding.

a. Suppose $r = 2 - \frac{100}{(t+7)^2}$ where $t$ is time in seconds. Use the chain rule $\frac{dA}{dt} = \frac{dA}{dr} \cdot \frac{dr}{dt}$ to find the rate at which the area is expanding.

b. Use your result in part a. to find the rate at which the area is expanding at $t = 4$ s.

44) [Technology Required] The formula for the volume of a sphere is $S = \frac{4}{3}\pi r^3$, where $r$ (in feet) is the radius of the sphere. Suppose a spherical snowball is melting in the sun.

a. Suppose $r = \frac{1}{(t+1)^2} - \frac{1}{12}$ where $t$ is time in minutes. Use the chain rule $\frac{dS}{dt} = \frac{dS}{dr} \cdot \frac{dr}{dt}$ to find the rate at which the snowball is melting.

b. Use your result in part a. to find the rate at which the volume is changing at $t = 1$ min.

**Answer**

a. $\frac{dS}{dt} = -\frac{8\pi r^2}{(t+1)^3} = -\frac{8\pi\left(\frac{1}{(t+1)^2} - \frac{1}{12}\right)^2}{(t+1)^3}$

b. The volume is decreasing at a rate of $-\frac{\pi}{36}$ ft$^3$/min

45) [Technology Required] The daily temperature in degrees Fahrenheit of Phoenix in the summer can be modeled by the function $T(x) = 94 - 10\cos\left[\frac{\pi}{12}(x-2)\right]$, where $x$ is hours after midnight. Find the rate at which the temperature is changing at 4 p.m.

46) [Technology Required] The depth (in feet) of water at a dock changes with the rise and fall of tides. The depth is modeled by the function $D(t) = 5\sin\left(\frac{\pi}{6}t - \frac{7\pi}{6}\right) + 8$, where $t$ is the number of hours after midnight. Find the rate at which the depth is changing at 6 a.m.

**Answer**

**2.3** ft/hr

# 3.5: Derivatives of Exponential and Hyperbolic Functions

**Learning Objectives**

- Find the derivative of exponential functions, both natural-based and non-natural-based.
- Find the derivative of logarithmic functions, both natural-based and non-natural-based.
- Apply the formulas for derivatives of the hyperbolic functions.
- Explore applications for the derivatives of exponential and hyperbolic functions in the sciences and engineering.

Hawk A.I. Section-Specific Tutor

Please note that, to access the Hawk A.I. Tutor, you will need a (free) OpenAI account.

So far, we have learned how to differentiate various functions, including polynomial, radical, rational, and trigonometric functions. In this section, we explore derivatives of exponential and hyperbolic functions.

## Discovering $e$

In Calculus (and often in Precalculus or College Algebra), a common "beginning" limit to investigate numerically is

$$\lim_{k\to\infty}\left(1+\frac{1}{k}\right)^k. \tag{3.5.1}$$

Table 3.5.1 shows values of this limit for large values of $k$.

**Table 3.5.1: Investigating a Famous Limit**

| $k$ | $\left(1+\frac{1}{k}\right)^k$ |
|---|---|
| 10 | 2.5937424601... |
| 100 | 2.70481382942153... |
| 1,000 | 2.71692393223552... |
| 10,000 | 2.71814592682436... |
| 100,000 | 2.71826823719753... |
| 1,000,000 | 2.71828046915643... |
| 10,000,000 | 2.71828169398037... |
| 100,000,000 | 2.71828178639580... |
| 1,000,000,000 | 2.71828203081451... |

It *appears* this limit is approaching some value around $2.71828...$. This exceptional value is a non-terminating, non-repeating number. That is, it is an irrational number - just like $\pi$. If we could assign importance to the value of this limit, it would be tied with the importance of the numbers $0$, $1$, $\pi$, and $i=\sqrt{-1}$.

This limit comes up so often in the sciences that we give it a unique name. Rather than calling it "the limit that approaches $2.718281828459045...$," we call it $e$. As was mentioned, it *appears* that this limit approaches a constant; however, the proof of this fact is reserved for later in the course. For now, it's important to have the limit, 3.5.1, in hand for use.

An important alternative form of 3.5.1 is found by letting $n=\frac{1}{k}$. As $k\to\infty$, $n\to 0$ and we get the form

$$\lim_{n\to 0}(1+n)^{1/n}. \tag{3.5.2}$$

Let's formalize this definition before we move on.

**Definition: $e$**

The limit

$$\lim_{k\to\infty}\left(1+\frac{1}{k}\right)^k = \lim_{n\to 0}(1+n)^{1/n}$$

is defined to be the irrational number $e$.

We will be using this unique number shortly; however, we need to discuss some Calculus before we do.

## Derivatives Exponential Functions

Just as when we found the derivatives of other functions, we can find the derivatives of exponential functions using formulas. Recall that all non-transformed exponential functions have the basic form $B(x) = b^x$, where $b > 0$ and $b \neq 1$. Our initial goal is to prove that exponential functions are continuous everywhere. Once we have this, the proof of the derivative of an exponential function becomes trivial.

### Proving that Exponential Functions are Continuous Everywhere

Believe it or not, we have had a long history with exponential functions. We began in Arithmetic with the definition of $b^n$, where $n \in \mathbb{N}$, as the product of $b$ multiplied by itself $n$ times. Later, in Algebra, we defined $b^0 = 1$, $b^{-n} = \frac{1}{b^n}$ for $n \in \mathbb{N}$, and $b^{s/t} = (\sqrt[t]{b})^s$ for positive integers $s$ and $t$. These define exponential functions over the *rational numbers* but leave open the question of the value of $b^r$ where $r$ is an *irrational number*. That is, we know that $4^{3.14} = 4^{314/100}$ is a shortcut notation for $\sqrt[100]{4^{314}}$, but what if that exponent is not a terminating decimal approximation of $\pi$, but instead is $\pi$ itself? What does $4^\pi$ mean?

By *assuming* the continuity of $B(x) = b^x$, $b > 0$, we may interpret $b^r$ as $\lim_{x\to r} b^x$ where the values of $x$ as we take the limit are rational. For example, we may view $4^\pi$ as the number satisfying

$$\begin{array}{ccccc} 4^3 & < & 4^\pi & < & 4^4 \\ 4^{3.1} & < & 4^\pi & < & 4^{3.2} \\ 4^{3.14} & < & 4^\pi & < & 4^{3.15} \\ 4^{3.141} & < & 4^\pi & < & 4^{3.142} \\ 4^{3.1415} & < & 4^\pi & < & 4^{3.1416} \\ & & \vdots & & \end{array}$$

As we see in the Table 3.5.2, $4^\pi \approx 77.88$.

**Table 3.5.2: Investigating $4^x$ as $x \to \pi$**

| $x$ | $4^x$ | $x$ | $4^x$ |
|---|---|---|---|
| $4^3$ | 64 | $4^{3.141593}$ | 77.8802710486 |
| $4^{3.1}$ | 73.5166947198 | $4^{3.1416}$ | 77.8810268071 |
| $4^{3.14}$ | 77.7084726013 | $4^{3.142}$ | 77.9242251944 |
| $4^{3.141}$ | 77.8162741237 | $4^{3.15}$ | 78.7932424541 |
| $4^{3.1415}$ | 77.8702309526 | $4^{3.2}$ | 84.4485062895 |
| $4^{3.14159}$ | 77.8799471543 | $4^4$ | 256 |

While we have stated (via the Generalized Direct Substitution Property) that all our basic functions (including exponentials) are continuous on their domains, we have yet to prove that result for exponential functions officially. To do so, we need to first prove that $B(x) = b^x$ is continuous at $x = 0$.

Suppose $x > 0$. $\forall \epsilon > 0$, if we choose $\delta = \log_b(1+\epsilon)$, then

$$
\begin{array}{rrcll}
 & 0 & < |x-0| & < \delta & \\
\implies & x & < \delta & & (x>0 \implies |x| = x) \\
\implies & x & < \log_b(1+\epsilon) & & \\
\implies & b^x & < 1+\epsilon & & \\
\implies & b^x - 1 & < \epsilon & & \\
\implies & |b^x - 1| & < \epsilon & & (x>0 \implies b^x > b^0 = 1 \implies b^x - 1 > 0 \\
 & & & & \implies b^x - 1 = |b^x - 1|)
\end{array}
$$

Therefore, $\lim\limits_{x \to 0^+} b^x = 1 = b^0$.

Moreover, if $x < 0$, then $\forall \epsilon > 0$, we choose $\delta = -\log_b(1-\epsilon)$. Therefore,

$$
\begin{array}{rrcll}
 & 0 < & |x-0| & < \delta & \\
\implies & -x & < \delta & & (x<0 \implies |x| = -x) \\
\implies & -x & < -\log_b(1-\epsilon) & & \\
\implies & x & > \log_b(1-\epsilon) & & \\
\implies & b^x & > 1-\epsilon & & \\
\implies & b^x - 1 & > -\epsilon & & \\
\implies & -(b^x - 1) & < \epsilon & & \\
\implies & |b^x - 1| & < \epsilon & & (x<0 \implies b^x < b^0 = 1 \implies b^x - 1 < 0 \\
 & & & & \implies -(b^x - 1) = |b^x - 1|)
\end{array}
$$

Therefore, $\lim\limits_{x \to 0^-} b^x = 1 = b^0$.

Since both one-sided limits are equal to $b^0$, $\lim\limits_{x \to 0} b^x = 1 = b^0$. Thus, $B(x) = b^x$ is continuous at $x = 0$.

We are now ready to prove that $B(x) = b^x$ is continuous everywhere.

Let $B(x) = b^x$ and let $a$ be arbitrary. Then

$$
\begin{array}{rcll}
\lim\limits_{x \to a} b^x & = & \lim\limits_{h \to 0} b^{a+h} & (\text{substituting } x = a+h \implies h = x-a \implies h \to 0 \text{ as } x \to a) \\
 & = & \lim\limits_{h \to 0} \left(b^a \cdot b^h\right) & \\
 & = & b^a \cdot \lim\limits_{h \to 0} b^h & (\text{Constant Multiple Limit Law}) \\
 & = & b^a \cdot b^0 & (b^x \text{ is continuous at } 0) \\
 & = & b^a &
\end{array}
$$

Since $a$ is arbitrary, this shows that the exponential function $B(x) = b^x$ is continuous everywhere.

The next theorem is a fascinating fact and is the student's favorite derivative. In words, the function $y = e^x$ is the only function (besides $y = 0$) whose derivative is itself!

**Theorem: Derivative of $e^x$**

$$\frac{d}{dx}\left(e^x\right) = e^x$$

**Proof**

Using the limit definition of the derivative, we get the following:

$$\begin{aligned}
\frac{d}{dx}\left(e^x\right) &= \lim_{h\to 0}\frac{e^{x+h}-e^x}{h} && \text{(definition of a derivative)}\\
&= \lim_{h\to 0}\frac{e^x\cdot e^h-e^x}{h}\\
&= \lim_{h\to 0}\frac{e^x\left(e^h-1\right)}{h}\\
&= e^x\cdot\lim_{h\to 0}\frac{e^h-1}{h} && \text{(since } e^x \text{ does not rely on } h\text{, it can be factored out)}
\end{aligned}$$

Recall that we defined $e$ to be $\lim_{n\to 0}(1+n)^{1/n}$. If we let $n=e^h-1$, then $n+1=e^h$. Since exponential functions are continuous everywhere,

$$\lim_{h\to 0}e^h=e^0=1.$$

This means that $n\to 0$ as $h\to 0$. Moreover, solving $n+1=e^h$ for $h$, we get $\ln(n+1)=h$. Thus,

$$\begin{aligned}
\frac{d}{dx}\left(e^x\right) &= e^x\cdot\lim_{h\to 0}\frac{e^h-1}{h}\\
&= e^x\cdot\lim_{n\to 0}\frac{n}{\ln(1+n)}\\
&= e^x\cdot\lim_{n\to 0}\frac{1}{\frac{1}{n}\ln(1+n)}\\
&= e^x\cdot\lim_{n\to 0}\frac{1}{\ln(1+n)^{1/n}}\\
&= e^x\cdot\frac{1}{\lim_{n\to 0}\ln(1+n)^{1/n}} && \text{(Limit Laws)}\\
&= e^x\cdot\frac{1}{\ln\left(\lim_{n\to 0}(1+n)^{1/n}\right)} && \text{(Limit Laws)}\\
&= e^x\cdot\frac{1}{\ln(e)} && \text{(definition of } e\text{)}\\
&= e^x\cdot\frac{1}{1}\\
&= e^x
\end{aligned}$$

*Q.E.D.*

Before going into examples, let's add a quick corollary.

**Corollary: Derivative of $b^x$**

$$\frac{d}{dx}\left(b^x\right)=b^x\ln(b)$$

**Proof**

$$\begin{aligned}\frac{d}{dx}\left(b^x\right) &= \frac{d}{dx}\left(e^{\ln\left(b^x\right)}\right)\\ &= \frac{d}{dx}\left(e^{x\ln(b)}\right)\\ &= e^{x\ln(b)}\cdot\ln(b) \qquad \text{(Chain Rule)}\\ &= e^{\ln\left(b^x\right)}\cdot\ln(b)\\ &= b^x\cdot\ln(b)\end{aligned}$$

*Q.E.D.*

### Example 3.5.1: Derivative of an Exponential Function

Find the derivative of $f(x)=e^{\tan(2x)}$.

**Solution**

Using the derivative formula and the Chain Rule,

$$f'(x)=e^{\tan(2x)}\frac{d}{dx}\left(\tan(2x)\right)=e^{\tan(2x)}\sec^2(2x)\cdot 2$$

### Example 3.5.2: Combining Differentiation Rules

Find the derivative of $y=\frac{e^{x^2}}{x}$.

**Solution**

Use the derivative of the natural exponential function, the Quotient Rule, and the Chain Rule.

$$\begin{aligned}y' &= \frac{\left(e^{x^2}\cdot 2\right)x\cdot x-1\cdot e^{x^2}}{x^2} \qquad \text{(Quotient Rule)}\\ &= \frac{e^{x^2}\left(2x^2-1\right)}{x^2}\end{aligned}$$

### Checkpoint 3.5.2

Find the derivative of $h(x)=xe^{2x}$.

**Answer**

$h'(x)=e^{2x}+2xe^{2x}$

### Example 3.5.3: Applying the Natural Exponential Function

A colony of mosquitoes has an initial population of 1000. After $t$ days, the population is given by $A(t)=1000e^{0.3t}$. Show that the ratio of the rate of change of the population, $A'(t)$, to the population, $A(t)$ is constant.

**Solution**

First find $A'(t)$. By using the Chain Rule, we have $A'(t)=300e^{0.3t}$. Thus, the ratio of the rate of change of the population to the population is given by

$$\frac{A'(t)}{A(t)} = \frac{300e^{0.3t}}{1000e^{0.3t}} = 0.3.$$

The ratio of the rate of change of the population to the population is the constant 0.3.

**? Checkpoint 3.5.3**

If $A(t) = 1000e^{0.3t}$ describes the mosquito population after $t$ days, as in the preceding example, what is the rate of change of $A(t)$ after four days?

**Answer**

996

**✓ Example 3.5.4: Applying Derivative Formulas**

Find the derivative of $h(x) = \frac{3^x}{3^x+2}$.

**Solution**

$$h'(x) = \frac{3^x \ln 3(3^x+2) - 3^x \ln 3(3^x)}{(3^x+2)^2} \quad \text{(Quotient Rule)}$$

$$= \frac{2 \cdot 3^x \ln 3}{(3x+2)^2}$$

**? Checkpoint 3.5.4**

Find the slope for the line tangent to $y = 3^x$ at $x = 2$.

**Answer**

$9\ln(3)$

## Derivatives of the Hyperbolic Functions

Recall that the hyperbolic sine and hyperbolic cosine are defined as

$$\sinh x = \frac{e^x - e^{-x}}{2}$$

and

$$\cosh x = \frac{e^x + e^{-x}}{2}.$$

The other hyperbolic functions are then defined in terms of $\sinh x$ and $\cosh x$. The graphs of the hyperbolic functions are shown in Figure 3.5.1.

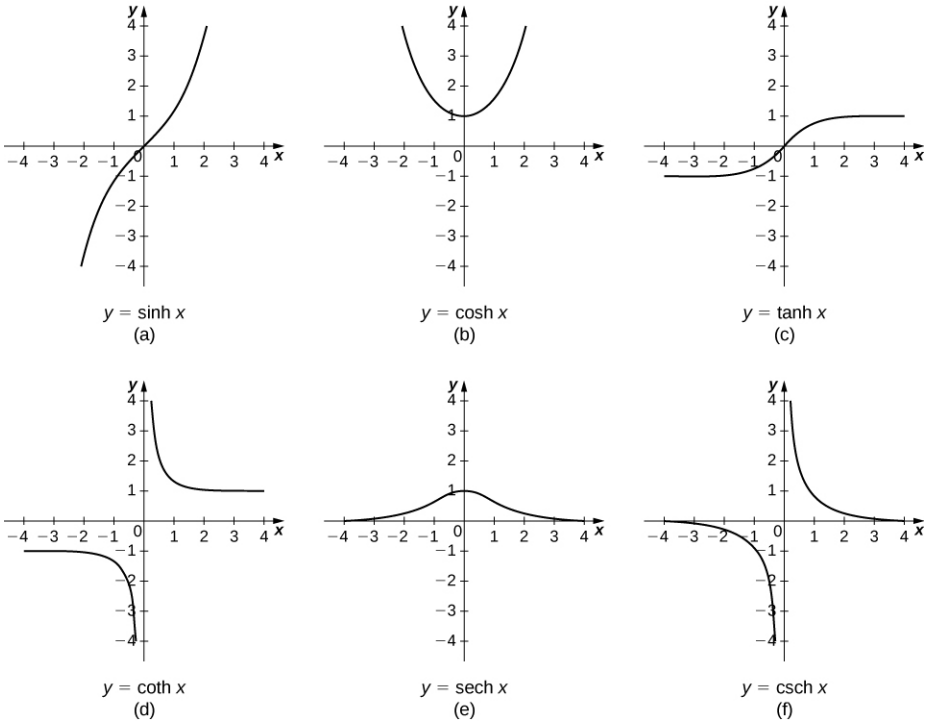

*Figure* **3.5.1***: Graphs of the hyperbolic functions.*

Developing differentiation formulas for the hyperbolic functions is easy. For example, looking at $\sinh x$ we have

$$\begin{aligned}\frac{d}{dx}(\sinh x) &= \frac{d}{dx}\left(\frac{e^x - e^{-x}}{2}\right) \\ &= \frac{1}{2}\left[\frac{d}{dx}(e^x) - \frac{d}{dx}(e^{-x})\right] \\ &= \frac{1}{2}[e^x + e^{-x}] \\ &= \cosh x.\end{aligned}$$

Similarly,

$$\frac{d}{dx}\cosh x = \sinh x.$$

We summarize the differentiation formulas for the hyperbolic functions in Table **3.5.3**.

**Table 3.5.3: Derivatives of the Hyperbolic Functions**

| $f(x)$ | $\frac{d}{dx}f(x)$ |
|---|---|
| $\sinh x$ | $\cosh x$ |
| $\cosh x$ | $\sinh x$ |
| $\tanh x$ | $\operatorname{sech}^2 x$ |
| $\coth x$ | $-\operatorname{csch}^2 x$ |
| $\operatorname{sech} x$ | $-\operatorname{sech} x \tanh x$ |
| $\operatorname{csch} x$ | $-\operatorname{csch} x \coth x$ |

Let's take a moment to compare the derivatives of the hyperbolic functions with the derivatives of the standard trigonometric functions. There are a lot of similarities and differences. For example, the derivatives of the sine functions match:

$$\frac{d}{dx}\sin x = \cos x$$

and

$$\frac{d}{dx}\sinh x = \cosh x.$$

The derivatives of the cosine functions, however, differ in sign:

$$\frac{d}{dx}\cos x = -\sin x,$$

but

$$\frac{d}{dx}\cosh x = \sinh x.$$

**Example 3.5.5**

Evaluate the following derivatives:

a. $\frac{d}{dx}(\sinh(x^2))$
b. $\frac{d}{dx}(\cosh x)^2$

**Solutions**

Using the formulas in Table 3.5.3 and the Chain Rule, we get

a.

$$\frac{d}{dx}(\sinh(x^2)) = \cosh(x^2)\cdot 2x$$

b.

$$\frac{d}{dx}(\cosh x)^2 = 2\cosh x \sinh x$$

**Checkpoint 3.5.6**

Evaluate the following derivatives:

a. $\frac{d}{dx}(\tanh(x^2+3x))$
b. $\frac{d}{dx}\left(\frac{1}{(\sinh x)^2}\right)$

**Answer a**

$\frac{d}{dx}(\tanh(x^2+3x)) = (\operatorname{sech}^2(x^2+3x))(2x+3)$

**Answer b**

$\frac{d}{dx}\left(\frac{1}{(\sinh x)^2}\right) = \frac{d}{dx}(\sinh x)^{-2} = -2(\sinh x)^{-3}\cosh x$

## READING QUESTIONS

1. How is the number $e$ defined using a limit?
2. What is the derivative of $f(x) = e^x$?
3. What is the derivative of $f(x) = b^x$, where $b$ is a positive constant?
4. How is the Chain Rule applied to find the derivative of $f(x) = e^{g(x)}$?
5. What is the derivative of $f(x) = \sinh x$?
6. What is the derivative of $f(x) = \cosh x$? How does this compare to the derivative of $\cos x$?
7. What is the derivative of $f(x) = \tanh x$?
8. Which of the six hyperbolic functions have derivatives that include a negative sign?
9. How are the differentiation formulas for hyperbolic functions derived?
10. If a population is given by $A(t) = 1000e^{0.3t}$, what does the ratio $\frac{A'(t)}{A(t)}$ represent?

## HOMEWORK

**In exercises 1 - 16, find $f'(x)$ for each function.**

1) $f(x) = x^2e^x$

**Answer**

$f'(x) = 2xe^x + x^2e^x$

2) $f(x) = \dfrac{e^{-x}}{x}$

3) $f(x) = \sqrt{e^{2x} + 2x}$

4) $f(x) = \dfrac{e^x - e^{-x}}{e^x + e^{-x}}$

**Answer**

$f'(x) = \dfrac{4}{(e^x + e^{-x})^2}$

5) $f(x) = \dfrac{10^x}{\ln 10}$

6) $f(x) = 2^{4x} + 4x^2$

**Answer**

$f'(x) = 2^{4x+2} \cdot \ln 2 + 8x$

7) $f(x) = 3^{\sin 3x}$

8) $f(x) = x^\pi \cdot \pi^x$

**Answer**

$f'(x) = \pi x^{\pi-1} \cdot \pi^x + x^\pi \cdot \pi^x \ln \pi$

9) $f(x) = \cosh(3x + 1)$

**Answer**

$f'(x) = 3\sinh(3x + 1)$

10) $f(x) = \sinh(x^2)$

11) $f(x) = \dfrac{1}{\cosh(x)}$

**Answer**

$$f'(x) = -\tanh(x)\operatorname{sech}(x)$$

12) $f(x) = \cosh^2(x) + \sinh^2(x)$

**Answer**

$$f'(x) = 4\cosh(x)\sinh(x)$$

13) $f(x) = \cosh^2(x) - \sinh^2(x)$

14) $f(x) = \tanh(\sqrt{x^2+1})$

**Answer**

$$f'(x) = \frac{x\operatorname{sech}^2(\sqrt{x^2+1})}{\sqrt{x^2+1}}$$

15) $f(x) = \dfrac{1+\tanh(x)}{1-\tanh(x)}$

16) $f(x) = \sinh^6(x)$

**Answer**

$$f'(x) = 6\sinh^5(x)\cosh(x)$$

17) Show that $\cosh(x)$ and $\sinh(x)$ satisfy $y'' = y$.

**Answer**

Answers may vary

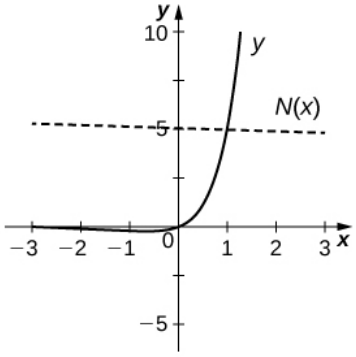
18) Use the quotient rule to verify that $\dfrac{d}{dx}\left(\tanh(x)\right) = \operatorname{sech}^2(x)$.

19) [Technology Required] Find an equation of the tangent line to the graph of $f(x) = 4xe^{(x^2-1)}$ at the point where $x = -1$. Graph both the function and the tangent line.

20) [Technology Required] Find the equation of the line that is normal to the graph of $f(x) = x \cdot 5^x$ at the point where $x = 1$. Graph both the function and the normal line.

**Answer**

$y = \frac{-1}{5+5\ln 5}x + \left(5 + \frac{1}{5+5\ln 5}\right)$



21) The formula $I(t) = \dfrac{\sin t}{e^t}$ is the formula for a decaying alternating current.

a. Complete the following table with the appropriate values.

| $t$ | $\frac{\sin t}{e^t}$ |
|---|---|
| 0 | (i) |
| $\pi/2$ | (ii) |
| $\pi$ | (iii) |
| $3\pi/2$ | (vi) |
| $2\pi$ | (v) |
| $2\pi$ | (vi) |
| $3\pi$ | (vii) |

b. Using only the values in the table, determine where the tangent line to the graph of $I(t)$ is horizontal.

22) [Technology Required] The population of Toledo, Ohio, in 2000 was approximately 500,000. Assume the population is increasing at a rate of 5% per year.

a. Write the exponential function that relates the total population as a function of $t$.

b. Use part a. to determine the rate at which the population is increasing in $t$ years.

c. Use part b. to determine the rate at which the population is increasing in 10 years

**Answer**

a. $P = 500,000(1.05)^t$ individuals
b. $P'(t) = 24395 \cdot (1.05)^t$ individuals per year
c. $39,737$ individuals per year

23) [Technology Required] An isotope of the element erbium has a half-life of approximately 12 hours. Initially there are 9 grams of the isotope present.

a. Write the exponential function that relates the amount of substance remaining as a function of $t$, measured in hours.

b. Use a. to determine the rate at which the substance is decaying in $t$ hours.

c. Use b. to determine the rate of decay at $t = 4$ hours.

24) [Technology Required] The number of cases of influenza in New York City from the beginning of 1960 to the beginning of 1964 is modeled by the function $N(t) = 5.3e^{0.093t^2 - 0.87t}, (0 \le t \le 4)$, where $N(t)$ gives the number of cases (in thousands) and $t$ is measured in years, with $t = 0$ corresponding to the beginning of 1960.

a. Show work that evaluates $N(0)$ and $N(4)$. Briefly describe what these values indicate about the disease in New York City.

b. Show work that evaluates $N'(0)$ and $N'(3)$. Briefly describe what these values indicate about the disease in the United States.

**Answer**

a. At the beginning of 1960 there were 5.3 thousand cases of the disease in New York City. At the beginning of 1963 there were approximately 723 cases of the disease in the United States.
b. At the beginning of 1960 the number of cases of the disease was decreasing at rate of $-4.611$ thousand per year; at the beginning of 1963, the number of cases of the disease was decreasing at a rate of $-0.2808$ thousand per year.

25) [Technology Required] The relative rate of change of a differentiable function $y = f(x)$ is given by $\frac{100 \cdot f'(x)}{f(x)}$. One model for population growth is a Gompertz growth function, given by $P(x) = ae^{-b \cdot e^{-cx}}$ where $a, b$, and $c$ are constants.

a. Find the relative rate of change formula for the generic Gompertz function.

b. Use part a. to find the relative rate of change of a population in $x = 20$ months when $a = 204,\ b = 0.0198$, and $c = 0.15$.

c. Briefly interpret what the result of part b. means.

**For exercises 26 - 29, use the population of New York City from 1790 to 1860, given in the following table.**

| Year since 1790 | Population |
|---|---|
| 0 | 33,131 |
| 10 | 60,515 |
| 20 | 96,373 |
| 30 | 123,706 |
| 40 | 202,300 |
| 50 | 312,710 |
| 60 | 515,547 |
| 70 | 813,669 |

New York City Population Over Time Source: http://en.Wikipedia.org/wiki/Largest..._United_States_by_population_by_decade

26) [Technology Required] Using a computer program or a calculator, fit a growth curve to the data of the form $p = ab^t$.

**Answer**

$p = 35741(1.045)^t$

27) [Technology Required] Using the exponential best fit for the data, write a table containing the derivatives evaluated at each year.

28) [Technology Required] Using the exponential best fit for the data, write a table containing the second derivatives evaluated at each year.

**Answer**

| Year since 1790 | $P''$ |
|---|---|
| 0 | 69.25 |
| 10 | 107.5 |
| 20 | 167.0 |
| 30 | 259.4 |
| 40 | 402.8 |
| 50 | 625.5 |
| 60 | 971.4 |
| 70 | 1508.5 |

29) [Technology Required] Using the tables of first and second derivatives and the best fit, answer the following questions:

a. Will the model be accurate in predicting the future population of New York City? Why or why not?

b. Estimate the population in 2010. Was the prediction correct from part a.?

30) [Technology Required] A chain hangs from two posts 2m apart to form a catenary described by the equation $y = 2\cosh(x/2) - 1$. Find the slope of the catenary at the left fence post.

**Answer**

$-0.521095$

# 3.6: Implicit Differentiation and the Derivatives of the Inverse Trigonometric and Hyperbolic Functions

**Learning Objectives**

- Use implicit differentiation to find the derivative given an implicitly defined relation between two variables.
- Use implicit differentiation to determine the equation of a tangent line to an implicitly-defined curve.
- Calculate the derivative of an inverse trigonometric function.
- Recognize the derivatives of the inverse hyperbolic functions.

Hawk A.I. Section-Specific Tutor

Please note that, to access the Hawk A.I. Tutor, you will need a (free) OpenAI account.

We have already studied how to find equations of tangent lines to functions and the rate of change of a function at a specific point. In all these cases, we had the explicit equation for the function and differentiated these functions explicitly. Suppose instead that we want to determine the equation of a tangent line to an arbitrary curve or the rate of change of an arbitrary curve at a point. In this section, we solve these problems by finding the derivatives of functions that define $y$ implicitly in terms of $x$.

## Implicit Differentiation

In most discussions of math, if the dependent variable $y$ is a function of the independent variable $x$, we express $y$ in terms of $x$. If this is the case, we say that $y$ is an **explicit function** of $x$. For example, when we write the equation $y = x^2 + 1$, we are defining $y$ explicitly in terms of $x$. On the other hand, if the relationship between the function $y$ and the variable $x$ is expressed by an equation where $y$ is not expressed entirely in terms of $x$, we say that the equation defines $y$ **implicitly** in terms of $x$. For example, the equation $y - x^2 = 1$ defines the function $y = x^2 + 1$ implicitly.

Implicit differentiation allows us to find slopes of tangents to curves that are not functions (they fail the Vertical Line Test). We are using the idea that portions of $y$ are functions that satisfy the given equation but that $y$ is not a function of $x$.

Generally, an equation defines a function implicitly if the function satisfies that equation. An equation may define many different functions implicitly. For example, the functions

$$y = \sqrt{25 - x^2}$$

and

$$y = \begin{cases} \sqrt{25 - x^2}, & \text{if } -5 \le x < 0 \\ -\sqrt{25 - x^2}, & \text{if } 0 \le x \le 5 \end{cases}$$

which are illustrated in Figure 3.6.1, are just two of the many functions defined implicitly by the equation $x^2 + y^2 = 25$.

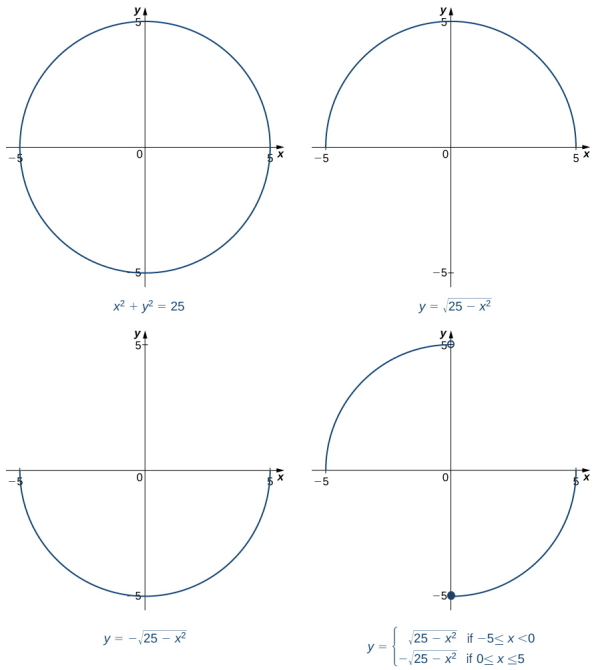


*Figure* **3.6.1**:*The equation* $x^2 + y^2 = 25$ *defines many functions implicitly.*

If we want to find the slope of the line tangent to the graph of $x^2 + y^2 = 25$ at the point $(3, 4)$, we could evaluate the derivative of the function $y = \sqrt{25 - x^2}$ at $x = 3$. On the other hand, if we want the slope of the tangent line at the point $(3, -4)$, we could use the derivative of $y = -\sqrt{25 - x^2}$. However, it is not always easy to solve for a function defined implicitly by an equation. Fortunately, the technique of **implicit differentiation** allows us to find the derivative of an implicitly defined function without ever solving for the function explicitly.

A simplified explanation of implicit differentiation is that you take the derivatives of both sides of a given equation (whether *explicitly* solved for $y$ or not) with respect to the independent variable and perform the Chain Rule whether or not it is necessary. For example, suppose $y = \sinh(x) - 2^x$. Then

$$\begin{aligned} \frac{d}{dx}(y) = \frac{d}{dx}(\sinh(x) - 2^x) \quad &\Rightarrow \quad \frac{dy}{dx} = \cosh(x)\frac{dx}{dx} - 2^x \ln(2)\frac{dx}{dx} \\ &\Rightarrow \quad \frac{dy}{dx} = \cosh(x) \cdot 1 - 2^x \ln(x) \cdot 1 \\ &\Rightarrow \quad \frac{dy}{dx} = \cosh(x) - 2^x \ln(x) \end{aligned}$$

While the results are no different than how we have performed differentiation so far, the *process* is important to understand. Suppose, instead, that we had the equation $\cos(x^2 + x) = \tanh(x) + 3y$ and were asked to find $y'$. We *could* start by solving for $y$, *or* we could take the derivative of both sides immediately as follows:

$$\begin{aligned} \frac{d}{dx}(\cos(x^2 + x)) = \frac{d}{dx}(\tanh(x) + 3y) \quad &\Rightarrow \quad -\sin(x^2 + x) \cdot \frac{d}{dx}(x^2 + x) \\ &\qquad = \operatorname{sech}^2(x)\frac{dx}{dx} + 3\frac{dy}{dx} \\ &\Rightarrow \quad -\sin(x^2 + x) \cdot (2x + 1) \cdot \frac{dx}{dx} \\ &\qquad = \operatorname{sech}^2(x) \cdot 1 + 3\frac{dy}{dx} \\ &\Rightarrow \quad -\sin(x^2 + x) \cdot (2x + 1) \cdot 1 \\ &\qquad = \operatorname{sech}^2(x) \cdot 1 + 3\frac{dy}{dx} \\ &\Rightarrow \quad \frac{-\sin(x^2 + x) \cdot (2x + 1) - \operatorname{sech}^2(x)}{3} = \frac{dy}{dx} \end{aligned}$$

However, the *real* power of implicit differentiation comes into play when given the equation for an implicitly defined curve. For example, if $e^{xy} - \sqrt{x+y} = \cot(y)$, then the derivative of $y$ with respect to $x$ can be found by taking the derivative *implicitly*.

$$\begin{aligned}
\frac{d}{dx}\left(e^{xy} - \sqrt{x+y}\right) = \frac{d}{dx}\left(\cot(y)\right) \quad &\Rightarrow \quad \frac{d}{dx}e^{xy} - \frac{d}{dx}\sqrt{x+y} = -\csc^2(y)\cdot\frac{dy}{dx} \\
&\Rightarrow \quad e^{xy}\cdot\frac{d}{dx}(xy) - \frac{1}{2\sqrt{x+y}}\cdot\frac{d}{dx}(x+y) \\
&\qquad = -\csc^2(y)\cdot\frac{dy}{dx} \\
&\Rightarrow \quad e^{xy}\cdot\left(\frac{dx}{dx}\cdot y + x\cdot\frac{dy}{dx}\right) - \frac{1}{2\sqrt{x+y}}\cdot\left(\frac{dx}{dx} + \frac{dy}{dx}\right) \\
&\qquad = -\csc^2(y)\cdot\frac{dy}{dx} \\
&\Rightarrow \quad e^{xy}\cdot\left(y + x\cdot\frac{dy}{dx}\right) - \frac{1}{2\sqrt{x+y}}\cdot\left(1 + \frac{dy}{dx}\right) \\
&\qquad = -\csc^2(y)\cdot\frac{dy}{dx}
\end{aligned}$$

At this point, we would feel compelled to solve for $\frac{dy}{dx}$; however, let's hold off for now. It's enough at this point to understand how implicit differentiation works.

### Example 3.6.1: Using Implicit Differentiation

Assuming that $y$ is defined implicitly by the equation $x^2 + y^2 = 25$, find $\frac{dy}{dx}$.

**Solution**

$$\begin{aligned}
\frac{d}{dx}(x^2+y^2) &= \frac{d}{dx}(25) && \text{(differentiating implicitly)} \\
\Rightarrow \quad \frac{d}{dx}(x^2) + \frac{d}{dx}(y^2) &= 0 && \text{(Sum and Constant derivative rules)} \\
\Rightarrow \quad 2x + 2y\frac{dy}{dx} &= 0 && \left(\frac{d}{dx}(x^2) = 2x\frac{dx}{dx} = 2x \text{ and } \frac{d}{dx}(y^2) = 2y\frac{dy}{dx}\right) \\
\Rightarrow \quad 2y\frac{dy}{dx} &= -2x && \text{(grouping like terms)} \\
\Rightarrow \quad \frac{dy}{dx} &= -\frac{x}{y} && \text{(dividing both sides by } 2y\text{)}
\end{aligned}$$

**Analysis**

Note that the resulting expression for $\frac{dy}{dx}$ is in terms of both the independent variable $x$ and the dependent variable $y$. Although in some cases it may be possible to express $\frac{dy}{dx}$ in terms of $x$ only, it is generally not possible to do so.

### Example 3.6.2: Using Implicit Differentiation and the Product Rule

Assuming that $y$ is defined implicitly by the equation $x^3\sin y + y = 4x + 3$, find $\frac{dy}{dx}$.

**Solution**

$$\frac{d}{dx}(x^3 \sin y + y) = \frac{d}{dx}(4x+3) \quad \text{(differentiating implicitly)}$$

$$\Rightarrow \quad \frac{d}{dx}(x^3 \sin y) + \frac{d}{dx}(y) = 4 \quad \left(\text{Sum Rule on the left, and } \frac{d}{dx}(4x+3) = 4 \text{ on the right}\right)$$

$$\Rightarrow \quad \left(\frac{d}{dx}(x^3) \cdot \sin y + \frac{d}{dx}(\sin y) \cdot x^3\right) + \frac{dy}{dx} = 4 \quad \text{(Product Rule)}$$

$$\Rightarrow \quad 3x^2 \sin y + (\cos y \frac{dy}{dx}) \cdot x^3 + \frac{dy}{dx} = 4 \quad \left(\frac{d}{dx}(x^3) = 3x^2, \text{ and Chain Rule to obtain } \frac{d}{dx}(\sin y) = \cos y \frac{dy}{dx}\right)$$

$$\Rightarrow \quad x^3 \cos y \frac{dy}{dx} + \frac{dy}{dx} = 4 - 3x^2 \sin y \quad \text{(grouping like terms)}$$

$$\Rightarrow \quad \frac{dy}{dx}(x^3 \cos y + 1) = 4 - 3x^2 \sin y \quad \text{(factoring)}$$

$$\Rightarrow \quad \frac{dy}{dx} = \frac{4 - 3x^2 \sin y}{x^3 \cos y + 1} \quad \left(\text{solving for } \frac{dy}{dx}\right)$$

## Example 3.6.3: Using Implicit Differentiation to Find a Second Derivative

Find $\frac{d^2y}{dx^2}$ if $x^2 + y^2 = 25$.

**Solution**

In Example **3.6.1**, we showed that $\frac{dy}{dx} = -\frac{x}{y}$. We can take the derivative of both sides of this equation to find $\frac{d^2y}{dx^2}$.

$$\frac{d^2y}{dx^2} = \frac{d}{dy}\left(-\frac{x}{y}\right) \quad \text{(differentiating implicitly)}$$

$$= -\frac{\left(1 \cdot y - x\frac{dy}{dx}\right)}{y^2} \quad \text{(Quotient Rule)}$$

$$= \frac{-y + x\frac{dy}{dx}}{y^2}$$

$$= \frac{-y + x\left(-\frac{x}{y}\right)}{y^2} \quad \left(\text{substituting } \frac{dy}{dx} = -\frac{x}{y}.\right)$$

$$= \frac{-y^2 - x^2}{y^3}$$

At this point we have found an expression for $\frac{d^2y}{dx^2}$. If we choose, we can simplify the expression further by recalling that $x^2 + y^2 = 25$ and making this substitution in the numerator to obtain $\frac{d^2y}{dx^2} = -\frac{25}{y^3}$.

## Checkpoint 3.6.3

Find $\frac{dy}{dx}$ for $y$ defined implicitly by the equation $4x^5 + \tan y = y^2 + 5x$.

**Answer**

$$\frac{dy}{dx} = \frac{5 - 20x^4}{\sec^2 y - 2y}$$

## Finding Tangent Lines Implicitly

Now that we have seen the technique of implicit differentiation, we can apply it to the problem of finding equations of tangent lines to curves described by equations.

**Great Advice to Save Time and Prevent Mistakes**

When asked to find the value of the derivative or the equation of the tangent line for an implicitly-defined curve at a given point, it's best to *not* solve for $\frac{dy}{dx}$ immediately after implicitly differentiating. Instead, once you have implicitly differentiated the relation, substitute the given values of $x$ and $y$ into the resulting equation. It is *at that point* that you should solve for $\frac{dy}{dx}$. Examples **3.6.4** and **3.6.5** illustrate this process.

**Example 3.6.4: Finding the Equation of a Tangent Line**

Find the equation of the line tangent to the curve $\cosh(xy) + xy = \frac{5}{4} + \ln(2)$ at the point $(1, \ln(2))$.

**Solution**

$$\begin{aligned}
& & \frac{d}{dx}(\cosh(xy) + xy) &= \frac{d}{dx}\left(\frac{5}{4} + \ln(2)\right) & \\
\Longrightarrow & & \frac{d}{dx}\cosh(xy) + \frac{d}{dx}(xy) &= 0 & \text{(Sum and Constant Rules)} \\
\Longrightarrow & & \sinh(xy) \cdot \frac{d}{dx}(xy) + \frac{d}{dx}(xy) &= 0 & \text{(Chain Rule)} \\
\Longrightarrow & & \sinh(xy) \cdot \left(\frac{d}{dx}x \cdot y + x \cdot \frac{d}{dx}y\right) + \left(\frac{d}{dx}x \cdot y + x \cdot \frac{d}{dx}y\right) &= 0 & \text{(Product Rule)} \\
\Longrightarrow & & \sinh(xy) \cdot \left(y + x \cdot \frac{dy}{dx}\right) + \left(y + x \cdot \frac{dy}{dx}\right) &= 0 & \text{(Power Rule)}
\end{aligned}$$

At this point, it is important to remember the task at hand. We are asked to find the equation of the tangent line to the curve $\cosh(xy) + xy = \frac{5}{4} + \ln(2)$ at the point $(1, \ln(2))$. There is *no need* to explicitly solve for $\frac{dy}{dx}$ at this moment. Instead, let's substitute $1$ for $x$ and $\ln(2)$ for $y$.

$$\begin{aligned}
& \sinh(\ln(2)) \cdot \left(\ln(2) + \frac{dy}{dx}\right) + \left(\ln(2) + \frac{dy}{dx}\right) &= 0 & \text{(substituting)} \\
\Longrightarrow & \quad (\sinh(\ln(2)) + 1) \cdot \left(\ln(2) + \frac{dy}{dx}\right) &= 0 & \\
\Longrightarrow & \quad \left(\ln(2) + \frac{dy}{dx}\right) &= 0 & \text{(dividing both sides by a nonzero constant*)} \\
\Longrightarrow & \quad \frac{dy}{dx}\Big|_{(1,\ln(2))} &= -\ln(2) &
\end{aligned}$$

Now that we have the slope of the tangent line at the point $(1, \ln(2))$, we use the point-slope form of a line to get the equation of the tangent line.

$$y - \ln(2) = -\ln(2)(x - 1) \Longrightarrow y = -\ln(2)x + 2\ln(2).$$

Figure **3.6.2** shows the curve and the tangent line.

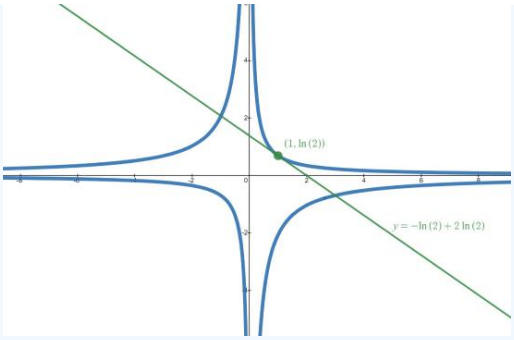

*Figure* **3.6.2**

* I leave it to the reader to check that $\sinh(\ln(2)) + 1 \neq 0$.

## Example 3.6.5: Finding the Equation of the Tangent Line to a Curve

Find the equation of the line tangent to the graph of $y^3 + x^3 - 3xy = 0$ at the point $\left(\frac{3}{2}, \frac{3}{2}\right)$ (Figure **3.6.3**). This curve is known as the folium (or leaf) of Descartes.

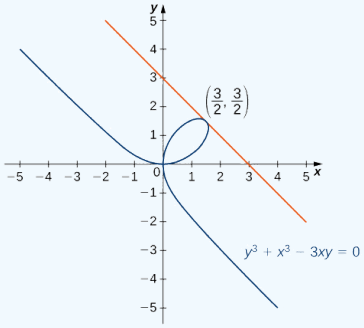

*Figure* **3.6.3**: *Finding the tangent line to the folium of Descartes at* $\left(\frac{3}{2}, \frac{3}{2}\right)$.

**Solution**

Begin by implicitly differentiating both sides.

$$\frac{d}{dx}\left(y^3 + x^3 - 3xy\right) = \frac{d}{dx}(0)$$

$$\implies 3y^2\frac{dy}{dx} + 3x^2 - \left(3y + 3x\frac{dy}{dx}\right) = 0$$

$$\implies 3y^2\frac{dy}{dx} + 3x^2 - 3y - 3x\frac{dy}{dx} = 0$$

It is important to read what we are asked to do now. We are not being asked to solve for $dy/dx$, but instead to find the equation of the tangent line at $\left(\frac{3}{2}, \frac{3}{2}\right)$. As such, we let $x = \frac{3}{2}$ and $y = \frac{3}{2}$ in our implicitly-differentiated equation.

$$3\left(\frac{3}{2}\right)^2\frac{dy}{dx} + 3\left(\frac{3}{2}\right)^2 - 3\left(\frac{3}{2}\right) - 3\left(\frac{3}{2}\right)\frac{dy}{dx} = 0$$

$$\implies \frac{27}{4}\frac{dy}{dx} + \frac{27}{4} - \frac{9}{2} - \frac{9}{2}\frac{dy}{dx} = 0$$

$$\implies 27\frac{dy}{dx} + 27 - 18 - 18\frac{dy}{dx} = 0$$

$$\implies 9\frac{dy}{dx} + 9 = 0$$

$$\implies \frac{dy}{dx} = -1$$

https://math.libretexts.org/@go/page/207606

Finally, substitute into the point-slope equation of the line to obtain

$$y = -x + 3.$$

**Example 3.6.6: Applying Implicit Differentiation**

In a simple video game, a rocket travels in an elliptical orbit whose path is described by the equation $4x^2 + 25y^2 = 100$. The rocket can fire missiles along lines tangent to its path. The object of the game is to destroy an incoming asteroid traveling along the positive $x$-axis toward $(0, 0)$. If the rocket fires a missile when it is located at $\left(3, \frac{8}{5}\right)$, where will it intersect the $x$-axis?

**Solution**

To solve this problem, we must determine where the line tangent to the graph of $4x^2 + 25y^2 = 100$ at $\left(3, \frac{8}{5}\right)$ intersects the $x$-axis. Begin by finding $\frac{dy}{dx}$ implicitly. Differentiating, we have

$$8x + 50y\frac{dy}{dx} = 0.$$

Letting $x = 3$ and $y = \frac{8}{5}$, we get

$$8(3) + 50\left(\frac{8}{5}\right)\frac{dy}{dx} = 0 \implies 24 + 80\frac{dy}{dx} = 0 \implies \frac{dy}{dx} = -\frac{3}{10}.$$

The equation of the tangent line is $y = -\frac{3}{10}x + \frac{5}{2}$. To determine where the line intersects the $x$-axis, solve $0 = -\frac{3}{10}x + \frac{5}{2}$. The solution is $x = \frac{25}{3}$. The missile intersects the $x$-axis at the point $\left(\frac{25}{3}, 0\right)$.

**Checkpoint 3.6.6**

Find the equation of the line tangent to the hyperbola $x^2 - y^2 = 16$ at the point $(5, 3)$.

**Answer**

$y = \frac{5}{3}x - \frac{16}{3}$

## Derivatives of Inverse Trigonometric Functions

We now focus on finding derivatives of inverse trigonometric functions. These derivatives will prove invaluable in the study of integration later in this text. The derivatives of inverse trigonometric functions are quite surprising in that their derivatives are algebraic functions. Previously, derivatives of algebraic functions have proven to be algebraic functions, and derivatives of trigonometric functions have been shown to be trigonometric functions. Here, for the first time, we see that the derivative of a function need not be of the same type as the original function.

**Theorem: Derivatives of the Inverse Trigonometric Functions**

$$\frac{d}{dx}\left(\sin^{-1}x\right) = \frac{1}{\sqrt{1-x^2}} \qquad \frac{d}{dx}\left(\csc^{-1}x\right) = -\frac{1}{x\sqrt{x^2-1}}$$

$$\frac{d}{dx}\left(\cos^{-1}x\right) = -\frac{1}{\sqrt{1-x^2}} \qquad \frac{d}{dx}\left(\sec^{-1}x\right) = \frac{1}{x\sqrt{x^2-1}}$$

$$\frac{d}{dx}\left(\tan^{-1}x\right) = \frac{1}{1+x^2} \qquad \frac{d}{dx}\left(\cot^{-1}x\right) = -\frac{1}{1+x^2}$$

**Proof that $\frac{d}{dx}\left(\sin^{-1}(x)\right) = \frac{1}{\sqrt{1-x^2}}$**

A **critical** step in this proof is to recall that the ranges of the inverse trigonometric functions are restricted. For the arcsine, we have

$$-\frac{\pi}{2} \le \sin^{-1}(x) \le \frac{\pi}{2}.$$

Therefore,

$$y = \sin^{-1}(x), \text{ where } \sin(y) = x \text{ and } -\frac{\pi}{2} \le y \le \frac{\pi}{2}.$$

An illustration of where the angle $y$ lies and the right triangles formed from this arcsine can be seen in Figure 3.6.4.

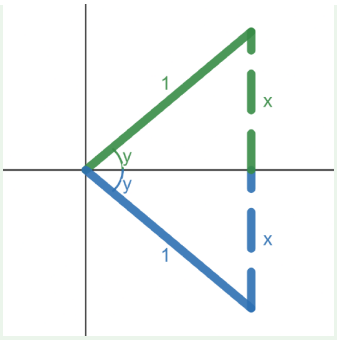

*Figure* **3.6.4**: *A graph of where the arcsine returns and the corresponding triangles.*

From Figure **3.6.2**, we can see that the length of the adjacent side, in either case, is $+\sqrt{1-x^2}$ (positive because these triangles both share adjacent sides along the positive $x$-axis).

If $\sin(y) = x$, then

$$\begin{aligned} \frac{d}{dx}(\sin(y)) &= \frac{d}{dx}(x) \implies \cos(y)\frac{dy}{dx} = 1 \\ &\implies \frac{dy}{dx} = \frac{1}{\cos(y)} \\ &\implies = \frac{1}{\sqrt{1-x^2}}. \end{aligned}$$

*Q.E.D.*

**Caution: Inverse Secant and Inverse Cosecant Ranges**

As was mentioned in Chapter 1 of this textbook, the definition we use for the ranges of the secant and cosecant functions are *very* specific to this book. A lot of other texts use a different definition. I have chosen to restrict the ranges of the inverse cosecant to $(0, \pi/2] \cup (\pi, 3\pi/2]$ and the inverse secant to $[0, \pi/2) \cup [\pi, 3\pi/2)$.

This choice is made to avoid challenging issues in Calculus.

The proof we just did indicates the thought process you must go through when proving the derivative of an inverse trigonometric function. You must address the fact that the inverse function has a restricted range. The possible angles an inverse trigonometric function returns are always limited to two quadrants. For each quadrant, drawing a right triangle whose hypotenuse lies on the terminal side of an angle in that restricted quadrant is beneficial.

**Example 3.6.7: Finding the Derivative of an Inverse Trigonometric Function**

Find the derivative of $h(x) = \sin^{-1}(2x^3)$.

**Solution**

$$\begin{aligned} \frac{d}{dx}(\sin^{-1}(2x^3)) &= \frac{1}{\sqrt{1-(2x^3)^2}} \cdot \frac{d}{dx}(2x^3) \\ &= \frac{1}{\sqrt{1-4x^6}} \cdot 6x^2 \\ &= \frac{6x^2}{\sqrt{1-4x^6}} \end{aligned}$$

**? Checkpoint 3.6.7**

Use the inverse function theorem to find the derivative of $g(x) = \tan^{-1} x$.

**Answer**

$g'(x) = \frac{1}{1+x^2}$

**✓ Example 3.6.8: Applying Differentiation Formulas to an Inverse Tangent Function**

Find the derivative of $f(x) = \tan^{-1}(x^2)$.

**Solution**

$$\begin{aligned} \frac{d}{dx}\left(\tan^{-1}\left(x^2\right)\right) &= \frac{1}{1+\left(x^2\right)^2} \cdot \frac{d}{dx}\left(x^2\right) \\ &= \frac{2x}{1+x^4} \end{aligned}$$

**✓ Example 3.6.9: Applying Differentiation Formulas to an Inverse Cosecant Function**

Find the derivative of $h(x) = x^2 \csc^{-1}(x)$.

**Solution**

$$\begin{aligned} \frac{d}{dx}\left(x^2 \csc^{-1}(x)\right) &= 2x \csc^{-1}(x) - \frac{x^2}{x\sqrt{x^2-1}} \\ &= 2x \csc^{-1}(x) - \frac{x}{\sqrt{x^2-1}} \end{aligned}$$

**? Checkpoint 3.6.9**

Find the derivative of $h(x) = \cos^{-1}(3x-1)$.

**Answer**

$h'(x) = \frac{-3}{\sqrt{6x-9x^2}}$

**✓ Example 3.6.10: Applying the Inverse Tangent Function**

The position of a particle at time $t$ is given by $s(t) = \tan^{-1}\left(\frac{1}{t}\right)$ for $t \geq \frac{1}{2}$. Find the velocity of the particle at time $t = 1$.

**Solution**

Begin by differentiating $s(t)$ in order to find $v(t)$. Thus,

$$v(t) = s'(t) = \frac{1}{1+\left(\frac{1}{t}\right)^2} \cdot \frac{-1}{t^2}.$$

Simplifying, we have

$$v(t) = -\frac{1}{t^2+1}.$$

Thus, $v(1) = -\frac{1}{2}$.

**? Checkpoint 3.6.10**

Find the equation of the line tangent to the graph of $f(x) = \sin^{-1} x$ at $x = 0$.

**Answer**

$y = x$

## Derivatives of Inverse Hyperbolic Functions

Looking at the graphs of the hyperbolic functions, we see that with appropriate range restrictions, they all have inverses. Most of the necessary range restrictions can be discerned by closely examining the graphs. The domains and ranges of the inverse hyperbolic functions are summarized in Table **3.6.1**.

**Table 3.6.1: Domains and Ranges of the Inverse Hyperbolic Functions**

| Function | Domain | Range |
|---|---|---|
| $\sinh^{-1} x$ | $(-\infty, \infty)$ | $(-\infty, \infty)$ |
| $\cosh^{-1} x$ | $(1, \infty)$ | $[0, \infty)$ |
| $\tanh^{-1} x$ | $(-1, 1)$ | $(-\infty, \infty)$ |
| $\coth^{-1} x$ | $(-\infty, 1) \cup (1, \infty)$ | $(-\infty, 0) \cup (0, \infty)$ |
| $\operatorname{sech}^{-1} x$ | $(0, 1)$ | $[0, \infty)$ |
| $\operatorname{csch}^{-1} x$ | $(-\infty, 0) \cup (0, \infty)$ | $(-\infty, 0) \cup (0, \infty)$ |

The graphs of the inverse hyperbolic functions are shown in the following figure.

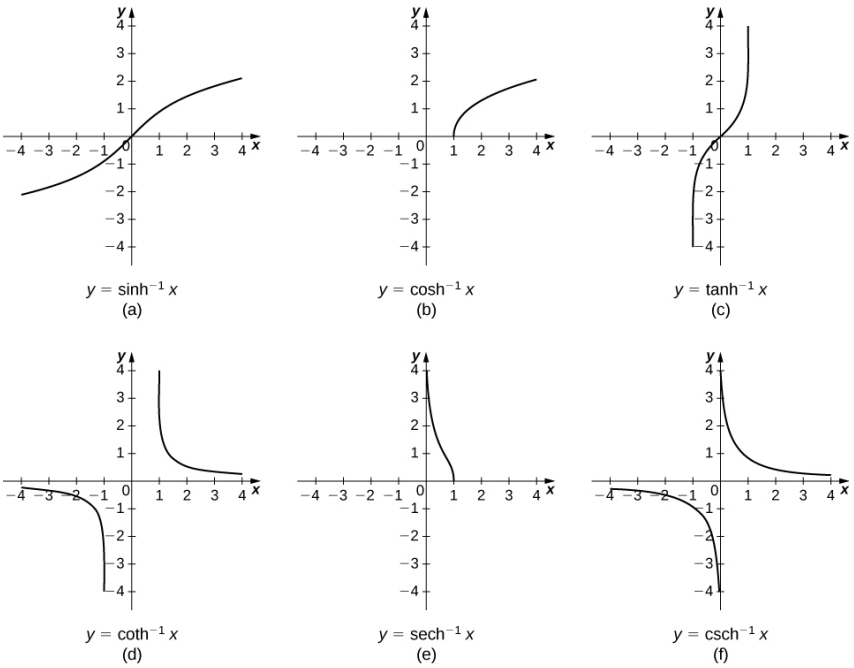

*Figure* **3.6.5***: Graphs of the inverse hyperbolic functions.*

To find the derivatives of the inverse functions, we use implicit differentiation. We have

$$\begin{aligned} y &= \sinh^{-1} x \\ \sinh y &= x \\ \frac{d}{dx} \sinh y &= \frac{d}{dx} x \\ \cosh y \frac{dy}{dx} &= 1. \end{aligned}$$

Recall that $\cosh^2 y - \sinh^2 y = 1$, so $\cosh y = \sqrt{1 + \sinh^2 y}$.Then,

$$\frac{dy}{dx} = \frac{1}{\cosh y} = \frac{1}{\sqrt{1+\sinh^2 y}} = \frac{1}{\sqrt{1+x^2}}.$$

We can derive differentiation formulas for the other inverse hyperbolic functions similarly. These differentiation formulas are summarized in Table **3.6.2**.

**Table 3.6.2: Derivatives of the Inverse Hyperbolic Functions**

| $f(x)$ | $\frac{d}{dx}f(x)$ |
|---|---|
| $\sinh^{-1} x$ | $\frac{1}{\sqrt{1+x^2}}$ |
| $\cosh^{-1} x$ | $\frac{1}{\sqrt{x^2-1}}$ |
| $\tanh^{-1} x$ | $\frac{1}{1-x^2}$ |
| $\coth^{-1} x$ | $\frac{1}{1-x^2}$ |
| $\operatorname{sech}^{-1} x$ | $\frac{-1}{x\sqrt{1-x^2}}$ |
| $\operatorname{csch}^{-1} x$ | $\frac{-1}{\lvert x\rvert\sqrt{1+x^2}}$ |

Note that the derivatives of $\tanh^{-1} x$ and $\coth^{-1} x$ are the same.

### Example 3.6.11: Differentiating Inverse Hyperbolic Functions

Evaluate the following derivatives:

a. $\frac{d}{dx}\left(\sinh^{-1}\left(\frac{x}{3}\right)\right)$
b. $\frac{d}{dx}\left(\tanh^{-1} x\right)^2$

**Solution**

Using the formulas in Table **3.6.3** and the Chain Rule, we obtain the following results:

a. $\frac{d}{dx}\left(\sinh^{-1}\left(\frac{x}{3}\right)\right) = \frac{1}{3\sqrt{1+\frac{x^2}{9}}} = \frac{1}{\sqrt{9+x^2}}$
b. $\frac{d}{dx}\left(\tanh^{-1} x\right)^2 = \frac{2\left(\tanh^{-1} x\right)}{1-x^2}$

### Checkpoint 3.6.11

Evaluate the following derivatives:

a. $\frac{d}{dx}\left(\cosh^{-1}(3x)\right)$
b. $\frac{d}{dx}\left(\coth^{-1} x\right)^3$

**Answer a**

$\frac{d}{dx}\left(\cosh^{-1}(3x)\right) = \frac{3}{\sqrt{9x^2-1}}$

**Answer b**

$\frac{d}{dx}\left(\coth^{-1} x\right)^3 = \frac{3\left(\coth^{-1} x\right)^2}{1-x^2}$

# 3.6.1: Resources and Key Concepts

## Resources

### Prerequisite Topics

The following is a list of prerequisite skills (all of which can be reviewed in CRC's Corequisite Codex) needed for this section **that have not already been mentioned in any previous section**. If you are enrolled in a course with a Support section, some (but definitely not all) of these topics might be covered or reviewed in the Support section of your course.

- **Solving Equations**
  - Solving Literal Equations: After differentiating implicitly, one needs to algebraically solve for $\frac{dy}{dx}$ (or $y'$), which is a literal equation solving skill.

### Videos

- Implicit differentiation
  - Implicit Differentiation - Differentiating Implicitly
  - Synthesis Questions
- Derivative of inverse trigonometric functions
  - Derivatives of Inverse Trigonometric Functions: Theorem, Proof, and Example
- Derivative of inverse hyperbolic functions
  - Derivatives of Inverse Hyperbolic Functions: Theorem, Proof, and Example

## Key Concepts

### Definitions

- **Explicit Function**: A function where the dependent variable $y$ is expressed directly in terms of the independent variable $x$ (e.g., $y = x^2 + 1$).
- **Implicit Function**: A function where the relationship between $x$ and $y$ is defined by an equation where $y$ is not expressed entirely in terms of $x$ (e.g., $y - x^2 = 1$ or $x^2 + y^2 = 25$). An equation defines a function implicitly if the function satisfies that equation.
- **Implicit Differentiation**: A technique to find the derivative $\frac{dy}{dx}$ for a function defined implicitly, by differentiating both sides of the equation with respect to $x$ and then algebraically solving for $\frac{dy}{dx}$.

### Theorems

- **Theorem: Derivatives of the Inverse Trigonometric Functions**:
  - $\frac{d}{dx}(\sin^{-1} x) = \frac{1}{\sqrt{1-x^2}}$
  - $\frac{d}{dx}(\cos^{-1} x) = -\frac{1}{\sqrt{1-x^2}}$
  - $\frac{d}{dx}(\tan^{-1} x) = \frac{1}{1+x^2}$
  - $\frac{d}{dx}(\csc^{-1} x) = -\frac{1}{x\sqrt{x^2-1}}$ (Note: text uses specific range for $\csc^{-1} x$)
  - $\frac{d}{dx}(\sec^{-1} x) = \frac{1}{x\sqrt{x^2-1}}$ (Note: text uses specific range for $\sec^{-1} x$)
  - $\frac{d}{dx}(\cot^{-1} x) = -\frac{1}{1+x^2}$
- **Derivatives of the Inverse Hyperbolic Functions**:
  - $\frac{d}{dx}(\sinh^{-1} x) = \frac{1}{\sqrt{1+x^2}}$
  - $\frac{d}{dx}(\cosh^{-1} x) = \frac{1}{\sqrt{x^2-1}}$ for $x > 1$
  - $\frac{d}{dx}(\tanh^{-1} x) = \frac{1}{1-x^2}$ for $|x| < 1$
  - $\frac{d}{dx}(\coth^{-1} x) = \frac{1}{1-x^2}$ for $|x| > 1$
  - $\frac{d}{dx}(\operatorname{sech}^{-1} x) = -\frac{1}{x\sqrt{1-x^2}}$ for $0 < x < 1$
  - $\frac{d}{dx}(\operatorname{csch}^{-1} x) = -\frac{1}{|x|\sqrt{1+x^2}}$ for $x \neq 0$

### Common Mistakes

- **Forgetting $\frac{dy}{dx}$ (or $y'$)**: When differentiating a term involving $y$ with respect to $x$, a common error is to forget to multiply by $\frac{dy}{dx}$ as required by the Chain Rule. For example, incorrectly differentiating $y^2$ as $2y$ instead of $2y\frac{dy}{dx}$.
- **Algebraic Errors when Solving for $\frac{dy}{dx}$**: After differentiating both sides, errors can occur when isolating the $\frac{dy}{dx}$ term.
- **Solving for $y$ Prematurely**: While sometimes possible, trying to solve the original equation for $y$ explicitly before differentiating can be much harder or impossible, defeating the purpose of implicit differentiation.
- **Not Substituting Point Values Before Solving for $\frac{dy}{dx}$ (When a specific point is given)**: When asked for the slope at a specific point, it's often easier to substitute the $x$ and $y$ coordinates of the point into the differentiated equation *before* solving for $\frac{dy}{dx}$.
- **Forgetting the Chain Rule**: When differentiating functions like $\ln(u(x))$, $\sin^{-1}(u(x))$, or $\sinh^{-1}(u(x))$, it's crucial to multiply by $u'(x)$.
- **Ignoring Domain Restrictions**: Derivatives of inverse functions (trigonometric and hyperbolic) often have specific domains where they are valid, related to the ranges of the original functions and the domains of the inverse functions. For example, $\frac{d}{dx}(\cosh^{-1} x)$ is for $x > 1$.
- **Inverse Secant and Cosecant Range Ambiguity**: Different textbooks may use different range restrictions for $\sec^{-1} x$ and $\csc^{-1} x$, which can affect the sign of their derivatives or the form involving $|x|$. This textbook explicitly states its chosen ranges.
- **Confusing Derivatives of Similar Functions**: For example, mixing up the derivatives of $\tan^{-1} x$ and $\tanh^{-1} x$. Note that $\frac{d}{dx}(\tanh^{-1} x) = \frac{d}{dx}(\coth^{-1} x) = \frac{1}{1-x^2}$, but their domains differ.

# 3.7: Derivatives of Logarithms and Logarithmic Differentiation

**Learning Objectives**

- Compute the derivative of a logarithmic function, both natural-based and non-natural-based.
- Use logarithmic differentiation to determine the derivative of products and ratios of functions.
- Use logarithmic differentiation to determine the derivative of functions to functional powers.

Hawk A.I. Section-Specific Tutor

Please note that, to access the Hawk A.I. Tutor, you will need a (free) OpenAI account.

Now that we have the Chain Rule and implicit differentiation under our belts, we can explore the derivatives of logarithmic functions and the relationship between a function's derivative and its inverse's derivative. For functions whose derivatives we already know, we can use this relationship to find derivatives of inverses without using the limit definition of the derivative. In particular, we will apply the formula for derivatives of inverse functions to trigonometric functions. This formula may also be used to extend the Power Rule to rational exponents.

## Derivative of the Logarithmic Function

Now that we have the derivative of the natural exponential function, we can use implicit differentiation to find the derivative of its inverse, the natural logarithmic function.

**Theorem: The Derivative of the Natural Logarithmic Function**

If $y = \ln x$, then

$$\frac{dy}{dx} = \frac{1}{x}.$$

**Proof**

If $y = \ln x$, then $e^y = x$. Differentiating both sides of this equation results in the equation

$$e^y \frac{dy}{dx} = 1.$$

Solving for $\frac{dy}{dx}$ yields

$$\frac{dy}{dx} = \frac{1}{e^y}.$$

Finally, we substitute $x = e^y$ to obtain

$$\frac{dy}{dx} = \frac{1}{x}.$$

*Q.E.D.*

The graph of $y = \ln x$ and its derivative $\frac{dy}{dx} = \frac{1}{x}$ are shown in Figure **3.7.1**.

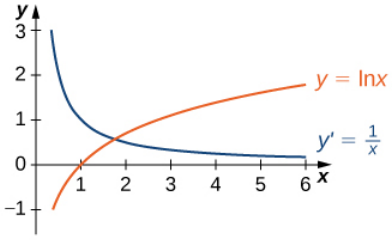

*Figure* **3.7.1**: *The function* $y = \ln x$ *is increasing on* $(0, +\infty)$. *Its derivative* $y' = \frac{1}{x}$ *is greater than zero on* $(0, +\infty)$

### Example 3.7.1: Taking a Derivative of a Natural Logarithm

Find the derivative of $f(x) = \ln(x^3 + 3x - 4)$.

**Solution**

$$\begin{aligned} f'(x) &= \frac{1}{x^3 + 3x - 4} \cdot \frac{d}{dx}(x^3 + 3x - 4) \qquad \text{(Chain Rule)} \\ &= \frac{1}{x^3 + 3x - 4} \cdot (3x^2 + 3) \\ &= \frac{3x^2 + 3}{x^3 + 3x - 4} \\ &= \frac{3(x^2 + 1)}{x^3 + 3x - 4} \end{aligned}$$

As an aside, cleaning up derivatives using our prerequisite Algebra is always a good idea. Sometimes, things clean up very nicely.

### Example 3.7.2: Using Properties of Logarithms in a Derivative

Find the derivative of $f(x) = \ln\left(\frac{x^2 \sin x}{2x+1}\right)$.

**Solution**

At first glance, taking this derivative appears rather complicated. However, by using the properties of logarithms before finding the derivative, we can make the problem much simpler.

$$f(x) = \ln\left(\frac{x^2 \sin x}{2x+1}\right) = 2\ln x + \ln(\sin x) - \ln(2x+1)$$

Hence,

$$\begin{aligned} f'(x) &= \frac{2}{x} + \frac{1}{\sin x} \cdot \cos x - \frac{1}{2x+1} \cdot 2 \qquad \text{(derivative of the natural log and the Chain Rule)} \\ &= \frac{2}{x} + \cot x - \frac{2}{2x+1} \end{aligned}$$

### Checkpoint 3.7.2

Differentiate: $f(x) = \ln(3x+2)^5$.

**Answer**

$f'(x) = \frac{15}{3x+2}$

Now that we can differentiate the natural logarithmic function, we can use this result to find the derivatives of $y = \log_b x$ for $b > 0$, $b \neq 1$.

**Theorem: The General Derivative of a Logarithmic Function**

$$\frac{d}{dx}\left(\log_b(x)\right) = \frac{1}{x\ln(b)}$$

**Proof**

If $y = \log_b x$, then $b^y = x$. It follows that $\ln(b^y) = \ln x$. Thus $y\ln b = \ln x$. Solving for $y$, we have $y = \frac{\ln x}{\ln b}$. Differentiating and keeping in mind that $\ln b$ is a constant, we see that

$$\frac{dy}{dx} = \frac{1}{x\ln b}.$$

*Q.E.D.*

**Example 3.7.3: Finding the Slope of a Tangent Line**

Find the slope of the line tangent to the graph of $y = \log_2(3x+1)$ at $x = 1$.

**Solution**

To find the slope, we must evaluate $\frac{dy}{dx}$ at $x = 1$.

$$\frac{dy}{dx} = \frac{3}{(3x+1)\ln 2}.$$

By evaluating the derivative at $x = 1$, we see that the tangent line has slope

$$\left.\frac{dy}{dx}\right|_{x=1} = \frac{3}{4\ln 2} = \frac{3}{\ln 16}.$$

## Aside: Revisiting the Generalized Power Rule

We now have enough "mathematical prowess" to continue our proof of the Generalized Power Rule from earlier in this chapter. This time, we add the ability to take the derivative of $y = x^n$, where $n$ is a rational number.

**Proof**

Let $y = x^n$, where $n$ is a rational number. Then $n$ can be written as $p/q$, for integers $p$ and $q$.

$$
\begin{aligned}
y = x^n \implies y &= x^{p/q} \\
\implies y^q &= x^p \\
\implies \frac{d}{dx}(y^q) &= \frac{d}{dx}(x^p) \\
\implies q y^{q-1}\frac{dy}{dx} &= p x^{p-1} \\
\implies \frac{dy}{dx} &= \frac{p x^{p-1}}{q y^{q-1}} \\
\implies \frac{dy}{dx} &= \frac{p}{q}\cdot\frac{x^{p-1}}{y^{q-1}} \\
\implies \frac{dy}{dx} &= \frac{p}{q}\cdot\frac{x^{p-1}}{(x^{p/q})^{q-1}} \\
\implies \frac{dy}{dx} &= \frac{p}{q}\cdot\frac{x^{p-1}}{x^{p-p/q}} \\
\implies \frac{dy}{dx} &= \frac{p}{q}\cdot x^{p/q-1} \\
\implies \frac{dy}{dx} &= n x^{n-1}
\end{aligned}
$$

*Q.E.D.*

## Logarithmic Differentiation

At this point, we can take derivatives of functions of the form $y = (g(x))^n$ for certain values of $n$, as well as functions of the form $y = b^{g(x)}$, where $b > 0$ and $b \neq 1$. Unfortunately, we still do not know the derivatives of functions such as $y = x^x$ or $y = x^{\sin(x)}$. These functions require a technique called **logarithmic differentiation**, which allows us to differentiate any function of the form $h(x) = g(x)^{f(x)}$. It can also be used to convert a very complex differentiation problem into a simpler one, such as finding the derivative of $y = \frac{x\sqrt{2x+1}}{e^x \sin^3 x}$.

### Example 3.7.4: Using Logarithmic Differentiation

Find the derivative of $y = (2x^4 + 1)^{\tan x}$.

**Solution**

Use logarithmic differentiation to find this derivative.

$$\begin{aligned}
\ln(y) &= \ln\left(2x^4+1\right)^{\tan(x)} && \text{(taking the natural logarithm of both sides)}\\
\Longrightarrow \ln(y) &= \tan(x)\ln\left(2x^4+1\right) && \text{(Properties of Logarithms)}\\
\Longrightarrow \frac{1}{y}\frac{dy}{dx} &= \sec^2(x)\ln\left(2x^4+1\right)+\frac{8x^3}{2x^4+1}\cdot\tan(x) && \text{(implicitly differentiating)}\\
\Longrightarrow \frac{dy}{dx} &= y\cdot\left(\sec^2(x)\ln\left(2x^4+1\right)+\frac{8x^3}{2x^4+1}\cdot\tan(x)\right)\\
\Longrightarrow \frac{dy}{dx} &= \left(2x^4+1\right)^{\tan(x)}\left(\sec^2(x)\ln\left(2x^4+1\right)+\frac{8x^3}{2x^4+1}\cdot\tan(x)\right) && \text{(substituting } y=\left(2x^4+1\right)^{\tan(x)}.\text{)}
\end{aligned}$$

### Example 3.7.5: Simplifying a "Tough" Differentiation Problem

Find the derivative of $y=\frac{x\sqrt{2x+1}}{e^x\sin^3 x}$.

**Solution**

This problem uses the Properties of Logarithms and the differentiation rules introduced in this chapter.

$$\begin{aligned}
\ln y &= \ln\frac{x\sqrt{2x+1}}{e^x\sin^3 x} && \text{(taking the natural logarithm of both sides)}\\
\Longrightarrow \ln y &= \ln x+\tfrac{1}{2}\ln(2x+1)-x\ln e-3\ln\sin x && \text{(Properties of Logarithms)}\\
\Longrightarrow \frac{1}{y}\frac{dy}{dx} &= \frac{1}{x}+\frac{1}{2x+1}-1-3\frac{\cos x}{\sin x} && \text{(implicitly differentiating)}\\
\Longrightarrow \frac{dy}{dx} &= y\left(\frac{1}{x}+\frac{1}{2x+1}-1-3\cot x\right)\\
\Longrightarrow \frac{dy}{dx} &= \frac{x\sqrt{2x+1}}{e^x\sin^3 x}\left(\frac{1}{x}+\frac{1}{2x+1}-1-3\cot x\right) && \left(\text{substituting } y=\frac{x\sqrt{2x+1}}{e^x\sin^3 x}.\right)
\end{aligned}$$

### Checkpoint 3.7.5A

Use logarithmic differentiation to find the derivative of $y=x^x$.

**Answer**

Solution: $\frac{dy}{dx}=x^x(1+\ln x)$

### Checkpoint 3.7.5B

Find the derivative of $y=(\tan x)^\pi$.

**Answer**

$y'=\pi(\tan x)^{\pi-1}\sec^2 x$

# 3.7.1: Resources and Key Concepts

## Resources

### Videos

- Derivative of logarithmic functions
  - Logarithmic Derivatives: Theorems, Proofs, and Example
- Derivative of function to a functional power
  - Derivatives of Functions to Functional Powers
  - Synthesis Questions

## Key Concepts

### Definitions

- **Logarithmic Differentiation**: A technique used to differentiate functions, particularly those of the form $h(x) = g(x)^{f(x)}$ or complex products/quotients, by first taking the natural logarithm of both sides of $y = h(x)$, using properties of logarithms to simplify, then differentiating implicitly with respect to $x$, and finally solving for $\frac{dy}{dx}$.

### Theorems

- **Theorem: The Derivative of the Natural Logarithmic Function**: If $y = \ln x$, then $\frac{dy}{dx} = \frac{1}{x}$.
- **Theorem: The General Derivative of a Logarithmic Function**: $\frac{d}{dx}(\log_b(x)) = \frac{1}{x\ln(b)}$.

### Common Mistakes

- **Incorrectly Applying Logarithm Properties**: Errors in using logarithm properties (e.g., $\ln(A+B) \neq \ln A + \ln B$) before differentiation can lead to incorrect derivatives.
- **Errors in Applying Logarithm Properties**: Incorrectly expanding or simplifying the logarithmic expression (e.g., $\ln(A+B) \neq \ln A + \ln B$) before differentiation.
- **Forgetting to Differentiate Implicitly**: After taking $\ln y$, forgetting that its derivative with respect to $x$ is $\frac{1}{y}\frac{dy}{dx}$, not just $\frac{1}{y}$.
- **Not Multiplying by $y$ at the End**: After finding $\frac{1}{y}\frac{dy}{dx} = \text{expression}$, forgetting to multiply the "expression" by $y$ (and substituting back the original function for $y$) to solve for $\frac{dy}{dx}$.
- **Applying Logarithmic Differentiation When it Cannot Be Applied**: While it might seem to be attractive to use logarithmic differentiation for any function that contains compositions of powers of rational functions, you must remain aware that the argument of a logarithm has to be positive. Therefore, using logarithmic differentiation to find the derivative of, for example, $y = \sqrt[3]{\frac{(x-2)^3}{x(x+8)^2}}$ would not work because the radicand *could* be negative (we can take odd roots of negative numbers).

Please note that, to access the Hawk A.I. Tutor, you will need a (free) OpenAI account.

We have seen that for quantities that change over time, the rates at which these quantities change are given by derivatives. If two related quantities are changing over time, the rates at which the quantities change are related. For example, suppose a balloon is being filled with air. In that case, both the balloon's radius and the balloon's volume are increasing. In this section, we consider several problems in which two or more related quantities are changing, and we study how to determine the relationship between the rates of change of these quantities.

## Setting up Related-Rates Problems

In many real-world applications, related quantities are changing with respect to time. For example, let's consider the balloon example again. The rate of change in the volume, $V$, is related to the rate of change in the radius, $r$. In this case, we say that $\frac{dV}{dt}$ and $\frac{dr}{dt}$ are **related rates** because $V$ is related to $r$. Here, we study several examples of related quantities that are changing with respect to time, and we look at how to calculate one rate of change given another rate of change.

**Example 3.8.1: Inflating a Balloon**

A spherical balloon is being filled with air at the constant rate of $2\ \text{cm}^3/\text{sec}$ (Figure 3.8.1). How fast is the radius increasing when the radius is $3$ cm?

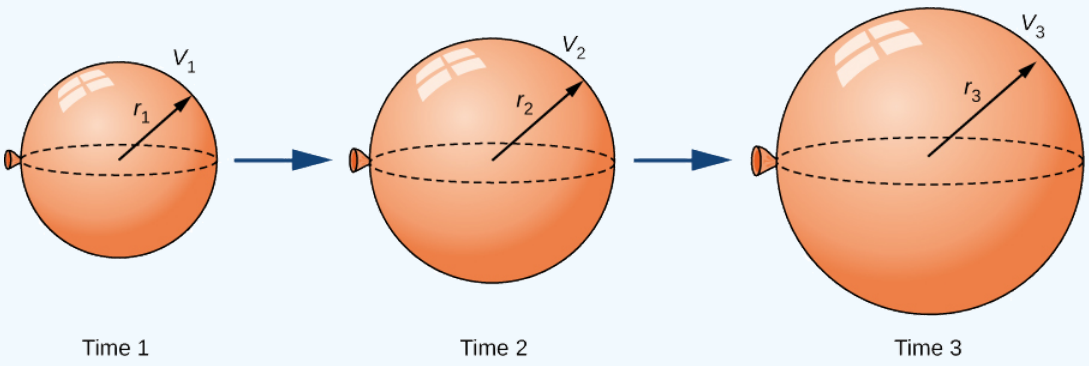

*Figure 3.8.1: As the balloon is filled with air, both the radius and the volume are increasing with respect to time.*

**Solution**

The volume of a sphere of radius $r$ centimeters is

$$V = \frac{4}{3}\pi r^3\ \text{cm}^3.$$

Since the balloon is being filled with air, both the volume and the radius are functions of time. Therefore, $t$ seconds after beginning to fill the balloon with air, the volume of air in the balloon is

$$V(t) = \frac{4}{3}\pi [r(t)]^3 \text{cm}^3.$$

Differentiating both sides of this equation with respect to time and applying the Chain Rule, we see that the rate of change in the volume is related to the rate of change in the radius by the equation

$$V'(t) = 4\pi\left[r(t)\right]^2 r'(t).$$

The balloon is being filled with air at the constant rate of $2\,\text{cm}^3/\text{sec}$, so $V'(t) = 2\,\text{cm}^3/\text{sec}$. Therefore,

$$2\,\text{cm}^3/\text{sec} = \left(4\pi\left[r(t)\right]^2\,\text{cm}^2\right)\cdot\left(r'(t)\,\text{cm/s}\right),$$

which implies

$$r'(t) = \frac{1}{2\pi\left[r(t)\right]^2}\,\text{cm/sec}.$$

When the radius $r = 3$ cm,

$$r'(t) = \frac{1}{18\pi}\,\text{cm/sec}.$$

**? Checkpoint 3.8.1**

What is the instantaneous rate of change of the radius when $r = 6$ cm?

**Answer**

$\frac{1}{72\pi}$ cm/sec, or approximately 0.0044 cm/sec

While memorizing procedures is the absolute worst way to enjoy Mathematics, applications (also known as "word problems") tend to confound students so much that it is beneficial to develop a procedure for solving them. Let's outline a modified problem-solving strategy developed by Polya.

In 1945 George Polya published the book *How To Solve It* which quickly became his most prized publication. It sold over one million copies and has been translated into 17 languages. In this book, he identifies basic principles of problem-solving. I have modified these problem-solving strategies to fit Calculus best (we will see these again in a section titled Optimization Problems).

**Polya's Modified Problem-Solving Process**

1. **Read** the given problem.
2. **Understand** the given problem. This might require you to rephrase the problem in terms that you can understand or, more commonly, to draw a picture of the situation.
3. **Label** unknowns. All problems presented in mathematics have unknown quantities. In this step, you take the time to label these unknowns using variables. This step is often combined with the previous step (especially when drawing pictures).
4. List the **Givens** and **Wants**. This step is dedicated to making a table with one column dedicated to the given information and another to the wanted or desired information. Normally, we only list the given and desired *rates* in this table.
5. Create a **Master Equation** involving the variables within the given and wanted rate information. This is a critical step in all problem-solving processes involving Polya's method.
   **Warning:** The Master Equation should be a relation between two variables (those listed in the Givens and Wants table). If your Master Equation has more than two variables, you need to find a relation between the excess variables to reduce the number of final variables in your Master Equation to two.
6. Find the **Rate Equation** from the Master Equation. This almost always requires implicit differentiation.
7. **Substitute** in any constants given within the problem.
8. **Solve** the resulting equation for the desired "wanted" piece of information.

Note that when solving a related-rates problem, it is crucial not to **substitute** known values too soon. For example, suppose the value for a changing quantity is substituted into an equation before both sides are differentiated. In that case, the quantity will

behave as a constant, and its derivative will not appear in the new equation found during the **rate equation** step. We examine this potential error in the following example.

## Examples of Polya's Problem-Solving Process

Let's implement the described strategy to solve several related-rates problems. The first example involves a plane flying overhead. The relationship we are studying is between the speed of the aircraft and the rate at which the distance between the plane and a person on the ground is changing.

### Example 3.8.2: An Airplane Flying at a Constant Elevation

An airplane is flying overhead at a constant elevation of 4000 ft. A man is viewing the plane from a position 3000 ft from the base of a radio tower. The airplane is flying horizontally away from the man. If the plane is flying at the rate of 600 ft/sec, at what rate does the distance between the man and the plane increase when the plane passes over the radio tower?

**Solution**

**Read.** This step is only listed so you can have a "win." All of us can *read* a problem, but *understanding* requires a bit more effort.

**Understand** and **Label.** Draw a picture, introducing variables to represent the quantities involved.

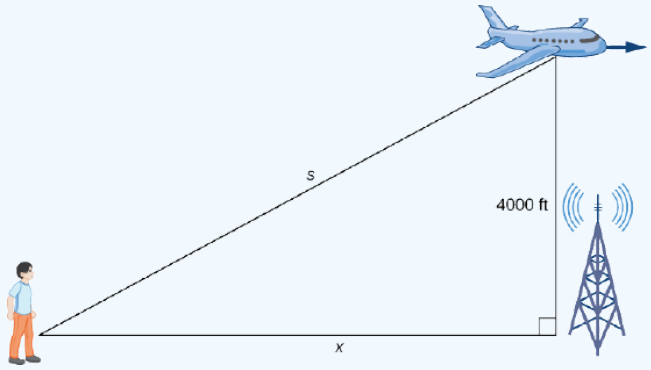

*Figure 3.8.2: An airplane is flying at a constant height of 4000 ft. The distances between the person and the airplane and the person and the place on the ground directly below the airplane are changing. We denote those quantities with the variables $s$ and $x$, respectively.*

As shown, $x$ denotes the distance between the man and the position on the ground directly below the airplane. The variable $s$ denotes the distance between the man and the plane. Note that both $x$ and $s$ are functions of time. We do not introduce a variable for the plane's height because it remains at a constant elevation of 4000 ft. Since an object's height above the ground is measured as the shortest distance between the object and the ground, the line segment of length 4000 ft is perpendicular to the line segment of length $x$ feet, creating a right triangle.

**Givens** and **Wants.**

| Given | Want |
|---|---|
| $\frac{dx}{dt} = 600$ feet per second | $\frac{ds}{dt}\Big\|_{x=3000}$ |

Since $x$ denotes the horizontal distance between the man and the point on the ground below the plane, $dx/dt$ represents the speed of the plane. We are told the plane's speed is 600 ft/sec. Therefore, $\frac{dx}{dt} = 600$ ft/sec. Since we are asked to find the rate of change in the distance between the man and the plane when the plane is directly above the radio tower, we need to find $ds/dt$ when $x = 3000$ ft.

As was mentioned in Polya's modified problem-solving process, we only list the given and desired *rate* information. That is, don't bother listing the facts that the height of the plane is always 4000 feet, and the distance from the tower to our position is always 3000 feet.

**Master Equation.** The variables within our table above are $x$ and $s$. From the figure, we can use the Pythagorean Theorem to write an equation relating these two variables:$[x(t)]^2 + 4000^2 = [s(t)]^2$.

**Rate Equation.** Differentiating this equation with respect to time and using the fact that the derivative of a constant is zero, we arrive at the equation

$$x\frac{dx}{dt} = s\frac{ds}{dt}.$$

**Substitute.** When we "stop time" to do the problem, we know that $\frac{dx}{dt} = 600$ ft/sec and $x = 3000$ ft. Thus,

$$(3000)(600) = s\frac{ds}{dt}.$$

**Solve.** You can see that the only thing we are missing is $s$. However, we can use the Pythagorean Theorem to determine the distance $s$ when $x = 3000$ ft and the height is $4000$ ft. Solving the equation

$$3000^2 + 4000^2 = s^2$$

for $s$, we have $s = 5000$ ft at the time of interest. Using these values, we conclude that $ds/dt$ is a solution of the equation

$$(3000)(600) = (5000) \cdot \frac{ds}{dt}.$$

Therefore,

$$\frac{ds}{dt} = \frac{3000 \cdot 600}{5000} = 360\,\text{ft/sec}.$$

*Note:* When solving related-rates problems, it is important not to substitute values for the variables too soon. For example, in the **Master Equation** step, we related the variable quantities $x(t)$ and $s(t)$ by the equation

$$[x(t)]^2 + 4000^2 = [s(t)]^2.$$

Since the plane remains at a constant height, it is not necessary to introduce a variable for the height, and we are allowed to use the constant 4000 to denote that quantity. However, the other two quantities are changing. If we mistakenly substituted $x(t) = 3000$ into the equation before differentiating, our equation would have been

$$3000^2 + 4000^2 = [s(t)]^2.$$

After differentiating, our equation would become

$$0 = s(t)\frac{ds}{dt}.$$

As a result, we would incorrectly conclude that $\frac{ds}{dt} = 0$.

**? Checkpoint 3.8.2**

What is the speed of the plane if the distance between the person and the plane is increasing at the rate of $300$ ft/sec?

**Answer**

$500$ ft/sec

**✓ Example 3.8.3: A Rocket Launch**

A rocket is launched so that it rises vertically. A camera is positioned $5000$ ft from the launch pad. When the rocket is $1000$ ft above the launch pad, its velocity is $600$ ft/sec.

*Figure* **3.8.3***: (credit: modification of work by Steve Jurvetson, Wikimedia Commons)*

Find the necessary rate of change of the camera's angle as a function of time so that it stays focused on the rocket.

**Solution**

**Read.** Again, this is a freebie step. Make sure you read the problem thoroughly!

**Understand** and **Label.** Draw a picture introducing the variables.

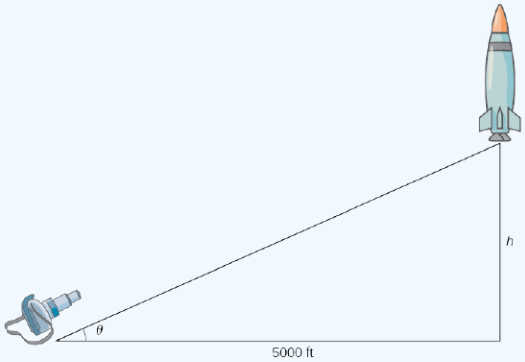

*Figure* **3.8.4***: A camera is positioned* **5000** *ft from the launch pad of the rocket. The rocket's height and the camera's angle are changing with respect to time. We denote those quantities with the variables* $h$ *and* $\theta$*,respectively.*

Let $h$ denote the height of the rocket above the launch pad and $\theta$ be the angle between the camera lens and the ground.

**Givens** and **Wants.** We are trying to find the rate of change in the camera angle with respect to time when the rocket is 1000 ft off the ground. That is, we need to find $\frac{d\theta}{dt}$ when $h = 1000$ ft. At that time, we know the velocity of the rocket is $\frac{dh}{dt} = 600$ ft/sec.

| Given | Want |
|---|---|
| $\frac{dh}{dt}\|_{h=1000} = 600$ feet per second | $\frac{d\theta}{dt}\|_{h=1000}$ |

**Master Equation.** Using the fact that we have drawn a right triangle, it is natural to think about trigonometric functions. Recall that $\tan(\theta)$ is the ratio of the length of the opposite side of the triangle to the length of the adjacent side. Thus, we have

$$\tan(\theta) = \frac{h}{5000}.$$

This gives us the equation

$$h = 5000\tan(\theta).$$

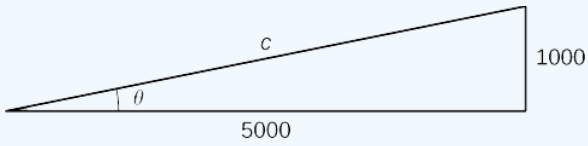
**Rate Equation.** Differentiating this equation with respect to time $t$, we obtain

$$\frac{dh}{dt} = 5000 \sec^2(\theta) \frac{d\theta}{dt}.$$

**Substitute.** Letting $h = 1000$ and $\frac{dh}{dt} = 600$, we get

$$600 = 5000 \sec^2(\theta) \frac{d\theta}{dt}.$$

**Solve.** We want to find $\frac{d\theta}{dt}$ when $h = 1000$ ft. We need to determine $\sec^2(\theta)$. Recall that $\sec(\theta)$ is the ratio of the length of the hypotenuse to the length of the adjacent side. We know the length of the adjacent side is $5000$ ft. To determine the length of the hypotenuse, we use the Pythagorean Theorem, where the length of one leg is $5000$ ft, the length of the other leg is $h = 1000$ ft, and the length of the hypotenuse is $c$ feet as shown in the following figure.



We see that

$$1000^2 + 5000^2 = c^2$$

and we conclude that the hypotenuse is

$$c = 1000\sqrt{26} \text{ ft}.$$

Therefore, when $h = 1000$, we have

$$\sec^2(\theta) = \left(\frac{1000\sqrt{26}}{5000}\right)^2 = \frac{26}{25}.$$

Doing a final substitution into our formula from the **Substitute** step, we arrive at

$$600 = 5000 \left(\frac{26}{25}\right) \frac{d\theta}{dt}.$$

Therefore, $\frac{d\theta}{dt} = \frac{3}{26}$ rad/sec.

## Checkpoint 3.8.3

What rate of change is necessary for the elevation angle of the camera if the camera is placed on the ground at a distance of $4000$ ft from the launch pad and the velocity of the rocket is $500$ ft/sec when the rocket is $2000$ ft off the ground?

**Answer**

$\frac{1}{10}$ rad/sec

In the following example, we consider water draining from a cone-shaped funnel. We compare the rate at which the level of water in the cone is decreasing with the rate at which the volume of water is decreasing.

## Example 3.8.4: Water Draining from a Funnel

Water is draining from the bottom of a cone-shaped funnel at the rate of $0.03 \text{ ft}^3/\text{sec}$. The height of the funnel is $2$ ft, and the radius at the top of the funnel is $1$ ft. At what rate is the height of the water in the funnel changing when the height of the water is $\frac{1}{2}$ ft?

**Solution**

This time, we will shorthand our steps to mirror the pacing you should get used to.

**Read.** Done.

**Understand** and **Label.** See the picture below.

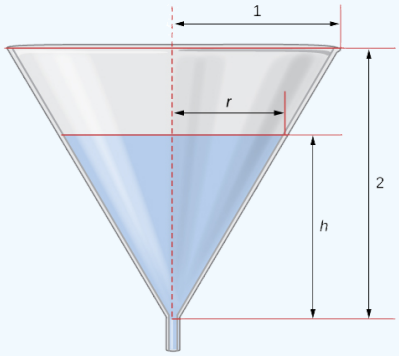


*Figure* 3.8.5*: Water is draining from a funnel of height* 2 *ft and radius* 1 *ft. The height of the water and the radius of the top layer of water change over time. We denote these quantities with the variables* $h$ *and* $r$*.*

Let $h$ denote the height of the water in the funnel, $r$ denote the radius of the water at its surface, and $V$ denote the volume of the water.

**Givens** and **Wants.**

| Given | Want |
|---|---|
| $\frac{dV}{dt} = -0.03 \text{ ft}^3/\text{sec}$ | $\frac{dh}{dt}\big\vert_{h=1/2}$ |

**Master Equation.**

$$V = \frac{1}{3}\pi r^2 h.$$

**Caution: Substitute Out a Variable**

Since the Master Equation involves more than two variables, we want to find a relation to rewrite $r$ in terms of either $h$ or $V$.

From the figure, we see that we have similar triangles. Therefore, the ratio of the sides in the two triangles is the same. Therefore, $\frac{r}{h} = \frac{1}{2}$ or $r = \frac{h}{2}$. Using this fact, the equation for volume can be simplified to

$$V = \frac{1}{3}\pi\left(\frac{h}{2}\right)^2 h = \frac{\pi}{12}h^3.$$

**Rate Equation.**

$$\frac{dV}{dt} = \frac{\pi}{4}h^2\frac{dh}{dt}.$$

**Substitute.**

$$-0.03 = \frac{\pi}{4}\cdot\left(\frac{1}{2}\right)^2\cdot\frac{dh}{dt},$$

**Solve.** The previous step implies

$$-0.03 = \frac{\pi}{16}\frac{dh}{dt}.$$

It follows that

$$\frac{dh}{dt} = -\frac{0.48}{\pi} \approx -0.153\,\text{ft/sec}.$$

## Checkpoint 3.8.4

At what rate is the height of the water changing when the height of the water is $\frac{1}{4}$ ft?

**Answer**

**−0.61** ft/sec

# 3.8E: EXERCISES

This page is a draft and is under active development.

## READING QUESTIONS

1. What does it mean for quantities to have "related rates"?
2. In the context of related rates, if a quantity $Q$ is changing over time, how is its rate of change typically represented?
3. Outline the key steps in Polya's Modified Problem-Solving Process as applied to related rates problems.
4. What is a "Master Equation" in a related rates problem? What does it relate?
5. How is the "Rate Equation" obtained from the "Master Equation"? What differentiation technique is primarily used?
6. Why is it crucial *not* to substitute known values for changing quantities into the Master Equation before differentiating? What happens if you do?
7. In Example 2.10.1 (inflating a balloon), what was the Master Equation relating volume $V$ and radius $r$? What was the resulting Rate Equation relating $\frac{dV}{dt}$ and $\frac{dr}{dt}$?
8. In Example 2.10.2 (airplane flying), what geometric theorem was used to establish the Master Equation?
9. When solving for a missing quantity (like $s$ in Example 2.10.2) at the instant of interest, when should this substitution be made – before or after finding the Rate Equation?
10. In Example 2.10.4 (water draining from a funnel), why was it necessary to find a relationship between the radius $r$ and height $h$ of the water before differentiating the volume formula? What geometric concept was used?

## HOMEWORK

**In exercises 1 - 3, find the quantities for the given equation.**

1) Find $\frac{dy}{dt}$ at $x = 1$ and $y = x^2 + 3$ if $\frac{dx}{dt} = 4$.

**Answer**

$$\frac{dy}{dt} = 8$$

2) Find $\frac{dx}{dt}$ at $x = -2$ and $y = 2x^2 + 1$ if $\frac{dy}{dt} = -1$.

3) Find $\frac{dz}{dt}$ at $(x, y) = (1, 3)$ and $z^2 = x^2 + y^2$ if $\frac{dx}{dt} = 4$ and $\frac{dy}{dt} = 3$.

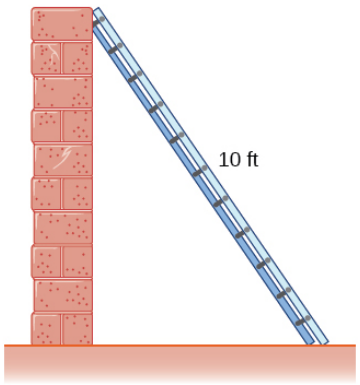
**Answer**

$$\frac{dz}{dt} = \frac{13}{\sqrt{10}}$$

**In exercises 4 - 15, sketch the situation if necessary and used related rates to solve for the quantities.**

4) If two electrical resistors are connected in parallel, the total resistance (measured in ohms, denoted by the Greek capital letter omega, $\omega$) is given by the equation $\frac{1}{R} = \frac{1}{R_1} + \frac{1}{R_2}$. If $R_1$ is increasing at a rate of $0.5\omega/\text{min}$ and $R_2$ decreases at a rate of $1.1\omega/\text{min}$, at what rate does the total resistance change when $R_1 = 20\omega$ and $R_2 = 50\omega/\text{min}$?

5) A $10$-ft ladder is leaning against a wall. If the top of the ladder slides down the wall at a rate of $2$ ft/sec, how fast is the bottom moving along the ground when the bottom of the ladder is $5$ ft from the wall?

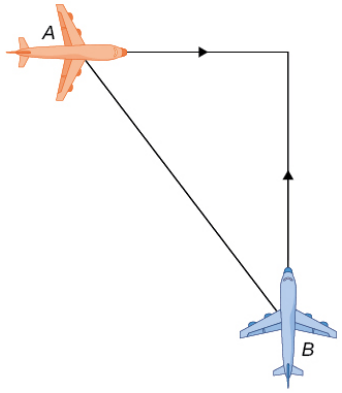


**Answer**

$2\sqrt{3}$ ft/sec

6) A $25$-ft ladder is leaning against a wall. If we push the ladder toward the wall at a rate of $1$ ft/sec, and the bottom of the ladder is initially $20$ ft away from the wall, how fast does the ladder move up the wall $5$ sec after we start pushing?

7) Two airplanes are flying in the air at the same height: airplane A is flying east at $250$ mi/h and airplane B is flying north at $300$ mi/h. If they are both heading to the same airport, located $30$ miles east of airplane A and $40$ miles north of airplane B, at what rate is the distance between the airplanes changing?



**Answer**

The distance is decreasing at $390$ mi/h.

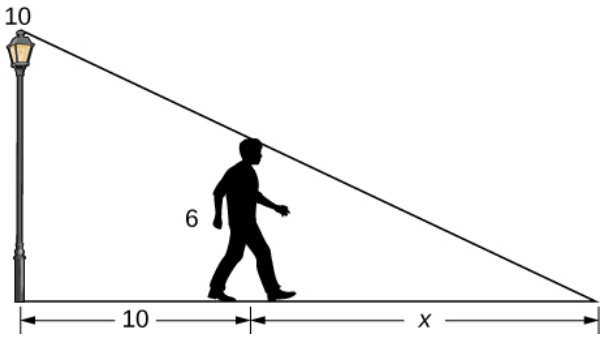
8) You and a friend are riding your bikes to a restaurant that you think is east; your friend thinks the restaurant is north. You both leave from the same point, with you riding at $16$ mph east and your friend riding $12$ mph north. After you traveled $4$ mi, at what rate is the distance between you changing?

9) Two buses are driving along parallel freeways that are $5$ mi apart, one heading east and the other heading west. Assuming that each bus drives a constant $55$ mph, find the rate at which the distance between the buses is changing when they are $13$ mi apart (as the crow flies), heading toward each other.

**Answer**

The distance between them shrinks at a rate of $\frac{1320}{13} \approx 101.5$ mph.

10) A $6$-ft-tall person walks away from a $10$-ft lamppost at a constant rate of $3$ ft/sec. What is the rate that the tip of the shadow moves away from the pole when the person is $10$ ft away from the pole?



11) Using the previous problem, what is the rate at which the tip of the shadow moves away from the person when the person is $10$ ft from the pole?

**Answer**

$\frac{9}{2}$ ft/sec

12) A $5$-ft-tall person walks toward a wall at a rate of $2$ ft/sec. A spotlight is located on the ground $40$ ft from the wall. How fast does the height of the person's shadow on the wall change when the person is $10$ ft from the wall?

13) Using the previous problem, what is the rate at which the shadow changes when the person is $10$ ft from the wall, if the person is walking away from the wall at a rate of $2$ ft/sec?

**Answer**

It grows at a rate $\frac{4}{9}$ ft/sec

14) A helicopter starting on the ground is rising directly into the air at a rate of $25$ ft/sec. You are running on the ground starting directly under the helicopter at a rate of $10$ ft/sec. Find the rate of change of the distance between the helicopter and yourself after $5$ sec.

15) Using the previous problem, assuming the helicopter is again rising at a rate of $25$ ft/sec and you are running on the ground starting directly under the helicopter at a rate of $10$ ft/sec, what is the rate at which the distance between you and the helicopter is changing when the helicopter has risen to a height of $60$ ft in the air, assuming that, initially, it was $30$ ft above you?

**Answer**

The distance is increasing at $\frac{135\sqrt{26}}{26}$ ft/sec

**In exercises 16 - 24, draw and label diagrams to help solve the related-rates problems.**

16) The side of a cube increases at a rate of $\frac{1}{2}$ m/sec. Find the rate at which the volume of the cube increases when the side of the cube is $4$ m.

17) The volume of a cube decreases at a rate of $10\ \text{m}^3$/sec. Find the rate at which the side of the cube changes when the side of the cube is $2$ m.

**Answer**

$-\frac{5}{6}$ m/sec

18) The radius of a circle increases at a rate of $2$ m/sec. Find the rate at which the area of the circle increases when the radius is $5$ m.

19) The radius of a sphere decreases at a rate of $3$ m/sec. Find the rate at which the surface area decreases when the radius is $10$ m.

**Answer**

$240\pi\ \text{m}^2/\text{sec}$

20) The radius of a sphere increases at a rate of $1$ m/sec. Find the rate at which the volume increases when the radius is $20$ m.

21) The radius of a sphere is increasing at a rate of $9$ cm/sec. Find the radius of the sphere when the volume and the radius of the sphere are increasing at the same numerical rate.

**Answer**

$\frac{1}{2\sqrt{\pi}}$ cm

22) The base of a triangle is shrinking at a rate of $1$ cm/min and the height of the triangle is increasing at a rate of $5$ cm/min. Find the rate at which the area of the triangle changes when the height is $22$ cm and the base is $10$ cm.

23) A triangle has two constant sides of length $3$ ft and $5$ ft. The angle between these two sides is increasing at a rate of $0.1$ rad/sec. Find the rate at which the area of the triangle is changing when the angle between the two sides is $\pi/6$.

**Answer**

The area is increasing at a rate $\frac{3\sqrt{3}}{8}\ \text{ft}^2/\text{sec}$.

24) A triangle has a height that is increasing at a rate of $2$ cm/sec and its area is increasing at a rate of $4\ \text{cm}^2/\text{sec}$. Find the rate at which the base of the triangle is changing when the height of the triangle is $4$ cm and the area is $20\ \text{cm}^2$.

**In exercises 25 - 27, consider an inverted right cone that is leaking water. (Inverted means the cone's point is facing down, like a funnel.) The dimensions of the conical tank are a height of 16 ft and a radius of 5 ft.**

25) How fast does the depth of the water change when the water is $10$ ft high if the cone leaks water at a rate of $10\ \text{ft}^3/\text{min}$?

**Answer**

The depth of the water decreases at $\frac{128}{125\pi}$ ft/min.

26) Find the rate at which the surface area of the water changes when the water is $10$ ft high if the cone leaks water at a rate of $10\ \text{ft}^3/\text{min}$.

27) If the water level is decreasing at a rate of $3$ in/min when the depth of the water is $8$ ft, determine the rate at which water is leaking out of the cone.

**Answer**

The volume is decreasing at a rate of $\frac{25\pi}{16}\ \text{ft}^3/\text{min}$.

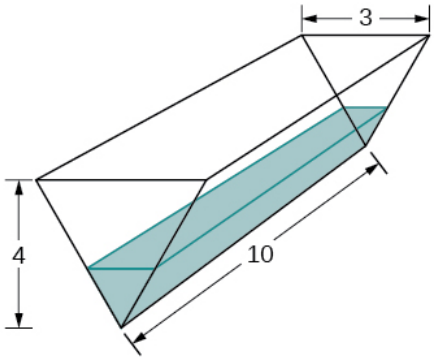
28) A vertical cylinder is leaking water at a rate of $1\ \text{ft}^3/\text{sec}$. If the cylinder has a height of $10$ ft and a radius of $1$ ft, at what rate is the height of the water changing when the height is $6$ ft?

29) A cylinder is leaking water but you are unable to determine at what rate. The cylinder has a height of $2$ m and a radius of $2$ m. Find the rate at which the water is leaking out of the cylinder if the rate at which the height is decreasing is $10$ cm/min when the height is $1$ m.

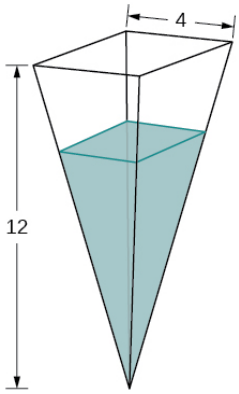
**Answer**

The water flows out at rate $\frac{2\pi}{5}\ \text{m}^3/\text{min}$.

30) A trough has ends shaped like isosceles triangles, with width $3$ m and height $4$ m, and the trough is $10$ m long. Water is being pumped into the trough at a rate of $5\ \text{m}^3/\text{min}$. At what rate does the height of the water change when the water is $1$ m deep?



31) A tank is shaped like an upside-down square pyramid, with base of $4$ m by $4$ m and a height of $12$ m (see the following figure). How fast does the height increase when the water is $2$ m deep if water is being pumped in at a rate of $\frac{2}{3}\ \text{m}^3$/sec?



**Answer**

$\frac{3}{2}$ m/sec

**For exercises 32 - 34, consider a pool shaped like the bottom half of a sphere, that is being filled at a rate of $25\ \text{ft}^3$/min. The radius of the pool is 10 ft.**

32) Find the rate at which the depth of the water is changing when the water has a depth of $5$ ft.

33) Find the rate at which the depth of the water is changing when the water has a depth of $1$ ft.

**Answer**

$\frac{25}{19\pi}$ ft/min

34) If the height is increasing at a rate of $1$ in/sec when the depth of the water is $2$ ft, find the rate at which water is being pumped in.

35) Gravel is being unloaded from a truck and falls into a pile shaped like a cone at a rate of $10\,\text{ft}^3/\text{min}$. The radius of the cone base is three times the height of the cone. Find the rate at which the height of the gravel changes when the pile has a height of $5$ ft.

**Answer**

$\frac{2}{45\pi}$ ft/min

36) Using a similar setup from the preceding problem, find the rate at which the gravel is being unloaded if the pile is $5$ ft high and the height is increasing at a rate of $4$ in/min.

**In exercises 37 - 41, draw the situations and solve the related-rate problems.**

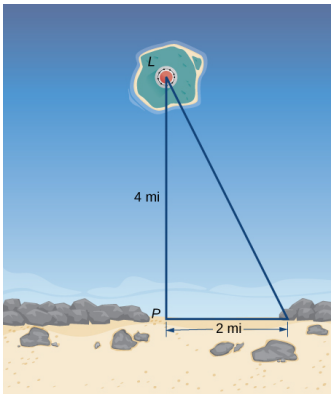
37) You are stationary on the ground and are watching a bird fly horizontally at a rate of $10$ m/sec. The bird is located $40$ m above your head. How fast does the angle of elevation change when the horizontal distance between you and the bird is $9$ m?

**Answer**

The angle decreases at $\frac{400}{1681}$ rad/sec.

38) You stand $40$ ft from a bottle rocket on the ground and watch as it takes off vertically into the air at a rate of $20$ ft/sec. Find the rate at which the angle of elevation changes when the rocket is $30$ ft in the air.

39) A lighthouse, $L$, is on an island $4$ mi away from the closest point, $P$, on the beach (see the following image). If the lighthouse light rotates clockwise at a constant rate of $10$ revolutions/min, how fast does the beam of light move across the beach $2$ mi away from the closest point on the beach?



**Answer**

$100\pi$ mi/min

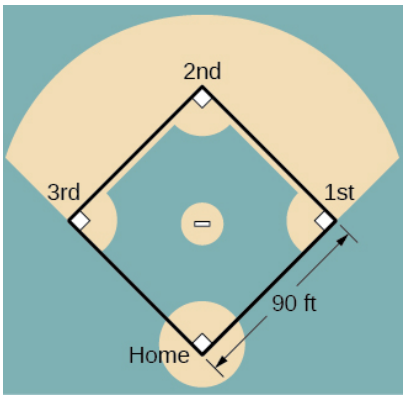
40) Using the same setup as the previous problem, determine at what rate the beam of light moves across the beach $1$ mi away from the closest point on the beach.

41) You are walking to a bus stop at a right-angle corner. You move north at a rate of $2$ m/sec and are $20$ m south of the intersection. The bus travels west at a rate of $10$ m/sec away from the intersection – you have missed the bus! What is the rate at which the angle between you and the bus is changing when you are $20$ m south of the intersection and the bus is $10$ m west of the intersection?

**Answer**

The angle is changing at a rate of $\frac{11}{25}$ rad/sec.

**In exercises 42 - 45, refer to the figure of baseball diamond, which has sides of 90 ft.**



42) A batter hits a ball toward third base at **75** ft/sec and runs toward first base at a rate of **24** ft/sec. At what rate does the distance between the ball and the batter change when **2** sec have passed?

43) A batter hits a ball toward second base at **80** ft/sec and runs toward first base at a rate of **30** ft/sec. At what rate does the distance between the ball and the batter change when the runner has covered one-third of the distance to first base? (Hint: Recall the law of cosines.)

**Answer**

The distance is increasing at a rate of **62.50** ft/sec.

44) A batter hits the ball and runs toward first base at a speed of **22** ft/sec. At what rate does the distance between the runner and second base change when the runner has run **30** ft?

45) Runners start at first and second base. When the baseball is hit, the runner at first base runs at a speed of **18** ft/sec toward second base and the runner at second base runs at a speed of **20** ft/sec toward third base. How fast is the distance between runners changing 1 sec after the ball is hit?

**Answer**

The distance is decreasing at a rate of **11.99** ft/sec.

# 3.9: Linear Approximations and Differentials

**Learning Objectives**

- Describe the linear approximation to a function at a point.
- Write the linearization of a given function.
- Draw a graph that illustrates the use of differentials to approximate the change in a quantity.
- Calculate the relative and percentage error when using a differential approximation.

Hawk A.I. Section-Specific Tutor

Please note that, to access the Hawk A.I. Tutor, you will need a (free) OpenAI account.

We have just seen how derivatives allow us to compare related quantities that change over time. In this section, we examine another application of derivatives: the ability to approximate functions locally by linear functions. Linear functions are the most straightforward functions to work with, so they provide a valuable tool for approximating function values. In addition, the ideas presented in this section are generalized later in the text when we study how to approximate functions by higher-degree polynomials using Taylor Polynomial Expansions.

## Linear Approximation of a Function at a Point

Consider a function $f$ that is differentiable at a point $x = a$. The tangent line to $f$ at the point $(a, f(a))$ is

$$y - f(a) = f'(a)(x - a) \implies y = f(a) + f'(a)(x - a).$$

For example, consider the function $f(x) = \frac{1}{x}$ at $a = 2$. Since $f$ is differentiable at $x = 2$ and $f'(x) = -\frac{1}{x^2}$, we see that $f'(2) = -\frac{1}{4}$. Therefore, the tangent line to the graph of $f$ at $a = 2$ is given by the equation

$$y = \frac{1}{2} - \frac{1}{4}(x - 2).$$

Figure 3.9.1*a* shows a graph of $f(x) = \frac{1}{x}$ along with the tangent line to $f$ at $x = 2$. Note that for $x$ near 2, the graph of the tangent line is close to the graph of $f$. As a result, we can use the equation of the tangent line to approximate $f(x)$ for $x$ near 2. For example, if $x = 2.1$, the $y$ value of the corresponding point on the tangent line is

$$y = \frac{1}{2} - \frac{1}{4}(2.1 - 2) = 0.475.$$

The actual value of $f(2.1)$ is given by

$$f(2.1) = \frac{1}{2.1} \approx 0.47619.$$

Therefore, the tangent line gives us a fairly good approximation of $f(2.1)$ (Figure 3.9.1*b*). However, note that for values of $x$ far from 2, the equation of the tangent line does not give us a good approximation. For example, if $x = 10$, the $y$-value of the corresponding point on the tangent line is

$$y = \frac{1}{2} - \frac{1}{4}(10 - 2) = \frac{1}{2} - 2 = -1.5,$$

whereas the value of the function at $x = 10$ is $f(10) = 0.1$.

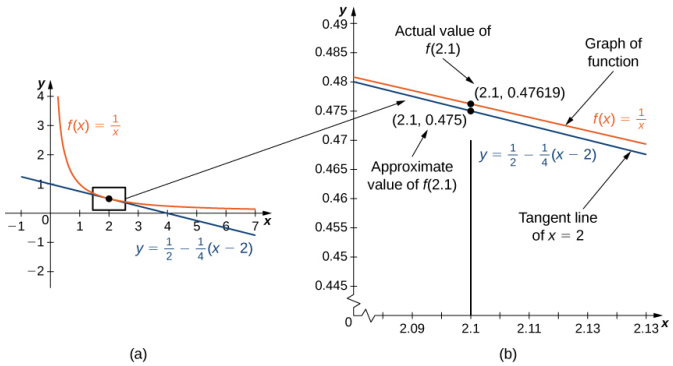


*Figure* **3.9.1a**: *The tangent line to* $f(x) = 1/x$ *at* $x = 2$ *provides a good approximation to* $f$ *for* $x$ *near* $2$.
*Figure* **3.9.1b**: *At* $x = 2.1$, *the value of* $y$ *on the tangent line to* $f(x) = 1/x$ *is* $0.475$. *The actual value of* $f(2.1)$ *is* $1/2.1$, *which is approximately* $0.47619$.

In general, for a differentiable function $f$, the equation of the tangent line to $f$ at $x = a$ can be used to approximate $f(x)$ for $x$ near $a$. Therefore, we can write

$$f(x) \approx f(a) + f'(a)(x - a) \text{ for } x \text{ near } a.$$

We call the linear function

$$L(x) = f(a) + f'(a)(x - a) \tag{3.9.1}$$

the **linear approximation,** or **tangent line approximation**, of $f$ at $x = a$. This function $L$ is also known as the **linearization** of $f$ at $x = a$.

To show how beneficial the linear approximation can be, we look at how to find the linear approximation for $f(x) = \sqrt{x}$ at $x = 9$.

### Example 3.9.1: Linear Approximation of $\sqrt{x}$

Find the linear approximation of $f(x) = \sqrt{x}$ at $x = 9$ and use the approximation to estimate $\sqrt{9.1}$.

**Solution**

Since we are looking for the linear approximation at $x = 9$, using Equation 3.9.1 we know the linear approximation is given by

$$L(x) = f(9) + f'(9)(x - 9).$$

We need to find $f(9)$ and $f'(9)$.

$$f(x) = \sqrt{x} \implies f(9) = \sqrt{9} = 3$$

and

$$f'(x) = \frac{1}{2\sqrt{x}} \implies f'(9) = \frac{1}{2\sqrt{9}} = \frac{1}{6}.$$

Therefore, the linear approximation is given by Figure 3.9.2.

$$L(x) = 3 + \frac{1}{6}(x - 9)$$

Using the linear approximation, we can estimate $\sqrt{9.1}$ by writing

$$\sqrt{9.1} = f(9.1) \approx L(9.1) = 3 + \frac{1}{6}(9.1 - 9) \approx 3.0167.$$

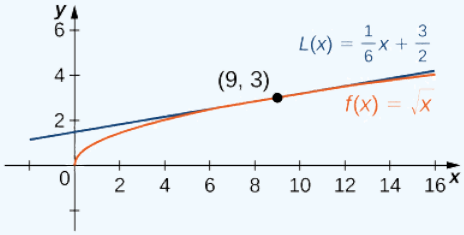

*Figure* **3.9.2***: The local linear approximation to* $f(x) = \sqrt{x}$ *at* $x = 9$ *provides an approximation to* $f$ *for* $x$ *near* **9**.

**Analysis**

Using a calculator, the value of $\sqrt{9.1}$ to four decimal places is **3.0166**. The value given by the linear approximation, **3.0167**, is very close to the value obtained with a calculator, so it appears that using this linear approximation is a good way to estimate $\sqrt{x}$, at least for $x$ near **9**. At the same time, it may seem odd to use a linear approximation when we can push a few buttons on a calculator to evaluate $\sqrt{9.1}$. However, how does the calculator evaluate $\sqrt{9.1}$? The calculator uses an approximation! Calculators and computers always use approximations to evaluate mathematical expressions; they just use higher-degree approximations.

## ? Checkpoint 3.9.1

Find the local linear approximation to $f(x) = \sqrt[3]{x}$ at $x = 8$. Use it to approximate $\sqrt[3]{8.1}$ to five decimal places.

**Answer**

$L(x) = 2 + \frac{1}{12}(x - 8)$; **2.00833**

## ✔ Example 3.9.2: Linear Approximation of $\sin x$

Find the linear approximation of $f(x) = \sin(x)$ at $x = \frac{\pi}{3}$ and use it to approximate $\sin(62°)$.

**Solution**

First, we recall that degree measure and calculus do not work well together. Therefore, we trade out **60°** for $\frac{\pi}{3}$ radians. The linear approximation is given by

$$L(x) = f\left(\frac{\pi}{3}\right) + f'\left(\frac{\pi}{3}\right)\left(x - \frac{\pi}{3}\right).$$

We see that

$$f(x) = \sin(x) \implies f\left(\frac{\pi}{3}\right) = \sin\left(\frac{\pi}{3}\right) = \frac{\sqrt{3}}{2}$$

$$f'(x) = \cos(x) \implies f'\left(\frac{\pi}{3}\right) = \cos\left(\frac{\pi}{3}\right) = \frac{1}{2}$$

Therefore, the linear approximation of $f$ at $x = \pi/3$ is given by Figure **3.9.3**.

$$L(x) = \frac{\sqrt{3}}{2} + \frac{1}{2}\left(x - \frac{\pi}{3}\right)$$

To estimate $\sin(62°)$ using $L$, we must first convert **62°** to radians. We have $62° = \frac{62\pi}{180}$ radians, so the estimate for $\sin(62°)$ is given by

$$\sin(62°) = f\left(\frac{62\pi}{180}\right) \approx L\left(\frac{62\pi}{180}\right) = \frac{\sqrt{3}}{2} + \frac{1}{2}\left(\frac{62\pi}{180} - \frac{\pi}{3}\right) = \frac{\sqrt{3}}{2} + \frac{1}{2}\left(\frac{2\pi}{180}\right) = \frac{\sqrt{3}}{2} + \frac{\pi}{180} \approx 0.88348.$$

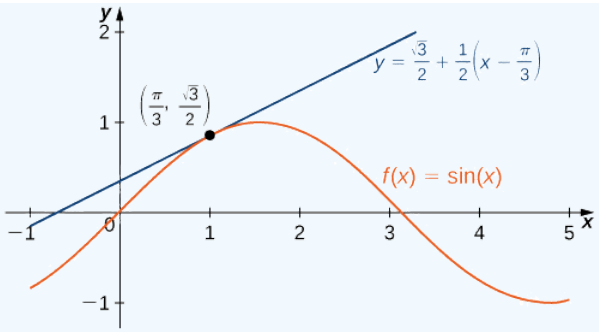

*Figure* **3.9.3***: The linear approximation to* $f(x) = \sin x$ *at* $x = \pi/3$ *provides an approximation to* $\sin x$ *for* $x$ *near* $\pi/3$.

## ? Checkpoint 3.9.2

Find the linear approximation for $f(x) = \cos x$ at $x = \frac{\pi}{2}$.

**Answer**

$L(x) = -x + \frac{\pi}{2}$

Linear approximations may be used in estimating roots and powers. In the next example, we find the linear approximation for $f(x) = (1 + x)^n$ at $x = 0$, which can be used to estimate roots and powers for real numbers near 1. The same idea can be extended to a function of the form $f(x) = (m + x)^n$ to estimate roots and powers near a different number $m$.

## ✔ Example 3.9.3: Approximating Roots and Powers

Find the linear approximation of $f(x) = (1 + x)^n$ at $x = 0$. Use this approximation to estimate $(1.01)^3$.

**Solution**

The linear approximation at $x = 0$ is given by

$$L(x) = f(0) + f'(0)(x - 0).$$

Because

$$f(x) = (1 + x)^n \implies f(0) = 1$$

$$f'(x) = n(1 + x)^{n-1} \implies f'(0) = n,$$

the linear approximation is given by Figure 3.9.4*a*.

$$L(x) = 1 + n(x - 0) = 1 + nx$$

We can approximate $(1.01)^3$ by evaluating $L(0.01)$ when $n = 3$. We conclude that

$$(1.01)^3 = f(1.01) \approx L(1.01) = 1 + 3(0.01) = 1.03.$$

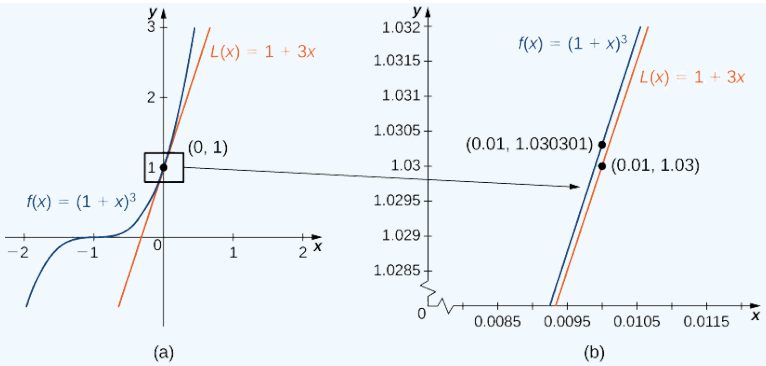

*Figure* **3.9.4a**: *The linear approximation of* $f(x)$ *at* $x = 0$ *is* $L(x)$.
*Figure* **3.9.4b**: *The actual value of* $1.01^3$ *is* $1.030301$. *The linear approximation of* $f(x)$ *at* $x = 0$ *estimates* $1.01^3$ *to be* $1.03$.

**Common Mistake**

In Example **3.9.3**, we linearized the function $f(x) = (1 + x)^3$ at $x = 0$ to approximate $(1.01)^3$. In this case, $(1.01)^3 = f(0.01) \approx L(0.01)$. It's common for students to make the mistake of thinking, to approximate $(1.01)^3$, we need to evaluate $f$ (and, therefore, $L$) at $1.01$; however, $f(x) = (1 + x)^3$ already has the $1$ (also known as the **whole part**) built-in. Therefore, we need to evaluate $f$ (and, therefore, $L$) at the **decimal part**.

**Checkpoint 3.9.3**

Find the linear approximation of $f(x) = (1 + x)^4$ at $x = 0$ without using the result from the preceding example.

**Answer**

$L(x) = 1 + 4x$

## Differentials

We have seen that linear approximations can be used to estimate function values. They can also be used to estimate the amount a function value changes due to a small change in the input. To discuss this more formally, we define a related concept: differentials. Differentials provide us with a way of estimating the amount a function changes due to a small change in input values.

When we first looked at derivatives, we used the Leibniz notation $dy/dx$ to represent the derivative of $y$ with respect to $x$. Although we used the expressions $dy$ and $dx$ in this notation, they did not have meaning on their own. Here, we see a meaning to the expressions $dy$ and $dx$. Suppose $y = f(x)$ is a differentiable function. Let $dx$ be an independent variable that can be assigned any nonzero real number, and define the dependent variable $dy$ by

$$dy = f'(x)\,dx. \tag{3.9.2}$$

The expressions $dy$ and $dx$ are called **differentials**. It is important to notice that $dy$ is a function of both $x$ and $dx$.

**Example 3.9.4: Computing Differentials**

For each of the following functions, find $dy$ and evaluate when $x = 3$ and $dx = 0.1$.

a. $y = x^2 + 2x$
b. $y = \cos x$

**Solutions**

The key step is calculating the derivative. We can obtain $dy$ directly when we have that.

a. Since $f(x) = x^2 + 2x$, we know $f'(x) = 2x + 2$, and therefore

$$dy = (2x + 2)\,dx.$$

When $x = 3$ and $dx = 0.1$,

$$dy = (2 \cdot 3 + 2)(0.1) = 0.8.$$

b. Since $f(x) = \cos x$, $f'(x) = -\sin(x)$. This gives us

$$dy = -\sin x \, dx.$$

When $x = 3$ and $dx = 0.1$,

$$dy = -\sin(3)(0.1) = -0.1 \sin(3).$$

**? Checkpoint 3.9.4**

For $y = e^{x^2}$, find $dy$.

**Answer**

$dy = 2xe^{x^2} dx$

We now connect differentials to linear approximations. Differentials can be used to estimate the change in the value of a function resulting from a small change in input values. Consider a function $f$ that is differentiable at point $a$. Suppose the input $x$ changes by a small amount. We are interested in how much the output $y$ changes. If $x$ changes from $a$ to $a + dx$, then the change in $x$ is $dx$ (also denoted $\Delta x$), and the change in $y$ is given by

$$\Delta y = f(a + dx) - f(a).$$

Instead of calculating the exact change in $y$, however, it is often easier to approximate the change in $y$ by using a linear approximation. For $x$ near $a$, $f(x)$ can be approximated by the linear approximation (Equation 3.9.1)

$$L(x) = f(a) + f'(a)(x - a).$$

Therefore, if $dx$ is small,

$$f(a + dx) \approx L(a + dx) = f(a) + f'(a)(a + dx - a).$$

That is,

$$f(a + dx) - f(a) \approx L(a + dx) - f(a) = f'(a) \, dx.$$

In other words, the actual change in the function $f$ if $x$ increases from $a$ to $a + dx$ is approximately the difference between $L(a + dx)$ and $f(a)$, where $L(x)$ is the linear approximation of $f$ at $a$. By definition of $L(x)$, this difference is equal to $f'(a) \, dx$. In summary,

$$\Delta y = f(a + dx) - f(a) \approx L(a + dx) - f(a) = f'(a) \, dx = dy.$$

Therefore, we can use the differential $dy = f'(a) \, dx$ to approximate the change in $y$ if $x$ increases from $x = a$ to $x = a + dx$. We can see this in the following graph.

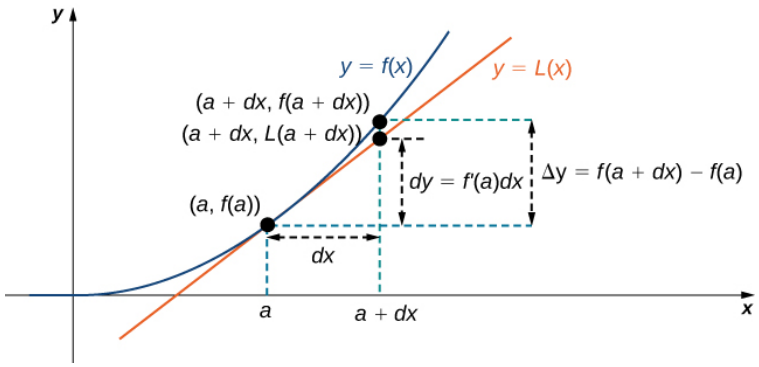

*Figure 3.9.5: The differential $dy = f'(a) \, dx$ is used to approximate the actual change in $y$ if $x$ increases from $a$ to $a + dx$.*

We now look at how to use differentials to approximate the change in the value of the function that results from a small change in the value of the input. Note that the calculation with differentials is much simpler than calculating actual values of functions, and the result is very close to what we would obtain with a more exact calculation.

### Example 3.9.5: Approximating Change with Differentials

Let $y = x^2 + 2x$. Compute $\Delta y$ and $dy$ at $x = 3$ if $dx = 0.1$.

**Solution**

The actual change in $y$ if $x$ changes from $x = 3$ to $x = 3.1$ is given by

$$\Delta y = f(3.1) - f(3) = [(3.1)^2 + 2(3.1)] - [3^2 + 2(3)] = 0.81.$$

The approximate change in $y$ is given by $dy = f'(3)\,dx$. Since $f'(x) = 2x + 2$, we have

$$dy = f'(3)\,dx = (2(3) + 2)(0.1) = 0.8.$$

### Checkpoint 3.9.5

For $y = x^2 + 2x$, find $\Delta y$ and $dy$ at $x = 3$ if $dx = 0.2$.

**Answer**

$dy = 1.6,\ \Delta y = 1.64$

### A Technical Aside: The Happy Accident of Leibniz's Notation

Leibniz notation is handy throughout Calculus; however, it can be confusing for students when it comes to differentials. Visually, it looks like we can divide both sides of Equation 3.9.2 by $dx$ to arrive at

$$\frac{dy}{dx} = f'(x),$$

however, this equivalence is a happy accident.

Technically speaking, $\frac{d}{dx}$ is an **operator**. That is, it is a set of instructions that accepts a function and returns the derivative of that function. For example, $\frac{d}{dx}(y) = \frac{dy}{dx}$ is the operator that returns the derivative of the function $y$ with respect to $x$; however, to say that you can "pull apart" the operator and multiply both sides by $dx$ to get $dy = f'(x)dx$ is an abuse of logic. Notationally, it works, but to be clear, it is not true that we are multiplying both sides by $dx$.

$$\frac{dy}{dx} \text{ is defined to be } f'(x).$$

Whereas,

$$dy \text{ is defined to be } f'(x)dx.$$

As a simple clarification, you have dealt with operators your entire life. For example, $+$ is an operator that accepts two numbers and returns the sum of those two numbers. Therefore, $3 + 2 = 5$ is true because the operator, $+$, returns the sum of $3$ and $2$ (which is $5$). I hope you would agree that "pulling apart" the operator and dividing by a "piece" of the operator to get

$$3| - 2 = 5 \implies 3|2 = \frac{5}{-}$$

leads to a breakdown in logic (and notation).

All of this is to say that, technically, you should not tell someone, "I see you have $dy = f'(x)dx$. Just *divide both sides* by $dx$ to get the derivative $\frac{dy}{dx} = f'(x)$." That statement is (again, very technically) an abuse of logic. Moreover, saying to your friend, "Oh, you have $\frac{dy}{dx} = f'(x)$? Great! Just *multiply both sides* by $dx$ to get $dy = f'(x)dx$," is a similar abuse in logic.

It's okay to *silently* view the notation this way, but you should realize this result is just a happy accident of Leibniz's notation.

## Calculating the Amount of Error

Any type of measurement is prone to a certain amount of error. In many applications, certain quantities are calculated based on measurements. For example, the area of a circle is calculated by measuring the radius of the circle. An error in the measurement of the radius leads to an error in the computed value of the area. Here, we examine this type of error and study how differentials can be used to estimate the error.

Consider a function $f$ with an input that is a measured quantity. Suppose the exact value of the measured quantity is $a$, but the measured value is $a+dx$. We say the **measurement error** is $dx$ (or $\Delta x$). As a result, an error occurs in the calculated quantity $f(x)$. This type of error is known as a **propagated error** and is given by

$$\Delta y = f(a+dx) - f(a).$$

Since all measurements are prone to some error, we do not know the exact value of a measured quantity, so we cannot calculate the propagated error exactly. However, given an estimate of the accuracy of a measurement, we can use differentials to approximate the propagated error $\Delta y$. Specifically, if $f$ is a differentiable function at $a$, the propagated error is

$$\Delta y \approx dy = f'(a)\,dx.$$

Unfortunately, we do not know the exact value $a$. However, we can use the measured value $a+dx$, and estimate

$$\Delta y \approx dy \approx f'(a+dx)\,dx.$$

In the next example, we look at how differentials can be used to estimate the error in calculating the volume of a box if we assume the measurement of the side length is made with a certain amount of accuracy.

### Example 3.9.6: Volume of a Cube

Suppose the side length of a cube is measured to be $5$ cm, but we think this could be off by at most $0.1$ cm.

a. Use differentials to estimate the error in the computed volume of the cube.
b. Compute the volume of the cube if the side length is (i) $4.9$ cm and (ii) $5.1$ cm to compare the estimated error with the actual potential error.

**Solutions**

a. The measurement of the side length is accurate to within $\pm 0.1$ cm. Therefore,

$$-0.1 \le dx \le 0.1.$$

The volume of a cube is given by $V = x^3$, which leads to

$$dV = 3x^2 dx.$$

Using the measured side length of $5$ cm, we can estimate that

$$-3(5)^2(0.1) \le dV \le 3(5)^2(0.1).$$

Therefore,

$$-7.5 \le dV \le 7.5.$$

That is, with our possible measurement error of $\pm 0.1$ cm, our estimation of the volume could be off by at most $\pm 7.5\ \text{cm}^3$.

b. If the side length is actually $4.9$ cm, then the volume of the cube is

$$V(4.9) = (4.9)^3 = 117.649\text{cm}^3.$$

If the side length is actually $5.1$ cm, then the volume of the cube is

$$V(5.1) = (5.1)^3 = 132.651\text{cm}^3.$$

Therefore, the actual volume of the cube is between $117.649$ and $132.651$. Since the side length is measured to be 5 cm, the computed volume is $V(5) = 5^3 = 125$. Therefore, the error in the computed volume is

$$117.649 - 125 \leq \Delta V \leq 132.651 - 125.$$

That is,

$$-7.351 \leq \Delta V \leq 7.651.$$

We see the estimated error $dV$ is relatively close to the actual potential error in the computed volume.

**? Checkpoint 3.9.6**

Estimate the error in the computed volume of a cube if the side length is measured to be $6$ cm with an accuracy of $0.2$ cm.

**Answer**

The volume measurement is accurate to within $21.6\,\text{cm}^3$.

The measurement error $dx$ $(= \Delta x)$ and the propagated error $\Delta y$ are absolute errors. We are typically interested in the size of an error relative to the size of the quantity being measured or calculated. Given an absolute error $\Delta q$ for a particular quantity, we define the **relative error** as $\frac{\Delta q}{q}$, where $q$ is the actual value of the quantity. The **percentage error** is the relative error expressed as a percentage. For example, if we measure the height of a ladder to be $63$ in. when the actual height is $62$ in., the absolute error is 1 in., but the relative error is $\frac{1}{62} = 0.016$, or $1.6\%$. By comparison, if we measure the width of a piece of cardboard to be $8.25$ in. when the actual width is $8$ in., our absolute error is $\frac{1}{4}$ in., whereas the relative error is $\frac{0.25}{8} = \frac{1}{32}$, or $3.1\%$. Therefore, the percentage error in the measurement of the cardboard is larger, even though $0.25$ in. is less than $1$ in.

**✓ Example 3.9.7: Relative and Percentage Error**

An astronaut using a camera measures the radius of Earth as $4000$ mi with an error of $\pm 80$ mi. Let's use differentials to estimate the relative and percentage error of using this radius measurement to calculate the volume of Earth, assuming the planet is a perfect sphere.

**Solution**

If the measurement of the radius is accurate to within $\pm 80$, we have

$$-80 \leq dr \leq 80.$$

Since the volume of a sphere is given by $V = (\frac{4}{3})\pi r^3$, we have

$$dV = 4\pi r^2 dr.$$

Using the measured radius of $4000$ mi, we can estimate

$$-4\pi(4000)^2(80) \leq dV \leq 4\pi(4000)^2(80).$$

To estimate the relative error, consider $\frac{dV}{V}$. Since we do not know the exact value of the volume $V$, we use the measured radius $r = 4000$ mi to estimate $V$. We obtain $V \approx (\frac{4}{3})\pi(4000)^3$. Therefore the relative error satisfies

$$\frac{-4\pi(4000)^2(80)}{4\pi(4000)^3/3} \leq \frac{dV}{V} \leq \frac{4\pi(4000)^2(80)}{4\pi(4000)^3/3},$$

which simplifies to

$$-0.06 \leq \frac{dV}{V} \leq 0.06.$$

The relative error is $0.06$ and the percentage error is $6\%$.

**Checkpoint 3.9.7**

Determine the percentage error if the radius of Earth is measured to be $3950$ mi with an error of $\pm 100$ mi.

**Answer**

$7.6\%$

## READING QUESTIONS

1. What is the formula for the linear approximation (or linearization) $L(x)$ of a function $f(x)$ at a point $x = a$?
2. What geometric line does the graph of $L(x)$ represent?
3. How are differentials $dx$ and $dy$ defined for a function $y = f(x)$?
4. What is the relationship between the differential $dy$ and the actual change in $y$, denoted $\Delta y$, when $x$ changes from $a$ to $a + dx$?
5. How can differentials be used to approximate the change in a function's value due to a small change in its input?
6. What is meant by "measurement error" and "propagated error"?
7. How is relative error defined? How is percentage error related to relative error?
8. In Example 1, how was the linear approximation of $f(x) = \sqrt{x}$ at $x = 9$ used to estimate $\sqrt{9.1}$?
9. Why might one use a linear approximation to estimate a value like $\sqrt{9.1}$ when a calculator can provide a more precise value?
10. When using differentials to estimate the error in the volume of a cube (Example 6), if the side length is measured as $x$ with a possible error of $dx$, what is the differential $dV$?

## HOMEWORK

1) What is the linear approximation for any generic linear function $y = mx + b$?

2) Determine the necessary conditions such that the linear approximation function is constant. Use a graph to prove your result.

**Answer**

$f'(a) = 0$

3) Explain why the linear approximation becomes less accurate as you increase the distance between $x$ and $a$. Use a graph to prove your argument.

4) When is the linear approximation exact?

**Answer**

The linear approximation exact when $y = f(x)$ is linear or constant.

**In exercises 5 - 10, find the linear approximation $L(x)$ to $y = f(x)$ near $x = a$ for the function.**

5) $f(x) = x + x^4, \quad a = 0$

6) $f(x) = \dfrac{1}{x}, \quad a = 2$

**Answer**

$L(x) = \frac{1}{2} - \frac{1}{4}(x - 2)$

7) $f(x) = \tan x, \quad a = \frac{\pi}{4}$

8) $f(x) = \sin x, \quad a = \frac{\pi}{2}$

**Answer**

$L(x) = 1$

9) $f(x) = x \sin x, \quad a = 2\pi$

10) $f(x) = \sin^2 x, \quad a = 0$

**Answer**

$L(x) = 0$

**In exercises 11 - 16, compute the values given within 0.01 by deciding on the appropriate $f(x)$ and $a$, and evaluating $L(x) = f(a) + f'(a)(x - a)$. Check your answer using a calculator.**

11) [Technology Required] $(2.001)^6$

12) [Technology Required] $\sin(0.02)$

**Answer**

$\sin(0.02) \approx 0.02$

13) [Technology Required] $\cos(0.03)$

14) [Technology Required] $(15.99)^{1/4}$

**Answer**

$(15.99)^{1/4} \approx 1.9996875$

15) [Technology Required] $\frac{1}{0.98}$

16) [Technology Required] $\sin(3.14)$

**Answer**

$\sin(3.14) \approx 0.001593$

**In exercises 17 - 22, determine the appropriate $f(x)$ and $a$, and evaluate $L(x) = f(a) + f'(a)(x-a)$. Calculate the numerical error in the linear approximations that follow.**

17) $(1.01)^3$

18) $\cos(0.01)$

**Answer**

$\cos(0.01) \approx L(0.01) = f(0) + f'(0)(0-0.01) = 1$; error, $\approx 0.00005$

19) $(\sin(0.01))^2$

20) $(1.01)^{-3}$

**Answer**

$(1.01)^{-3} \approx L(1.01) = f(1) + f'(1)(1.01-1) = 0.97$; error, $\approx 0.0006$

21) $\left(1 + \frac{1}{10}\right)^{10}$

22) $\sqrt{8.99}$

**Answer**

$\sqrt{8.99} \approx L(8.99) = f(9) + f'(9)(8.99-9) = 3 - \frac{1}{600}$; error, $\approx 4.632 \times 10^{-7}$

**In exercises 23 - 26, find the differential of the function.**

23) $y = 3x^4 + x^2 - 2x + 1$

24) $y = x \cos x$

**Answer**

$dy = (\cos x - x \sin x)\, dx$

25) $y = \sqrt{1+x}$

26) $y = \dfrac{x^2+2}{x-1}$

**Answer**

$dy = \left(\dfrac{x^2-2x-2}{(x-1)^2}\right)dx$

**In exercises 27 - 32, find the differential and evaluate for the given $x$ and $dx$.**

27) $y = 3x^2 - x + 6,\ x = 2,\ dx = 0.1$

28) $y = \dfrac{1}{x+1},\ x = 1,\ dx = 0.25$

**Answer**

$$dy = -\frac{1}{(x+1)^2}dx, \quad dy = -\tfrac{1}{16}$$

29) $y = \tan x,\ x = 0,\ dx = \frac{\pi}{10}$

30) $y = \dfrac{3x^2+2}{\sqrt{x+1}},\ x = 0,\ dx = 0.1$

**Answer**

$$dy = \frac{9x^2+12x-2}{2(x+1)^{3/2}}dx, \quad dy = -0.1$$

31) $y = \dfrac{\sin(2x)}{x},\ x = \pi,\ dx = 0.25$

32) $y = x^3 + 2x + \dfrac{1}{x},\ x = 1,\ dx = 0.05$

**Answer**

$$dy = \left(3x^2 + 2 - \frac{1}{x^2}\right)dx, \quad dy = 0.2$$

**In exercises 33 - 38, find the change in volume $dV$ or in surface area $dA$.**

33) $dV$ if the sides of a cube change from 10 to 10.1.

34) $dA$ if the sides of a cube change from $x$ to $x + dx$.

**Answer**

$$dA = 12x\,dx$$

35) $dA$ if the radius of a sphere changes from $r$ by $dr$.

36) $dV$ if the radius of a sphere changes from $r$ by $dr$.

**Answer**

$$dV = 4\pi r^2 dr$$

37) $dV$ if a circular cylinder with $r = 2$ changes height from $3$ cm to $3.05cm$.

38) $dV$ if a circular cylinder of height 3 changes from $r = 2$ to $r = 1.9$ cm.

**Answer**

$$dV = -1.2\pi\ \text{cm}^3$$

**In exercises 39 - 41, use differentials to estimate the maximum and relative error when computing the surface area or volume.**

39) A spherical golf ball is measured to have a radius of $5$ mm, with a possible measurement error of $0.1$ mm. What is the possible change in volume?

40) A pool has a rectangular base of 10 ft by 20 ft and a depth of 6 ft. What is the change in volume if you only fill it up to 5.5 ft?

**Answer**

$$-100\ \text{ft}^3$$

41) An ice cream cone has height 4 in. and radius 1 in. If the cone is 0.1 in. thick, what is the difference between the volume of the cone, including the shell, and the volume of the ice cream you can fit inside the shell?

**In exercises 42 - 44, confirm the approximations by using the linear approximation at $x = 0$.**

42) $\sqrt{1-x} \approx 1 - \frac{1}{2}x$

43) $\dfrac{1}{\sqrt{1-x^2}} \approx 1$

44) $\sqrt{c^2+x^2} \approx c$

# CHAPTER OVERVIEW

## 4: Appropriate Applications

A rocket launch involves two related quantities that change over time. Being able to solve this type of problem is just one application of derivatives introduced in this chapter. We also look at how derivatives are used to find maximum and minimum values of functions. As a result, we will be able to solve applied optimization problems, such as maximizing revenue and minimizing surface area. In addition, we examine how derivatives are used to evaluate complicated limits, to approximate roots of functions, and to provide accurate graphs of functions.

# 4.1: Graphing Using Calculus - Maxima and Minima

**Learning Objectives**

- Define absolute extrema, local extrema, and critical numbers.
- Explain how to find the critical points of a function over a closed interval.
- Describe the Extreme Value Theorem and Fermat's Theorem.
- Describe how to use critical points to locate absolute extrema over a closed interval.

Hawk A.I. Section-Specific Tutor

Please note that, to access the Hawk A.I. Tutor, you will need a (free) OpenAI account.

Given a particular function, we are often interested in determining the largest and smallest values. This information is important in creating accurate graphs. Finding a function's maximum and minimum values is also practical because this method can solve optimization problems, such as maximizing profit, minimizing the amount of material used in manufacturing an aluminum can, or finding the maximum height a rocket can reach. This section uses derivatives to find a function's largest and smallest values.

## Absolute Extrema

Consider the function $f(x) = x^2 + 1$ over the interval $(-\infty, \infty)$. As $x \to \pm\infty, f(x) \to \infty$. Therefore, the function does not have a largest value. However, since $x^2 + 1 \geq 1$ for all real numbers $x$ and $x^2 + 1 = 1$ when $x = 0$, the function has a smallest value, 1, when $x = 0$. We say that 1 is the **absolute minimum** of $f(x) = x^2 + 1$ and it occurs at $x = 0$. We say that $f(x) = x^2 + 1$ does not have an **absolute maximum** (Figure 4.1.1).

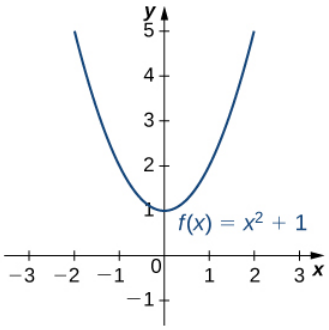

*Figure 4.1.1: The given function has an absolute minimum of 1 at $x = 0$. The function does not have an absolute maximum.*

**Definition: Absolute Extrema**

Let $f$ be a function defined over an interval $I$ and let $c \in I$. We say $f$ has an **absolute maximum** on $I$ at $c$ if $f(c) \geq f(x)$ for all $x \in I$. We say $f$ has an **absolute minimum** on $I$ at $c$ if $f(c) \leq f(x)$ for all $x \in I$. If $f$ has an absolute maximum on $I$ at $c$ or an absolute minimum on $I$ at $c$, we say $f$ has an **absolute extremum** on $I$ at $c$.

Before proceeding, let's note two important issues regarding this definition. First, the term absolute here does not refer to absolute value. An absolute extremum may be positive, negative, or zero. Second, if a function $f$ has an absolute extremum over an interval $I$ at $c$, the absolute extremum is $f(c)$. The real number $c$ is a point in the domain at which the absolute extremum occurs. For example, consider the function $f(x) = \frac{1}{x^2+1}$ over the interval $(-\infty, \infty)$. Since

$$f(0) = 1 \geq \frac{1}{x^2 + 1} = f(x)$$

for all real numbers $x$, we say $f$ has an absolute maximum over $(-\infty, \infty)$ at $x = 0$. The absolute maximum is $f(0) = 1$. It occurs at $x = 0$, as shown in Figure 4.1.2b.

A function may have both an absolute maximum and an absolute minimum, just one extremum, or neither. Figure 4.1.2 shows several functions and some of the different possibilities regarding **absolute extrema** ("extrema" is the plural form of extremum). However, the following theorem, called the **Extreme Value Theorem**, guarantees that a continuous function $f$ over a closed interval $[a, b]$ has both an absolute maximum and an absolute minimum.

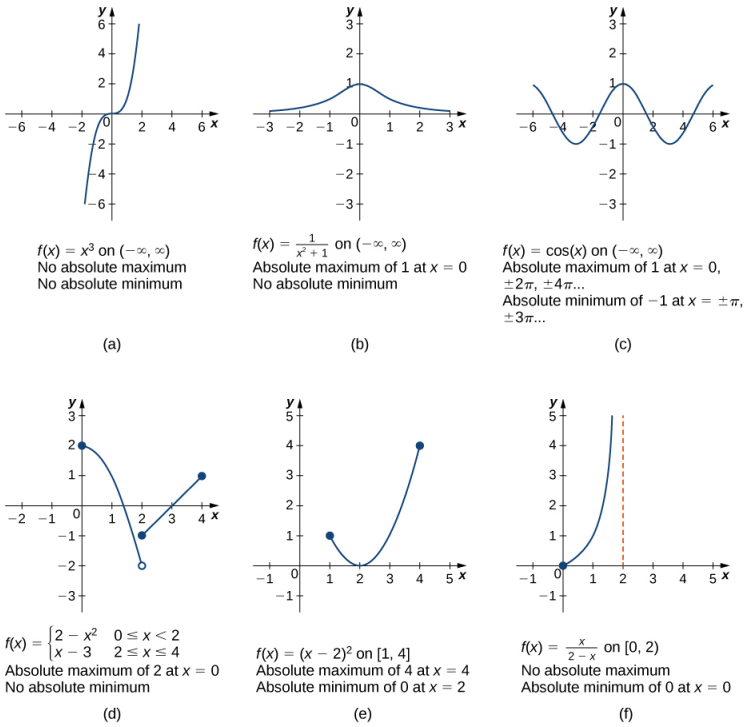

*Figure 4.1.2: Graphs (a), (b), and (c) show several possibilities for absolute extrema for functions with a domain of $(-\infty, \infty)$. Graphs (d), (e), and (f) show several possibilities for absolute extrema for functions with a domain that is a bounded interval.*

**Theorem: Extreme Value Theorem (EVT)**

If $f$ is a continuous function over the closed interval $[a, b]$, then there is a point in $[a, b]$ at which $f$ has an absolute maximum over $[a, b]$ and there is a point in $[a, b]$ at which $f$ has an absolute minimum over $[a, b]$.

The proof of the Extreme Value Theorem is beyond the scope of this text. Typically, it is proved in a course on Real Analysis. There are a couple of key points to note about the statement of this theorem. To apply the Extreme Value Theorem, the function must be continuous over a closed interval. Suppose the interval $I$ is open, or the function has even one point of discontinuity. In that case, the function may not have an absolute maximum or absolute minimum over $I$.

For example, consider the functions shown in Figure 4.1.2*d*, 4.1.2*e*, and 4.1.2*f*. All three of these functions are defined over closed intervals. However, the function in graph 4.1.2*e* is the only one with both an absolute maximum and an absolute minimum over its domain. The Extreme Value Theorem cannot be applied to the functions in graphs 4.1.2*d* and 4.1.2*f* because neither of these functions is continuous over a closed interval. Although the function in graph 4.1.2*d* is defined over the closed interval $[0, 4]$, the function is discontinuous at $x = 2$. The function has an absolute maximum over the closed interval $[0, 4]$ but does not have an absolute minimum. The function in graph 4.1.2*f* is continuous over the half-open interval $[0, 2)$, but is not defined at $x = 2$, and therefore is not continuous over a closed interval. The function has an absolute minimum over $[0, 2)$ but does not have an absolute maximum over $[0, 2)$. These two graphs illustrate why a function over a closed interval may fail to have an absolute maximum and/or minimum.

**Caution: Continuity, Closed Intervals, and the EVT**

The Extreme Value Theorem only applies to functions that are continuous over a closed interval $[a, b]$.

Before looking at how to find absolute extrema, let's examine the related concept of local extrema. This idea is useful in determining where absolute extrema occur.

## Local Extrema and Critical Numbers

Consider the function $f$ shown in Figure **4.1.3**. The graph can be described as two mountains with a valley in the middle. The absolute maximum value of the function occurs at the higher peak, at $x = 2$. However, $x = 0$ is also a point of interest. Although $f(0)$ is not the largest value of $f$, the value $f(0)$ is larger than $f(x)$ for all $x$ near $0$. We say $f$ has a **local maximum** (or **relative maximum**) at $x = 0$. Similarly, the function $f$ does not have an absolute minimum, but it does have a **local minimum** (or **relative minimum**) at $x = 1$ because $f(1)$ is less than $f(x)$ for $x$ near 1.

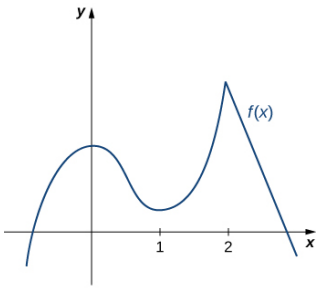

*Figure* **4.1.3***: This function $f$ has two local maxima and one local minimum. The local maximum at $x = 2$ is also the absolute maximum.*

**Definition: Local Extrema**

A function $f$ has a **local maximum** at $c$ if there exists an open interval $I$ containing $c$ such that $I$ is contained in the domain of $f$ and $f(c) \geq f(x)$ for all $x \in I$. A function $f$ has a **local minimum** at $c$ if there exists an open interval $I$ containing $c$ such that $I$ is contained in the domain of $f$ and $f(c) \leq f(x)$ for all $x \in I$. A function $f$ has a **local extremum** at $c$ if $f$ has a local maximum at $c$ or $f$ has a local minimum at $c$.

Note that if $f$ has an absolute extremum at $c$ and $f$ is defined over an interval containing $c$, then $f(c)$ is also considered a local extremum.

**Common Mistake**

Local extrema require the function to be defined in a neighborhood containing $c$. That is, the function must be defined on both sides of $c$ for the possibility of a local extremum at $c$. Hence, endpoints of a function's domain are never considered local extrema, even if they are absolute extrema.

Given the graph of a function $f$, it is sometimes easy to see where a local maximum or local minimum occurs. However, since the interesting features on the graph of a function may not be visible because they occur at a tiny scale, we might miss out on seeing these local extrema. Also, we may not have a graph of the function. In these cases, how can we use a formula for a function to determine where these extrema occur?

To answer this question, let's look at Figure **4.1.3** again. The local extrema occur at $x = 0$, $x = 1$, and $x = 2$. Notice that at $x = 0$ and $x = 1$, $f'(x) = 0$. At $x = 2$, the derivative $f'(x)$ does not exist, since the function $f$ has a corner there. In fact, if $f$ has a local extremum at a point $(c, f(c))$, the derivative $f'(c)$ must satisfy one of the following conditions: either $f'(c) = 0$ or $f'(c)$ is undefined.

Such a value $c$ is known as a **critical number**, and the corresponding point $(c, f(c))$ is called a **critical point**. Critical numbers (and, therefore, critical points) are important in finding extreme values for functions.

**Definition: Critical Numbers and Critical Points**

Let $c$ be an interior point in the domain of $f$. We say that $c$ is a **critical number** of $f$ if $f'(c) = 0$ or $f'(c)$ is undefined. The corresponding point, $(c, f(c))$, is called a **critical point**.

**Note: Critical Numbers, Points, and Values... Oh My!**

On the Cartesian coordinate system, the notation $(a, f(a))$ is used to reference a **point**. It is definitely *not* a number *nor* is it a value. In fact, we refer to $f(a)$ as the **value** of the function $f$ at the **number** $a$.

If you are okay with those previous statements, then you should be fine with the distinction between a **critical point**, $(a, f(a))$, the **critical number**, $x = a$, and the **critical value**, $f(a)$.

It is unfortunate that most authors blur the line between these definitions and call $x = a$ a critical point. In this text, I endeavor to be consistent with my language.

As mentioned earlier, if $f$ has a local extremum at $x = c$, then $c$ must be a critical number of $f$. This fact is known as **Fermat's Theorem.**

**Theorem: Fermat's Theorem**

If $f$ has a local extremum at $c$ and $f$ is differentiable at $c$, then $f'(c) = 0$.

**Proof**

Suppose $f$ has a local extremum at $c$ and $f$ is differentiable at $c$. Without loss of generality, suppose the local extremum at $c$ is a local maximum (the case in which $f$ has a local minimum at $c$ can be handled similarly). There then exists an open interval I such that $f(c) \geq f(x)$ for all $x \in I$. Since $f$ is differentiable at $c$, we know that

$$f'(c) = \lim_{x \to c} \frac{f(x) - f(c)}{x - c}.$$

Since this limit exists, both one-sided limits also exist and are equal $f'(c)$. Therefore,

$$f'(c) = \lim_{x \to c^+} \frac{f(x) - f(c)}{x - c,} \tag{4.1.1}$$

and

$$f'(c) = \lim_{x \to c^-} \frac{f(x) - f(c)}{x - c}.$$

Since $f(c)$ is a local maximum, we see that $f(x) - f(c) \leq 0$ for $x$ near $c$. Therefore, for $x$ near $c$ (but $x > c$), we have $\frac{f(x)-f(c)}{x-c} \leq 0$. From Equation 4.1.1 we conclude that $f'(c) \leq 0$. Similarly, it can be shown that $f'(c) \geq 0$. Therefore, $f'(c) = 0$.

*Q.E.D.*

From Fermat's Theorem, we conclude the following corollary.

**Corollary**

If $f$ has a local extremum at $c$, then either $f'(c) = 0$ or $f'(c)$ is undefined.

In other words, local extrema can only occur at critical points.

**Caution: Critical Points Need Not Be Local Extremums**

Fermat's Theorem does not claim that a function $f$ *must* have a local extremum at a critical point. Rather, it states that critical points are candidates for local extrema.

The cautionary statement above needs some explanation. Consider the function $f(x) = x^3$. We have $f'(x) = 3x^2 = 0$ when $x = 0$. Therefore, $x = 0$ is a critical number. However, $f(x) = x^3$ is increasing over $(-\infty, \infty)$, and thus $f$ does not have a local extremum at $x = 0$.

In Figure 4.1.4, we see several different possibilities for critical points. In some cases, the functions have local extrema at critical points. In contrast, in other cases, the functions do not. Note that these graphs do not show all possibilities for the behavior of a function at a critical point.

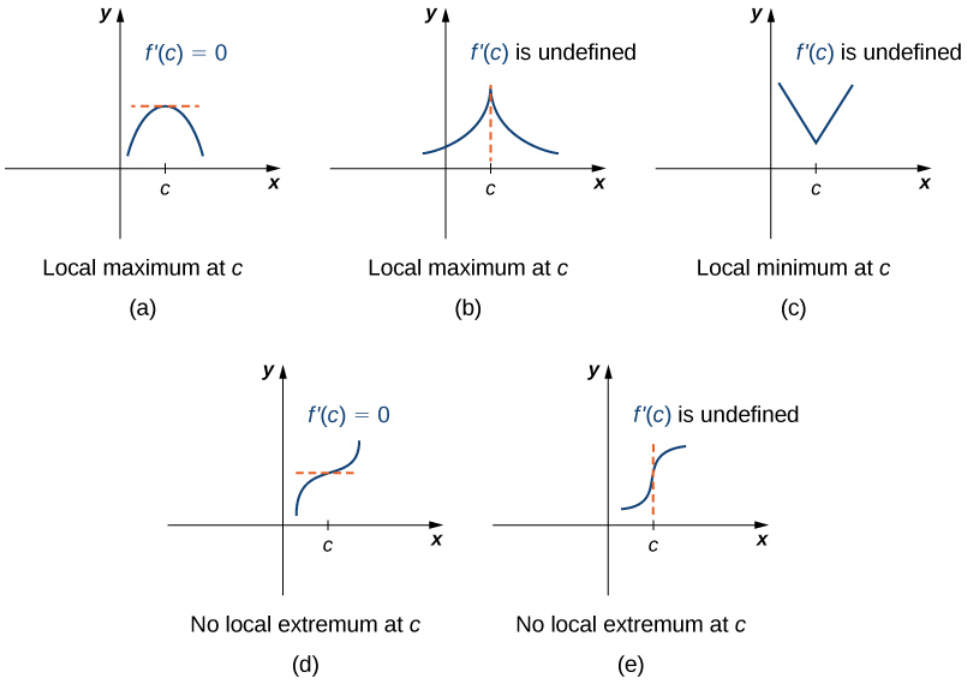

*Figure 4.1.4a: A function $f$ has a critical number at $c$ if $f'(c) = 0$ or $f'(c)$ is undefined. A function may or may not have a local extremum at a critical number.*

Later in this chapter, we look at analytical methods for determining whether a function has a local extremum at a critical point. For now, let's turn our attention to finding critical points. We will use graphical observations to determine whether a critical point is associated with a local extremum.

**Example 4.1.1: Locating Critical Points**

For each of the following functions, find all critical numbers. Use a graphing utility to determine whether the function has a local extremum at each critical number.

a. $f(x) = \frac{1}{3}x^3 - \frac{5}{2}x^2 + 4x$
b. $f(x) = (x^2 - 1)^3$
c. $f(x) = \frac{4x}{1+x^2}$

**Solutions**

a. The derivative $f'(x) = x^2 - 5x + 4$ is defined for all real numbers $x$. Therefore, we only need to find the values for $x$ where $f'(x) = 0$. Since $f'(x) = x^2 - 5x + 4 = (x - 4)(x - 1)$, the critical numbers are $x = 1$ and $x = 4$. From the graph of $f$ in Figure 4.1.5, we see that $f$ has a local maximum at $x = 1$ and a local minimum at $x = 4$.

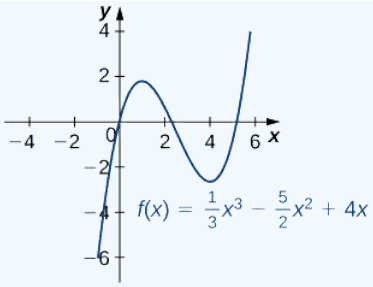

*Figure* **4.1.5***: This function has a local maximum and a local minimum.*

b. Using the Chain Rule, we see the derivative is

$$f'(x) = 3(x^2-1)^2(2x) = 6x(x^2-1)^2.$$

Therefore, $f$ has critical points when $x = 0$ and when $x^2 - 1 = 0$. We conclude that the critical numbers are $x = 0$, and $x = \pm 1$. From the graph of $f$ in Figure **4.1.6**, we see that $f$ has a local (and absolute) minimum at $x = 0$, but does not have a local extrema at $x = 1$ and $x = -1$.

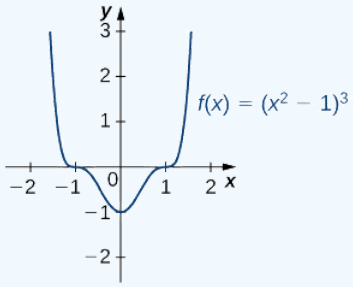

*Figure* **4.1.6***: This function has three critical numbers: $x = 0$, $x = 1$, and $x = -1$. The function has a local (and absolute) minimum at $x = 0$ but does not have extrema at the other two critical points.*

c. By the Quotient Rule, we see that the derivative is

$$f'(x) = \frac{4(1+x^2) - 4x(2x)}{(1+x^2)^2} = \frac{4-4x^2}{(1+x^2)^2}.$$

The derivative is defined everywhere. Therefore, we only need to find values for $x$ where $f'(x) = 0$. Solving $f'(x) = 0$, we see that $4 - 4x^2 = 0$, which implies $x = \pm 1$. Therefore, the critical numbers are $x = \pm 1$. From the graph of $f$ in Figure **4.1.7**, we see that f has an absolute maximum at $x = 1$ and an absolute minimum at $x = -1$. Hence, $f$ has a local maximum at $x = 1$ and a local minimum at $x = -1$. (Note that if $f$ has an absolute extremum over an interval $I$ at a point $c$ that is not an endpoint of $I$, then $f$ has a local extremum at $c$.)

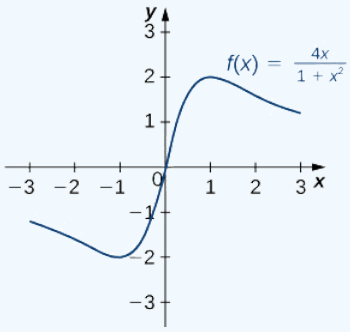

*Figure* **4.1.7***: This function has an absolute maximum and minimum.*

**Checkpoint 4.1.1**

Find all critical numbers for $f(x) = x^3 - \frac{1}{2}x^2 - 2x + 1$.

**Answer**

$x = \frac{-2}{3}, x = 1$

## Locating Absolute Extrema

The Extreme Value Theorem states that a continuous function over a closed interval attains an absolute maximum and minimum. Figure 4.1.2 shows that one or both of these absolute extrema could occur at an endpoint. If an absolute extremum does not occur at an endpoint, however, it must occur at an **interior point**, in which case the absolute extremum is a local extremum. Therefore, by Fermat's Theorem, the interior point point $(c, f(c))$ at which the local extremum occurs must be a critical point. We summarize this result in the following theorem.

**Theorem: Location of Absolute Extrema**

Let $f$ be a continuous function over a closed interval $I$. The absolute maximum of $f$ over $I$ and the absolute minimum of $f$ over $I$ must occur at endpoints of $I$ or at critical points of $f$ in the interior of $I$.

Therefore, when finding the absolute extrema of a given function defined over a closed interval, we evaluate the function at the endpoints of the interval. These will be *candidates* for absolute extrema. In addition, we determine the critical points. The critical values (the values of the function at the critical numbers) will also be *candidates* for absolute extrema. The largest of these function values will be the absolute maximum of the function on the given interval, and the least will be the absolute minimum.

Now, let's use this strategy to find the absolute maximum and minimum values for continuous functions.

**Example 4.1.2: Locating Absolute Extrema**

For each function, find the absolute maximum and minimum over the specified interval and state where those values occur.

a. $f(x) = -x^2 + 3x - 2$ over $[1, 3]$.
b. $f(x) = x^2 - 3x^{2/3}$ over $[0, 2]$.

**Solutions**

a. Evaluate $f$ at the endpoints $x = 1$ and $x = 3$.

$$f(1) = 0 \quad \text{and} \quad f(3) = -2$$

Since $f'(x) = -2x + 3$, $f'$ is defined for all real numbers $x$. Hence, there are no critical points where the derivative is undefined. It remains to check where $f'(x) = 0$. Since $f'(x) = -2x + 3 = 0$ at $x = \frac{3}{2}$ and $\frac{3}{2}$ is in the interval $[1, 3]$, $f(\frac{3}{2})$ is a *candidate* for an absolute extremum of $f$ over $[1, 3]$. We evaluate $f(\frac{3}{2})$ and find

$$f\left(\frac{3}{2}\right) = \frac{1}{4}.$$

We then set up the following table to compare the functions values we found.

| $x$ | $f(x)$ | Conclusion |
|---|---|---|
| 1 | 0 | |
| $\frac{3}{2}$ | $\frac{1}{4}$ | Absolute maximum |
| 3 | $-2$ | Absolute minimum |

From the table, we find that the absolute maximum of $f$ over the interval $[1, 3]$ is $\frac{1}{4}$, and it occurs at $x = \frac{3}{2}$. The absolute minimum of $f$ over the interval $[1, 3]$ is $-2$, and it occurs at $x = 3$ as shown in Figure 4.1.8.

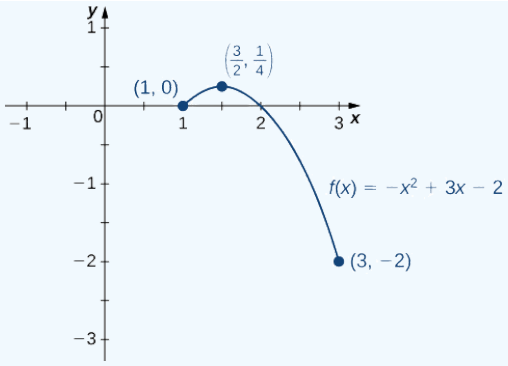

*Figure* **4.1.8***: This function has both an absolute maximum and an absolute minimum.*

b. Evaluate $f$ at the endpoints $x = 0$ and $x = 2$.

$$f(0) = 0 \quad \text{and} \quad f(2) = 4 - 3\,(2)^{2/3} \approx -0.762$$

The derivative of $f$ is given by

$$f'(x) = 2x - \frac{2}{x^{1/3}} = \frac{2x^{4/3} - 2}{x^{1/3}}$$

for $x \neq 0$. The derivative is zero when $2x^{4/3} - 2 = 0$, which implies $x = \pm 1$. The derivative is undefined at $x = 0$. Therefore, the critical numbers of $f$ are $x = 0$, 1, and $-1$. We already evaluated $f(0)$. The point $x = -1$ is not in the interval of interest, so we need only evaluate $f(1)$. We find that $f(1) = -2$. Finally, we compare the values in the following table.

| $x$ | $f(x)$ | Conclusion |
|---|---|---|
| 0 | 0 | Absolute maximum |
| 1 | −2 | Absolute minimum |
| 2 | −0.762 | |

We conclude that the absolute maximum of $f$ over the interval $[0, 2]$ is zero, and it occurs at $x = 0$. The absolute minimum is $-2$, and it occurs at $x = 1$ as shown in Figure **4.1.9**.

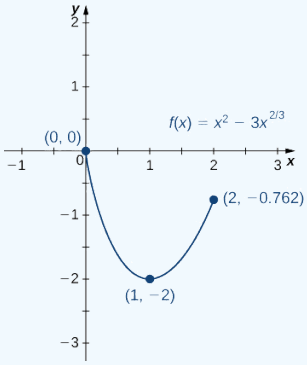

*Figure* **4.1.9***: This function has an absolute maximum at an endpoint of the interval.*

**? Checkpoint 4.1.2**

Find the absolute maximum and absolute minimum of $f(x) = x^2 - 4x + 3$ over the interval $[1, 4]$.

**Answer**

The absolute maximum is 3 and it occurs at $x = 4$. The absolute minimum is $-1$ and it occurs at $x = 2$.

At this point, we know how to locate absolute extrema for continuous functions over closed intervals. We have also defined local extrema and determined that if a function $f$ has a local extremum at a number $c$, then $c$ must be a critical number of $f$. However, $c$ being a critical number is not a sufficient condition for $f$ to have a local extremum at $c$. Later in this chapter, we show how to determine whether a function has a local extremum at a critical point. First, however, we need to introduce the Mean Value Theorem, which will help as we analyze the behavior of the graph of a function.

# 4.1E: EXERCISES

This page is a draft and is under active development.

## READING QUESTIONS

1. What is the difference between an absolute maximum and a local maximum?
2. State the Extreme Value Theorem. What two conditions must a function $f$ satisfy on an interval $[a, b]$ for this theorem to guarantee the existence of absolute extrema?
3. Can a function that is not continuous on a closed interval still have an absolute maximum and minimum on that interval? Can the EVT be used to guarantee it?
4. What is a critical number of a function $f$?
5. What is a critical point of a function $f$?
6. State Fermat's Theorem regarding local extrema and derivatives.
7. If $f'(c) = 0$, does $f$ necessarily have a local extremum at $c$? Explain.
8. According to the "Location of Absolute Extrema" theorem, where should you look for the absolute maximum and minimum of a continuous function on a closed interval?
9. Describe the process for finding the absolute extrema of a continuous function on a closed interval $[a, b]$.
10. What does the term "relative extrema" mean, as clarified in the "Some Clarifications" box?

## HOMEWORK

1) In Precalculus, you learned a formula for the position of the maximum or minimum of a quadratic equation $y = ax^2 + bx + c$, which was $m = -\frac{b}{2a}$. Prove this formula using calculus.

2) If you are finding an absolute minimum over an interval $[a, b]$, why do you need to check the endpoints? Draw a graph that supports your hypothesis.

**Answer**

On a closed interval, the endpoints often lie above or below any local (relative) extrema. Answers may vary for the graph.

3) If you are examining a function over an interval $(a, b)$, for $a$ and $b$ finite, is it possible not to have an absolute maximum or absolute minimum?

4) When you are checking for critical points to locate the extrema of a function $f$, explain why you also need to determine points where $f'(x)$ is undefined. Draw a graph to support your explanation.

**Answer**

Points on the graph of $f$ where there is a corner, a cusp, or a jump discontinuity or removable discontinuity can easily be absolute (or local) extrema of the function. Answers may vary for the graph.

5) Can you have a finite absolute maximum for $y = ax^2 + bx + c$ over $(-\infty, \infty)$? Explain why or why not using graphical arguments.

6) Can you have a finite absolute maximum for $y = ax^3 + bx^2 + cx + d$ over $(-\infty, \infty)$ assuming $a$ is non-zero? Explain why or why not using graphical arguments.

**Answer**

No; answers will vary

7) Let $m$ be the number of local minima and $M$ be the number of local maxima. Can you create a function where $M > m + 2$? Draw a graph to support your explanation.

8) Is it possible to have more than one absolute maximum? Use a graphical argument to prove your hypothesis.

**Answer**

Since the absolute maximum is the function (output) value rather than the x value, the answer is no; answers will vary

9) Is it possible to have no absolute minimum or maximum for a function? If so, construct such a function. If not, explain why this is not possible.

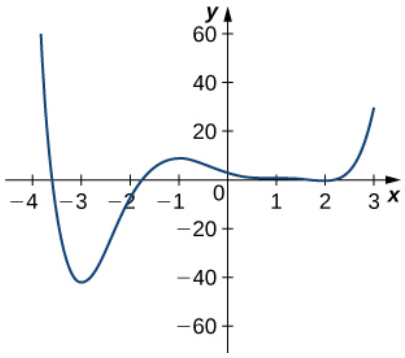
10) Graph the function $y = e^{ax}$. For which values of $a$, on any infinite domain, will you have an absolute minimum and absolute maximum?

**Answer**

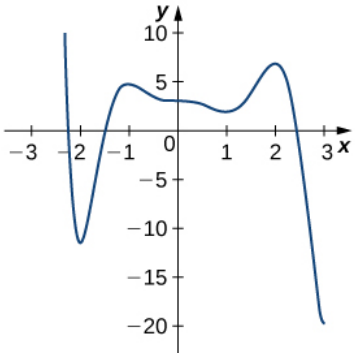
When $a = 0$

**In exercises 11 - 14, determine where the local and absolute maxima and minima occur on the graph given. Assume domains are closed intervals unless otherwise specified.**

11)



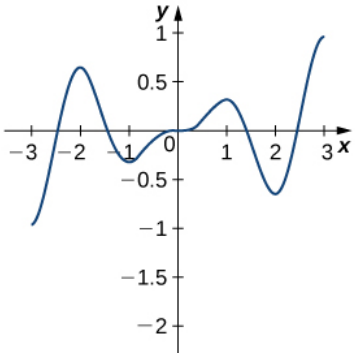
12)



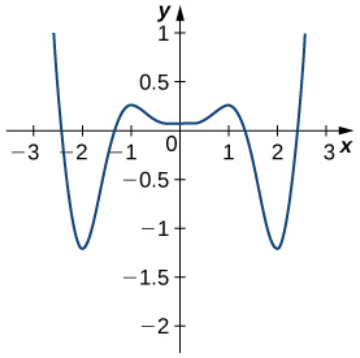
**Answer**

Absolute minimum at 3; Absolute maximum at −2.2; local minima at −2, 1; local maxima at −1, 2

13)



14)



**Answer**

Absolute minima at −2, 2; absolute maxima at −2.5, 2.5; local minimum at 0; local maxima at −1, 1

**For exercises 15 - 18, draw graphs of $f(x)$, which is continuous, over the interval $[-4, 4]$ with the following properties:**

15) Absolute maximum at $x = 2$ and absolute minima at $x = \pm 3$

16) Absolute minimum at $x = 1$ and absolute maximum at $x = 2$

**Answer**

Answers may vary.

17) Absolute maximum at $x = 4$, absolute minimum at $x = -1$, local maximum at $x = -2$, and a critical point that is not a maximum or minimum at $x = 2$

18) Absolute maxima at $x = 2$ and $x = -3$, local minimum at $x = 1$, and absolute minimum at $x = 4$

**Answer**

Answers may vary.

**In exercises 19 - 28, find the critical points in the domains of the given functions.**

19) $y = 4x^3 - 3x$

20) $y = 4\sqrt{x} - x^2$

**Answer**

$x = 1$

21) $y = \dfrac{1}{x - 1}$

22) $y = \ln(x - 2)$

**Answer**

None

23) $y = \tan(x)$

24) $y = \sqrt{4 - x^2}$

**Answer**

$x = 0$

25) $y = x^{3/2} - 3x^{5/2}$

26) $y = \dfrac{x^2 - 1}{x^2 + 2x - 3}$

**Answer**

None

27) $y = \sin^2(x)$

28) $y = x + \dfrac{1}{x}$

**Answer**

$x = -1$ and $x = 1$

**In exercises 29 - 39, find the local and/or absolute maxima for the functions over the specified domain.**

29) $f(x) = x^2 + 3$ over $[-1, 4]$

30) $y = x^2 + \dfrac{2}{x}$ over $[1, 4]$

**Answer**

Absolute maximum: $x = 4, y = \frac{33}{2}$; absolute minimum: $x = 1, y = 3$

31) $y = (x - x^2)^2$ over $[-1, 1]$

32) $y = \dfrac{1}{x - x^2}$ over $[0, 1]$

**Answer**

Absolute minimum: $x = \frac{1}{2}, y = 4$

33) $y = \sqrt{9 - x}$ over $[1, 9]$

34) $y = x + \sin(x)$ over $[0, 2\pi]$

**Answer**

Absolute maximum: $x = 2\pi, y = 2\pi$; absolute minimum: $x = 0, y = 0$

35) $y = \dfrac{x}{1 + x}$ over $[0, 100]$

36) $y = |x + 1| + |x - 1|$ over $[-3, 2]$

**Answer**

Absolute maximum: $x = -3, y = 6$; absolute minimum: $-1 \le x \le 1, y = 2$

37) $y = \sqrt{x} - \sqrt{x^3}$ over $[0, 4]$

38) $y = \sin x + \cos x$ over $[0, 2\pi]$

**Answer**

Absolute maximum: $x = \frac{\pi}{4}, y = \sqrt{2}$; absolute minimum: $x = \frac{5\pi}{4}, y = -\sqrt{2}$

39) $y = 4 \sin \theta - 3 \cos \theta$ over $[0, 2\pi]$

**In exercises 40 - 45, find the local and absolute minima and maxima for the functions over $(-\infty, \infty)$.**

40) $y = x^2 + 4x + 5$

**Answer**

Absolute minimum: $x = -2, y = 1$

41) $y = x^3 - 12x$

42) $y = 3x^4 + 8x^3 - 18x^2$

**Answer**

Absolute minimum: $x = -3, y = -135$; local maximum: $x = 0, y = 0$; local minimum: $x = 1, y = -7$

43) $y = x^3(1 - x)^6$

44) $y = \dfrac{x^2 + x + 6}{x - 1}$

**Answer**

Local maximum: $x = 1 - 2\sqrt{2}, y = 3 - 4\sqrt{2}$; local minimum: $x = 1 + 2\sqrt{2}, y = 3 + 4\sqrt{2}$

45) $y = \dfrac{x^2 - 1}{x - 1}$

**In exercises 46 - 50, use a calculator to graph the function and to estimate the absolute and local maxima and minima. Then, solve for them explicitly.**

46) [Technology Required] $y = 3x\sqrt{1 - x^2}$

**Answer**

Absolute maximum: $x = \frac{\sqrt{2}}{2}, y = \frac{3}{2}$; absolute minimum: $x = -\frac{\sqrt{2}}{2}, y = -\frac{3}{2}$

47) [Technology Required] $y = x + \sin(x)$

48) [Technology Required] $y = 12x^5 + 45x^4 + 20x^3 - 90x^2 - 120x + 3$

**Answer**

Local maximum: $x = -2, y = 59$; local minimum: $x = 1, y = -130$

49) [Technology Required] $y = \dfrac{x^3 + 6x^2 - x - 30}{x - 2}$

50) [Technology Required] $y = \dfrac{\sqrt{4 - x^2}}{\sqrt{4 + x^2}}$

**Answer**

Absolute maximum: $x = 0, y = 1$; absolute minimum: $x = -2, 2, y = 0$

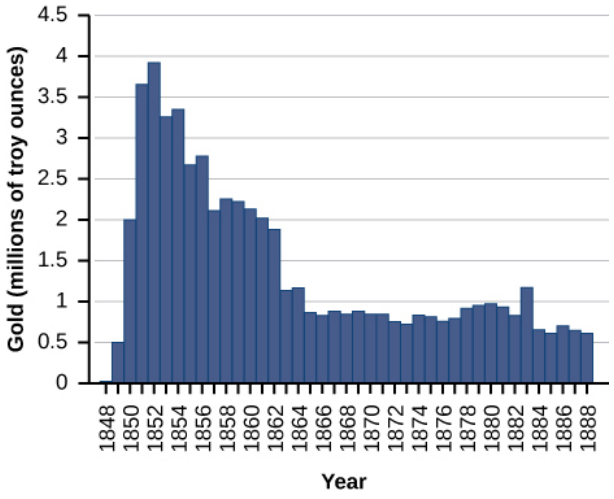
51) A company that produces cell phones has a cost function of $C = x^2 - 1200x + 36,400$, where $C$ is cost in dollars and $x$ is number of cell phones produced (in thousands). How many units of cell phone (in thousands) minimizes this cost function?

52) A ball is thrown into the air and its position is given by $h(t) = -4.9t^2 + 60t + 5m$. Find the height at which the ball stops ascending. How long after it is thrown does this happen?

**Answer**

$h = \frac{9245}{49}$ m, $t = \frac{300}{49}$ s

**For exercises 53-54, consider the production of gold during the California gold rush (1848–1888). The production of gold can be modeled by $G(t) = \dfrac{(25t)}{(t^2 + 16)}$, where $t$ is the number of years since the rush began $(0 \le t \le 40)$ and $G$ is ounces of gold produced (in millions). A summary of the data is shown in the following figure.**



53) Find when the maximum (local and global) gold production occurred, and the amount of gold produced during that maximum.

54) Find when the minimum (local and global) gold production occurred. What was the amount of gold produced during this minimum?

**Answer**

The global minimum was in 1848, when no gold was produced.

**In exercises 55 & 56, find the critical points, maxima, and minima for the given piecewise functions.**

55) $y = \begin{cases} x^2 - 4x, & \text{if } 0 \le x \le 1 \\ x^2 - 4, & \text{if } 1 < x \le 2 \end{cases}$

56) $y = \begin{cases} x^2 + 1, & \text{if } x \le 1 \\ x^2 - 4x + 5, & \text{if } x > 1 \end{cases}$

**Answer**

Absolute minima: $x = 0, x = 2, y = 1$; local maximum at $x = 1, y = 2$

**In exercises 57 - 58, find the critical points of the following generic functions. Are they maxima, minima, or neither? State the necessary conditions.**

57) $y = ax^2 + bx + c$, given that $a > 0$

58) $y = (x - 1)^a$, given that $a > 1$

**Answer**

No maxima/minima if $a$ is odd, minimum at $x = 1$ if $a$ is even

# 4.2: A Theoretical Interlude - The Mean Value Theorem

**Learning Objectives**

- Explain the meaning of Rolle's theorem
- Describe the significance of the Mean Value Theorem
- Use the Racetrack Principle to prove inequalities
- State two critical consequences of the Mean Value Theorem

Hawk A.I. Section-Specific Tutor

Please note that, to access the Hawk A.I. Tutor, you will need a (free) OpenAI account.

The Mean Value Theorem is one of the most important theorems in Calculus. We look at some of its implications at the end of this section. First, let's start with a particular case of the Mean Value Theorem, called Rolle's Theorem.

## Rolle's Theorem

Informally, **Rolle's Theorem** states that if the outputs of a differentiable function $f$ are equal at the endpoints of an interval, then there must be an interior point $c$ where $f'(c) = 0$. Figure 4.2.1 illustrates this theorem.

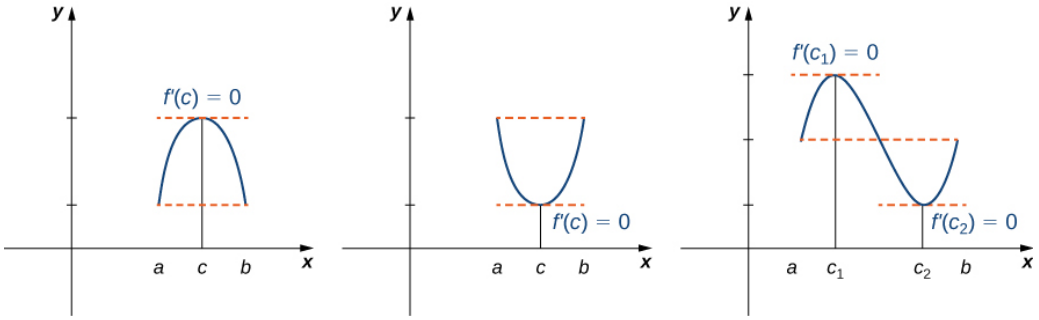


*Figure 4.2.1: If a differentiable function $f$ satisfies $f(a) = f(b)$, then its derivative must be zero at some point(s) between $a$ and $b$.*

**Theorem: Rolle's Theorem**

Let $f$ be a continuous function over the closed interval $[a, b]$ and differentiable over the open interval $(a, b)$ such that $f(a) = f(b)$. There then exists at least one $c \in (a, b)$ such that $f'(c) = 0$.

**Proof**

Let $k = f(a) = f(b)$. We consider three cases:

**Case 1 - $f(x) = k$ for all $x \in (a, b)$:** If $f(x) = k$ for all $x \in (a, b)$, then $f'(x) = 0$ for all $x \in (a, b)$.

**Case 2 - There exists $x \in (a, b)$ such that $f(x) > k$:** Since $f$ is a continuous function over the closed, bounded interval $[a, b]$, by the Extreme Value Theorem, it has an absolute maximum. Also, since there is a point $x \in (a, b)$ such that $f(x) > k$, the absolute maximum is greater than $k$. Therefore, the absolute maximum does not occur at either endpoint. As a result, the absolute maximum must occur at an interior point $c \in (a, b)$. Because $f$ has a maximum at an interior point $c$, and $f$ is differentiable at $c$, by Fermat's Theorem, $f'(c) = 0$.

**Case 3 - There exists $x \in (a, b)$ such that $f(x) < k$:** The case when there exists a point $x \in (a, b)$ such that $f(x) < k$ is analogous to case 2, with maximum replaced by minimum.

*Q.E.D.*

### Caution: $f$ Must Be Differentiable!

An important point about Rolle's Theorem is that the differentiability of the function $f$ is critical. If $f$ is not differentiable, even at a single point, the result may not hold. For example, the function $f(x) = |x| - 1$ is continuous over the closed interval $[-1, 1]$ and $f(-1) = 0 = f(1)$, but $f'(c) \neq 0$ for any $c \in (-1, 1)$ as shown Figure 4.2.2.

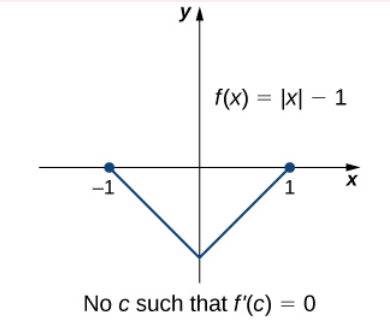

*Figure 4.2.2: Since $f(x) = |x| - 1$ is not differentiable at $x = 0$, the conditions of Rolle's Theorem are not satisfied. In fact, the conclusion does not hold here; there is no $c \in (-1, 1)$ such that $f'(c) = 0$.*

Let's now consider functions that satisfy the conditions of Rolle's Theorem and calculate explicitly the numbers $c$ where $f'(c) = 0$.

### Example 4.2.1

For each of the following functions, verify that the function satisfies the criteria stated in Rolle's Theorem and find all numbers $c$ in the given interval where $f'(c) = 0$.

a. $f(x) = x^2 + 2x$ over $[-2, 0]$
b. $f(x) = x^3 - 4x$ over $[-2, 2]$

**Solutions**

a. Since $f$ is a polynomial, it is continuous and differentiable everywhere. In addition, $f(-2) = 0 = f(0)$. Therefore, $f$ satisfies the criteria of Rolle's Theorem. We conclude that there exists at least one value $c \in (-2, 0)$ such that $f'(c) = 0$. Since $f'(x) = 2x + 2 = 2(x + 1)$, we see that $f'(c) = 2(c + 1) = 0$ implies $c = -1$ as shown in Figure 4.2.3.

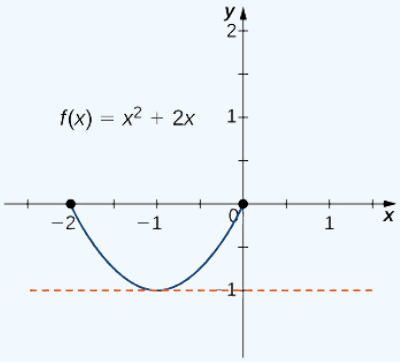

*Figure 4.2.3: This function is continuous and differentiable over $[-2, 0]$, $f'(c) = 0$ when $c = -1$.*

b. As in part a., $f$ is a polynomial and is continuous and differentiable everywhere. Also, $f(-2) = 0 = f(2)$. That said, $f$ satisfies the criteria of Rolle's Theorem. Differentiating, we find that $f'(x) = 3x^2 - 4$. Therefore, $f'(c) = 0$ when $x = \pm\frac{2}{\sqrt{3}}$. Both points are in the interval $[-2, 2]$, and, therefore, both points satisfy the conclusion of Rolle's Theorem as shown in Figure 4.2.4.

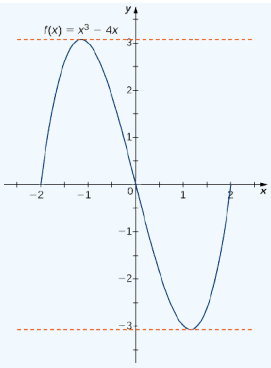

*Figure* **4.2.4**: *For this polynomial over* $[-2,2]$, $f'(c)=0$ *at* $x=\pm 2/\sqrt{3}$.

**? Checkpoint 4.2.1**

Verify that the function $f(x)=2x^2-8x+6$ defined over the interval $[1,3]$ satisfies the conditions of Rolle's Theorem. Find all numbers $c$ guaranteed by Rolle's Theorem.

**Answer**

$c=2$

A creative use of Rolle's Theorem is to prove a given equation has *exactly* one root. We did something almost like this when working through continuity in the limits unit. Recall, by the Intermediate Value Theorem, if $f$ is a continuous function on a closed interval $[a,b]$, where the signs of $f(a)$ and $f(b)$ are opposite, there must exist some number $c\in(a,b)$ such that $f(c)=0$. This was used to show the *existence* of a root to a given equation in the interval $[a,b]$. This proof is commonly called an **existence proof** because you are proving something (a root) exists.

We are now extending this concept to a **uniqueness proof**. We not only want to prove that there *exists* a root to a given equation, but we also want to prove that root is the only such root (i.e., that the root is *unique*).

**✔ Example 4.2.2**

Prove the equation $2x=\cos(x)$ has only one solution.

**Solution**

**Existence.** We begin our proof by showing that a solution to the equation exists.

Let $f(x)=2x-\cos(x)$. Then $f$ has a zero precisely when $2x=\cos(x)$ has a solution. Since $f$ is the sum of a polynomial function and a cosine function, both of which are continuous on $\mathbb{R}$, $f$ is continuous on $\mathbb{R}$. Moreover, $f(0)=-1<0$ and $f(\pi/2)=\pi>0$. By the Intermediate Value Theorem, $f$ must have a zero on the interval $(0,\pi/2)$. Therefore, the given equation must have a solution on the interval $(0,\pi/2)$.

**Uniqueness.** We continue our proof by showing that the solution on the interval $(0,\pi/2)$ must be the *only* solution. To showcase this result, we argue using a **proof by contradiction**.[1]

Let's ***assume*** that the given equation has more than one solution. This means the function, $f$, would have more than one zero. That is, there must exist two values, $c$ and $d$, such that $f(c)=0=f(d)$, where $c\neq d$.

We have the following three conditions met:

1. $f$ is continuous on the closed interval $[c,d]$,
2. $f'(x)=2+\sin(x)$ exists on the open interval $(c,d)$, and
3. $f(c)=f(d)$.

Thus, by Rolle's Theorem, there must exist a number $k\in(c,d)$ such that $f'(k)=0$.

However, $f'(x) = 2 + \sin(x) \geq 1$ for all $x \in \mathbb{R}$. This contradicts the statement that $f'(k) = 0$ for some $k \in (c, d)$. Hence, our only ***assumption***, that the given equation has more than one solution, must be incorrect. Since we have already shown that a solution exists, the equation must only have that one solution.

*Q.E.D.*

## The Mean Value Theorem and Its Meaning

Rolle's Theorem is a special case of the **Mean Value Theorem**. In Rolle's Theorem, we consider differentiable functions on closed intervals having the same function values at the endpoints of the interval. The Mean Value Theorem generalizes Rolle's Theorem by considering functions that do not necessarily have the same function values at the endpoints. Consequently, we can view the Mean Value Theorem as a slanted version of Rolle's Theorem (see Figure 4.2.5). The Mean Value Theorem states that if $f$ is continuous over the closed interval $[a, b]$ and differentiable over the open interval $(a, b)$, then there exists a point $c \in (a, b)$ such that the tangent line to the graph of $f$ at $c$ is parallel to the secant line connecting $(a, f(a))$ and $(b, f(b))$.

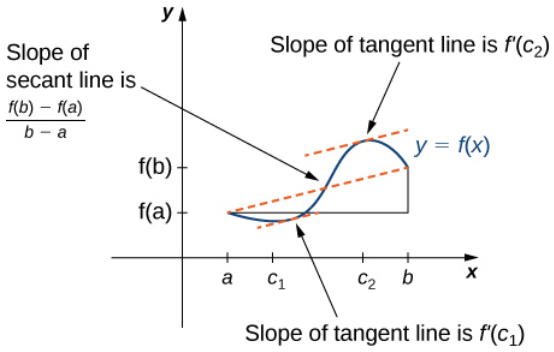

*Figure 4.2.5: The Mean Value Theorem says that for a function that meets its conditions, at some point, the tangent line has the same slope as the secant line between the ends. For this function, there are two values $c_1$ and $c_2$ such that the tangent line to $f$ at $c_1$ and $c_2$ has the same slope as the secant line.*

### Theorem: The Mean Value Theorem (MVT)

Let $f$ be continuous over the closed interval $[a, b]$ and differentiable over the open interval $(a, b)$. Then, there exists at least one point $c \in (a, b)$ such that

$$f'(c) = \frac{f(b) - f(a)}{b - a}$$

**Proof**

The proof follows from Rolle's Theorem by introducing an appropriate function that satisfies the criteria of Rolle's Theorem. Consider the line connecting $(a, f(a))$ and $(b, f(b))$. Since the slope of that line is

$$\frac{f(b) - f(a)}{b - a}$$

and the line passes through the point $(a, f(a))$, the equation of that line can be written as

$$y = \frac{f(b) - f(a)}{b - a}(x - a) + f(a).$$

Let $g(x)$ denote the vertical difference between the point $(x, f(x))$ and the point $(x, y)$ on that line. Therefore,

$$g(x) = f(x) - \left[\frac{f(b) - f(a)}{b - a}(x - a) + f(a)\right].$$

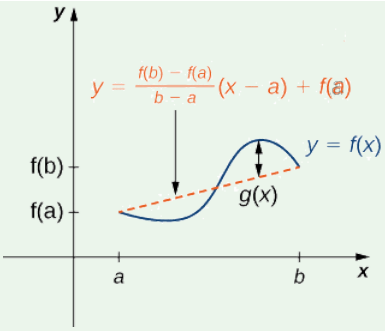

*Figure* **4.2.6**: *The value* $g(x)$ *is the vertical difference between the point* $(x, f(x))$ *and the point* $(x, y)$ *on the secant line connecting* $(a, f(a))$ *and* $(b, f(b))$.

Since the graph of $f$ intersects the secant line when $x = a$ and $x = b$, we see that $g(a) = 0 = g(b)$. Since $f$ is a differentiable function over $(a, b)$, $g$ is also a differentiable function over $(a, b)$. Furthermore, since $f$ is continuous over $[a, b]$, $g$ is also continuous over $[a, b]$. Therefore, $g$ satisfies the criteria of Rolle's Theorem. Consequently, there exists a point $c \in (a, b)$ such that $g'(c) = 0$. Since

$$g'(x) = f'(x) - \frac{f(b) - f(a)}{b - a},$$

we see that

$$g'(c) = f'(c) - \frac{f(b) - f(a)}{b - a}.$$

Since $g'(c) = 0$, we conclude that

$$f'(c) = \frac{f(b) - f(a)}{b - a}.$$

*Q.E.D.*

As a notational point, the Mean Value Theorem is often written as the MVT. In the following example, we show how the MVT can be applied to the function $f(x) = \sqrt{x}$ over the interval $[0, 9]$. The method is the same for other functions, although sometimes with more interesting consequences.

### Example 4.2.3

For $f(x) = \sqrt{x}$ over the interval $[0, 9]$, show that $f$ satisfies the hypothesis of the Mean Value Theorem. Find the numbers $c$ guaranteed by the Mean Value Theorem.

**Solution**

We know that $f(x) = \sqrt{x}$ is continuous over $[0, 9]$ and differentiable over $(0, 9)$. Therefore, $f$ satisfies the hypotheses of the Mean Value Theorem. As such, there must exist at least one value $c \in (0, 9)$ such that $f'(c)$ is equal to the slope of the line connecting $(0, f(0))$ and $(9, f(9))$ (see Figure **4.2.7**). To determine the value(s) of $c$, first calculate the derivative of $f$.

$$f'(x) = \frac{1}{(2\sqrt{x})}.$$

The slope of the line connecting $(0, f(0))$ and $(9, f(9))$ is given by

$$\frac{f(9) - f(0)}{9 - 0} = \frac{\sqrt{9} - \sqrt{0}}{9 - 0} = \frac{3}{9} = \frac{1}{3}.$$

We want to find $c$ such that $f'(c) = \frac{1}{3}$. That is, we want to find $c$ such that

$$\frac{1}{2\sqrt{c}} = \frac{1}{3}.$$

Solving this equation for $c$, we obtain $c = \frac{9}{4}$. At this point, the slope of the tangent line equals the slope of the line joining the endpoints.

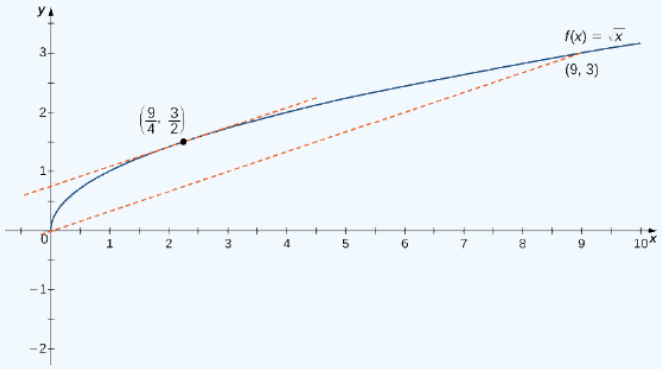

*Figure* **4.2.7***: The slope of the tangent line at* $c = 9/4$ *is the same as the slope of the line segment connecting (0,0) and (9,3).*

One application that helps illustrate the Mean Value Theorem involves velocity. For example, suppose we drive a car for one hour down a straight road with an average velocity of 45 miles per hour. Let $s(t)$ and $v(t)$ denote the position and velocity of the car, respectively, for $0 \leq t \leq 1$ hour. Assuming that the position function, $s(t)$, is differentiable, we can apply the Mean Value Theorem to conclude that, at some time $c \in (0,1)$, the speed of the car was precisely

$$v(c) = s'(c) = \frac{s(1) - s(0)}{1 - 0} = 45 \text{ mph}.$$

**Example 4.2.4**

If a rock is dropped from a height of 100 ft, its position $t$ seconds after it is dropped until it hits the ground is given by the function $s(t) = -16t^2 + 100$.

a. Determine how long it takes before the rock hits the ground.
b. Find the average velocity $v_{avg}$ of the rock for when the rock is released and the rock hits the ground.
c. Find the time $t$ guaranteed by the Mean Value Theorem when the instantaneous velocity of the rock is $v_{avg}$.

**Solutions**

a. When the rock hits the ground, its position is $s(t) = 0$. Solving the equation $-16t^2 + 100 = 0$ for $t$, we find that $t = \pm\frac{5}{2}$ seconds. Since we are only considering $t \geq 0$, the ball will hit the ground $\frac{5}{2}$ seconds after it is dropped.

b. The average velocity is given by

$$v_{avg} = \frac{s(5/2) - s(0)}{5/2 - 0} = \frac{0 - 100}{5/2} = -40 \text{ ft/sec}.$$

c. The instantaneous velocity is given by the derivative of the position function. Therefore, we need to find a time $t$ such that $v(t) = s'(t) = v_{avg} = -40$ feet per second. Since $s(t)$ is continuous over the interval $[0, \frac{5}{2}]$ and differentiable over the interval $(0, \frac{5}{2})$, by the Mean Value Theorem, there is guaranteed to be a point $c \in (0, \frac{5}{2})$ such that

$$s'(c) = \frac{s(5/2) - s(0)}{5/2 - 0} = -40.$$

Taking the derivative of the position function $s(t)$, we find that $s'(t) = -32t$. Therefore, the equation reduces to $s'(c) = -32c = -40$. Solving this equation for $c$, we have $c = \frac{5}{4}$. Therefore, $\frac{5}{4}$ seconds after the rock is dropped, the instantaneous velocity equals the average velocity of the rock during its free fall: $-40$ feet per second.

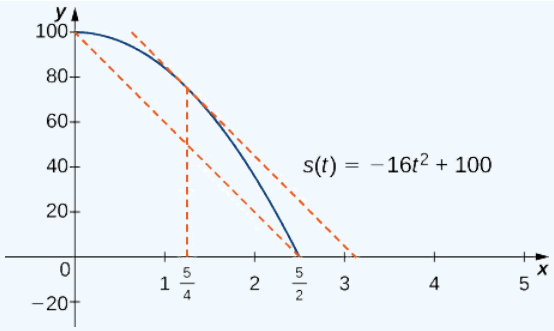

*Figure* **4.2.8***: At time* $t = 5/4$ *sec, the velocity of the rock is equal to its average velocity from the time it is dropped until it hits the ground.*

**? Checkpoint 4.2.4**

Suppose a ball is dropped from a height of 200 ft. Its position at time $t$ is $s(t) = -16t^2 + 200$. Find the time $t$ when the instantaneous velocity of the ball equals its average velocity.

**Answer**

$\frac{5}{2\sqrt{2}}$ seconds

## Corollaries of the Mean Value Theorem

Let's look at three Mean Value Theorem corollaries. These results have important consequences, which we will use in upcoming sections.

At this point, we know the derivative is zero if we are given a constant function. The Mean Value Theorem allows us to conclude that the converse is also true. In particular, if $f'(x) = 0$ for all $x$ in some interval $I$, then $f(x)$ is constant over that interval. This result may seem intuitively obvious, but it has important implications that are not obvious, and we discuss them shortly.

**Corollary: Functions with a Derivative of Zero**

Let $f$ be differentiable over an interval $I$. If $f'(x) = 0$ for all $x \in I$, then $f(x) =$ constant for all $x \in I$.

**Proof**

Since $f$ is differentiable over $I$, $f$ must be continuous over $I$. Suppose $f(x)$ is not constant for all $x$ in $I$. Then there exist $a, b \in I$, where $a \neq b$ and $f(a) \neq f(b)$. Choose the notation so that $a < b$. Therefore,

$$\frac{f(b) - f(a)}{b - a} \neq 0.$$

Since $f$ is a differentiable function, by the Mean Value Theorem, there exists $c \in (a, b)$ such that

$$f'(c) = \frac{f(b) - f(a)}{b - a}.$$

Therefore, there exists $c \in I$ such that $f'(c) \neq 0$, which contradicts the assumption that $f'(x) = 0$ for all $x \in I$.

*Q.E.D.*

From this corollary, it follows that if two functions have the same derivative, they differ by, at most, a constant.

### Corollary: Constant Difference Theorem

If $f$ and $g$ are differentiable over an interval $I$ and $f'(x) = g'(x)$ for all $x \in I$, then $f(x) = g(x) + C$ for some constant $C$.

**Proof**

Let $h(x) = f(x) - g(x)$. Then, $h'(x) = f'(x) - g'(x) = 0$ for all $x \in I$. By the previous corollary, there is a constant $C$ such that $h(x) = C$ for all $x \in I$. Therefore, $f(x) = g(x) + C$ for all $x \in I$.

*Q.E.D.*

This corollary can be used to prove identities (like your trigonometric identities from your previous Trigonometry course).

### Example 4.2.5

Prove the following identity.

$$2\sin^{-1}(x) = \cos^{-1}(1 - 2x^2), \text{ where } x \geq 0$$

**Solution**

Let $f(x) = 2\sin^{-1}(x)$ and $g(x) = \cos^{-1}(1 - 2x^2)$. Note that the normal domain of $f$ is $[-1, 1]$ and we could quickly determine the domain of $g$ to also be $[-1, 1]$; however, we have been told that $x \geq 0$. Therefore, the domains of both functions are $[0, 1]$.

Computing the derivatives, we get

$$f'(x) = 2 \cdot \frac{1}{\sqrt{1 - x^2}} = \frac{2}{\sqrt{1 - x^2}}$$

and

$$\begin{aligned} g'(x) &= -\frac{1}{\sqrt{1 - (1 - 2x^2)^2}} \cdot (-4x) \\ &= \frac{4x}{\sqrt{1 - (1 - 4x^2 + 4x^4)}} \\ &= \frac{4x}{\sqrt{4x^2 - 4x^4}} \\ &= \frac{4x}{2x\sqrt{1 - x^2}} \qquad (\text{since } x \geq 0) \\ &= \frac{2}{\sqrt{1 - x^2}} \\ &= f'(x) \end{aligned}$$

Since $f'(x) = g'(x)$ for $x \in (0, 1)$, $f(x) = g(x) + C$ for all $x \in (0, 1)$ by the Constant Difference Theorem. That is, there exists $C$ such that

$$2\sin^{-1}(x) = \cos^{-1}(1 - 2x^2) + C$$

Since this equation is true for all $x \in (0, 1)$, we can let $x$ be any value in $(0, 1)$ to find the value of $C$. Let $x = \frac{1}{2}$. Then

$$2\sin^{-1}\left(\frac{1}{2}\right) = \cos^{-1}\left(1 - 2\left(\frac{1}{2}\right)^2\right) + C \implies 2\left(\frac{\pi}{6}\right) = \cos^{-1}\left(\frac{1}{2}\right) + C \implies \frac{\pi}{3} = \frac{\pi}{3} + C \implies C = 0.$$

To check the edges of the domain, let $x = 0$ and $x = 1$ in the original equation to get $0 = 0$ and $\pi = \pi$, respectively. Thus, the identity is true for all $x \in [0, 1]$.

A final corollary adds a unique use of the Mean Value Theorem to our toolbox. In my undergraduate studies, I had moments when I required an inequality to be true but had no idea how to show it was true. For example, there might have been a moment when I needed the inequality

$$\ln(x) \leq x - 1, \text{ for } x \geq 1$$

to be true, but I had no clue how to show the truthfulness of the statement. Many students would "hand-wave" the process and say, "This is true." However, at this level, that type of justification is insufficient. This is where the **Racetrack Principle** comes into play.

### Corollary: The Racetrack Principle

If $f$ and $g$ are continuous for all $x \geq a$ and differentiable for all $x > a$, and if $f(a) = g(a)$ and $f'(x) \geq g'(x)$ for all $x > a$, then $f(x) \geq g(x)$ for all $x \geq a$.

**Proof**

Let $f$ and $g$ be continuous functions on the interval $[a, \infty)$, and suppose both are differentiable on $(a, \infty)$. Also, suppose $f(a) = g(a)$ and $f'(x) \geq g'(x)$ for all $x > a$.

Let $h(x) = f(x) - g(x)$. Then $h$ is continuous on $[a, \infty)$ and differentiable on $(a, \infty)$. Moreover, $h(a) = f(a) - g(a) = 0$ and $h'(x) = f'(x) - g'(x) \geq 0$ for all $x > a$.

If we let $b > a$ be arbitrary, then by the MVT there exists $c \in (a, b)$ such that

$$h'(c) = \frac{h(b) - h(a)}{b - a}.$$

However, we know that $h'(c) \geq 0$ (since $c > a$). Therefore,

$$h'(c) = \frac{h(b) - h(a)}{b - a} \geq 0.$$

Since $b > a$, we can multiply all three side of this inequality by $(b - a)$ without changing the inequality signs to get

$$h'(c)(b - a) = h(b) - h(a) \geq 0.$$

This means that

$$\begin{aligned} f(b) - g(b) - (f(a) - g(a)) &\geq 0 && \text{(substituting } h(a) = f(a) - g(a)\text{)} \\ f(b) - g(b) - (0) &\geq 0 && \text{(using the assumption that } f(a) = g(a)\text{)} \\ f(b) &\geq g(b) \end{aligned}$$

Since $b$ was arbitrary, $f(x) \geq g(x)$ for all $x \geq a$.

*Q.E.D.*

This is called the Racetrack Principle because you can imagine the validity of this statement if you visualize a racetrack with two cars. Their positions (the functions) are continuous and differentiable (at least for $x > a$). This means that no car can teleport and radically change its position between moments in time, and their velocities always exist. These two conditions also allow us to immediately use the MVT if needed. Additionally, $f(a) = g(a)$ means that the two cars start the race at the same position. Finally, $f'(x) \geq g'(x)$ means that car "$f$" is as fast or faster than car "$g$." It should then make sense that car "$f$" will always be in the lead (or at least neck-and-neck with car "$g$").

Let's do an example to see the power of the Racetrack Principle.

**Example 4.2.6**

Prove the inequality.

$$\ln(x) \leq x - 1, \text{ for } x \geq 1$$

**Solution**

Let $f(x) = x - 1$ and $g(x) = \ln(x)$. Both functions are continuous and differentiable for all $x > 0$. Thus, they are continuous on $[1, \infty)$ and differentiable on $(1, \infty)$. Moreover, $f(1) = 0 = g(1)$. Finally,

$$f'(x) = 1 \text{ and } g'(x) = 1/x.$$

For $x \geq 1$, $f'$ is always 1, but $g'$ is *at most* 1. In fact, for $x > 1$, $g'(x) < 1$. Hence, $f'(x) \geq g'(x)$ for all $x \geq 1$. Therefore, $f(x) \geq g(x)$ for all $x \geq 1$, by the Racetrack Principle. That is,

$$x - 1 \geq \ln(x), \text{ for } x \geq 1.$$

## Footnotes

[1] A **proof by contradiction** is a proof style where you allow the antecedent (the "if" part) to be true and *assume* the consequent (the "then" part) is *false*. You will eventually arrive at a logical contradiction using logical, deductive arguments. If your arguments up to that point were clean, flawless, deductive logic, then the only weakness would have to be the *assumption* that the consequent was false. Thus, the consequent must have been *true* all along. This proof style is commonly used in courtrooms.

## READING QUESTIONS

1. What are the three conditions a function $f$ must satisfy on an interval $[a, b]$ for Rolle's Theorem to apply?
2. If the conditions for Rolle's Theorem are met, what does the theorem conclude about the derivative $f'(c)$ for some $c$ in $(a, b)$?
3. What are the two conditions a function $f$ must satisfy on an interval $[a, b]$ for the Mean Value Theorem to apply?
4. If the conditions for the Mean Value Theorem are met, what does the theorem conclude about the derivative $f'(c)$ for some $c$ in $(a, b)$? What is this value equal to in terms of $f(a)$, $f(b)$, $a$, and $b$?
5. Geometrically, what does the conclusion of the Mean Value Theorem mean about the tangent line at $x = c$ and the secant line connecting $(a, f(a))$ and $(b, f(b))$?
6. How can Rolle's Theorem be used to prove that an equation has at most one root in an interval (uniqueness)?
7. If $f'(x) = 0$ for all $x$ in an interval $I$, what can be concluded about the function $f(x)$ on $I$?
8. If two functions $f(x)$ and $g(x)$ have the same derivative on an interval $I$ (i.e., $f'(x) = g'(x)$ for all $x \in I$), how are $f(x)$ and $g(x)$ related?
9. What is the Racetrack Principle? What conditions must be met for it to apply?
10. In Example 4 (the falling rock), how was the Mean Value Theorem applied to find a time when the instantaneous velocity equaled the average velocity?

## HOMEWORK

1)Why do you need continuity to apply the Mean Value Theorem? Construct a counterexample.

2) Why do you need differentiability to apply the Mean Value Theorem? Find a counterexample.

**Answer**

One example is $f(x) = |x| + 3, -2 \le x \le 2$

3) When are Rolle's theorem and the Mean Value Theorem equivalent?

4) If you have a function with a discontinuity, is it still possible to have $f'(c)(b-a) = f(b) - f(a)$? Draw such an example or prove why not.

**Answer**

Yes, but the Mean Value Theorem still does not apply

**In exercises 5 - 9, determine over what intervals (if any) the Mean Value Theorem applies. Justify your answer.**

5) $y = \sin(\pi x)$

6) $y = \dfrac{1}{x^3}$

**Answer**

$(-\infty, 0), (0, \infty)$

7) $y = \sqrt{4 - x^2}$

8) $y = \sqrt{x^2 - 4}$

**Answer**

$(-\infty, -2), (2, \infty)$

9) $y = \ln(3x - 5)$

**In exercises 10 - 13, graph the functions on a calculator and draw the secant line that connects the endpoints. Estimate the number of points $c$ such that $f'(c)(b-a) = f(b) - f(a)$.**

10) [Technology Required] $y = 3x^3 + 2x + 1$ over $[-1, 1]$

**Answer**

2 points

11) [Technology Required] $y = \tan\left(\frac{\pi}{4}x\right)$ over $\left[-\frac{3}{2}, \frac{3}{2}\right]$

12) [Technology Required] $y = x^2\cos(\pi x)$ over $[-2, 2]$

**Answer**

5 points

13) [Technology Required] $y = x^6 - \frac{3}{4}x^5 - \frac{9}{8}x^4 + \frac{15}{16}x^3 + \frac{3}{32}x^2 + \frac{3}{16}x + \frac{1}{32}$ over $[-1, 1]$

**In exercises 14 - 19, use the Mean Value Theorem and find all points $0 < c < 2$ such that $f(2) - f(0) = f'(c)(2 - 0)$.**

14) $f(x) = x^3$

**Answer**

$c = \frac{2\sqrt{3}}{3}$

15) $f(x) = \sin(\pi x)$

16) $f(x) = \cos(2\pi x)$

**Answer**

$c = \frac{1}{2}, 1, \frac{3}{2}$

17) $f(x) = 1 + x + x^2$

18) $f(x) = (x - 1)^{10}$

**Answer**

$c = 1$

19) $f(x) = (x - 1)^9$

**In exercises 20 - 23, show there is no $c$ such that $f(1) - f(-1) = f'(c)(2)$. Explain why the Mean Value Theorem does not apply over the interval $[-1, 1]$.**

20) $f(x) = \left|x - \frac{1}{2}\right|$

**Answer**

Not differentiable

21) $f(x) = \dfrac{1}{x^2}$

22) $f(x) = \sqrt{|x|}$

**Answer**

Not differentiable

23) $f(x) = \lfloor x \rfloor$ (Hint: This is called the floor function and it is defined so that $f(x)$ is the largest integer less than or equal to $x$.)

**In exercises 24 - 34, determine whether the Mean Value Theorem applies for the functions over the given interval $[a, b]$. Justify your answer.**

24) $y = e^x$ over $[0, 1]$

**Answer**

Yes

25) $y = \ln(2x + 3)$ over $\left[-\frac{3}{2}, 0\right]$

26) $f(x) = \tan(2\pi x)$ over $[0, 2]$

**Answer**

The Mean Value Theorem does not apply since the function is discontinuous at $x = \frac{1}{4}, \frac{3}{4}, \frac{5}{4}, \frac{7}{4}$.

27) $y = \sqrt{9 - x^2}$ over $[-3, 3]$

28) $y = \dfrac{1}{|x+1|}$ over $[0,3]$

**Answer**

Yes

29) $y = x^3 + 2x + 1$ over $[0,6]$

30) $y = \dfrac{x^2+3x+2}{x}$ over $[-1,1]$

**Answer**

The Mean Value Theorem does not apply; discontinuous at $x = 0$.

31) $y = \dfrac{x}{\sin(\pi x)+1}$ over $[0,1]$

32) $y = \ln(x+1)$ over $[0, e-1]$

**Answer**

Yes

33) $y = x\sin(\pi x)$ over $[0,2]$

34) $y = 5 + |x|$ over $[-1,1]$

**Answer**

The Mean Value Theorem does not apply; not differentiable at $x = 0$.

**For exercises 35 - 37, consider the roots of each equation.**

35) Show that the equation $y = x^3 + 3x^2 + 16$ has exactly one real root. What is it?

36) Find the conditions for exactly one root (double root) for the equation $y = x^2 + bx + c$

**Answer**

$b = \pm 2\sqrt{c}$

37) Find the conditions for $y = e^x - b$ to have one root. Is it possible to have more than one root?

**In exercises 38 - 42, use a calculator to graph the function over the interval $[a,b]$ and graph the secant line from $a$ to $b$. Use the calculator to estimate all values of $c$ as guaranteed by the Mean Value Theorem. Then, find the exact value of $c$, if possible, or write the final equation and use a calculator to estimate to four digits.**

38) [Technology Required] $y = \tan(\pi x)$ over $\left[-\frac{1}{4}, \frac{1}{4}\right]$

**Answer**

$c \approx \pm 0.1533$

$c = \pm\frac{1}{\pi}\cos^{-1}\left(\frac{\sqrt{\pi}}{2}\right)$

39) [Technology Required] $y = \dfrac{1}{\sqrt{x+1}}$ over $[0,3]$

40) [Technology Required] $y = |x^2 + 2x - 4|$ over $[-4,0]$

**Answer**

The Mean Value Theorem does not apply.

41) [Technology Required] $y = x + \dfrac{1}{x}$ over $\left[\frac{1}{2}, 4\right]$

42) [Technology Required] $y = \sqrt{x+1} + \dfrac{1}{x^2}$ over $[3,8]$

**Answer**

$\dfrac{1}{2\sqrt{c+1}} - \dfrac{2}{c^3} = \dfrac{521}{2880}$

$c \approx 3.133, 5.867$

43) At 10:17 a.m., you pass a police car at 55 mph that is stopped on the freeway. You pass a second police car at 55 mph at 10:53 a.m., which is located 39 mi from the first police car. If the speed limit is 60 mph, can the police cite you for speeding?

44) Two cars drive from one stoplight to the next, leaving at the same time and arriving at the same time. Is there ever a time when they are going the same speed? Prove or disprove.

**Answer**

Yes

45) Show that $y = \sec^2 x$ and $y = \tan^2 x$ have the same derivative. What can you say about $y = \sec^2 x - \tan^2 x$?

46) Show that $y = \csc^2 x$ and $y = \cot^2 x$ have the same derivative. What can you say about $y = \csc^2 x - \cot^2 x$?

**Answer**

It is constant.

# 4.3: Graphing Using Calculus - Shaping the Curve

**Learning Objectives**

- Explain how the sign of the first derivative affects the shape of a function's graph.
- State the First Derivative Test for critical points.
- Use concavity and inflection points to explain how the sign of the second derivative affects the shape of a function's graph.
- Explain the Concavity Test for a function over an open interval.
- Explain the relationship between a function and its first and second derivatives.
- State the Second Derivative Test for local extrema.

Hawk A.I. Section-Specific Tutor

Please note that, to access the Hawk A.I. Tutor, you will need a (free) OpenAI account.

Earlier in this chapter we stated that if a function $f$ has a local extremum at a point $(c, f(c))$, then $c$ must be a critical number of $f$. However, a function is not guaranteed to have a local extremum at a critical number. For example, $f(x) = x^3$ has a critical point at $(0, 0)$ since $f'(x) = 3x^2$ is zero at $x = 0$, but $f$ does not have a local extremum at $x = 0$. Using the results from the previous section, we can now determine whether a critical point of a function corresponds to a local extreme value. In this section, we also see how the second derivative provides information about the shape of a graph by describing whether the graph of a function curves upward or downward.

## Increasing/Decreasing Functions

We begin this section by allowing for one final corollary from the Mean Value Theorem. This corollary discusses when a function is increasing and when it is decreasing. Recall that a function $f$ is increasing over $I$ if $f(x_1) < f(x_2)$ whenever $x_1 < x_2$, whereas $f$ is decreasing over $I$ if $f(x_1) > f(x_2)$ whenever $x_1 < x_2$. Using the Mean Value Theorem, we can show that if the derivative of a function is positive, then the function is increasing; if the derivative is negative, then the function is decreasing (Figure 4.3.1). We use this fact throughout the remainder of this chapter, where we show how to use the derivative of a function to locate the local maximum and minimum values of the function and how to determine the shape of the graph.

**Corollary: Increasing and Decreasing Functions**

Let $f$ be continuous over the closed interval $[a, b]$ and differentiable over the open interval $(a, b)$.

i. If $f'(x) > 0$ for all $x \in (a, b)$, then $f$ is an increasing function over $[a, b]$.
ii. If $f'(x) < 0$ for all $x \in (a, b)$, then $f$ is a decreasing function over $[a, b]$.

**Proof (by contradiction)**

We will prove i. by contradiction; the proof of ii. is similar.

***Assume*** $f$ is *not* an increasing function on $I$. Then there exist $a$ and $b$ in $I$ such that $a < b$, but $f(a) \geq f(b)$. Since $f$ is a differentiable function over $I$, by the Mean Value Theorem there exists $c \in (a, b)$ such that

$$f'(c) = \frac{f(b) - f(a)}{b - a}.$$

Since $f(a) \geq f(b)$, we know that $f(b) - f(a) \leq 0$. Also, $a < b$ tells us that $b - a > 0$. We conclude that

$$f'(c) = \frac{f(b) - f(a)}{b - a} \leq 0.$$

However, $f'(x) > 0$ for all $x \in I$. This is a contradiction. The only ***assumption*** we made was that $f$ was *not* an increasing function on $I$. Therefore, $f$ must be an increasing function over $I$.

*Q.E.D.*

Figure **4.3.1** demonstrates this corollary perfectly.

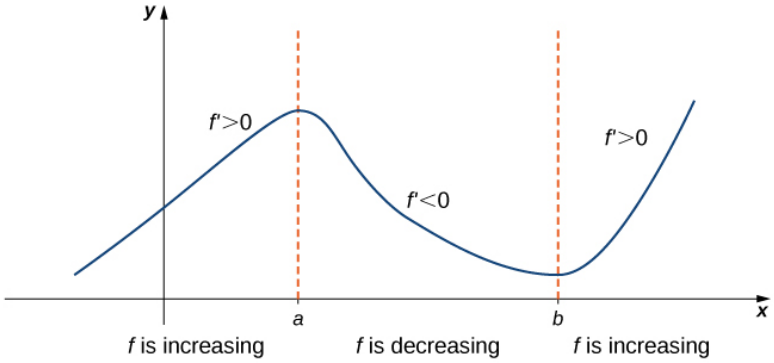

*Figure* **4.3.1***: If a function has a positive derivative over some interval* $I$*, then the function increases over that interval* $I$*; if the derivative is negative over some interval* $I$*, then the function decreases over that interval* $I$*.*

## The First Derivative Test

The previous corollary shows that if the derivative of a function is positive over an interval $I$, then the function is increasing over $I$. On the other hand, if the function's derivative is negative over an interval $I$, then the function is decreasing over $I$, as shown in the following figure.

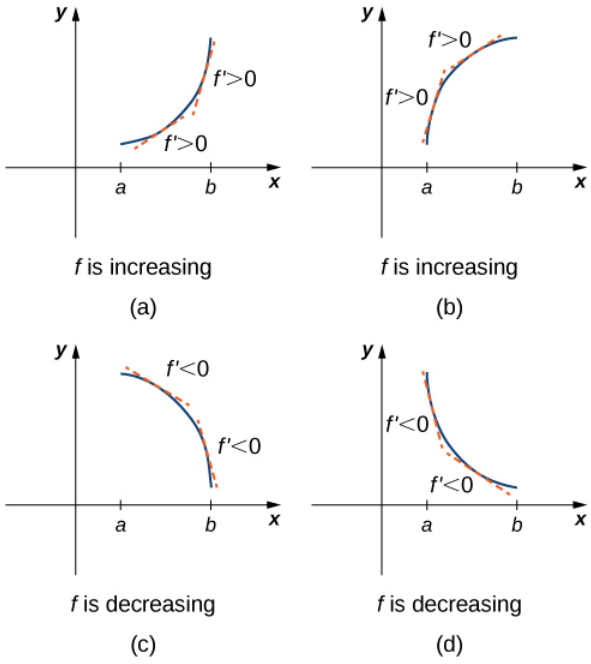

*Figure* **4.3.2***: Both functions are increasing over the interval* $(a, b)$*. At each point* $x$*, the derivative* $f'(x) > 0$*. Both functions decrease over the interval* $(a, b)$*. At each point* $x$*, the derivative* $f'(x) < 0$*.*

A *continuous* function $f$ has a local maximum at point $c$ if and only if $f$ switches from increasing to decreasing at point $c$. Similarly, $f$ has a local minimum at $c$ if and only if $f$ switches from decreasing to increasing at $c$. If $f$ is a continuous function over an interval $I$ containing $c$ and differentiable over $I$, except possibly at $c$, the only way $f$ can switch from increasing to decreasing (or vice versa) at point $c$ is if $f'$ changes sign as $x$ increases through $c$. If $f$ is differentiable at $c$, the only way that $f'$ can change sign as $x$ increases through $c$ is if $f'(c) = 0$. Therefore, for a function $f$ that is continuous over an interval $I$ containing $c$ and differentiable over $I$, except possibly at $c$, the only way $f$ can switch from increasing to decreasing (or vice versa) is if $f'(c) = 0$ or $f'(c)$ is

undefined. Consequently, to locate local extrema for a function $f$, we look for numbers $c$ in the domain of $f$ such that $f'(c) = 0$ or $f'(c)$ is undefined. Recall that such numbers are called critical numbers of $f$.

Note that $f$ need not have a local extrema at a critical number. The critical points are *candidates* for local extrema only. In Figure 4.3.3, we show that if a continuous function $f$ has a local extremum, it must occur at a critical point. Still, it can be the case that a function does not have a local extremum at a critical point. We show that if $f$ has a local extremum at a critical point, then the sign of $f'$ switches as $x$ increases through that point.

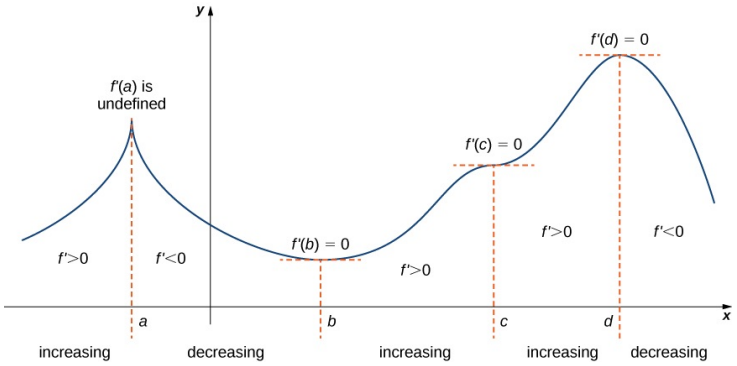

*Figure 4.3.3: The function $f$ has four critical points: $a, b, c$,and $d$. The function $f$ has local maxima at $a$ and $d$, and a local minimum at $b$. The function $f$ does not have a local extremum at $c$. The sign of $f'$ changes at all local extrema.*

Using Figure 4.3.3, we summarize the main results regarding local extrema.

- If a continuous function $f$ has a local extremum, it must occur at a critical number $c$.
- The function has a local extremum at the critical number $c$ if and only if the derivative, $f'$, switches sign as $x$ increases through $c$.
- Therefore, to test whether a function has a local extremum at a critical number $c$, we must determine the sign of $f'(x)$ to the left and right of $c$.

This result is known as the **First Derivative Test**.

**Theorem: First Derivative Test**

Suppose that $f$ is a continuous function over an interval $I$ containing a critical number $c$. If $f$ is differentiable over $I$, except possibly at $c$, then $f(c)$ satisfies one of the following descriptions:

i. If $f'$ changes sign from positive when $x < c$ to negative when $x > c$, then $f(c)$ is a local maximum of $f$.
ii. If $f'$ changes sign from negative when $x < c$ to positive when $x > c$, then $f(c)$ is a local minimum of $f$.
iii. If $f'$ has the same sign for $x < c$ and $x > c$, then $f(c)$ is neither a local maximum nor a local minimum of $f$

Now let's look at how to use this strategy to locate all local extrema for particular functions.

**Example 4.3.1**

Use the First Derivative Test to find the location of all local extrema for $f(x) = x^3 - 3x^2 - 9x - 1$. Use graphing technology to confirm your results.

**Solution**

The derivative is $f'(x) = 3x^2 - 6x - 9$. To find the critical numbers, we need to find where $f'(x) = 0$. Factoring the polynomial, we conclude that the critical numbers must satisfy

$$3(x^2 - 2x - 3) = 3(x - 3)(x + 1) = 0.$$

Therefore, the critical numbers are $x = 3$ and $x = -1$. Now divide the interval $(-\infty, \infty)$ into the smaller intervals $(-\infty, -1)$, $(-1, 3)$, and $(3, \infty)$.

Since $f'$ is a continuous function, to determine the sign of $f'(x)$ over each subinterval, it suffices to choose a point over each of the intervals $(-\infty,-1)$, $(-1,3)$, and $(3,\infty)$, and determine the sign of $f'$ at each of these points. For example, let's choose $x=-2$, $x=0$, and $x=4$ as test points.

**Table: 4.3.1: First Derivative Test for $f(x)=x^3-3x^2-9x-1$.**

| Interval | Test Point | Sign of $f'(x)=3(x-3)(x+1)$ at Test Point | Conclusion |
|---|---|---|---|
| $(-\infty,-1)$ | $x=-2$ | (+)(−)(−)=+ | $f$ is increasing. |
| $(-1,3)$ | $x=0$ | (+)(−)(+)=- | $f$ is decreasing. |
| $(3,\infty)$ | $x=4$ | (+)(+)(+)=+ | $f$ is increasing. |

Since $f'$ switches sign from positive to negative as $x$ increases through $-1$, $f$ has a local maximum at $x=-1$. Since $f'$ switches sign from negative to positive as $x$ increases through $3$, $f$ has a local minimum at $x=3$. These analytical results agree with the following graph.

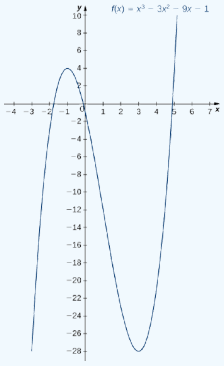

*Figure 4.3.4: The function $f$ has a maximum at $x=-1$ and a minimum at $x=3$*

## Checkpoint 4.3.1

Use the First Derivative Test to locate all local extrema for $f(x)=-x^3+\frac{3}{2}x^2+18x$.

**Answer**

$f$ has a local minimum at $-2$ and a local maximum at $3$.

## Example 4.3.2

Use the First Derivative Test to find the location of all local extrema for $f(x)=5x^{1/3}-x^{5/3}$. Use graphing technology to confirm your results.

**Solution**

The derivative is

$$f'(x)=\frac{5}{3}x^{-2/3}-\frac{5}{3}x^{2/3}=\frac{5}{3x^{2/3}}-\frac{5x^{2/3}}{3}=\frac{5-5x^{4/3}}{3x^{2/3}}=\frac{5(1-x^{4/3})}{3x^{2/3}}.$$

The derivative $f'(x)=0$ when $1-x^{4/3}=0$. Therefore, $f'(x)=0$ at $x=\pm 1$. The derivative $f'(x)$ is undefined at $x=0$. Therefore, we have three critical numbers: $x=0$, $x=1$, and $x=-1$. Consequently, divide the interval $(-\infty,\infty)$ into the smaller intervals $(-\infty,-1)$, $(-1,0)$, $(0,1)$, and $(1,\infty)$.

Since $f'$ is continuous over each subinterval, it suffices to choose a test point $x$ in each of the intervals and determine the sign of $f'$ at each of these points. The points $x=-2$, $x=-\frac{1}{2}$, $x=\frac{1}{2}$, and $x=2$ are test points for these intervals.

Table: 4.3.2: First Derivative Test for $f(x) = 5x^{1/3} - x^{5/3}$.

| Interval | Test Point | Sign of $f'(x) = \frac{5(1-x^{4/3})}{3x^{2/3}}$ at Test Point | Conclusion |
|---|---|---|---|
| $(-\infty, -1)$ | $x = -2$ | $\frac{(+)(-)}{+} = -$ | $f$ is decreasing. |
| $(-1, 0)$ | $x = -\frac{1}{2}$ | $\frac{(+)(+)}{+} = +$ | $f$ is increasing. |
| $(0, 1)$ | $x = \frac{1}{2}$ | $\frac{(+)(+)}{+} = +$ | $f$ is increasing. |
| $(1, \infty)$ | $x = 2$ | $\frac{(+)(-)}{+} = -$ | $f$ is decreasing. |

Since $f$ is decreasing over the interval $(-\infty, -1)$ and increasing over the interval $(-1, 0)$, $f$ has a local minimum at $x = -1$. Since $f$ is increasing over the interval $(-1, 0)$ and the interval $(0, 1)$, $f$ does not have a local extremum at $x = 0$. Since $f$ is increasing over the interval $(0, 1)$ and decreasing over the interval $(1, \infty)$, $f$ has a local maximum at $x = 1$. The analytical results agree with the following graph.

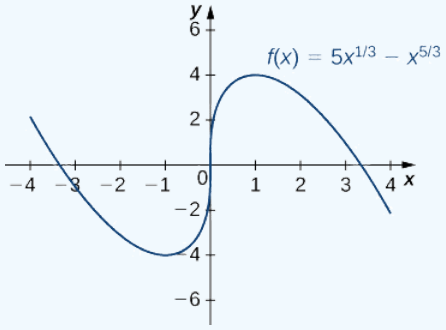

*Figure 4.3.5: The function $f$ has a local minimum at $x = -1$ and a local maximum at $x = 1$*

**? Checkpoint 4.3.2**

Use the First Derivative Test to find all local extrema for $f(x) = \frac{3}{x-1}$.

**Answer**

$f$ has no local extrema because $f'$ does not change sign at $x = 1$.

## Concavity and Points of Inflection

We now know how to determine where a function is increasing or decreasing. However, there is another issue to consider regarding the shape of the graph of a function. If the graph curves, does it curve upward or curve downward? This notion is called the **concavity** of the function.

Figure 4.3.6*a* shows a function $f$ with a graph that curves upward. As $x$ increases, the slope of the tangent line increases. Thus, since the derivative increases as $x$ increases, $f'$ is an increasing function. We say this function $f$ is **concave up**. Figure 4.3.6*b* shows a function $f$ that curves downward. As $x$ increases, the slope of the tangent line decreases. Since the derivative decreases as $x$ increases, $f'$ is a decreasing function. We say this function $f$ is **concave down**.

**Definition: Concavity**

Let $f$ be a function that is differentiable over an open interval $I$. If $f'$ is increasing over $I$, we say $f$ is **concave up** over $I$. If $f'$ is decreasing over $I$, we say $f$ is **concave down** over $I$.

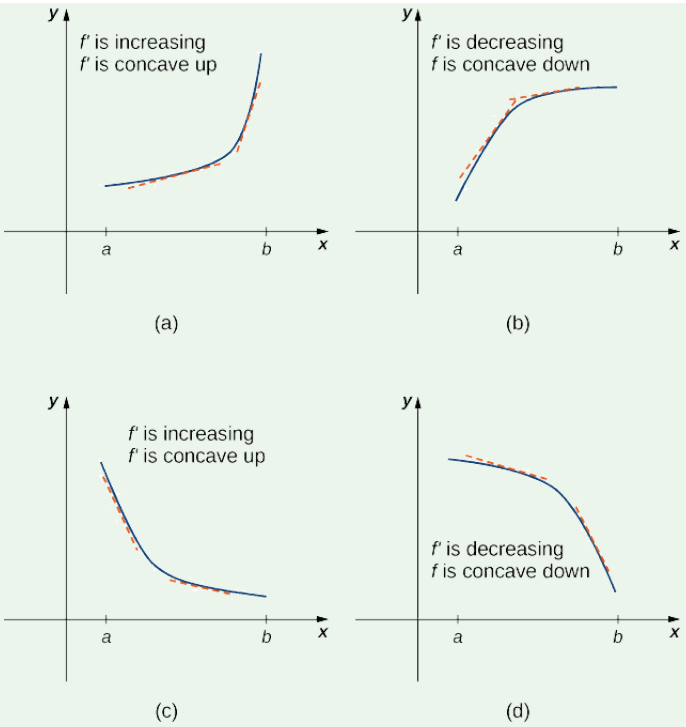

*Figure* **4.3.6***: (a), (c) Since* $f'$ *is increasing over the interval* $(a, b)$*, we say* $f$ *is concave up over* $(a, b).(b), (d)$ *Since* $f'$ *is decreasing over the interval* $(a, b)$*, we say* $f$ *is concave down over* $(a, b)$*.*

**Note: Another Viewpoint**

An equivalent way to define concavity is that a differentiable (and, therefore, continuous) function is concave up over an open interval $I$ if it lies above all of its tangent lines on the interval. Likewise, the function is said to be concave down on $I$ if it lies below all of its tangent lines on $I$.

In general, without having the graph of a function $f$, how can we determine its concavity? By definition, a function $f$ is concave up if $f'$ is increasing. From our previous corollary, we know that if $f'$ is a differentiable function, then $f'$ is increasing if its derivative $f''(x) > 0$. Therefore, a function $f$ that is twice differentiable is concave up when $f''(x) > 0$. Similarly, a function $f$ is concave down if $f'$ is decreasing. We know that a differentiable function $f'$ is decreasing if its derivative $f''(x) < 0$. Therefore, a twice-differentiable function $f$ is concave down when $f''(x) < 0$. Applying this logic is known as the **Concavity Test**.

**Theorem: Concavity Test**

Let $f$ be a function that is twice differentiable over an interval $I$.

i. If $f''(x) > 0$ for all $x \in I$, then $f$ is concave up over $I$
ii. If $f''(x) < 0$ for all $x \in I$, then $f$ is concave down over $I$.

We conclude that we can determine the concavity of a function $f$ by looking at the second derivative of $f$. In addition, we observe that a function $f$ can switch concavity (Figure **4.3.7**). However, a continuous function can switch concavity only at a point $x$ if $f''(x) = 0$ or $f''(x)$ is undefined. Consequently, to determine the intervals where a function $f$ is concave up and concave down, we look for those values of $x$ where $f''(x) = 0$ or $f''(x)$ is undefined. When we have determined these points, we divide the domain of $f$ into smaller intervals and determine the sign of $f''$ over each of these smaller intervals. If $f''$ changes sign as we pass through a point $x$, then $f$ changes concavity. It is important to remember that a function $f$ may not change concavity at a point $x$ even if $f''(x) = 0$ or $f''(x)$ is undefined. If, however, $f$ does change concavity at a point $a$ and $f$ is continuous at $a$, we say the point $(a, f(a))$ is an **inflection point** of $f$.

**Definition: Inflection Point**

If $f$ is continuous at $a$ and $f$ changes concavity at $a$, the point $(a,\ f(a))$ is an **inflection point** of $f$.

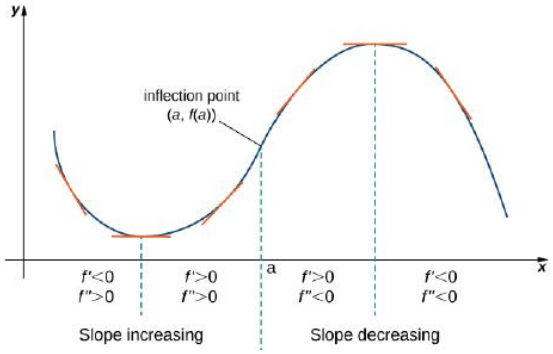

*Figure* **4.3.7**: *Since* $f''(x) > 0$ *for* $x < a$, *the function* $f$ *is concave up over the interval* $(-\infty, a)$. *Since* $f''(x) < 0$ *for* $x > a$, *the function* $f$ *is concave down over the interval* $(a, \infty)$. *The point* $(a, f(a))$ *is an inflection point of* $f$.

**Example 4.3.3**

For the function $f(x) = x^3 - 6x^2 + 9x + 30$, determine all intervals where $f$ is concave up and all intervals where $f$ is concave down. List all inflection points for $f$. Use a graphing utility to confirm your results.

**Solution**

To determine concavity, we need to find the second derivative $f''(x)$. The first derivative is $f'(x) = 3x^2 - 12x + 9$, so the second derivative is $f''(x) = 6x - 12$. If the function changes concavity, it occurs either when $f''(x) = 0$ or $f''(x)$ is undefined. Since $f''$ is defined for all real numbers $x$, we need only find where $f''(x) = 0$. Solving the equation $6x - 12 = 0$, we see that $x = 2$ is the only place where $f$ could change concavity. We now test points over the intervals $(-\infty, 2)$ and $(2, \infty)$ to determine the concavity of $f$. The points $x = 0$ and $x = 3$ are test points for these intervals.

**Table: 4.3.3: Test for Concavity for $f(x) = x^3 - 6x^2 + 9x + 30$.**

| Interval | Test Point | Sign of $f''(x) = 6x - 12$ at Test Point | Conclusion |
|---|---|---|---|
| $(-\infty, 2)$ | $x = 0$ | − | $f$ is concave down |
| $(2, \infty)$ | $x = 3$ | + | $f$ is concave up |

We conclude that $f$ is concave down over the interval $(-\infty, 2)$ and concave up over the interval $(2, \infty)$. Since $f$ changes concavity at $x = 2$, the point $(2, f(2)) = (2, 32)$ is an inflection point. Figure **4.3.8** confirms the analytical results.

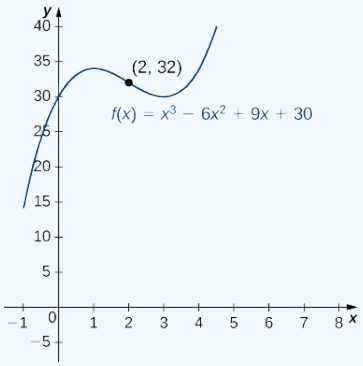

*Figure* **4.3.8**: *The given function has a point of inflection at* $(2, 32)$ *where the graph changes concavity.*

**? Checkpoint 4.3.3**

For $f(x) = -x^3 + \frac{3}{2}x^2 + 18x$, find all intervals where $f$ is concave up and all intervals where $f$ is concave down.

**Answer**

$f$ is concave up over the interval $(-\infty, \frac{1}{2})$ and concave down over the interval $(\frac{1}{2}, \infty)$

We now summarize, in Table 4.3.4, the information that the first and second derivatives of a function $f$ provide about the graph of $f$ and illustrate this information in Figure 4.3.9.

**Table: 4.3.4: What Derivatives Tell Us about Graphs**

| Sign of $f'$ | Sign of $f''$ | Is $f$ increasing or decreasing? | Concavity |
|---|---|---|---|
| Positive | Positive | Increasing | Concave up |
| Positive | Negative | Increasing | Concave down |
| Negative | Positive | Decreasing | Concave up |
| Negative | Negative | Decreasing | Concave down |

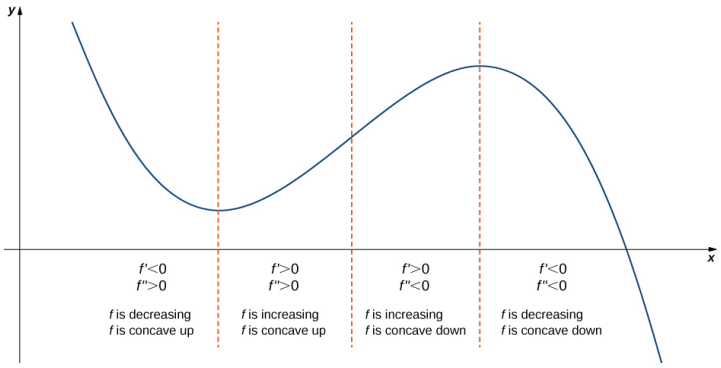

*Figure 4.3.9:Consider a twice-differentiable function $f$ over an open interval $I$. If $f'(x) > 0$ for all $x \in I$, the function is increasing over $I$. If $f'(x) < 0$ for all $x \in I$, the function is decreasing over $I$. If $f''(x) > 0$ for all $x \in I$, the function is concave up. If $f''(x) < 0$ for all $x \in I$, the function is concave down on $I$.*

## The Second Derivative Test

The First Derivative Test provides an analytical tool for finding local extrema. Still, the second derivative can also be used to locate extreme values. Using the second derivative can sometimes be a more straightforward method than using the first derivative.

We know that if a *continuous* function has a local extremum, it must occur at a critical point. However, a function does not need a local extremum at a critical point. Here, we examine how the **Second Derivative Test** can determine whether a function has a local extremum at a critical point. Let $f$ be a twice-differentiable function such that $f'(a) = 0$ and $f''$ is continuous over an open interval $I$ containing $a$. Suppose $f''(a) < 0$. Since $f''$ is continuous over $I$, $f''(x) < 0$ for all $x \in I$ (Figure 4.3.10). Then $f'$ is a decreasing function over $I$. Since $f'(a) = 0$, we conclude that for all $x \in I$, $f'(x) > 0$ if $x < a$ and $f'(x) < 0$ if $x > a$. Therefore, by the First Derivative Test, $f$ has a local maximum at $x = a$.

On the other hand, suppose there exists a point $b$ such that $f'(b) = 0$ but $f''(b) > 0$. Since $f''$ is continuous over an open interval $I$ containing $b$, $f''(x) > 0$ for all $x \in I$ (Figure 4.3.10). Then $f'$ is an increasing function over $I$. Since $f'(b) = 0$, we conclude that for all $x \in I$, $f'(x) < 0$ if $x < b$ and $f'(x) > 0$ if $x > b$. Therefore, by the First Derivative Test, $f$ has a local minimum at $x = b$.

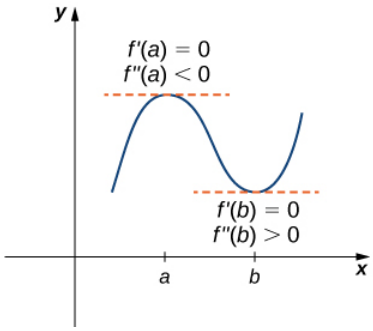

*Figure 4.3.10: Consider a twice-differentiable function $f$ such that $f''$ is continuous. Since $f'(a) = 0$ and $f''(a) < 0$, there is an interval $I$ containing $a$ such that for all $x$ in $I$, $f$ is increasing if $x < a$ and $f$ is decreasing if $x > a$. As a result, $f$ has a local maximum at $x = a$. Since $f'(b) = 0$ and $f''(b) > 0$, there is an interval $I$ containing $b$ such that for all $x$ in $I$, $f$ is decreasing if $x < b$ and $f$ is increasing if $x > b$. As a result, $f$ has a local minimum at $x = b$.*

**Theorem: Second Derivative Test**

Suppose $f'(c) = 0$ and $f''$ is continuous over an interval containing $c$.

i. If $f''(c) > 0$, then $f$ has a local minimum at $c$.
ii. If $f''(c) < 0$, then $f$ has a local maximum at $c$.
iii. If $f''(c) = 0$, then the test is inconclusive.

Note, when $f''(c) = 0$ (case iii), $f$ may have a local maximum, local minimum, or neither at $c$. For example, the functions $f(x) = x^3$, $f(x) = x^4$, and $f(x) = -x^4$ all have critical points at $(0, 0)$. In each case, the second derivative is zero at $x = 0$. However, the function $f(x) = x^4$ has a local minimum at $x = 0$ whereas the function $f(x) = -x^4$ has a local maximum at $x = 0$, and the function $f(x) = x^3$ does not have a local extremum at $x = 0$.

Let's now look at how to use the Second Derivative Test to determine whether $f$ has a local maximum or local minimum at a critical number $c$ where $f'(c) = 0$.

**Example 4.3.4**

Use the second derivative to find the location of all local extrema for $f(x) = x^5 - 5x^3$.

**Solution**

To apply the Second Derivative Test, we first need to find critical numbers $c$ where $f'(c) = 0$. The derivative is $f'(x) = 5x^4 - 15x^2$. Therefore, $f'(x) = 5x^4 - 15x^2 = 5x^2(x^2 - 3) = 0$ when $x = 0, \pm\sqrt{3}$.

To determine whether $f$ has a local extremum at any of these points, we need to evaluate the sign of $f''$ at these points. The second derivative is

$$f''(x) = 20x^3 - 30x = 10x(2x^2 - 3).$$

In the following table, we evaluate the second derivative at each critical point and use the Second Derivative Test to determine whether $f$ has a local maximum or minimum at any of these points.

**Table: 4.3.5: Second Derivative Test for $f(x) = x^5 - 5x^3$.**

| $x$ | $f''(x)$ | Conclusion |
|---|---|---|
| $-\sqrt{3}$ | $-30\sqrt{3}$ | Local maximum |
| $0$ | $0$ | Second Derivative Test is inconclusive |
| $\sqrt{3}$ | $30\sqrt{3}$ | Local minimum |

By the Second Derivative Test, we conclude that $f$ has a local maximum at $x = -\sqrt{3}$ and $f$ has a local minimum at $x = \sqrt{3}$. The Second Derivative Test is inconclusive at $x = 0$. We apply the First Derivative Test to determine whether $f$ has a local extremum at $x = 0$. To evaluate the sign of $f'(x) = 5x^2(x^2 - 3)$ for $x \in (-\sqrt{3}, 0)$ and $x \in (0, \sqrt{3})$, let $x = -1$ and $x = 1$ be the two test points. Since $f'(-1) < 0$ and $f'(1) < 0$, we conclude that $f$ is decreasing on both intervals and, therefore, $f$ does not have a local extrema at $x = 0$ as shown in the following graph.

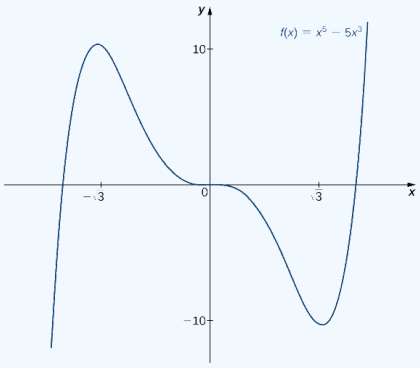

*Figure* **4.3.11**: *The function $f$ has a local maximum at $x = -\sqrt{3}$ and a local minimum at $x = \sqrt{3}$*

## Checkpoint 4.3.4

Consider the function $f(x) = x^3 - (\frac{3}{2})x^2 - 18x$. The points $c = 3, -2$ satisfy $f'(c) = 0$. Use the Second Derivative Test to determine whether $f$ has a local maximum or local minimum at those points.

**Answer**

$f$ has a local maximum at $-2$ and a local minimum at $3$.

We have now developed the tools to determine where a function is increasing and decreasing and understand the graph's basic shape. The next section discusses what happens to a function as $x \to \pm\infty$. At that point, we have enough tools to provide accurate graphs of various functions.

# 4.3E: EXERCISES

This page is a draft and is under active development.

## READING QUESTIONS

1. How does the sign of the first derivative, $f'(x)$, relate to whether a function $f(x)$ is increasing or decreasing on an interval?
2. What is the First Derivative Test used for? Describe how it determines if a critical point $c$ corresponds to a local maximum, local minimum, or neither.
3. What does it mean for a function to be "concave up" on an interval? How does this relate to the behavior of $f'(x)$?
4. What does it mean for a function to be "concave down" on an interval? How does this relate to the behavior of $f'(x)$?
5. What is the Concavity Test? How does the sign of the second derivative, $f''(x)$, determine the concavity of $f(x)$?
6. What is an inflection point? What conditions must be met for $(a, f(a))$ to be an inflection point?
7. If $f''(a) = 0$, does $f(x)$ necessarily have an inflection point at $x = a$? Explain.
8. What is the Second Derivative Test used for?
9. Under what conditions does the Second Derivative Test determine that a critical point $c$ (where $f'(c) = 0$) is a local maximum? A local minimum?
10. When is the Second Derivative Test inconclusive? What should be done in such a case?
11. Can a function have a local extremum at a point where its derivative is undefined? If so, give an example.

## HOMEWORK

1) If $c$ is a critical point of $f(x)$, when is there no local maximum or minimum at $c$? Explain.

2) For the function $y = x^3$, is $x = 0$ both an inflection point and a local maximum/minimum?

**Answer**

It is not a local maximum/minimum because $f'$ does not change sign

3) For the function $y = x^3$, is $x = 0$ an inflection point?

4) Is it possible for a point $c$ to be both an inflection point and a local extremum of a twice differentiable function?

**Answer**

No

5) Why do you need continuity for the first derivative test? Come up with an example.

6) Explain whether a concave-down function has to cross $y = 0$ for some value of $x$.

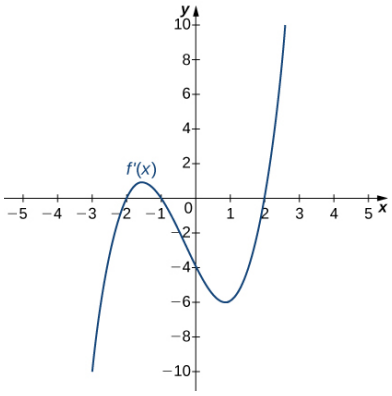
**Answer**

False; for example, $y = \sqrt{x}$.

7) Explain whether a polynomial of degree $2$ can have an inflection point.

**In exercises 8 - 12, analyze the graphs of $f'$, then list all intervals where $f$ is increasing or decreasing.**

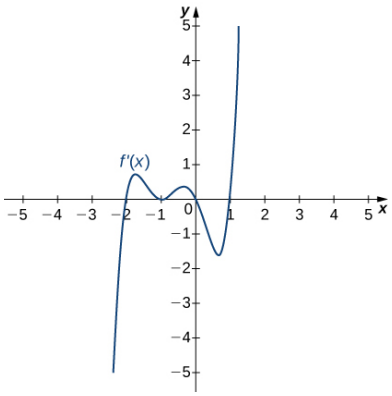
8)



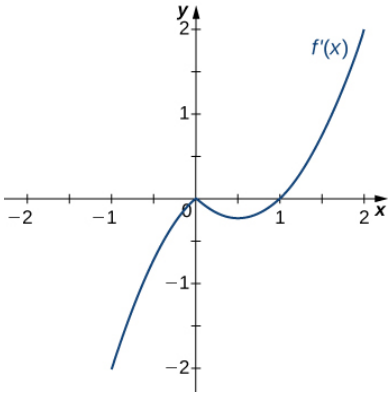
**Answer**

Increasing for $-2 < x < -1$ and $x > 2$;
Decreasing for $x < -2$ and $-1 < x < 2$

9)



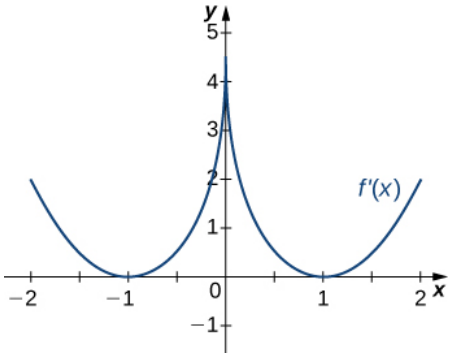
10)



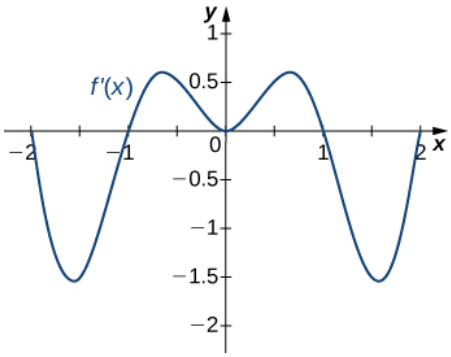
**Answer**

Decreasing for $x < 1$,
Increasing for $x > 1$

11)



12)



**Answer**

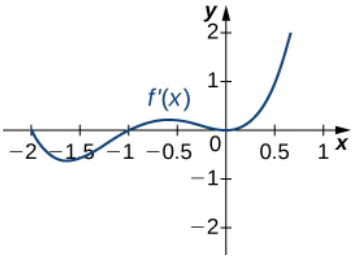
Decreasing for $-2 < x < -1$ and $1 < x < 2$;
Increasing for $-1 < x < 1$ and $x < -2$ and $x > 2$

**In exercises 13 - 17, analyze the graphs of $f'$, then list all intervals where**

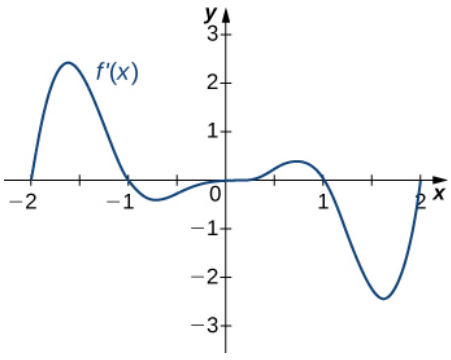
**a. $f$ is increasing and decreasing and**

**b. the minima and maxima are located.**

13)



14)

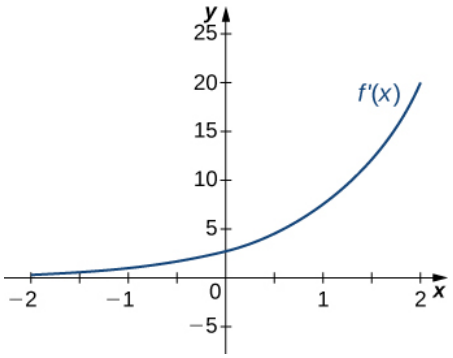


**Answer**

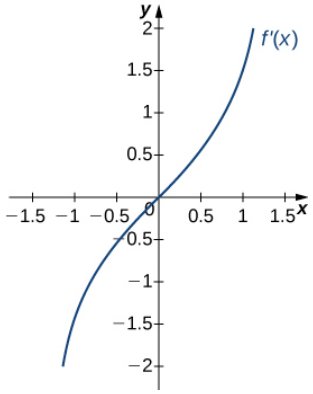
a. Increasing over $-2 < x < -1,\ 0 < x < 1, x > 2$, Decreasing over $x < -2,\ -1 < x < 0,\ 1 < x < 2$;

b. Maxima at $x = -1$ and $x = 1$, Minima at $x = -2$ and $x = 0$ and $x = 2$

15)



16)

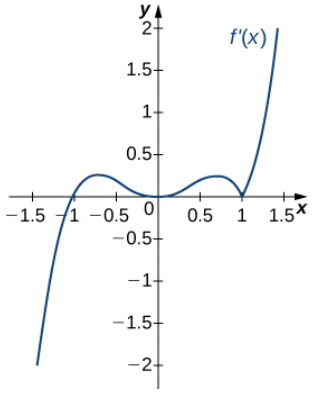


**Answer**

a. Increasing over $x > 0$, Decreasing over $x < 0$;

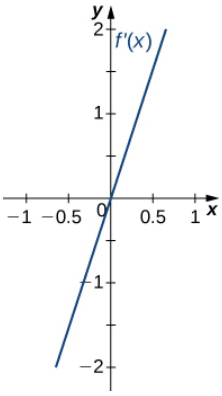
b. Minimum at $x = 0$

17)



**In exercises 18 - 22, analyze the graphs of $f'$, then list all inflection points and intervals $f$ that are concave up and concave down.**

18)

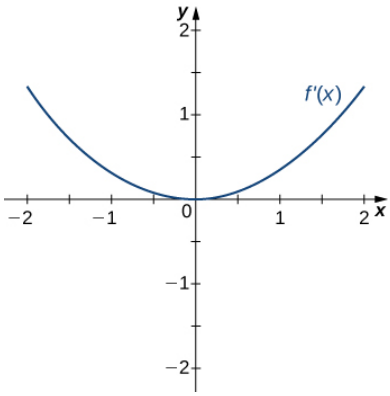


**Answer**

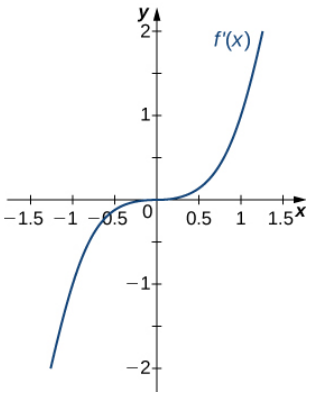
Concave up for all $x$,

No inflection points

19)



20)

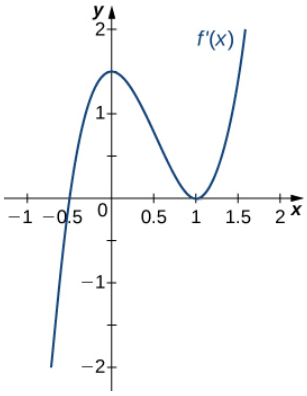


**Answer**

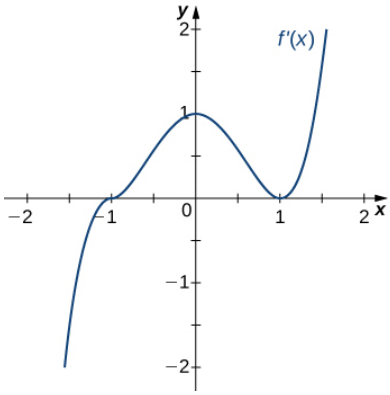
Concave up for all $x$,

No inflection points

21)



22)



**Answer**

Concave up for $x < 0$ and $x > 1$,
Concave down for $0 < x < 1$,
Inflection points at $x = 0$ and $x = 1$

**For exercises 23 - 27, draw a graph that satisfies the given specifications for the domain $x = [-3, 3]$. The function does not have to be continuous or differentiable.**

23) $f(x) > 0,\ f'(x) > 0$ over $x > 1,\ -3 < x < 0,\ f'(x) = 0$ over $0 < x < 1$

24) $f'(x) > 0$ over $x > 2,\ -3 < x < -1,\ f'(x) < 0$ over $-1 < x < 2,\ f''(x) < 0$ for all $x$

**Answer**

Answers will vary

25) $f''(x) < 0$ over $-1 < x < 1,\ f''(x) > 0,\ -3 < x < -1,\ 1 < x < 3$, local maximum at $x = 0$, local minima at $x = \pm 2$

26) There is a local maximum at $x = 2$, local minimum at $x = 1$, and the graph is neither concave up nor concave down.

**Answer**

Answers will vary

27) There are local maxima at $x = \pm 1$, the function is concave up for all $x$, and the function remains positive for all $x$.

**For the following exercises, determine**

**a. intervals where $f$ is increasing or decreasing and**

**b. local minima and maxima of $f$.**

28) $f(x) = \sin x + \sin^3 x$ over $-\pi < x < \pi$

**Answer**

a. Increasing over $-\frac{\pi}{2} < x < \frac{\pi}{2}$, decreasing over $x < -\frac{\pi}{2},\ x > \frac{\pi}{2}$

b. Local maximum at $x = \frac{\pi}{2}$; local minimum at $x = -\frac{\pi}{2}$

29) $f(x) = x^2 + \cos x$

**For exercise 30, determine**

**a. intervals where $f$ is concave up or concave down, and**

**b. the inflection points of $f$.**

30) $f(x) = x^3 - 4x^2 + x + 2$

**Answer**

a. Concave up for $x > \frac{4}{3}$, concave down for $x < \frac{4}{3}$

b. Inflection point at $x = \frac{4}{3}$

**For exercises 31 - 37, determine**

**a. intervals where $f$ is increasing or decreasing,**

**b. local minima and maxima of $f$,**

**c. intervals where $f$ is concave up and concave down, and**

**d. the inflection points of $f$.**

31) $f(x) = x^2 - 6x$

32) $f(x) = x^3 - 6x^2$

**Answer**

a. Increasing over $x < 0$ and $x > 4$, decreasing over $0 < x < 4$

b. Maximum at $x = 0$, minimum at $x = 4$

c. Concave up for $x > 2$, concave down for $x < 2$

d. Inflection point at $x = 2$

33) $f(x) = x^4 - 6x^3$

34) $f(x) = x^{11} - 6x^{10}$

**Answer**

a. Increasing over $x < 0$ and $x > \frac{60}{11}$, decreasing over $0 < x < \frac{60}{11}$

b. Maximum at $x = 0$, minimum at $x = \frac{60}{11}$

c. Concave down for $x < \frac{54}{11}$, concave up for $x > \frac{54}{11}$

d. Inflection point at $x = \frac{54}{11}$

35) $f(x) = x + x^2 - x^3$

36) $f(x) = x^2 + x + 1$

**Answer**

a. Increasing over $x > -\frac{1}{2}$, decreasing over $x < -\frac{1}{2}$

b. Minimum at $x = -\frac{1}{2}$

c. Concave up for all $x$

d. No inflection points

37) $f(x) = x^3 + x^4$

**For exercises 38 - 47, determine**

**a. intervals where $f$ is increasing or decreasing,**

**b. local minima and maxima of $f$,**

**c. intervals where $f$ is concave up and concave down, and**

**d. the inflection points of $f$. Sketch the curve, then use a calculator to compare your answer. If you cannot determine the exact answer analytically, use a calculator.**

38) [Technology Required] $f(x) = \sin(\pi x) - \cos(\pi x)$ over $x = [-1, 1]$

**Answer**

a. Increases over $-\frac{1}{4} < x < \frac{3}{4}$, decreases over $x > \frac{3}{4}$ and $x < -\frac{1}{4}$
b. Minimum at $x = -\frac{1}{4}$, maximum at $x = \frac{3}{4}$
c. Concave up for $-\frac{3}{4} < x < \frac{1}{4}$, concave down for $x < -\frac{3}{4}$ and $x > \frac{1}{4}$
d. Inflection points at $x = -\frac{3}{4},\ x = \frac{1}{4}$

39) [Technology Required] $f(x) = x + \sin(2x)$ over $x = [-\frac{\pi}{2}, \frac{\pi}{2}]$

40) [Technology Required] $f(x) = \sin x + \tan x$ over $(-\frac{\pi}{2}, \frac{\pi}{2})$

**Answer**

a. Increasing for all $x$
b. No local minimum or maximum
c. Concave up for $x > 0$, concave down for $x < 0$
d. Inflection point at $x = 0$

41) [Technology Required] $f(x) = (x-2)^2(x-4)^2$

42) [Technology Required] $f(x) = \dfrac{1}{1-x}, \quad x \neq 1$

**Answer**

a. Increasing for all $x$ where defined
b. No local minima or maxima
c. Concave up for $x < 1$; concave down for $x > 1$
d. No inflection points in domain

43) [Technology Required] $f(x) = \dfrac{\sin x}{x}$ over $x = [-2\pi, 0) \cup (0, 2\pi]$

44) $f(x) = \sin(x)e^x$ over $x = [-\pi, \pi]$

**Answer**

a. Increasing over $-\frac{\pi}{4} < x < \frac{3\pi}{4}$, decreasing over $x > \frac{3\pi}{4},\ x < -\frac{\pi}{4}$
b. Minimum at $x = -\frac{\pi}{4}$, maximum at $x = \frac{3\pi}{4}$
c. Concave up for $-\frac{\pi}{2} < x < \frac{\pi}{2}$, concave down for $x < -\frac{\pi}{2},\ x > \frac{\pi}{2}$
d. Inflection points at $x = \pm\frac{\pi}{2}$

45) $f(x) = \ln x\sqrt{x}, \quad x > 0$

46) $f(x) = \frac{1}{4}\sqrt{x} + \frac{1}{x}, \quad x > 0$

**Answer**

a. Increasing over $x > 4$, decreasing over $0 < x < 4$
b. Minimum at $x = 4$
c. Concave up for $0 < x < 8\sqrt[3]{2}$, concave down for $x > 8\sqrt[3]{2}$
d. Inflection point at $x = 8\sqrt[3]{2}$

47) $f(x) = \dfrac{e^x}{x}, \quad x \neq 0$

**In exercises 48 - 52, interpret the sentences in terms of $f$, $f'$, and $f''$.**

48) The population is growing more slowly. Here $f$ is the population.

**Answer**

$f > 0,\ f' > 0,\ f'' < 0$

49) A bike accelerates faster, but a car goes faster. Here $f =$ Bike's position minus Car's position.

50) The airplane lands smoothly. Here $f$ is the plane's altitude.

**Answer**

$f > 0,\ f' < 0,\ f'' > 0$

51) Stock prices are at their peak. Here $f$ is the stock price.

52) The economy is picking up speed. Here $f$ is a measure of the economy, such as GDP.

**Answer**

$f > 0,\ f' > 0,\ f'' > 0$

**For exercises 53 - 57, consider a third-degree polynomial $f(x)$, which has the properties $f'(1) = 0$ and $f'(3) = 0$. Determine whether the following statements are true or false. Justify your answer.**

53) $f(x) = 0$ for some $1 \le x \le 3$.

54) $f''(x) = 0$ for some $1 \le x \le 3$.

**Answer**

True, by the Mean Value Theorem

55) There is no absolute maximum at $x = 3$.

56) If $f(x)$ has three roots, then it has $1$ inflection point.

**Answer**

True, examine derivative

57) If $f(x)$ has one inflection point, then it has three real roots.

# 4.4: An Interlude for Limits - L'Hospital's Rule and Indeterminate Forms

**Learning Objectives**

- Recognize when to apply l'Hôpital's Rule.
- Identify indeterminate forms produced by quotients, products, subtractions, and powers, and apply l'Hôpital's Rule in each case.

Please note that, to access the Hawk A.I. Tutor, you will need a (free) OpenAI account.

This section examines a powerful tool for evaluating limits. This tool, **l'Hôpital's Rule**, uses derivatives to calculate limits. With this rule, we will be able to evaluate many limits we have not yet been able to determine. Instead of relying on numerical evidence to conjecture that a limit exists, we can show definitively that a limit exists and determine its exact value.

## Applying l'Hôpital's Rule

l'Hôpital's Rule can be used to evaluate limits involving the quotient of two functions. Consider

$$\lim_{x\to a}\frac{f(x)}{g(x)}.$$

If $\lim_{x\to a} f(x) = L_1$ and $\lim_{x\to a} g(x) = L_2 \neq 0$, then

$$\lim_{x\to a}\frac{f(x)}{g(x)} = \frac{L_1}{L_2}.$$

However, what happens if $\lim_{x\to a} f(x) = 0$ and $\lim_{x\to a} g(x) = 0$? We call this one of the **indeterminate forms,** of type $\frac{0}{0}$. This is considered an indeterminate form because we cannot *determine* the exact behavior of $\frac{f(x)}{g(x)}$ as $x \to a$ without further analysis. We have seen examples of this earlier in the text. For example, consider

$$\lim_{x\to 2}\frac{x^2-4}{x-2}$$

and

$$\lim_{x\to 0}\frac{\sin x}{x}.$$

For the first of these examples, we can evaluate the limit by factoring the numerator and writing

$$\lim_{x\to 2}\frac{x^2-4}{x-2} = \lim_{x\to 2}\frac{(x+2)(x-2)}{x-2} = \lim_{x\to 2}(x+2) = 2+2 = 4.$$

For $\lim_{x\to 0}\frac{\sin x}{x}$, we were able to show, using a geometric argument, that

$$\lim_{x\to 0}\frac{\sin x}{x} = 1.$$

Here, we use a different technique for evaluating limits such as these. Not only does this technique provide an easier way to evaluate these limits, but it also (and more importantly) provides us with a way to evaluate many other limits we could not previously calculate.

The idea behind l'Hôpital's Rule can be explained using local linear approximations. Consider two differentiable functions $f$ and $g$ such that $\lim_{x\to a} f(x) = 0 = \lim_{x\to a} g(x)$ and such that $g'(a) \neq 0$. For $x$ near $a$,we can write

$$f(x) \approx f(a) + f'(a)(x-a)$$

and

$$g(x) \approx g(a) + g'(a)(x - a).$$

Therefore,

$$\frac{f(x)}{g(x)} \approx \frac{f(a) + f'(a)(x - a)}{g(a) + g'(a)(x - a)}.$$

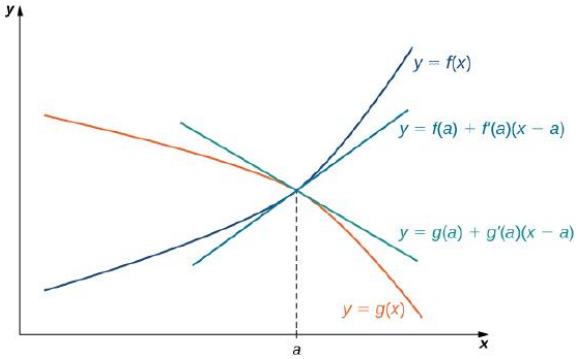

*Figure* **4.4.1***: If* $\lim_{x \to a} f(x) = \lim_{x \to a} g(x)$*, then the ratio* $f(x)/g(x)$ *is approximately equal to the ratio of their linear approximations near* $a$*.*

Since $f$ is differentiable at $a$, then $f$ is continuous at $a$, and therefore $f(a) = \lim_{x \to a} f(x) = 0$. Similarly, $g(a) = \lim_{x \to a} g(x) = 0$. If we also assume that $f'$ and $g'$ are continuous at $x = a$, then $f'(a) = \lim_{x \to a} f'(x)$ and $g'(a) = \lim_{x \to a} g'(x)$. Using these ideas, we conclude that

$$\lim_{x \to a} \frac{f(x)}{g(x)} = \lim_{x \to a} \frac{f'(x)(x - a)}{g'(x)(x - a)} = \lim_{x \to a} \frac{f'(x)}{g'(x)}.$$

Note that the assumption that $f'$ and $g'$ are continuous at $a$ and $g'(a) \neq 0$ can be loosened. We state l'Hôpital's Rule formally for the indeterminate form $\frac{0}{0}$.

**Caution: Abusive Notation**

Note that the notation $\frac{0}{0}$ does not mean we are actually dividing zero by zero. Rather, we are using the notation $\frac{0}{0}$ to *represent* a quotient of limits, each of which is zero.

**Theorem: l'Hôpital's Rule (0/0 Case)**

Suppose $f$ and $g$ are differentiable functions over an open interval containing $a$, except possibly at $a$. If $\lim_{x \to a} f(x) = 0$ and $\lim_{x \to a} g(x) = 0$, then

$$\lim_{x \to a} \frac{f(x)}{g(x)} = \lim_{x \to a} \frac{f'(x)}{g'(x)},$$

assuming the limit on the right exists or is $\infty$ or $-\infty$. This result also holds if we consider one-sided limits, or if $a = \infty$ or $a = -\infty$.

**Proof**

We provide a proof of this theorem in the special case when $f$, $g$, $f'$, and $g'$ are all continuous over an open interval containing $a$. In that case, since $\lim_{x \to a} f(x) = 0 = \lim_{x \to a} g(x)$ and $f$ and $g$ are continuous at $a$, it follows that $f(a) = 0 = g(a)$. Therefore,

$$\begin{aligned}
\lim_{x\to a}\frac{f(x)}{g(x)} &= \lim_{x\to a}\frac{f(x)-f(a)}{g(x)-g(a)} && (f(a)=0=g(a))\\
&= \lim_{x\to a}\frac{\frac{f(x)-f(a)}{x-a}}{\frac{g(x)-g(a)}{x-a}} && \left(\text{multiplying numerator and denominator by } \tfrac{1}{x-a}\right)\\
&= \frac{\lim\limits_{x\to a}\frac{f(x)-f(a)}{x-a}}{\lim\limits_{x\to a}\frac{g(x)-g(a)}{x-a}} && \text{(Limit Laws)}\\
&= \frac{f'(a)}{g'(a)} && \text{(definition of the derivative)}\\
&= \frac{\lim\limits_{x\to a}f'(x)}{\lim\limits_{x\to a}g'(x)} && \text{(continuity of } f' \text{ and } g')\\
&= \lim_{x\to a}\frac{f'(x)}{g'(x)} && \text{(The limit of a quotient)}
\end{aligned}$$

Note that l'Hôpital's Rule states we can calculate the limit of a quotient $\frac{f}{g}$ by considering the limit of the quotient of the derivatives $\frac{f'}{g'}$. It is essential to realize that we are not calculating the derivative of the quotient $\frac{f}{g}$.

*Q.E.D.*

## Example 4.4.1

Evaluate each of the following limits by applying l'Hôpital's Rule.

a. $\lim\limits_{x\to 0}\dfrac{1-\cos x}{x}$
b. $\lim\limits_{x\to 1}\dfrac{\sin(\pi x)}{\ln x}$
c. $\lim\limits_{x\to\infty}\dfrac{e^{1/x}-1}{1/x}$
d. $\lim\limits_{x\to 0}\dfrac{\sin x - x}{x^2}$

**Solutions**

a. Since the numerator $1-\cos x\to 0$ and the denominator $x\to 0$, we can apply l'Hôpital's Rule to evaluate this limit. We have

$$\begin{aligned}
\lim_{x\to 0}\frac{1-\cos x}{x} &\overset{\text{l'H}}{=} \lim_{x\to 0}\frac{\frac{d}{dx}(1-\cos x)}{\frac{d}{dx}(x)}\\
&= \lim_{x\to 0}\frac{\sin x}{1}\\
&= \frac{\lim\limits_{x\to 0}\sin x}{\lim\limits_{x\to 0}1}\\
&= \frac{0}{1}=0.
\end{aligned}$$

b. As $x\to 1$, the numerator $\sin(\pi x)\to 0$ and the denominator $\ln(x)\to 0$. Therefore, we can apply l'Hôpital's Rule. We obtain

$$\lim_{x\to 1}\frac{\sin(\pi x)}{\ln x} \overset{\text{l'H}}{=} \lim_{x\to 1}\frac{\pi\cos(\pi x)}{1/x}$$
$$= \lim_{x\to 1}(\pi x)\cos(\pi x)$$
$$= (\pi\cdot 1)(-1)$$
$$= -\pi.$$

c. As $x\to\infty$, the numerator $e^{1/x}-1\to 0$ and the denominator $\frac{1}{x}\to 0$. Therefore, we can apply l'Hôpital's Rule. We obtain

$$\lim_{x\to\infty}\frac{e^{1/x}-1}{\frac{1}{x}} \overset{\text{l'H}}{=} \lim_{x\to\infty}\frac{e^{1/x}\left(\frac{-1}{x^2}\right)}{\left(\frac{-1}{x^2}\right)}$$
$$= \lim_{x\to\infty} e^{1/x}$$
$$= e^0$$
$$= 1.$$

d. As $x\to 0$, both the numerator and denominator approach zero. Therefore, we can apply l'Hôpital's Rule. We obtain

$$\lim_{x\to 0}\frac{\sin x - x}{x^2} \overset{\text{l'H}}{=} \lim_{x\to 0}\frac{\cos x - 1}{2x}.$$

Since the numerator and denominator of this new quotient both approach zero as $x\to 0$, we apply l'Hôpital's Rule again. In doing so, we see that

$$\lim_{x\to 0}\frac{\cos x - 1}{2x} \overset{\text{l'H}}{=} \lim_{x\to 0}\frac{-\sin x}{2} = 0.$$

Therefore, we conclude that

$$\lim_{x\to 0}\frac{\sin x - x}{x^2} = 0.$$

**Checkpoint 4.4.1**

Evaluate

$$\lim_{x\to 0}\frac{x}{\tan x}.$$

**Answer**

1

We can also use l'Hôpital's Rule to evaluate limits of quotients $\frac{f(x)}{g(x)}$ in which $f(x)\to\pm\infty$ and $g(x)\to\pm\infty$. Limits of this form are classified as indeterminate forms of type $\frac{\infty}{\infty}$.

**Caution: More Notational Abuse**

Again, note that we are not actually dividing $\infty$ by $\infty$. Since $\infty$ is not a real number, that is impossible; rather, $\infty/\infty$ is used to *represent* a quotient of limits, each of which is $\infty$ or $-\infty$.

**Theorem: l'Hôpital's Rule ($\infty/\infty$ Case)**

Suppose $f$ and $g$ are differentiable functions over an open interval containing $a$, except possibly at $a$. Suppose $\lim_{x\to a} f(x)=\infty$ (or $-\infty$) and $\lim_{x\to a} g(x)=\infty$ (or $-\infty$). Then,

$$\lim_{x\to a}\frac{f(x)}{g(x)} = \lim_{x\to a}\frac{f'(x)}{g'(x)}$$

assuming the limit on the right exists or is $\infty$ or $-\infty$. This result also holds if the limit is infinite, if $a = \infty$ or $-\infty$, or if the limit is one-sided.

## Example 4.4.2

Evaluate each of the following limits by applying l'Hôpital's Rule.

a. $\lim\limits_{x\to\infty} \dfrac{3x+5}{2x+1}$

b. $\lim\limits_{x\to 0^+} \dfrac{\ln x}{\cot x}$

**Solutions**

a. Since $3x+5$ and $2x+1$ are first-degree polynomials with positive leading coefficients, $\lim\limits_{x\to\infty}(3x+5)=\infty$ and $\lim\limits_{x\to\infty}(2x+1)=\infty$. Therefore, we apply l'Hôpital's Rule and obtain

$$\begin{aligned}\lim_{x\to\infty}\frac{3x+5}{2x+1} &\overset{\text{l'H}}{=} \lim_{x\to\infty}\frac{3}{2}\\ &= \frac{3}{2}\end{aligned}$$

Note that this limit can also be calculated without invoking l'Hôpital's Rule. Earlier in the textbook, we showed how to evaluate such a limit by dividing the numerator and denominator by the highest power of x in the denominator. In doing so, we saw that

$$\lim_{x\to\infty}\frac{3x+5}{2x+1}=\lim_{x\to\infty}\frac{3+5/x}{2+1/x}=\frac{3}{2}.$$

l'Hôpital's Rule provides us with an alternative means of evaluating this type of limit.

b. Here, $\lim\limits_{x\to 0^+}\ln x=-\infty$ and $\lim\limits_{x\to 0^+}\cot x=\infty$. Therefore, we can apply l'Hôpital's Rule and obtain

$$\begin{aligned}\lim_{x\to 0^+}\frac{\ln(x)}{\cot(x)} &\overset{\text{l'H}}{=} \lim_{x\to 0^+}\frac{1/x}{-\csc^2(x)}\\ &= \lim_{x\to 0^+}\frac{1}{-x\csc^2(x)}\end{aligned}$$

Now as $x\to 0^+, \csc^2 x\to\infty$. Therefore, the first term in the denominator is approaching zero, and the second term is getting really large. In such a case, anything can happen with the product. Therefore, we cannot make any conclusion yet. To evaluate the limit, we use the definition of $\csc x$ to write

$$\lim_{x\to 0^+}\frac{1}{-x\csc^2 x}=\lim_{x\to 0^+}\frac{\sin^2 x}{-x}.$$

Now $\lim\limits_{x\to 0^+}\sin^2 x=0$ and $\lim\limits_{x\to 0^+}-x=0$, so we apply l'Hôpital's Rule again. We find

$$\begin{aligned}\lim_{x\to 0^+}\frac{\sin^2(x)}{-x} &\overset{\text{l'H}}{=} \lim_{x\to 0^+}\frac{2\sin(x)\cos(x)}{-1}\\ &= \frac{0}{-1}\\ &= 0.\end{aligned}$$

We conclude that

$$\lim_{x\to 0^+}\frac{\ln x}{\cot x}=0.$$

**Checkpoint 4.4.2**

Evaluate

$$\lim_{x\to\infty}\frac{\ln x}{5x}.$$

**Answer**

**0**

As mentioned, l'Hôpital's Rule is a handy tool for evaluating limits. It is important to remember, however, that to apply l'Hôpital's Rule to a quotient $\frac{f(x)}{g(x)}$, it is essential that the limit of $\frac{f(x)}{g(x)}$ be of the form $\frac{0}{0}$ or $\frac{\infty}{\infty}$. Consider the following example.

**Example 4.4.3**

Consider $\lim_{x\to 1}\frac{x^2+5}{3x+4}$. Show that the limit cannot be evaluated by applying l'Hôpital's Rule.

**Solution**

Because the limits of the numerator and denominator are not zero or infinite, we cannot apply l'Hôpital's Rule. If we try to do so, we get

$$\frac{d}{dx}(x^2+5)=2x$$

and

$$\frac{d}{dx}(3x+4)=3.$$

At which point we would conclude erroneously that

$$\lim_{x\to 1}\frac{x^2+5}{3x+4}=\lim_{x\to 1}\frac{2x}{3}=\frac{2}{3}.$$

However, since $\lim_{x\to 1}(x^2+5)=6$ and $\lim_{x\to 1}(3x+4)=7$, we actually have

$$\lim_{x\to 1}\frac{x^2+5}{3x+4}=\frac{6}{7}.$$

We can conclude that

$$\lim_{x\to 1}\frac{x^2+5}{3x+4}\neq\lim_{x\to 1}\frac{\frac{d}{dx}(x^2+5)}{\frac{d}{dx}(3x+4)}.$$

**Checkpoint 4.4.3**

Explain why we cannot apply l'Hôpital's Rule to evaluate $\lim_{x\to 0^+}\frac{\cos x}{x}$. Evaluate $\lim_{x\to 0^+}\frac{\cos x}{x}$ by other means.

**Answer**

$\lim_{x\to 0^+}\cos x=1$. Therefore, we cannot apply l'Hôpital's Rule. The limit of the quotient is $\infty$.

## Other Indeterminate Forms

l'Hôpital's Rule is very useful for evaluating limits involving the indeterminate forms $\frac{0}{0}$ and $\frac{\infty}{\infty}$. However, we can also use l'Hôpital's Rule to help evaluate limits involving other indeterminate forms that arise when evaluating limits. The expressions $0\cdot\infty$, $\infty-\infty$, $1^\infty$, $\infty^0$, and $0^0$ are all considered indeterminate forms. These expressions are not real numbers. Rather, they represent

forms that arise when trying to evaluate certain limits. Next, we realize why these are indeterminate forms and then understand how to use l'Hôpital's Rule in these cases. The key idea is that we must rewrite the indeterminate forms in such a way that we arrive at the indeterminate form $\frac{0}{0}$ or $\frac{\infty}{\infty}$.

### Indeterminate Form of Type $0 \cdot \infty$

Suppose we want to evaluate $\lim\limits_{x \to a} (f(x) \cdot g(x))$, where $f(x) \to 0$ and $g(x) \to \infty$ (or $-\infty$) as $x \to a$. Since one term in the product is approaching zero, but the other is becoming arbitrarily large (in magnitude), anything can happen to the product. We use the notation $0 \cdot \infty$ to denote the form in this situation. The expression $0 \cdot \infty$ is considered indeterminate because we cannot *determine* without further analysis the exact behavior of the product $f(x)g(x)$ as $x \to \infty$. For example, let $n$ be a positive integer and consider

$$f(x) = \frac{1}{(x^n + 1)}$$

and

$$g(x) = 3x^2.$$

As $x \to \infty, f(x) \to 0$ and $g(x) \to \infty$. However, the limit as $x \to \infty$ of $f(x)g(x) = \frac{3x^2}{(x^n+1)}$ varies, depending on $n$. If $n = 2$, then $\lim\limits_{x \to \infty} f(x)g(x) = 3$. If $n = 1$, then $\lim\limits_{x \to \infty} f(x)g(x) = \infty$. If $n = 3$, then $\lim\limits_{x \to \infty} f(x)g(x) = 0$. Here, we consider another limit involving the indeterminate form $0 \cdot \infty$ and show how to rewrite the function as a quotient to use l'Hôpital's Rule.

**Example 4.4.4**

Evaluate $\lim\limits_{x \to 0^+} x \ln(x)$.

**Solution**

We first note that, as $x \to 0^+$, $\ln(x) \to -\infty$. Therefore, this limit is indeterminate of the form $0 \cdot \infty$.

Rewrite the function $x \ln(x)$ as a quotient to apply l'Hôpital's Rule. If we write

$$x \ln(x) = \frac{\ln(x)}{1/x},$$

we see that $\ln(x) \to -\infty$ as $x \to 0^+$ and $\frac{1}{x} \to \infty$ as $x \to 0^+$. Therefore, we can apply l'Hôpital's Rule and obtain

$$\begin{aligned} \lim_{x \to 0^+} \frac{\ln(x)}{1/x} &\overset{\text{l'H}}{=} \lim_{x \to 0^+} \frac{\frac{d}{dx}(\ln(x))}{\frac{d}{dx}(1/x)} \\ &= \lim_{x \to 0^+} \frac{1/x}{-1/x^2} \\ &= \lim_{x \to 0^+} (-x) \\ &= 0. \end{aligned}$$

We conclude that

$$\lim_{x \to 0^+} x \ln(x) = 0.$$

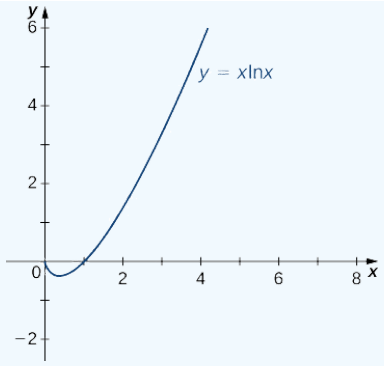

*Figure* **4.4.2***: Finding the limit at* $x = 0$ *of the function* $f(x) = x \ln x$.

**Checkpoint 4.4.4**

Evaluate

$$\lim_{x \to 0} x \cot x.$$

**Answer**

**1**

### Indeterminate Form of Type $\infty - \infty$

Another type of indeterminate form is $\infty - \infty$. Consider the following example. Let $n$ be a positive integer and let $f(x) = 3x^n$ and $g(x) = 3x^2 + 5$. As $x \to \infty$, $f(x) \to \infty$ and $g(x) \to \infty$. We are interested in $\lim_{x \to \infty} (f(x) - g(x))$. Depending on whether $f(x)$ grows faster, $g(x)$ grows faster, or they grow at the same rate, as we see next, anything can happen in this limit. Since $f(x) \to \infty$ and $g(x) \to \infty$, we write $\infty - \infty$ to denote the form of this limit.

**Caution: Yet More Notational Abuse**

As with our other indeterminate forms, $\infty - \infty$ has no meaning on its own, and we must do more analysis to determine the value of the limit.

For example, suppose the exponent $n$ in the function $f(x) = 3x^n$ is $n = 3$, then

$$\lim_{x \to \infty} (f(x) - g(x)) = \lim_{x \to \infty} (3x^3 - 3x^2 - 5) = \infty.$$

On the other hand, if $n = 2$, then

$$\lim_{x \to \infty} (f(x) - g(x)) = \lim_{x \to \infty} (3x^2 - 3x^2 - 5) = -5.$$

However, if $n = 1$, then

$$\lim_{x \to \infty} (f(x) - g(x)) = \lim_{x \to \infty} (3x - 3x^2 - 5) = -\infty.$$

Therefore, the limit cannot be determined by considering only $\infty - \infty$. Next, we see how to rewrite an expression involving the indeterminate form $\infty - \infty$ as a fraction to apply l'Hôpital's Rule.

**Example 4.4.5**

Evaluate

$$\lim_{x \to 0^+} \left( \frac{1}{x^2} - \frac{1}{\tan x} \right).$$

**Solution**

As $x \to 0^+$, $\frac{1}{x^2} \to \infty$ and $\frac{1}{\tan(x)} \to \infty$. Therefore, this limit is of the form $\infty - \infty$.

By combining the fractions, we can write the function as a quotient. Since the least common denominator is $x^2 \tan x$, we have

$$\frac{1}{x^2} - \frac{1}{\tan x} = \frac{(\tan x) - x^2}{x^2 \tan x}.$$

As $x \to 0^+$, the numerator $\tan x - x^2 \to 0$ and the denominator $x^2 \tan x \to 0$. Therefore, we can apply l'Hôpital's Rule. Taking the derivatives of the numerator and the denominator, we have

$$\lim_{x \to 0^+} \frac{(\tan x) - x^2}{x^2 \tan x} \overset{\text{l'H}}{=} \lim_{x \to 0^+} \frac{(\sec^2 x) - 2x}{x^2 \sec^2 x + 2x \tan x}.$$

As $x \to 0^+$, $(\sec^2 x) - 2x \to 1$ and $x^2 \sec^2 x + 2x \tan x \to 0$. Since the denominator is positive as $x$ approaches zero from the right, we conclude that

$$\lim_{x \to 0^+} \frac{(\sec^2 x) - 2x}{x^2 \sec^2 x + 2x \tan x} = \infty.$$

Therefore,

$$\lim_{x \to 0^+} \left( \frac{1}{x^2} - \frac{1}{\tan x} \right) = \infty.$$

**? Checkpoint 4.4.5**

Evaluate $\lim_{x \to 0^+} \left( \frac{1}{x} - \frac{1}{\sin x} \right)$.

**Answer**

0

Another indeterminate form that arises when evaluating limits involves exponents. The expressions $0^0$, $\infty^0$, and $1^\infty$ are all indeterminate forms. These expressions are meaningless because we cannot evaluate them as we would evaluate an expression involving real numbers. Rather, these expressions represent forms that arise when finding limits. Now, we examine how l'Hôpital's Rule can be used to evaluate limits involving these indeterminate forms.

Since l'Hôpital's Rule applies to quotients, we use the natural logarithm function and its properties to reduce a problem evaluating a limit involving exponents to a related problem involving a limit of a quotient. For example, suppose we want to evaluate $\lim_{x \to a} f(x)^{g(x)}$ and we arrive at the indeterminate form $\infty^0$. We proceed as follows. Let

$$y = f(x)^{g(x)}.$$

Then,

$$\ln y = \ln(f(x)^{g(x)}) = g(x) \ln(f(x)).$$

Therefore,

$$\lim_{x \to a} [\ln(y)] = \lim_{x \to a} [g(x) \ln(f(x))].$$

Since $\lim_{x \to a} f(x) = \infty$, we know that $\lim_{x \to a} \ln(f(x)) = \infty$. Therefore, $\lim_{x \to a} g(x) \ln(f(x))$ is of the indeterminate form $0 \cdot \infty$, and we can use the techniques discussed earlier to rewrite the expression $g(x) \ln(f(x))$ in a form so that we can apply l'Hôpital's Rule.

The indeterminate forms $0^0$ and $1^\infty$ can be handled similarly.

## Example 4.4.6

Evaluate

$$\lim_{x\to\infty} x^{1/x}.$$

**Solution**

As $x \to \infty$, $\frac{1}{x} \to 0$. Therefore, this limit is indeterminate of the form $\infty^0$.

Let $y = x^{1/x}$. Then,

$$\ln(x^{1/x}) = \frac{1}{x}\ln x = \frac{\ln x}{x}.$$

We need to evaluate $\lim\limits_{x\to\infty} \dfrac{\ln x}{x}$, which is now of the form $\frac{\infty}{\infty}$. Applying l'Hôpital's Rule, we obtain

$$\begin{aligned} \lim_{x\to\infty} \ln(y) &= \lim_{x\to\infty} \frac{\ln(x)}{x} \\ &\overset{\text{l'H}}{=} \lim_{x\to\infty} \frac{1/x}{1} \\ &= 0. \end{aligned}$$

Therefore, $\lim\limits_{x\to\infty} \ln y = 0$. Since the natural logarithm function is continuous, we conclude that

$$\ln\left(\lim_{x\to\infty} y\right) = 0,$$

which leads to

$$\lim_{x\to\infty} x^{1/x} = \lim_{x\to\infty} y = e^{\ln(\lim_{x\to\infty} y)} = e^0 = 1.$$

Hence,

$$\lim_{x\to\infty} x^{1/x} = 1.$$

## Checkpoint 4.4.6

Evaluate

$$\lim_{x\to\infty} x^{1/\ln(x)}.$$

**Answer**

$e$

## Example 4.4.7

Evaluate

$$\lim_{x\to 0^+} x^{\sin(x)}.$$

**Solution**

This limit is definitely indeterminate of the form $0^0$.

Let

$$y = x^{\sin(x)}.$$

Therefore,

$$\ln(y) = \ln\left(x^{\sin(x)}\right) = \sin(x)\ln(x).$$

We now evaluate $\lim\limits_{x\to 0^+} \sin(x)\ln(x)$. Since $\lim\limits_{x\to 0^+} \sin(x) = 0$ and $\lim\limits_{x\to 0^+} \ln(x) = -\infty$, we have the indeterminate form $0\cdot\infty$. To apply l'Hôpital's Rule, we need to rewrite $\sin(x)\ln(x)$ as a fraction. We could write

$$\sin(x)\ln(x) = \frac{\sin(x)}{1/\ln(x)}$$

or

$$\sin(x)\ln(x) = \frac{\ln(x)}{1/\sin(x)} = \frac{\ln(x)}{\csc(x)}.$$

Let's consider the first option. In this case, applying l'Hôpital's Rule, we would obtain

$$\begin{aligned}\lim_{x\to 0^+} \sin(x)\ln(x) &= \lim_{x\to 0^+} \frac{\sin(x)}{1/\ln(x)} \\ &= \lim_{x\to 0^+} \frac{\cos(x)}{-1/(x(\ln(x))^2)} \\ &= \lim_{x\to 0^+} \left(-x(\ln(x))^2\cos(x)\right).\end{aligned}$$

Unfortunately, we not only have another expression involving the indeterminate form $0\cdot\infty$, but the new limit is even more complicated to evaluate than the one with which we started. Instead, we try the second option. By writing

$$\sin(x)\ln(x) = \frac{\ln(x)}{1/\sin(x)} = \frac{\ln(x)}{\csc(x)},$$

and applying l'Hôpital's Rule, we obtain

$$\begin{aligned}\lim_{x\to 0^+} \sin(x)\ln(x) &= \lim_{x\to 0^+} \frac{\ln(x)}{\csc(x)} \\ &\overset{\text{l'H}}{=} \lim_{x\to 0^+} \frac{1/x}{-\csc(x)\cot(x)} \\ &= \lim_{x\to 0^+} \frac{-1}{x\csc(x)\cot(x)}.\end{aligned}$$

Using the fact that $\csc(x) = \frac{1}{\sin(x)}$ and $\cot(x) = \frac{\cos(x)}{\sin(x)}$, we can rewrite the expression on the right-hand side as

$$\lim_{x\to 0^+} \frac{-\sin^2(x)}{x\cos(x)} = \lim_{x\to 0^+} \left[\frac{\sin(x)}{x}\cdot(-\tan(x))\right] = \left(\lim_{x\to 0^+} \frac{\sin(x)}{x}\right)\cdot\left(\lim_{x\to 0^+}(-\tan(x))\right) = 1\cdot 0 = 0.$$

We conclude that $\lim\limits_{x\to 0^+} \ln(y) = 0$. Therefore, $\ln\left(\lim\limits_{x\to 0^+} y\right) = 0$ and we have

$$\lim_{x\to 0^+} y = \lim_{x\to 0^+} x^{\sin(x)} = e^0 = 1.$$

Hence,

$$\lim_{x\to 0^+} x^{\sin(x)} = 1.$$

**? Checkpoint 4.4.7**

Evaluate $\lim\limits_{x\to 0^+} x^x$.

**Answer**

1

## Growth Rates of Functions

We have shown how to use a function's first and second derivatives to describe the shape of a graph. To graph a function $f$ defined on an unbounded domain, we also need to know the behavior of $f$ as $x \to \pm\infty$.

Suppose the functions $f$ and $g$ both approach infinity as $x \to \infty$. Although the values of both functions become arbitrarily large as the values of $x$ become sufficiently large, sometimes one function grows more quickly than the other.

We say $g$ grows more rapidly than $f$ as $x \to \infty$ if

$$\lim_{x\to\infty} \frac{g(x)}{f(x)} = \infty \quad \text{or, equivalently,} \quad \lim_{x\to\infty} \frac{f(x)}{g(x)} = 0.$$

On the other hand, if there exists a constant $M \neq 0$ such that

$$\lim_{x\to\infty} \frac{f(x)}{g(x)} = M,$$

we say $f$ and $g$ grow at the same rate as $x \to \infty$.

Next, we see how to use l'Hôpital's Rule to compare the growth rates of power, exponential, and logarithmic functions.

### Example 4.4.8

For each of the following pairs of functions, use l'Hôpital's Rule to evaluate

$$\lim_{x\to\infty} \frac{f(x)}{g(x)}.$$

a. $f(x) = x^2$ and $g(x) = e^x$
b. $f(x) = \ln(x)$ and $g(x) = x^2$

**Solutions**

a. Since $\lim_{x\to\infty} x^2 = \infty$ and $\lim_{x\to\infty} e^x = \infty$, we can use l'Hôpital's Rule to evaluate $\lim_{x\to\infty} \left[\frac{x^2}{e^x}\right]$. We obtain

$$\lim_{x\to\infty} \frac{x^2}{e^x} \overset{\text{l'H}}{=} \lim_{x\to\infty} \frac{2x}{e^x}.$$

Since $\lim_{x\to\infty} 2x = \infty$ and $\lim_{x\to\infty} e^x = \infty$, we can apply l'Hôpital's Rule again. Since

$$\lim_{x\to\infty} \frac{2x}{e^x} \overset{\text{l'H}}{=} \lim_{x\to\infty} \frac{2}{e^x} = 0,$$

we conclude that

$$\lim_{x\to\infty} \frac{x^2}{e^x} = 0.$$

Therefore, $e^x$ grows more rapidly than $x^2$ as $x \to \infty$ (See Figure 4.4.3 and Table 4.4.1)

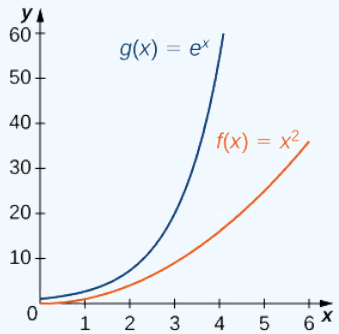

*Figure 4.4.3: An exponential function grows at a faster rate than a power function.*

**Table 4.4.1: Growth rates of a power function and an exponential function.**

| $x$ | 5 | 10 | 15 | 20 |
|---|---|---|---|---|
| $x^2$ | 25 | 100 | 225 | 400 |
| $e^x$ | 148 | 22,026 | 3,269,017 | 485,165,195 |

b. Since $\lim_{x\to\infty} \ln x = \infty$ and $\lim_{x\to\infty} x^2 = \infty$, we can use l'Hôpital's Rule to evaluate $\lim_{x\to\infty} \frac{\ln x}{x^2}$. We obtain

$$\lim_{x\to\infty} \frac{\ln x}{x^2} \overset{\text{l'H}}{=} \lim_{x\to\infty} \frac{1/x}{2x} = \lim_{x\to\infty} \frac{1}{2x^2} = 0.$$

Thus, $x^2$ grows more rapidly than $\ln x$ as $x \to \infty$ (see Figure 4.4.4 and Table 4.4.2).

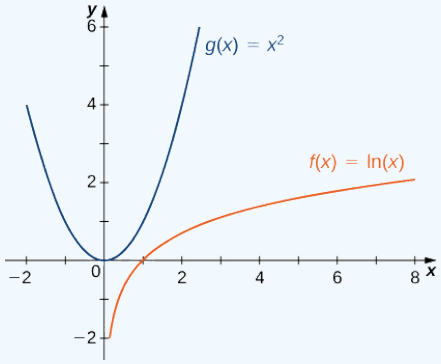

*Figure 4.4.4: A power function grows at a faster rate than a logarithmic function.*

**Table 4.4.2: Growth rates of a power function and a logarithmic function**

| $x$ | 10 | 100 | 1000 | 10,000 |
|---|---|---|---|---|
| $\ln(x)$ | 2.303 | 4.605 | 6.908 | 9.210 |
| $x^2$ | 100 | 10,000 | 1,000,000 | 100,000,000 |

**? Checkpoint 4.4.8**

Compare the growth rates of $x^{100}$ and $2^x$.

**Answer**

The function $2^x$ grows faster than $x^{100}$.

Using the same ideas as in Example 4.4.8a, it is not difficult to show that $e^x$ grows more rapidly than $x^p$ for any $p > 0$. In Figure 4.4.5 and Table 4.4.3, we compare $e^x$ with $x^3$ and $x^4$ as $x \to \infty$.

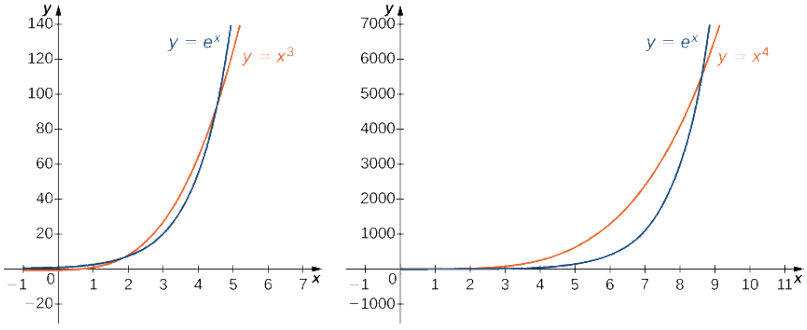

*Figure 4.4.5: The exponential function $e^x$ grows faster than $x^p$ for any $p > 0$. (a) A comparison of $e^x$ with $x^3$. (b) A comparison of $e^x$*

*with $x^4$.*

**Table 4.4.3: An exponential function grows at a faster rate than any power function**

| $x$ | 5 | 10 | 15 | 20 |
|---|---|---|---|---|
| $x^3$ | 125 | 1000 | 3375 | 8000 |
| $x^4$ | 625 | 10,000 | 50,625 | 160,000 |
| $e^x$ | 148 | 22,026 | 3,269,017 | 485,165,195 |

Similarly, it is not difficult to show that $x^p$ grows more rapidly than $\ln x$ for any $p > 0$. In Figure 4.4.6 and Table 4.4.4, we compare $\ln x$ with $\sqrt[3]{x}$ and $\sqrt{x}$.

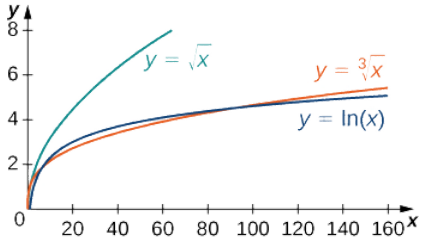

*Figure 4.4.6: The function $y = \ln(x)$ grows more slowly than $x^p$ for any $p > 0$ as $x \to \infty$.*

**Table 4.4.4: A logarithmic function grows at a slower rate than any root function**

| $x$ | 10 | 100 | 1000 | 10,000 |
|---|---|---|---|---|
| $\ln(x)$ | 2.303 | 4.605 | 6.908 | 9.210 |
| $\sqrt[3]{x}$ | 2.154 | 4.642 | 10 | 21.544 |
| $\sqrt{x}$ | 3.162 | 10 | 31.623 | 100 |

# 4.4E: EXERCISES

This page is a draft and is under active development.

## READING QUESTIONS

1. What are the two primary indeterminate forms for which L'Hôpital's Rule can be directly applied?
2. State L'Hôpital's Rule for the $\frac{0}{0}$ case. What conditions must be met by the functions $f$ and $g$?
3. If $\lim\limits_{x\to a}\dfrac{f(x)}{g(x)}$ is of the form $\frac{0}{0}$, what limit do you evaluate according to L'Hôpital's Rule?
4. Does L'Hôpital's Rule apply if $\lim\limits_{x\to a} f(x)=0$ but $\lim_{x\to a} g(x)=5$? Why or why not?
5. How can the indeterminate form $0\cdot\infty$ be rewritten so that L'Hôpital's Rule might be applicable?
6. How can the indeterminate form $\infty-\infty$ be rewritten so that L'Hôpital's Rule might be applicable?
7. What technique is used to handle indeterminate forms involving exponents, such as $0^0$, $\infty^0$, or $1^\infty$, before L'Hôpital's Rule can be applied?
8. If $\lim\limits_{x\to a}\ln(y)=L$, what is $\lim\limits_{x\to a} y$?
9. When comparing the growth rates of two functions $f(x)$ and $g(x)$ that both approach $\infty$ as $x\to\infty$, what does it mean if $\lim\limits_{x\to\infty}\dfrac{f(x)}{g(x)}=0$? Which function grows more rapidly?
10. Based on the examples, which type of function generally grows faster as $x\to\infty$: an exponential function ($e^x$), a power function ($x^p, p>0$), or a logarithmic function ($\ln x$)?

## HOMEWORK

**In exercises 1 - 6, evaluate the limit.**

1) Evaluate the limit $\lim\limits_{x\to\infty}\dfrac{e^x}{x}$.

2) Evaluate the limit $\lim\limits_{x\to\infty}\dfrac{e^x}{x^k}$.

**Answer**

$$\lim_{x\to\infty}\frac{e^x}{x^k} \quad = \quad \infty$$

3) Evaluate the limit $\lim\limits_{x\to\infty}\dfrac{\ln x}{x^k}$.

4) Evaluate the limit $\lim\limits_{x\to a}\dfrac{x-a}{x^2-a^2}$.

**Answer**

$$\lim_{x\to a}\frac{x-a}{x^2-a^2} \quad = \quad \frac{1}{2a}$$

5. Evaluate the limit $\lim\limits_{x\to a}\dfrac{x-a}{x^3-a^3}$.

6. Evaluate the limit $\lim\limits_{x\to a}\dfrac{x-a}{x^n-a^n}$.

**Answer**

$$\lim_{x\to a}\frac{x-a}{x^n-a^n} \quad = \quad \frac{1}{na^{n-1}}$$

**In exercises 7 - 11, determine whether you can apply l'Hôpital's Rule directly. Explain why or why not. Then, indicate if there is some way you can alter the limit so you can apply l'Hôpital's Rule.**

7) $\lim\limits_{x\to 0^+} x^2\ln x$

8) $\lim\limits_{x\to\infty} x^{1/x}$

**Answer**

Cannot apply directly; use logarithms

9) $\lim\limits_{x\to 0} x^{2/x}$

10) $\lim_{x\to 0} \dfrac{x^2}{1/x}$

**Answer**

Cannot apply directly; rewrite as $\lim_{x\to 0} x^3$

11) $\lim_{x\to\infty} \dfrac{e^x}{x}$

**In exercises 12 - 40, evaluate the limits with either l'Hôpital's Rule or previously learned methods.**

12) $\lim_{x\to 3} \dfrac{x^2-9}{x-3}$

**Answer**

$$\lim_{x\to 3} \frac{x^2-9}{x-3} = 6$$

13) $\lim_{x\to 3} \dfrac{x^2-9}{x+3}$

14) $\lim_{x\to 0} \dfrac{(1+x)^{-2}-1}{x}$

**Answer**

$$\lim_{x\to 0} \frac{(1+x)^{-2}-1}{x} = -2$$

15) $\lim_{x\to \pi/2} \dfrac{\cos x}{\frac{\pi}{2}-x}$

16) $\lim_{x\to \pi} \dfrac{x-\pi}{\sin x}$

**Answer**

$$\lim_{x\to \pi} \frac{x-\pi}{\sin x} = -1$$

17) $\lim_{x\to 1} \dfrac{x-1}{\sin x}$

18) $\lim_{x\to 0} \dfrac{(1+x)^n-1}{x}$

**Answer**

$$\lim_{x\to 0} \frac{(1+x)^n-1}{x} = n$$

19) $\lim_{x\to 0} \dfrac{(1+x)^n-1-nx}{x^2}$

20) $\lim_{x\to 0} \dfrac{\sin x-\tan x}{x^3}$

**Answer**

$$\lim_{x\to 0} \frac{\sin x-\tan x}{x^3} = -\frac{1}{2}$$

21) $\lim_{x\to 0} \dfrac{\sqrt{1+x}-\sqrt{1-x}}{x}$

22) $\lim_{x\to 0} \dfrac{e^x-x-1}{x^2}$

**Answer**

$$\lim_{x\to 0} \frac{e^x-x-1}{x^2} = \frac{1}{2}$$

23) $\lim_{x\to 0} \dfrac{\tan x}{\sqrt{x}}$

24) $\lim_{x\to 1} \dfrac{x-1}{\ln x}$

**Answer**

$$\lim_{x\to 1} \frac{x-1}{\ln x} = 1$$

25) $\lim_{x\to 0}(x+1)^{1/x}$

26) $\lim_{x\to 1}\dfrac{\sqrt{x}-\sqrt[3]{x}}{x-1}$

**Answer**

$$\lim_{x\to 1}\frac{\sqrt{x}-\sqrt[3]{x}}{x-1} = \frac{1}{6}$$

27) $\lim_{x\to 0^+} x^{2x}$

28) $\lim_{x\to\infty} x\sin\left(\frac{1}{x}\right)$

**Answer**

$$\lim_{x\to\infty} x\sin\left(\frac{1}{x}\right) = 1$$

29) $\lim_{x\to 0}\dfrac{\sin x - x}{x^2}$

30) $\lim_{x\to 0^+} x\ln\left(x^4\right)$

**Answer**

$$\lim_{x\to 0^+} x\ln\left(x^4\right) = 0$$

31) $\lim_{x\to\infty}(x-e^x)$

32) $\lim_{x\to\infty} x^2 e^{-x}$

**Answer**

$$\lim_{x\to\infty} x^2 e^{-x} = 0$$

33) $\lim_{x\to 0}\dfrac{3^x-2^x}{x}$

34) $\lim_{x\to 0}\dfrac{1+1/x}{1-1/x}$

**Answer**

$$\lim_{x\to 0}\frac{1+1/x}{1-1/x} = -1$$

35) $\lim_{x\to\pi/4}(1-\tan x)\cot x$

36) $\lim_{x\to\infty} xe^{1/x}$

**Answer**

$$\lim_{x\to\infty} xe^{1/x} = \infty$$

37) $\lim_{x\to 0} x^{1/\cos x}$

38) $\lim_{x\to 0^+} x^{1/x}$

**Answer**

$$\lim_{x\to 0^+} x^{1/x} = 0$$

39) $\lim_{x\to 0}\left(1-\dfrac{1}{x}\right)^x$

40) $\lim_{x\to\infty}\left(1-\dfrac{1}{x}\right)^x$

**Answer**

$$\lim_{x\to\infty}\left(1-\frac{1}{x}\right)^x = \frac{1}{e}$$

**For exercises 41 - 50, use a calculator to graph the function and estimate the value of the limit, then use l'Hôpital's Rule to find the limit directly.**

41) [Technology Required] $\lim\limits_{x\to 0}\dfrac{e^x-1}{x}$

42) [Technology Required] $\lim\limits_{x\to 0} x\sin\left(\frac{1}{x}\right)$

**Answer**

$$\lim_{x\to 0} x\sin\left(\frac{1}{x}\right) \;=\; 0$$

43) [Technology Required] $\lim\limits_{x\to 1}\dfrac{x-1}{1-\cos(\pi x)}$

44) [Technology Required] $\lim\limits_{x\to 1}\dfrac{e^{x-1}-1}{x-1}$

**Answer**

$$\lim_{x\to 1}\frac{e^{x-1}-1}{x-1} \;=\; 1$$

45) [Technology Required] $\lim\limits_{x\to 1}\dfrac{(x-1)^2}{\ln x}$

46) [Technology Required] $\lim\limits_{x\to \pi}\dfrac{1+\cos x}{\sin x}$

**Answer**

$$\lim_{x\to \pi}\frac{1+\cos x}{\sin x} \;=\; 0$$

47) [Technology Required] $\lim\limits_{x\to 0}\left(\csc x-\dfrac{1}{x}\right)$

48) [Technology Required] $\lim\limits_{x\to 0^+}\tan\left(x^x\right)$

**Answer**

$$\lim_{x\to 0^+}\tan\left(x^x\right) \;=\; \tan 1$$

49) [Technology Required] $\lim\limits_{x\to 0^+}\dfrac{\ln x}{\sin x}$

50) [Technology Required] $\lim\limits_{x\to 0}\dfrac{e^x-e^{-x}}{x}$

**Answer**

$$\lim_{x\to 0}\frac{e^x-e^{-x}}{x} \;=\; 2$$

# 4.5: Graphing Using Calculus - Putting it Altogether

**Learning Objectives**

- Estimate the end behavior of a function as $x$ increases or decreases without bound.
- Prove the equation of the slant asymptote to a function.
- Recognize an oblique asymptote on the graph of a function.
- Use the Guidelines to Graphing Using Calculus to analyze a function and its derivatives to draw its graph accurately.

Hawk A.I. Section-Specific Tutor

Please note that, to access the Hawk A.I. Tutor, you will need a (free) OpenAI account.

We have gathered *almost* everything we need to graph a given function using Calculus accurately. In this section, we finalize the topic by focusing on the end behavior of the graph of a function (specifically, whether or not the function has an oblique asymptote). Once that topic is finished, we present a tactic for graphing a function using Calculus.

## End Behavior

The behavior of a function as $x \to \pm\infty$ is called the function's **end behavior**, and finding the end behavior of a function is the precise reason we introduced ourselves to l'Hôpital's Rule. If $f$ is a function of $x$, then as $x \to \infty$ or $x \to -\infty$, the function could exhibit one of the following types of behavior:

1. **No End Behavior:** A given function may have a restricted domain. For example, the function might be defined on the closed interval $[-1, 10]$. The function does not have an end behavior in these cases because it is not defined as $x \to \pm\infty$.
2. **Horizontal Asymptote(s):** If
$$\lim_{x \to \pm\infty} f(x) = L,$$
where $L$ is finite, the function approaches a horizontal asymptote $y = L$ as $x \to \infty$ or as $x \to -\infty$ (or both).
3. **Slant Asymptote(s):** If
$$\lim_{x \to \pm\infty} f(x) = \pm\infty,$$
then there is a little more work we need to do to determine if the function is mimicking a linear or nonlinear function near the edges of the domain.
4. **Oscillatory Behavior:** If
$$\lim_{x \to \pm\infty} f(x) \text{ DNE and is not } \pm\infty,$$
then the function does not have any asymptotic end behavior; however, it could be the case that the function is periodic and is following an oscillatory pattern as its end behavior.

**Notes About the End Behavior of a Function**

- Each of the limits mentioned in the list above could have different "asymptote types" at each end of the function. That is, it's possible that $\lim_{x \to -\infty} f(x) = 5$ and $\lim_{x \to \infty} (f(x) = -\infty$ (or a constant not equal to $5$). Do not assume that end behavior is symmetric.
- The list presented above is purposeful in its order.
  - When determining the end behavior of a given function, you immediately throw out the possibility for end behavior if your function has a restricted domain.
  - If the domain is unrestricted, you take limits as $x \to \pm\infty$.
    - If a limit is finite, then your function has a horizontal asymptote.

- If the limit is infinite, then you have some extra work determining if there is an underlying linear or nonlinear function the original function is approaching as $x \to \pm\infty$.
- If the limit DNE and is not infinite, then your function might have oscillatory behavior and, if true, you will need to find the period of the oscillation.

Since we have already covered the topic of horizontal asymptotes, the remainder of this subsection is dedicated to the discussion of **slant asymptotes**.

**Definition: Slant Asymptote**

The line $y = mx + b$ is called a **slant asymptote** of the function $f$ if

$$\lim_{x\to\infty} (f(x) - y) = 0$$

or

$$\lim_{x\to-\infty} (f(x) - y) = 0.$$

**Example 4.5.1**

Determine the slant asymptote of $f(x) = 3x - 1 + e^{-2x}$

**Solution**

As $x \to \infty$, $e^{-2x} \to 0$ leaving us with $3x - 1$. Thus, our claim is that $y = 3x - 1$ is a slant asymptote for the function $f$ as $x \to \infty$. To prove this statement, we use the definition.

$$\begin{aligned} \lim_{x\to\infty} [f(x) - y] &= \lim_{x\to\infty} \left(3x - 1 + e^{-2x} - (3x - 1)\right) \\ &= \lim_{x\to\infty} e^{-2x} \\ &= 0 \end{aligned}$$

Thus, we have proven that $y = 3x - 1$ is a slant asymptote of $f(x) = 3x - 1 + e^{-2x}$ as $x \to \infty$.

It is important to mention here that the function in Example **4.5.1** does not have a slant asymptote as $x \to -\infty$. This is because, as $x \to -\infty$, there is not a term in $f(x)$ that "disappears" to leave us with only a linear function.

## Guidelines for Drawing the Graph of a Function

We now have enough analytical tools to draw graphs of various algebraic and transcendental functions. Before showing how to graph specific functions, let's look at a general strategy when graphing any function. Notice in the steps provided that I follow the Mathematical Mantra and step through the graphing process doing mathematics in the order we learned topics (except the domain, which I often do first despite having learned that skill *after* learning how to find intercepts).

**Tactic: Drawing the Graph of a Function**

Given a function $f$, use the following steps to sketch its graph by hand:

1. **Domain:** Determine the domain of the function.
2. **Intercepts:** Locate the $x$- and $y$-intercepts. Create a table of values to hold all the data you will collect.
3. **Symmetry:** Determine if $f$ is odd, even, or neither. If it's neither odd nor even, determine if it is periodic. This step is *incredibly* useful because once you know a function is, for example, odd, you can focus your energy on gathering all the information about the function for $x \geq 0$. After you precisely graph the function for these $x$-values, you can use the symmetry of the function to graph the other half.
4. **Vertical Asymptotes:** Use Calculus to determine the behavior of the function near any vertical asymptote(s). This step will involve limits of the form

$$\lim_{x\to a^+} f(x) \text{ and } \lim_{x\to a^-} f(x).$$

5. **End Behavior:** Use Calculus to determine the end behavior of the function. This step will involve limits of the form

$$\lim_{x\to\infty} f(x) \text{ and } \lim_{x\to-\infty} f(x).$$

   If either of these limits is a finite number $L$, then $y = L$ is a horizontal asymptote. If either of these limits is $\infty$ or $-\infty$, determine whether $f$ has a slant asymptote.
6. **First Derivative Information:** Calculate $f'$. Find all critical points and determine the intervals where $f$ is increasing and where $f$ is decreasing. Determine whether $f$ has any local extrema.
7. **Second Derivative Information:** Calculate $f''$. Determine the intervals where $f$ is concave up and where $f$ is concave down. Use this information to determine whether $f$ has any inflection points. The second derivative can also be used as an alternate means to determine or verify that $f$ has a local extremum at a critical point.
8. **Graph like a boss**

## Graphing Examples

Now, let's use this strategy to graph several different functions. We start by graphing a polynomial function.

**Example 4.5.2**

Sketch a graph of $R(x) = \frac{x^2}{x^2+1}$.

**Solution**

**Domain:** Since $R(x)$ is a rational function and its denominator, $x^2+1$, is always greater than or equal to $1$, the domain is $\mathbb{R} = (-\infty, \infty)$.

**Intercepts:** $(0,0)$ is the only intercept.

**Symmetry:** $R(-x) = \frac{(-x)^2}{(-x)^2+1} = \frac{x^2}{x^2+1} = R(x)$. Therefore, $R$ is an even function. As such, we will limit the rest of our investigation to the interval $[0,\infty)$ and reflect our graph across the $y$-axis when we are finished.

**Vertical Asymptote(s):** Since the domain of $R$ is all real numbers and $R$ is continuous, there is not going to be a vertical asymptote.

**End Behavior:**

$$\begin{aligned}\lim_{x\to\infty} R(x) &= \lim_{x\to\infty} \frac{x^2}{x^2+1}\\ &= \lim_{x\to\infty} \frac{1}{1+\frac{1}{x^2}}\\ &= \frac{1}{1+0}\\ &= 1\end{aligned}$$

Thus, $R$ has a horizontal asymptote of $y = 1$ as $x \to \infty$.

**First Derivative Information:**

$$\begin{aligned}R'(x) &= \frac{2x(x^2+1) - x^2(2x)}{(x^2+1)^2}\\ &= \frac{2x(x^2+1-x^2)}{(x^2+1)^2}\\ &= \frac{2x}{(x^2+1)^2}\end{aligned}$$

$R'(x) = 0$, when $x = 0$. Otherwise, $R'(x)$ always exists. Thus, the only critical point of $R$ is $(0, 0)$.

For $x > 0$, $R'(x) > 0$. Therefore, $R$ is increasing on the interval $(0, \infty)$. Since $R$ is an even function, $R$ will be decreasing for $x < 0$. This means that $(0, 0)$ is a local minimum. All of the information can be seen on the number line for $R'$ in Figure 4.5.1A below.

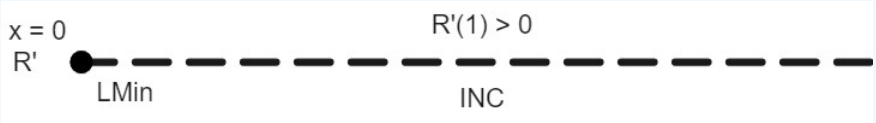

*Figure 4.5.1A: The number line sign graph for $R'$.*

**Second Derivative Information:**

$$\begin{aligned} R''(x) &= \frac{2(x^2+1)^2 - 2x \cdot 2(x^2+1) \cdot 2x)}{(x^2+1)^4} \\ &= \frac{(x^2+1)\left(2(x^2+1) - 8x^2\right)}{(x^2+1)^4} \\ &= \frac{-6x^2+2}{(x^2+1)^3} \\ &= \frac{-2(3x^2-1)}{(x^2+1)^3} \end{aligned}$$

$R''(x) = 0$, when $x = \pm\frac{1}{\sqrt{3}}$. Otherwise, $R''(x)$ always exists.

All of the information for $R''$ can be seen on the number line for $R''$ in Figure 4.5.1B below (again, we only concern ourselves with $x$-values greater than 0 because $R$ is even).

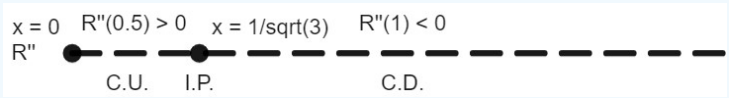

*Figure 4.5.1B: The number line sign graph for $R''$.*

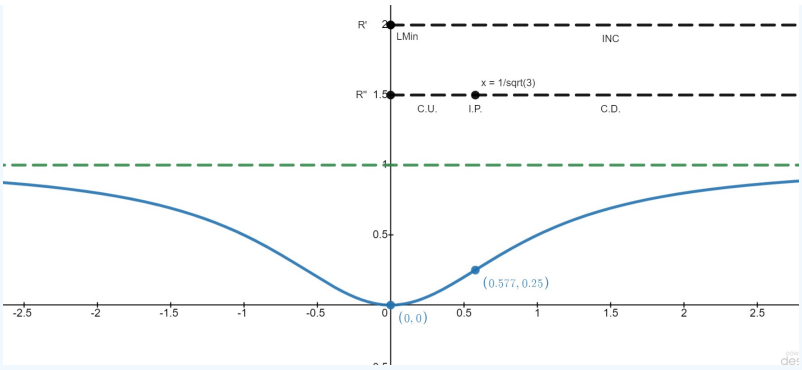
**Graph Like a Boss:** Before graphing, it's best to collect all the important information into one clean "pile." It's also **required** that you compute the function values for $R$ wherever there are local extrema, inflection points, and intercepts.

| $x$ | $R(x)$ | Note(s) |
|---|---|---|
| 0 | 0 | $x$- and $y$-intercept, LMin |
| $\frac{1}{\sqrt{3}} \approx 0.577$ | $\frac{1}{4}$ | I.P. |

**Symmetry:** Even

**Horizontal Asymptote:** $y = 1$ as $x \to \infty$

https://math.libretexts.org/@go/page/175477



Notice in Example **4.5.2** that we approximated the value of $\frac{1}{\sqrt{3}}$. When graphing by hand, it is sometimes necessary to use technology to get decimal approximations to place our points properly.

### Example 4.5.3

Sketch the graph of $f(x) = x\sqrt{1-x^2}$.

**Solution**

**Domain:** We require $1 - x^2 \geq 0 \implies 1 \geq x^2 \implies x \in [-1, 1]$.

**Intercepts:** $(0, 0)$ and $(\pm 1, 0)$ are the intercepts.

**Symmetry:** $f(-x) = -x\sqrt{1-(-x)^2} = -x\sqrt{1-x^2} = -f(x)$. Therefore, $f$ is an odd function. As such, we will limit the rest of our investigation to the interval $[0, 1]$ and reflect our graph about the origin when we are finished.

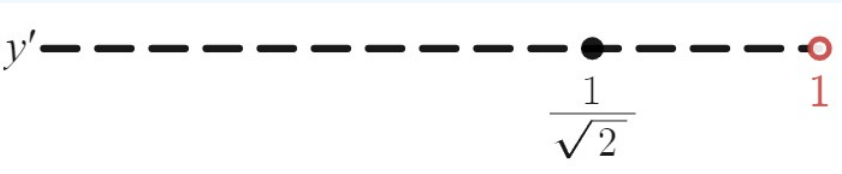
**Vertical Asymptote(s):** Since the domain of $f$ is a closed interval and $f$ is continuous, there is not going to be a vertical asymptote.

**End Behavior:** Since the domain of $f$ does not extend to infinity (in either direction), there is no end behavior to speak of.

**First Derivative Information:**

$$\begin{aligned} f'(x) &= \sqrt{1-x^2} + x \cdot \frac{-2x}{2\sqrt{1-x^2}} \\ &= \sqrt{1-x^2} - \frac{x^2}{\sqrt{1-x^2}} \\ &= \frac{1-x^2-x^2}{\sqrt{1-x^2}} \\ &= \frac{1-2x^2}{\sqrt{1-x^2}} \end{aligned}$$

$f'(x) = 0$, when $x = \pm\frac{1}{\sqrt{2}}$, and $f'(x)$ does not exist at $x = \pm 1$. Since $f$ is odd, we will only worry about $x = \frac{1}{\sqrt{2}}$ and $x = 1$. The corresponding critical points are $(1, 0)$ and $\left(\frac{1}{\sqrt{2}}, \frac{1}{2}\right)$. We first draw the number line.



Testing each interval (and only substituting these values into the numerator of $f'$ because the denominator is always positive), we get $f'\left(\frac{1}{2}\right) > 0$ and $f'\left(\frac{3}{4}\right) < 0$. Therefore, $f$ is increasing on $\left(0, \frac{1}{\sqrt{2}}\right)$ and decreasing on $\left(\frac{1}{\sqrt{2}}, 0\right)$. Hence, $f$ has a local maximum at the point $\left(\frac{1}{\sqrt{2}}, \frac{1}{2}\right)$. All of this information can be seen on the number line for $f'$ in Figure **4.5.2A** below.

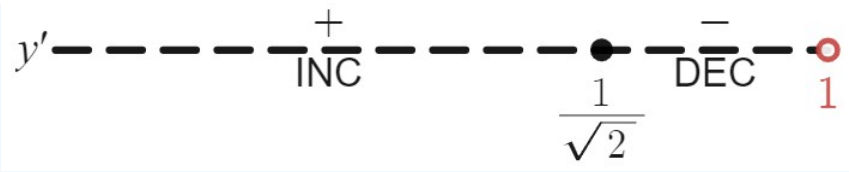


*Figure* **4.5.2*A***: *The number line sign graph for* $f'$.

**Second Derivative Information:**

$$\begin{aligned} f''(x) &= \frac{-4x\sqrt{1-x^2} - (1-2x^2)\cdot\frac{-x}{\sqrt{1-x^2}}}{1-x^2} \\ &= \frac{-4x(1-x^2) + x(1-2x^2)}{(1-x^2)^{3/2}} \\ &= \frac{x(2x^2-3)}{(1-x^2)^{3/2}} \end{aligned}$$

$f''(x) = 0$, when $x = \pm\frac{\sqrt{6}}{2}$ and when $x = 0$. Moreover, $f''$ does not exist when $x = \pm 1$. Again, since $f$ is odd, we will only concern ourselves with $x = 0$, $x = \frac{\sqrt{6}}{2}$, and $x = 1$; **however**, $\frac{\sqrt{6}}{2} > 1$ and, as such, is outside of the domain of $f$. Hence, we only need to worry about $x = 0$ and $x = 1$. Since $f''\left(\frac{1}{2}\right) < 0$, $f$ is concave down on $(0, 1)$ (see Figure **4.5.2*B***).

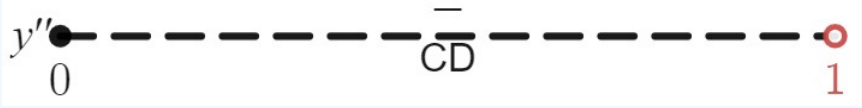

*Figure* **4.5.2*B***: *The number line sign graph for* $f''$.

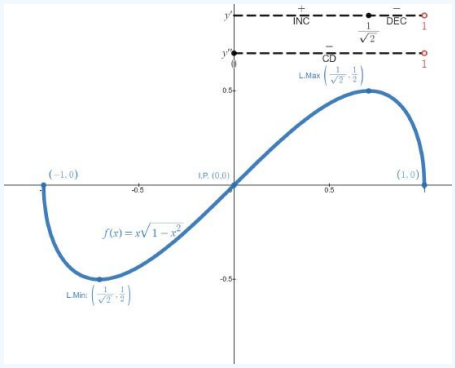
**Graph Like a Boss:**

| $x$ | $R(x)$ | **Note(s)** |
|---|---|---|
| **0** | **0** | $x$- and $y$-intercept, I.P. |
| $\frac{1}{\sqrt{2}} \approx 0.707$ | $\frac{1}{2}$ | L.Max |
| **1** | **0** | $x$-intercept |

**Symmetry:** Odd



**Note: Tricks to Knowing When a Function Does Not Have a Vertical Asymptote**

Both functions in Examples **4.5.2** and **4.5.3** were continuous on their domains. Moreover, the function's domain in Example **4.5.3** was a closed interval. When a function is continuous and has a domain of either $\mathbb{R}$ or a closed interval, you can guarantee that the function does not have any vertical asymptotes. This is because of the definition of a vertical asymptote from Chapter

2. $x = a$ is a vertical asymptote of $f$ if any of the limits (single-sided or total) as $x \to a$ becomes infinite. For a continuous function, this condition can only occur at the edge of its domain and only if the domain doesn't include that edge.

**Example 4.5.4**

Sketch the graph of $f(x) = \frac{x^2}{x-1}$

**Solution**

**Domain:** The domain of $f$ is the set of all real numbers $x$ except $x = 1$.

**Intercepts:** We can see that when $x = 0$, $f(x) = 0$, so $(0, 0)$ is the only intercept.

**Symmetry:** Since $f(-x) = \frac{(-x)^2}{(-x)-1} = \frac{x^2}{-x-1} = -\frac{x^2}{x+1} \neq \pm f(x)$, $f$ is neither odd nor even.

**Vertical Asymptote(s):** To check for vertical asymptotes, look at where the denominator is zero. Here, the denominator is zero at $x = 1$. Looking at both one-sided limits as $x \to 1$, we find

$$\lim_{x \to 1^+} \frac{x^2}{x-1} = \infty$$

and

$$\lim_{x \to 1^-} \frac{x^2}{x-1} = -\infty.$$

Therefore, $x = 1$ is a vertical asymptote, and we have determined the behavior of $f$ as $x$ approaches $1$ from the right and the left.

**End Behavior:** Evaluate the limits at infinity. Since the degree of the numerator is one more than the degree of the denominator, $f$ must have a slant asymptote. To find the slant asymptote, use long division of polynomials to write

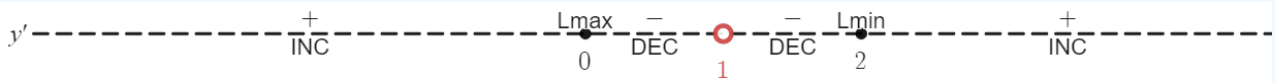
$$f(x) = \frac{x^2}{x-1} = x + 1 + \frac{1}{x-1}.$$

Since $\frac{1}{x-1} \to 0$ as $x \to \pm\infty$, $f(x)$ approaches the line $y = x + 1$ as $x \to \pm\infty$. The line $y = x + 1$ is a slant asymptote for $f$.

**First Derivative Information:** Calculate the first derivative:

$$f'(x) = \frac{(x-1)(2x) - x^2(1)}{(x-1)^2} = \frac{x^2 - 2x}{(x-1)^2}.$$

We have $f'(x) = 0$ when $x^2 - 2x = x(x-2) = 0$. Therefore, $x = 0$ and $x = 2$ are critical points. Since $f$ is undefined at $x = 1$, we need to divide the interval $(-\infty, \infty)$ into the smaller intervals $(-\infty, 0), (0, 1), (1, 2)$, and $(2, \infty)$, and choose a test point from each interval to evaluate the sign of $f'(x)$ in each of these smaller intervals. Doing so, we get the following sign chart for $f'$.

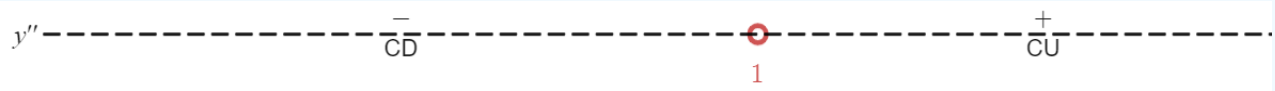


From this sign chart, we see that $f$ has a local maximum at $x = 0$ and a local minimum at $x = 2$. The value of $f$ at the local maximum is $f(0) = 0$ and the value of $f$ at the local minimum is $f(2) = 4$. Therefore, $(0, 0)$ and $(2, 4)$ are important points on the graph.

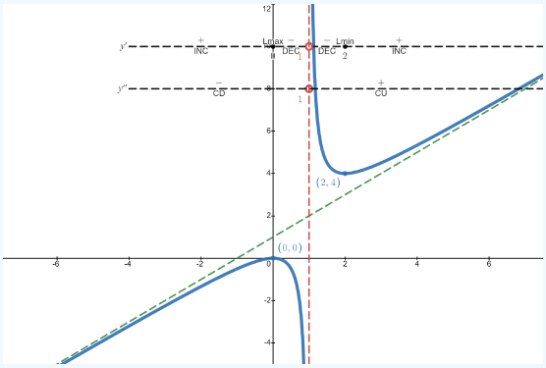
**Second Derivative Information:** Calculate the second derivative:

$$\begin{aligned} f''(x) &= \frac{(x-1)^2(2x-2)-2(x-1)(x^2-2x)}{(x-1)^4} \\ &= \frac{2(x-1)[(x-1)^2-(x^2-2x)]}{(x-1)^4} \\ &= \frac{2[x^2-2x+1-x^2+2x]}{(x-1)^3} \\ &= \frac{2}{(x-1)^3}. \end{aligned}$$

We see that $f''(x)$ is never zero or undefined for $x$ in the domain of $f$. Since $f$ is undefined at $x=1$, to check concavity we just divide the interval $(-\infty,\infty)$ into the two smaller intervals $(-\infty,1)$ and $(1,\infty)$, and choose a test point from each interval to evaluate the sign of $f''(x)$ in each of these intervals.



**Graph Like a Boss:** When graphing this function by hand, it's best first to plot all the key points ($(0,0)$ and $(2,4)$) as well as the slant asymptote. Once that is done, you can get a good idea of the scale of things. We arrive at the following graph for $f$ from the information gathered.



**? Checkpoint 4.5.4**

Find the oblique asymptote for $f(x)=\frac{3x^3-2x+1}{2x^2-4}$.

**Answer**

$y=\frac{3}{2}x$

**✓ Example 4.5.5**

Sketch a graph of $f(x)=(x-1)^{2/3}$

**Solution**

**Domain:** Since the cube-root function is defined for all real numbers $x$ and $(x-1)^{2/3}=(\sqrt[3]{x-1})^2$, the domain of $f$ is all real numbers.

**Intercepts:** To find the $y$-intercept, evaluate $f(0)$. Since $f(0)=1$, the $y$-intercept is $(0,1)$. To find the $x$-intercept, solve $(x-1)^{2/3}=0$. The solution of this equation is $x=1$, so the $x$-intercept is $(1,0)$.

**Symmetry:** Since

$$\begin{aligned} f(-x) &= (-x-1)^{2/3} \\ &= (x+1)^{2/3} \\ &\neq \pm f(x), \end{aligned}$$

we know that $f$ is neither odd nor even.

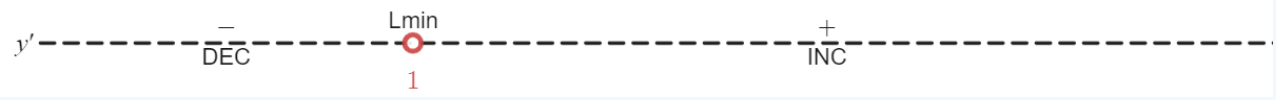
**Vertical Asymptote(s):** The function has no vertical asymptotes.

**End Behavior:** Since $\lim_{x\to\pm\infty}(x-1)^{2/3}=\infty$, the function continues to grow without bound as $x\to\infty$ and $x\to-\infty$.

**First Derivative Information:** To determine where $f$ is increasing or decreasing, calculate $f'$. We find

$$f'(x)=\frac{2}{3}(x-1)^{-1/3}=\frac{2}{3(x-1)^{1/3}}$$

This function is not zero anywhere, but it is undefined when $x=1$. Therefore, the only critical point is $x=1$. Divide the interval $(-\infty,\infty)$ into the smaller intervals $(-\infty,1)$ and $(1,\infty)$, and choose test points in each of these intervals to determine the sign of $f'(x)$ in each of these smaller intervals.



We conclude that $f$ has a local minimum at $x=1$. Evaluating $f$ at $x=1$, we find that the value of $f$ at the local minimum is zero. Note that $f'(1)$ is undefined, so to determine the behavior of the function at this critical point, we need to examine $\lim_{x\to1}f'(x)$. Looking at the one-sided limits, we have

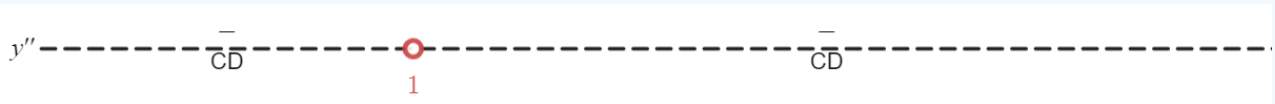
$$\lim_{x\to1^+}\frac{2}{3(x-1)^{1/3}}=\infty \text{ and } \lim_{x\to1^-}\frac{2}{3(x-1)^{1/3}}=-\infty.$$

Therefore, $f$ has a cusp at $x=1$.

**Second Derivative Information:** To determine concavity, we calculate the second derivative of $f$:

$$f''(x)=-\frac{2}{9}(x-1)^{-4/3}=\frac{-2}{9(x-1)^{4/3}}.$$

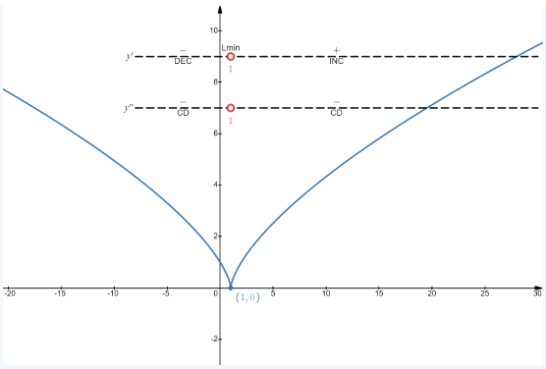
We find that $f''(x)$ is defined for all $x$, but is undefined when $x=1$. Therefore, divide the interval $(-\infty,\infty)$ into the smaller intervals $(-\infty,1)$ and $(1,\infty)$, and choose test points to evaluate the sign of $f''(x)$ in each of these intervals.



We conclude that $f$ is concave down everywhere.

**Graph Like a Boss:**

Combining all this information, we arrive at the following graph for $f$.



**Checkpoint 4.5.5**

Consider the function $f(x) = 5 - x^{2/3}$. Determine the point on the graph where a cusp is located. Determine the end behavior of $f$.

**Answer**

The function $f$ has a cusp at $(0, 5)$, since $\lim_{x \to 0^-} f'(x) = \infty$ and $\lim_{x \to 0^+} f'(x) = -\infty$. For end behavior, $\lim_{x \to \pm\infty} f(x) = -\infty$.

# 4.5E: EXERCISES

This page is a draft and is under active development.

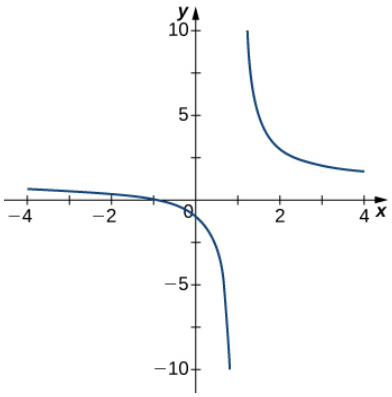
## READING QUESTIONS

1. What is meant by the "end behavior" of a function?
2. List the four types of end behavior a function might exhibit as $x \to \pm\infty$.
3. How is a horizontal asymptote defined using limits?
4. How is a slant (oblique) asymptote $y = mx + b$ defined using limits?
5. For a rational function, under what condition regarding the degrees of the numerator and denominator will it have a slant asymptote? How is the equation of the slant asymptote found?
6. Outline the 8-step "Tactic: Drawing the Graph of a Function."
7. Why is determining the domain of a function listed as the first step in the graphing strategy?
8. How can checking for symmetry (even, odd, or periodic) simplify the graphing process?
9. What Calculus tool is used to determine the behavior of a function near a vertical asymptote?
10. What information does the first derivative $f'(x)$ provide about the graph of $f(x)$?
11. What information does the second derivative $f''(x)$ provide about the graph of $f(x)$?
12. In Example 2 ($R(x) = \frac{x^2}{x^2+1}$), how was the end behavior determined?
13. In Example 5 ($f(x) = (x-1)^{2/3}$), what feature did the graph have at $x = 1$ where $f'(x)$ was undefined?

## HOMEWORK

**For exercises 1 - 5, examine the graphs. Identify where the vertical asymptotes are located.**

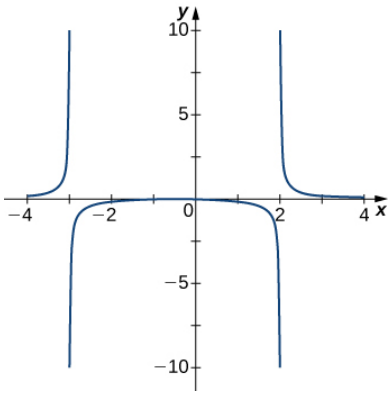
1)



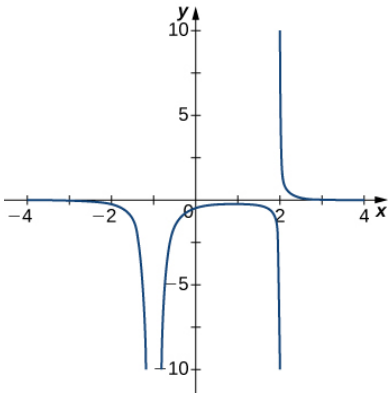
**Answer**

$x = 1$

2)



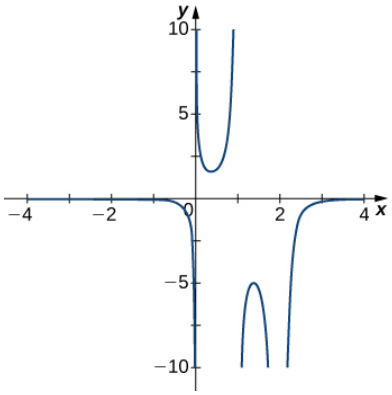
3)



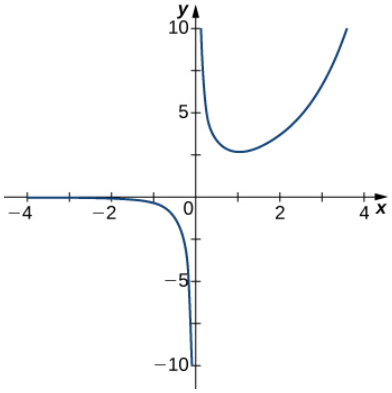
**Answer**

$x = -1,\ x = 2$

4)



5)



**Answer**

$x = 0$

**For the functions $f(x)$ in exercises 6 - 10, determine whether there is an asymptote at $x = a$. Justify your answer without graphing on a calculator.**

6) $f(x) = \dfrac{x+1}{x^2+5x+4},\quad a = -1$

7) $f(x) = \dfrac{x}{x-2},\quad a = 2$

**Answer**

Yes, there is a vertical asymptote at $x = 2$.

8) $f(x) = (x+2)^{3/2}, \quad a = -2$

9) $f(x) = (x-1)^{-1/3}, \quad a = 1$

**Answer**

Yes, there is vertical asymptote at $x = 1$.

10) $f(x) = 1 + x^{-2/5}, \quad a = 1$

**In exercises 11 - 20, evaluate the limit.**

11) $\lim\limits_{x\to\infty} \dfrac{1}{3x+6}$

**Answer**

$\lim\limits_{x\to\infty} \dfrac{1}{3x+6} = 0$

12) $\lim\limits_{x\to\infty} \dfrac{2x-5}{4x}$

13) $\lim\limits_{x\to\infty} \dfrac{x^2-2x+5}{x+2}$

**Answer**

$\lim\limits_{x\to\infty} \dfrac{x^2-2x+5}{x+2} = \infty$

14) $\lim\limits_{x\to-\infty} \dfrac{3x^3-2x}{x^2+2x+8}$

15) $\lim\limits_{x\to-\infty} \dfrac{x^4-4x^3+1}{2-2x^2-7x^4}$

**Answer**

$\lim\limits_{x\to-\infty} \dfrac{x^4-4x^3+1}{2-2x^2-7x^4} = -\dfrac{1}{7}$

16) $\lim\limits_{x\to\infty} \dfrac{3x}{\sqrt{x^2+1}}$

17) $\lim\limits_{x\to-\infty} \dfrac{\sqrt{4x^2-1}}{x+2}$

**Answer**

$\lim\limits_{x\to-\infty} \dfrac{\sqrt{4x^2-1}}{x+2} = -2$

18) $\lim\limits_{x\to\infty} \dfrac{4x}{\sqrt{x^2-1}}$

19) $\lim\limits_{x\to-\infty} \dfrac{4x}{\sqrt{x^2-1}}$

**Answer**

$\lim\limits_{x\to-\infty} \dfrac{4x}{\sqrt{x^2-1}} = -4$

20) $\lim\limits_{x\to\infty} \dfrac{2\sqrt{x}}{x-\sqrt{x}+1}$

**For exercises 21 - 25, find the horizontal and vertical asymptotes.**

21) $f(x) = x - \dfrac{9}{x}$

**Answer**

Horizontal: none,

Vertical: $x = 0$

22) $f(x) = \dfrac{1}{1-x^2}$

23) $f(x) = \dfrac{x^3}{4 - x^2}$

**Answer**

Horizontal: none,
Vertical: $x = \pm 2$

24) $f(x) = \dfrac{x^2 + 3}{x^2 + 1}$

25) $f(x) = \sin(x)\sin(2x)$

**Answer**

Horizontal: none,
Vertical: none

26) $f(x) = \cos x + \cos(3x) + \cos(5x)$

27) $f(x) = \dfrac{x \sin(x)}{x^2 - 1}$

**Answer**

Horizontal: $y = 0$,
Vertical: $x = \pm 1$

28) $f(x) = \dfrac{x}{\sin(x)}$

29) $f(x) = \dfrac{1}{x^3 + x^2}$

**Answer**

Horizontal: $y = 0$,
Vertical: $x = 0$ and $x = -1$

30) $f(x) = \dfrac{1}{x - 1} - 2x$

31) $f(x) = \dfrac{x^3 + 1}{x^3 - 1}$

**Answer**

Horizontal: $y = 1$,
Vertical: $x = 1$

32) $f(x) = \dfrac{\sin x + \cos x}{\sin x - \cos x}$

33) $f(x) = x - \sin x$

**Answer**

Horizontal: none,
Vertical: none

34) $f(x) = \dfrac{1}{x} - \sqrt{x}$

**For exercises 35 - 38, construct a function $f(x)$ that has the given asymptotes.**

35) $x = 1$ and $y = 2$

**Answer**

Answers will vary, for example: $y = \dfrac{2x}{x - 1}$

36) $x = 1$ and $y = 0$

37) $y = 4,\ x = -1$

**Answer**

Answers will vary, for example: $y = \dfrac{4x}{x+1}$

38) $x = 0$

**In exercises 39 - 43, graph the function on a graphing calculator on the window $x = [-5, 5]$ and estimate the horizontal asymptote or limit. Then, calculate the actual horizontal asymptote or limit.**

39) [Technology Required] $f(x) = \dfrac{1}{x+10}$

**Answer**

$\lim\limits_{x\to\infty} \dfrac{1}{x+10} = 0$ so $f$ has a horizontal asymptote of $y = 0$.

40) [Technology Required] $f(x) = \dfrac{x+1}{x^2+7x+6}$

41) [Technology Required] $\lim\limits_{x\to-\infty} x^2+10x+25$

**Answer**

$\lim\limits_{x\to-\infty} x^2+10x+25 = \infty$

42) [Technology Required] $\lim\limits_{x\to-\infty} \dfrac{x+2}{x^2+7x+6}$

43) [Technology Required] $\lim\limits_{x\to\infty} \dfrac{3x+2}{x+5}$

**Answer**

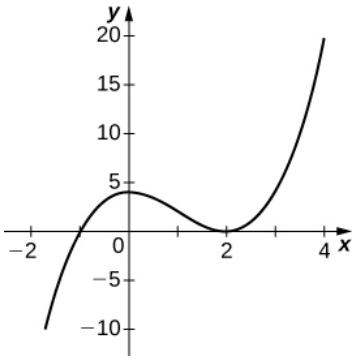
$\lim\limits_{x\to\infty} \dfrac{3x+2}{x+5} = 3$ so this function has a horizontal asymptote of $y = 3$.

**In exercises 44 - 55, draw a graph of the functions without using a calculator. Be sure to notice all important features of the graph: local maxima and minima, inflection points, and asymptotic behavior.**

44) $y = 3x^2 + 2x + 4$

45) $y = x^3 - 3x^2 + 4$

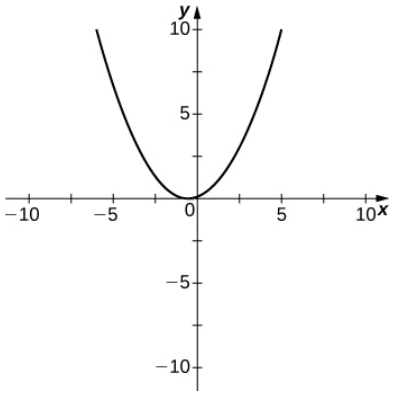
**Answer**



46) $y = \dfrac{2x+1}{x^2+6x+5}$

47) $y = \dfrac{x^3+4x^2+3x}{3x+9}$

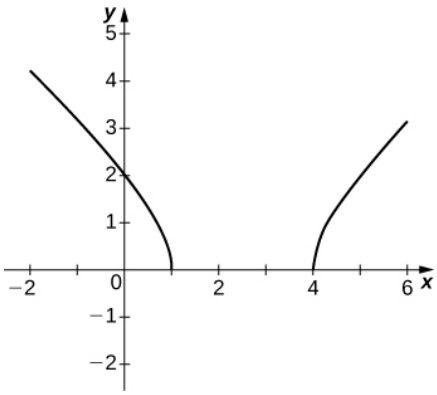
**Answer**



48) $y = \dfrac{x^2 + x - 2}{x^2 - 3x - 4}$

49) $y = \sqrt{x^2 - 5x + 4}$

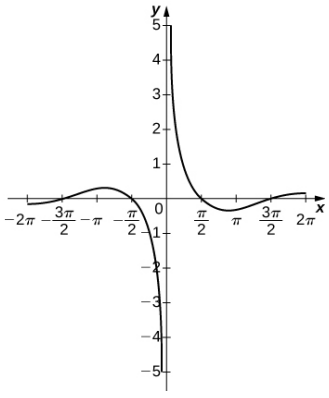
**Answer**



50) $y = 2x\sqrt{16 - x^2}$

51) $y = \dfrac{\cos x}{x}$, on $x = [-2\pi, 2\pi]$

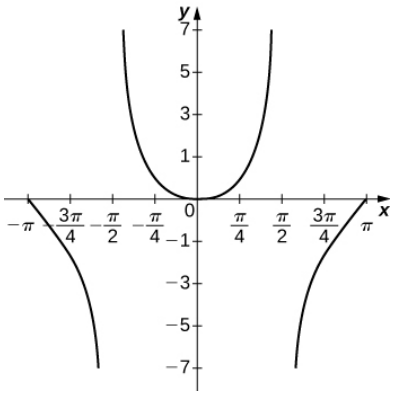
**Answer**



52) $y = e^x - x^3$

53) $y = x \tan x, \quad x = [-\pi, \pi]$

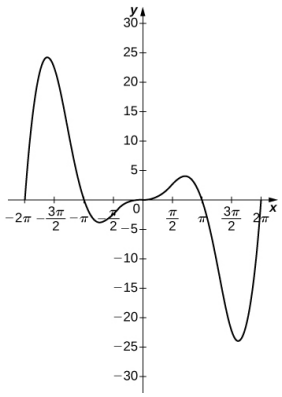
**Answer**



54) $y = x\ln(x), \quad x > 0$

55) $y = x^2\sin(x), \quad x = [-2\pi, 2\pi]$

**Answer**



56) For $f(x) = \dfrac{P(x)}{Q(x)}$ to have an asymptote at $y = 2$ then the polynomials $P(x)$ and $Q(x)$ must have what relation?

57) For $f(x) = \dfrac{P(x)}{Q(x)}$ to have an asymptote at $x = 0$, then the polynomials $P(x)$ and $Q(x)$. must have what relation?

**Answer**

$Q(x)$. must have have $x^{k+1}$ as a factor, where $P(x)$ has $x^k$ as a factor.

58) If $f'(x)$ has asymptotes at $y = 3$ and $x = 1$, then $f(x)$ has what asymptotes?

59) Both $f(x) = \dfrac{1}{x-1}$ and $g(x) = \dfrac{1}{(x-1)^2}$ have asymptotes at $x = 1$ and $y = 0$. What is the most obvious difference between these two functions?

**Answer**

$\lim\limits_{x\to 1^-} f(x) = -\infty$ and $\lim\limits_{x\to 1^-} g(x) = \infty$

60) True or false: Every ratio of polynomials has vertical asymptotes.

# 4.6: Optimization

**Learning Objectives**

- Use the Problem Solving Process to set up and solve optimization problems in several applied fields.

Hawk A.I. Section-Specific Tutor

Please note that, to access the Hawk A.I. Tutor, you will need a (free) OpenAI account.

One common application of Calculus is calculating a function's minimum or maximum value. For example, companies often want to minimize production costs or maximize revenue. In manufacturing, minimizing the amount of material used to package a product with a certain volume is often desirable. In this section, we show how to set up these minimization and maximization problems and solve them using the tools developed in this chapter.

## Solving Optimization Problems over a Closed, Bounded Interval

The basic idea of the optimization problems that follow is the same - we have a particular quantity that we are interested in maximizing or minimizing. However, we also have some auxiliary conditions that need to be satisfied. For example, in Example **4.6.1**, we are interested in maximizing the area of a rectangular garden. Certainly, if we keep making the side lengths of the garden larger, the area will continue to become larger. However, what if we restrict how much fencing we can use for the perimeter? In this case, we cannot make the garden as large as we like. Let's look at how we can maximize the area of a rectangle subject to some constraint on the perimeter.

**Example 4.6.1**

A rectangular garden is to be constructed using a rock wall on one side of the garden and wire fencing for the other three sides (Figure **4.6.1**). Given $100\,\text{ft}$ of wire fencing, determine the dimensions that would create a garden of maximum area. What is the maximum area?

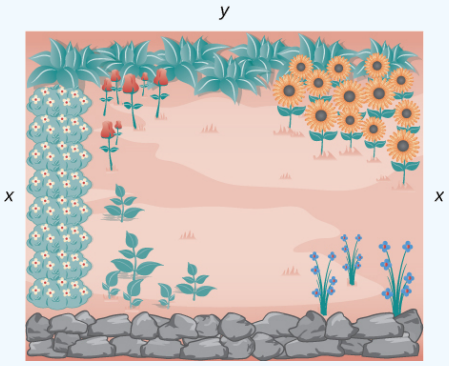


*Figure* **4.6.1***: We want to determine the measurements* $x$ *and* $y$ *that will create a garden with a maximum area using* $100\,\text{ft}$ *of fencing.*

**Solution**

Let $x$ denote the length of the side of the garden perpendicular to the rock wall and $y$ denote the length of the side parallel to the rock wall. Then the area of the garden is

$$A = x \cdot y.$$

We want to find the maximum possible area subject to the constraint that the total fencing is $100\,\text{ft}$. From Figure **4.6.1**, the total amount of fencing used will be $2x + y$. Therefore, the constraint equation is

$$2x + y = 100.$$

Solving this equation for $y$, we have $y = 100 - 2x$. Thus, we can write the area as

$$A(x) = x \cdot (100 - 2x) = 100x - 2x^2.$$

Before trying to maximize the area function $A(x) = 100x - 2x^2$, we need to determine the domain under consideration. To construct a rectangular garden, we certainly need the lengths of both sides to be positive. Therefore, we need $x > 0$ and $y > 0$. Since $y = 100 - 2x$, if $y > 0$, then $x < 50$. Therefore, we are trying to determine the maximum value of $A(x)$ for $x$ over the open interval $(0, 50)$. We do not know that a function necessarily has a maximum value over an open interval. However, we know a continuous function has an absolute maximum (and absolute minimum) over a closed interval. Therefore, let's consider the function $A(x) = 100x - 2x^2$ over the closed interval $[0, 50]$. Suppose the maximum value occurs at an interior point. In that case, we have found the value $x$ in the open interval $(0, 50)$ that maximizes the area of the garden.

Therefore, we consider the following problem:

Maximize $A(x) = 100x - 2x^2$ over the interval $[0, 50]$.

As mentioned earlier, since $A$ is a continuous function on a closed, bounded interval, by the Extreme Value Theorem, it has a maximum and a minimum. These extreme values occur either at endpoints or critical points. At the endpoints, $A(x) = 0$. Since the area is positive for all $x$ in the open interval $(0, 50)$, the maximum must occur at a critical point. Differentiating the function $A(x)$, we obtain

$$A'(x) = 100 - 4x.$$

Therefore, the only critical point is $x = 25$ (Figure 4.6.2). We conclude that the maximum area must occur when $x = 25$.

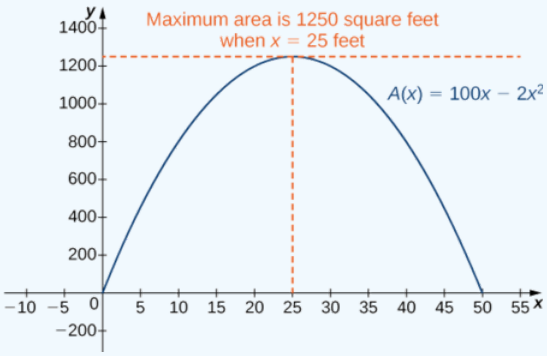

*Figure 4.6.2: To maximize the area of the garden, we need to find the maximum value of the function $A(x) = 100x - 2x^2$.*

Then we have $y = 100 - 2x = 100 - 2(25) = 50$. To maximize the area of the garden, let $x = 25$ ft and $y = 50$ ft. The area of this garden is $1250\,\text{ft}^2$.

## ? Checkpoint 4.6.1

Determine the maximum area if we want to make the same rectangular garden as in Figure 4.6.2, but we have $200$ ft of fencing.

**Answer**

The maximum area is $5000\,\text{ft}^2$.

Now let's look at a general strategy for solving optimization problems similar to Example 4.6.1.

While memorizing procedures is the absolute worst way to enjoy Mathematics, applications (also known as "word problems") tend to confound students so much that it is beneficial to develop a procedure for solving them. We will borrow the strategy we used from the Related Rates material.

### Polya's Modified Problem-Solving Process

1. **Read** the given problem.
2. **Understand** the given problem. This might require you to rephrase the problem in terms that you can understand or, more commonly, to draw a picture of the situation.
3. **Label** unknowns. All problems presented in mathematics have unknown quantities. In this step, you take the time to label these unknowns using variables. This step is often combined with the previous step (especially when drawing pictures).
4. **Identify** what needs to be optimized (e.g., area, cost, profit, angle, etc.).
5. Create a **Master Equation** for the quantity to be optimized. This is a critical step in all problem-solving processes involving Polya's method.
   **Warning:** The Master Equation should be a relation between two variables (the variable to be optimized and one other). If your Master Equation has more than two variables, you need to find a relation between the excess variables to reduce the number of final variables in your Master Equation to two.
6. Unlike in the Related Rates material, it will be useful in this step to identify the **realistic domain** for your Master Equation. If the realistic domain is a closed and bounded interval, we can invoke the Extreme Value Theorem. In Example 4.6.6, we show what to do if the realistic domain is unbounded or open.
7. **Optimize** by locating the absolute maximum or minimum value of the Master Equation on the *realistic* domain.

Now let's apply this strategy to maximize the volume of an open-top box given a constraint on the amount of material to be used.

### Example 4.6.2

An open-top box is to be made from a $24$ in. by $36$ in. piece of cardboard by removing a square from each corner of the box and folding up the flaps on each side. What size square should be cut out of each corner to get a box with the maximum volume?

**Solution**

**Read:** Just as in the Related Rates material, I include this step so you have a "win."

**Understand and Label:** Drawing a picture of the situation (and appropriately labeling things), we let $x$ be the side length of the square to be removed from each corner (Figure 4.6.3). Then, the remaining four flaps can be folded to form an open-top box. Let $V$ be the volume of the resulting box.

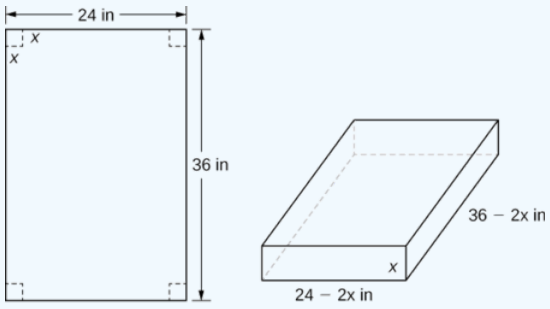

*Figure 4.6.3: A square with side length $x$ inches is removed from each corner of the piece of cardboard. The remaining flaps are folded to form an open-top box.*

**Identify:** We are trying to maximize the volume of a box. Therefore, the problem is to maximize $V$.

**Master Equation:** The volume of a box is

$$V = L \cdot W \cdot H,$$

where $L$, $W$, and $H$ are the length, width, and height, respectively. From our drawing, this means

$$L = 36 - 2x, W = 24 - 2x, \text{ and } H = x.$$

Therefore,

$$V = (36 - 2x)(24 - 2x)x.$$

**Realistic Domain:** To determine the domain of consideration, let's examine Figure 4.6.3. Certainly, we need $x > 0$. Furthermore, the square's side length must be less than half the length of the shorter side, 24 in.; otherwise, one of the flaps would be completely cut off. Therefore, we are trying to determine whether there is a maximum volume of the box for $x$ over the open interval $(0, 12)$. Since $V$ is a continuous function over the closed interval $[0, 12]$, we know $V$ will have an absolute maximum over the closed interval. Therefore, we consider $V$ over the closed interval $[0, 12]$ and check whether the absolute maximum occurs at an interior point.

**Optimize:** Since $V(x)$ is a continuous function over the closed, bounded interval $[0, 12]$, $V$ must have an absolute maximum (and an absolute minimum). Since $V(x) = 0$ at the endpoints and $V(x) > 0$ for $0 < x < 12$, the maximum must occur at a critical point. Moreover,

$$V(x) = 4x^3 - 120x^2 + 864x$$

implies

$$V'(x) = 12x^2 - 240x + 864.$$

To find the critical points, we need to solve the equation

$$12x^2 - 240x + 864 = 0.$$

Dividing both sides of this equation by 12, the problem simplifies to solving the equation

$$x^2 - 20x + 72 = 0.$$

Using the Quadratic Formula, we find that the critical points are

$$\begin{aligned} x &= \frac{20 \pm \sqrt{(-20)^2 - 4(1)(72)}}{2} \\ &= \frac{20 \pm \sqrt{112}}{2} \\ &= \frac{20 \pm 4\sqrt{7}}{2} \\ &= 10 \pm 2\sqrt{7} \end{aligned}$$

Since $10 + 2\sqrt{7}$ is not in the domain of consideration, the only critical point we need to consider is $10 - 2\sqrt{7}$. To verify this critical point is a maximum, we quickly compute

$$V''(x) = 24x - 240$$

and see that $V''(10 - 2\sqrt{7}) = -48\sqrt{7} < 0$. Thus, the continuous function is concave down at this critical point. Therefore, the volume is maximized if we let $x = 10 - 2\sqrt{7}$ in. The maximum volume is

$$V(10 - 2\sqrt{7}) = 640 + 448\sqrt{7} \approx 1825 \text{ in}^3.$$

as shown in the following graph.

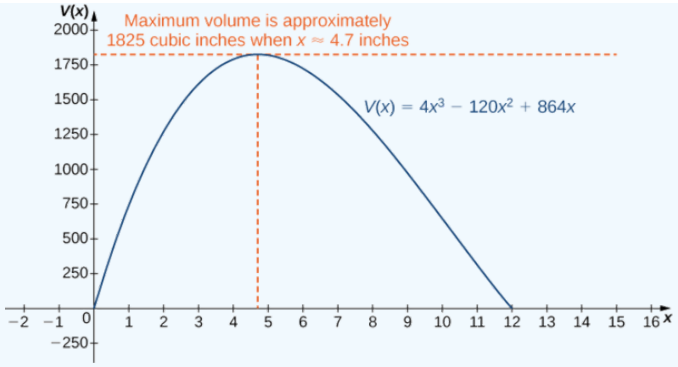

*Figure* **4.6.4***: Maximizing the box's volume leads to finding the maximum value of a cubic polynomial.*

## Checkpoint 4.6.2

Suppose the dimensions of the cardboard in Example **4.6.2** are **20 in.** by **30 in.** Let $x$ be the side length of each square and write the volume of the open-top box as a function of $x$. Determine the domain of consideration for $x$.

**Answer**

$V(x) = x(20 - 2x)(30 - 2x)$. The domain is $[0, 10]$.

## Example 4.6.3

An island is **2** mi due north of its closest point along a straight shoreline. A visitor stays at a cabin on the shore that is **6** mi west of that point. The visitor is planning to go from the cabin to the island. Suppose the visitor runs at a **8** mph rate and swims at a **3** mph rate. How far should the visitor run before swimming to minimize the time it takes to reach the island?

**Solution**

**Read, Understand, and Label:** Let $x$ be the distance running and let $y$ be the distance swimming (Figure **4.6.5**). Let $T$ be the time it takes to get from the cabin to the island.

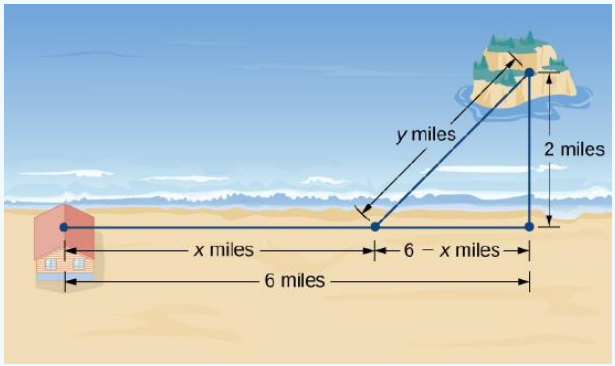

*Figure* **4.6.5***: How can we choose $x$ and $y$ to minimize the travel time from the cabin to the island?*

**Identify:** The problem is to minimize the total time it takes to reach the island, $T$.

**Master Equation:** To find the time spent traveling from the cabin to the island, add the time spent running and the time spent swimming. Since Distance = Rate \times Time ($D = R \times T$), the time spent running is

$$T_{running} = \frac{D_{running}}{R_{running}} = \frac{x}{8},$$

and the time spent swimming is

$$T_{swimming} = \frac{D_{swimming}}{R_{swimming}} = \frac{y}{3}.$$

Therefore, the total time spent traveling is

$$T = \frac{x}{8} + \frac{y}{3}.$$

From Figure 4.6.5, the line segment of $y$ miles forms the hypotenuse of a right triangle with legs of length 2 mi and $6 - x$ mi. Therefore, by the Pythagorean Theorem, $2^2 + (6-x)^2 = y^2$, and we obtain $y = \sqrt{(6-x)^2 + 4}$. Thus, the total time spent traveling is given by the function

$$T(x) = \frac{x}{8} + \frac{\sqrt{(6-x)^2+4}}{3}.$$

**Realistic Domain:** From Figure 4.6.5, we see that $0 \le x \le 6$. Therefore, $[0, 6]$ is the domain of consideration.

**Optimize:** Since $T(x)$ is a continuous function over a closed, bounded interval, it has a maximum and a minimum. Let's begin by looking for any critical points of $T$ over the interval $[0, 6]$. The derivative is

$$\begin{aligned} T'(x) &= \frac{1}{8} - \frac{1}{2}\frac{[(6-x)^2+4]^{-1/2}}{3} \cdot 2(6-x) \\ &= \frac{1}{8} - \frac{(6-x)}{3\sqrt{(6-x)^2+4}} \end{aligned}$$

If $T'(x) = 0$, then

$$\frac{1}{8} = \frac{6-x}{3\sqrt{(6-x)^2+4}} \tag{4.6.1}$$

Therefore,

$$3\sqrt{(6-x)^2+4} = 8(6-x). \tag{4.6.2}$$

Squaring both sides of this equation, we see that if $x$ satisfies this equation, then $x$ must satisfy

$$9[(6-x)^2+4] = 64(6-x)^2,$$

which implies

$$55(6-x)^2 = 36.$$

We conclude that if $x$ is a critical point, then $x$ satisfies

$$(x-6)^2 = \frac{36}{55}.$$

[Note that since we are squaring, $(x-6)^2 = (6-x)^2$.]

Therefore, the possibilities for critical points are

$$x = 6 \pm \frac{6}{\sqrt{55}}.$$

Since $x = 6 + 6/\sqrt{55}$ is not in the domain, it is not a possibility for a critical point. On the other hand, $x = 6 - 6/\sqrt{55}$ is in the domain. Since we squared both sides of Equation 4.6.2 to arrive at the possible critical points, it remains to verify that $x = 6 - 6/\sqrt{55}$ satisfies Equation 4.6.1. Since $x = 6 - 6/\sqrt{55}$ does satisfy that equation, we conclude that $x = 6 - 6/\sqrt{55}$ is a critical point, and it is the only one. To justify that the time is minimized for this value of $x$, we need to check the values of $T(x)$ at the endpoints $x = 0$ and $x = 6$ and compare them with the value of $T(x)$ at the critical point $x = 6 - 6/\sqrt{55}$. We find that $T(0) \approx 2.108\,\text{h}$ and $T(6) \approx 1.417\,\text{h}$, whereas

$$T(6 - 6/\sqrt{55}) \approx 1.368\,\text{h}.$$

Therefore, we conclude that $T$ has a local minimum at $x \approx 5.19$ mi.

**Checkpoint 4.6.3**

Suppose the island is $1$ mi from shore, and the distance from the cabin to the point on the shore closest to the island is $15$ mi. Suppose a visitor swims at the $2.5$ mph rate and runs at a $6$ mph rate. Let $x$ denote the distance the visitor will run before swimming, and find a function for the time it takes the visitor to get from the cabin to the island.

**Answer**

$T(x) = \frac{x}{6} + \frac{\sqrt{(15-x)^2+1}}{2.5}$

In business, companies are interested in **maximizing revenue.** In the following example, we consider a scenario in which a company has collected data on how many cars it can lease, depending on the price it charges its customers to rent a car. Let's use these data to determine the price the company should charge to maximize the amount of money it brings in.

**Example 4.6.4**

Owners of a car rental company have determined that if they charge customers $p$ dollars per day to rent a car, where $50 \le p \le 200$, the number of cars $n$ they rent per day can be modeled by the linear function $n(p) = 1000 - 5p$. They will rent all their cars if they charge $\$50$ per day or less. They will not rent cars if they charge $\$200$ per day or more. Assuming the owners plan to charge customers between $\$50$ per day and $\$200$ per day to rent a car, how much should they charge to maximize their revenue?

**Solution**

**Read, Understand, and Label:** There is not really a point in drawing anything. Let $p$ be the price charged per car per day, and let $n$ be the number of cars rented daily. Let $R$ be the revenue per day.

**Identify:** The problem is to maximize $R$.

**Master Equation:** The revenue (per day) is equal to the number of cars rented per day times the price charged per car per day—that is, $R = n \times p$.

Since the number of cars rented per day is modeled by the linear function $n(p) = 1000 - 5p$, the revenue $R$ can be represented by the function

$$\begin{aligned} R(p) &= n \times p \\ &= (1000 - 5p)p \\ &= -5p^2 + 1000p. \end{aligned}$$

**Realistic Domain:** Since the owners plan to charge between $\$50$ per car per day and $\$200$ per car per day, the problem is to find the maximum revenue $R(p)$ for $p$ in the closed interval $[50, 200]$.

**Optimize:** Since $R$ is a continuous function over the closed, bounded interval $[50, 200]$, it has an absolute maximum (and an absolute minimum) in that interval. To find the maximum value, look for critical points. The derivative is $R'(p) = -10p + 1000$. Therefore, the critical point is $p = 100$. When $p = 100, R(100) = \$50,000$. When $p = 50, R(p) = \$37,500$. When $p = 200, R(p) = \$0$.

Therefore, the absolute maximum occurs at $p = \$100$. The car rental company should charge $\$100$ per day per car to maximize revenue, as shown in the following figure.

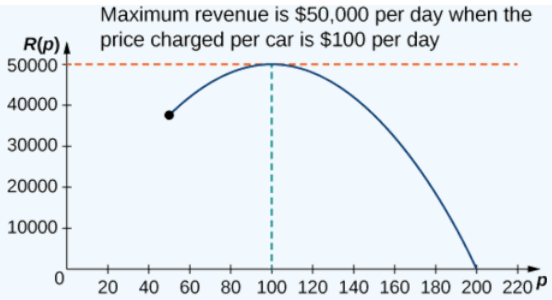

*Figure* **4.6.6***: To maximize revenue, a car rental company has to balance the rental price against the number of cars people will rent at that price.*

## ? Checkpoint 4.6.4

A car rental company charges its customers $p$ dollars per day, where $60 \le p \le 150$. They determine that the number of cars rented per day can be modeled by the linear function $n(p) = 750 - 5p$. How much should the company charge each customer to maximize revenue?

**Answer**

The company should charge $75 per car per day.

## ✔ Example 4.6.5

A rectangle is to be inscribed in the ellipse

$$\frac{x^2}{4} + y^2 = 1.$$

What should the rectangle's dimensions be to maximize its area? What is the maximum area?

**Solution**

**Read, Understand, and Label:** For a rectangle to be inscribed in the ellipse, the sides of the rectangle must be parallel to the axes. Let $L$ be the length of the rectangle and $W$ be its width. Let $A$ be the area of the rectangle.

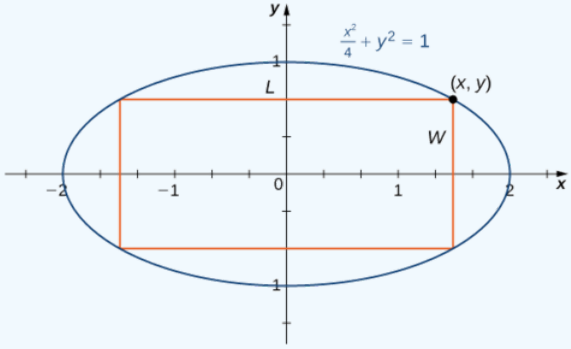

*Figure* **4.6.7***: We want to maximize the area of a rectangle inscribed in an ellipse.*

**Identify:** The problem is to maximize $A$.

**Master Equation:** The area of the rectangle is $A = LW$.

Let $(x, y)$ be the corner of the rectangle that lies in the first quadrant, as shown in Figure 4.6.7. We can write length $L = 2x$ and width $W = 2y$. Since $\frac{x^2}{4} + y^2 = 1$ and $y > 0$, we have $y = \sqrt{1 - \frac{x^2}{4}}$. Therefore, the area is

$$A = LW = (2x)(2y) = 4x\sqrt{1 - \frac{x^2}{4}} = 2x\sqrt{4 - x^2}$$

**Realistic Domain:** From Figure 4.6.7, we see that to inscribe a rectangle in the ellipse, the $x$-coordinate of the corner in the first quadrant must satisfy $0 < x < 2$. Therefore, the problem reduces to looking for the maximum value of $A(x)$ over the open interval $(0, 2)$. Since $A(x)$ will have an absolute maximum (and absolute minimum) over the closed interval $[0, 2]$, we consider $A(x) = 2x\sqrt{4 - x^2}$ over the interval $[0, 2]$. If the absolute maximum occurs at an interior point, we have found an absolute maximum in the open interval.

**Optimize:** As mentioned earlier, $A(x)$ is a continuous function over the closed, bounded interval $[0, 2]$. Therefore, it has an absolute maximum (and absolute minimum). At the endpoints $x = 0$ and $x = 2$, $A(x) = 0$. For $0 < x < 2$, $A(x) > 0$.

Therefore, the maximum must occur at a critical point. Taking the derivative of $A(x)$, we obtain

$$\begin{aligned} A'(x) &= 2\sqrt{4 - x^2} + 2x \cdot \frac{1}{2\sqrt{4 - x^2}}(-2x) \\ &= 2\sqrt{4 - x^2} - \frac{2x^2}{\sqrt{4 - x^2}} \\ &= \frac{8 - 4x^2}{\sqrt{4 - x^2}}. \end{aligned}$$

To find critical points, we need to find where $A'(x) = 0$. We can see that if $x$ is a solution of

$$\frac{8 - 4x^2}{\sqrt{4 - x^2}} = 0, \tag{4.6.3}$$

then $x$ must satisfy

$$8 - 4x^2 = 0.$$

Therefore, $x^2 = 2$. Thus, $x = \pm\sqrt{2}$ are the possible solutions of Equation 4.6.3. Since we are considering $x$ over the interval $[0, 2]$, $x = \sqrt{2}$ is a possibility for a critical point, but $x = -\sqrt{2}$ is not. Therefore, we check whether $\sqrt{2}$ is a solution of Equation 4.6.3. Since $x = \sqrt{2}$ is a solution of Equation 4.6.3, we conclude that $\sqrt{2}$ is the only critical point of $A(x)$ in the interval $[0, 2]$.

Therefore, $A(x)$ must have an absolute maximum at the critical point $x = \sqrt{2}$. To determine the rectangle's dimensions, we need to find the length $L$ and the width $W$. If $x = \sqrt{2}$ then

$$y = \sqrt{1 - \frac{(\sqrt{2})^2}{4}} = \sqrt{1 - \frac{1}{2}} = \frac{1}{\sqrt{2}}.$$

Therefore, the dimensions of the rectangle are $L = 2x = 2\sqrt{2}$ and $W = 2y = \frac{2}{\sqrt{2}} = \sqrt{2}$. The area of this rectangle is $A = LW = (2\sqrt{2})(\sqrt{2}) = 4$.

**? Checkpoint 4.6.5**

Modify the area function $A$ if the rectangle is to be inscribed in the unit circle $x^2 + y^2 = 1$. What is the domain of consideration?

**Answer**

$A(x) = 4x\sqrt{1 - x^2}$. The domain of consideration is $[0, 1]$.

## Solving Optimization Problems when the Interval Is Not Closed or Is Unbounded

In the previous examples, we considered functions on closed, bounded domains. Consequently, by the Extreme Value Theorem, we were guaranteed that the functions had absolute extrema. Let's now consider functions for which the domain is neither closed nor bounded.

Many functions still have at least one absolute extrema, even if the domain is not closed or unbounded. For example, the function $f(x) = x^2 + 4$ over $(-\infty, \infty)$ has an absolute minimum of 4 at $x = 0$. Therefore, we can still consider functions over unbounded

domains or open intervals and determine whether they have absolute extrema. In the next example, we try to minimize a function over an unbounded domain. Although the domain of consideration is $(0, \infty)$, the function has an absolute minimum.

In the following example, we look at constructing a box of least surface area with a prescribed volume. It is not difficult to show that for a closed-top box, by symmetry, among all boxes with a specified volume, a cube will have the smallest surface area. Consequently, we consider the modified problem of determining which open-topped box with a specified volume has the smallest surface area.

### Example 4.6.6

A rectangular box with a square base, an open top, and a volume of $216\,\text{in}^3$ is to be constructed. What should the dimensions of the box be to minimize the surface area of the box? What is the minimum surface area?

**Solution**

**Read, Understand, and Label:** Draw a rectangular box and introduce the variable $x$ to represent the length of each side of the square base; let $y$ represent the height of the box. Let $S$ denote the surface area of the open-top box.

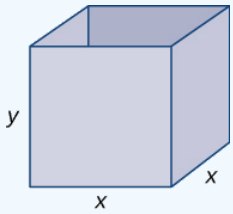

*Figure 4.6.8: We want to minimize the surface area of a square-based box with a given volume.*

**Identify:** We need to minimize the surface area. Therefore, we need to minimize $S$.

**Master Equation:** Since the box has an open top, we need only determine the area of the four vertical sides and the base. The area of each of the four vertical sides is $x \cdot y$. The area of the base is $x^2$. Therefore, the surface area of the box is

$$S = 4xy + x^2.$$

Since the volume of this box is $x^2y$ and the volume is given as $216\,\text{in}^3$, the constraint equation is

$$x^2y = 216.$$

Solving the constraint equation for $y$, we have $y = \frac{216}{x^2}$. Therefore, we can write the surface area as a function of $x$ only:

$$S(x) = 4x\left(\frac{216}{x^2}\right) + x^2.$$

Therefore, $S(x) = \frac{864}{x} + x^2$.

**Realistic Domain:** Since we are requiring that $x^2y = 216$, we cannot have $x = 0$. Therefore, we need $x > 0$. On the other hand, $x$ is allowed to have any positive value. Note that as $x$ becomes large, the height of the box $y$ becomes correspondingly small so that $x^2y = 216$. Similarly, as $x$ becomes small, the height of the box becomes correspondingly large. We conclude that the domain is the open, unbounded interval $(0, \infty)$. Unlike the previous examples, we cannot reduce our problem to looking for an absolute maximum or minimum over a closed, bounded interval. However, in the next step, we discover why this function must have an absolute minimum over the interval $(0, \infty)$.

**Optimize:** Note that as $x \to 0^+$, $S(x) \to \infty$. Also, as $x \to \infty$, $S(x) \to \infty$. Since $S$ is a continuous function that approaches infinity at the ends, it must have an absolute minimum at some $x \in (0, \infty)$. This minimum must occur at a critical point of $S$. The derivative is

$$S'(x) = -\frac{864}{x^2} + 2x.$$

Therefore, $S'(x) = 0$ when $2x = \frac{864}{x^2}$. Solving this equation for $x$, we obtain $x^3 = 432$, so $x = \sqrt[3]{432} = 6\sqrt[3]{2}$. Since this is the only critical point of $S$, the absolute minimum must occur at $x = 6\sqrt[3]{2}$ (see Figure 4.6.9).

When $x = 6\sqrt[3]{2}$, $y = \frac{216}{(6\sqrt[3]{2})^2} = 3\sqrt[3]{2}$ in. Therefore, the dimensions of the box should be $x = 6\sqrt[3]{2}$ in. and $y = 3\sqrt[3]{2}$ in. With these dimensions, the surface area is

$$S(6\sqrt[3]{2}) = \frac{864}{6\sqrt[3]{2}} + (6\sqrt[3]{2})^2 = 108\sqrt[3]{4}\,\text{in}^2$$

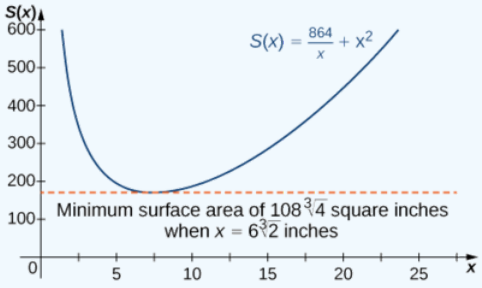

*Figure* **4.6.9***: We can use a graph to determine the dimensions of a box given the volume and the minimum surface area.*

## ? Checkpoint 4.6.6

Consider the same open-top box, which is to have volume $216\,\text{in}^3$. Suppose the cost of the material for the base is $20¢/\text{in}^2$ and the cost of the material for the sides is $30¢/\text{in}^2$, and we are trying to minimize the cost of this box. Write the cost as a function of the side lengths of the base. (Let $x$ be the side length of the base and $y$ be the height of the box.)

**Answer**

$c(x) = \frac{259.2}{x} + 0.2x^2$ dollars

# 5.1: Antiderivatives and Indefinite Integrals

**Learning Objectives**

- Find the general antiderivative of a given function.
- Explain the terms and notation used for an indefinite integral.
- State the Power Rule for integrals.
- Use antidifferentiation to solve simple initial-value problems.

Hawk A.I. Section-Specific Tutor

Please note that, to access the Hawk A.I. Tutor, you will need a (free) OpenAI account.

At this point, we have seen how to calculate derivatives of many functions and have been introduced to a variety of their applications. We now ask a question that turns this process around: Given a function $f$, how do we find a function with the derivative $f$, and why would we be interested in such a function?

We answer the first part of this question by defining antiderivatives. An **antiderivative** of a function $f$ is a function whose derivative is $f$. The need for antiderivatives arises in many situations, and we look at various examples throughout the remainder of the text. Here, we examine one specific example that involves rectilinear motion.

In our examination of derivatives, we showed that given a position function, $s(t)$, of an object, its velocity function, $v(t)$, is the derivative of $s(t)$. That is, $v(t) = s'(t)$. Furthermore, the acceleration, $a(t)$, is the derivative of the velocity $v(t)$. That is, $a(t) = v'(t) = s''(t)$. Now, suppose we are given an acceleration function $a$ but not the velocity function $v$ or the position function $s$. Since $a(t) = v'(t)$, determining the velocity function requires us to find an antiderivative of the acceleration function. Since $v(t) = s'(t)$, determining the position function requires us to find an antiderivative of the velocity function.

Rectilinear motion is just one case where the need for antiderivatives arises. We will see many more examples throughout the remainder of the text. Let's look at the terminology and notation for antiderivatives and determine the antiderivatives for several functions. We examine techniques for finding antiderivatives of more complicated functions later in the text.

## The Reverse of Differentiation

At this point, we know how to find derivatives of various functions. We now ask the opposite question. Given a function $f$, how can we find a function with derivative $f$? If we can find a function $F$ with derivative $f$, we call $F$ an **antiderivative** of $f$.

**Definition: Antiderivative**

A function $F$ is an **antiderivative** of the function $f$ if

$$F'(x) = f(x)$$

for all $x$ in the domain of $f$.

Consider the function $f(x) = 2x$. Knowing the Power Rule of differentiation, we conclude that $F(x) = x^2$ is an antiderivative of $f$ since $F'(x) = 2x$.

Are there any other antiderivatives of $f$?

Yes; since the derivative of any constant $C$ is zero, $x^2 + C$ is also an antiderivative of $2x$. Therefore, $x^2 + 5$ and $x^2 - \sqrt{2}$ are also antiderivatives of $f(x) = 2x$.

Are there any others that are not of the form $x^2 + C$ for some constant $C$?

The answer is no. From the corollary following the Mean Value Theorem, we know that if $F$ and $G$ are differentiable functions such that $F'(x) = G'(x)$, then $F(x) - G(x) = C$ for some constant $C$. This fact leads to the following important theorem.

### Theorem: General Form of an Antiderivative

Let $F$ be an antiderivative of $f$ over an interval $I$. Then,

I. for each constant $C$, the function $F(x) + C$ is also an antiderivative of $f$ over $I$;
II. if $G$ is an antiderivative of $f$ over $I$, there is a constant $C$ for which $G(x) = F(x) + C$ over $I$.

In other words, the most general form of the antiderivative of $f$ over $I$ is $F(x) + C$.

We use this fact and our knowledge of derivatives to find all the antiderivatives for several functions.

### Example 5.1.1: Finding Antiderivatives

For each of the following functions, find all antiderivatives.

a. $f(x) = 3x^2$
b. $f(x) = \frac{1}{x}$
c. $f(x) = \cos x$
d. $f(x) = e^x$

**Solutions**

a. Because

$$\frac{d}{dx}\left(x^3\right) = 3x^2,$$

$F(x) = x^3$ is an antiderivative of $3x^2$. Therefore, every antiderivative of $3x^2$ is of the form $x^3 + C$ for some constant $C$, and every function of the form $x^3 + C$ is an antiderivative of $3x^2$.

b. Let $f(x) = \ln|x|$. For $x > 0,\ f(x) = \ln|x| = \ln(x)$ and

$$\frac{d}{dx}(\ln x) = \frac{1}{x}.$$

For $x < 0,\ f(x) = \ln|x| = \ln(-x)$ and

$$\frac{d}{dx}(\ln(-x)) = -\frac{1}{-x} = \frac{1}{x}.$$

Therefore,

$$\frac{d}{dx}(\ln|x|) = \frac{1}{x}.$$

Thus, $F(x) = \ln|x|$ is an antiderivative of $\frac{1}{x}$. Therefore, every antiderivative of $\frac{1}{x}$ is of the form $\ln|x| + C$ for some constant $C$ and every function of the form $\ln|x| + C$ is an antiderivative of $\frac{1}{x}$.

c. We have

$$\frac{d}{dx}(\sin x) = \cos x,$$

so $F(x) = \sin x$ is an antiderivative of $\cos x$. Therefore, every antiderivative of $\cos x$ is of the form $\sin x + C$ for some constant $C$ and every function of the form $\sin x + C$ is an antiderivative of $\cos x$.

d. Since

$$\frac{d}{dx}\left(e^x\right) = e^x,$$

then $F(x) = e^x$ is an antiderivative of $e^x$. Therefore, every antiderivative of $e^x$ is of the form $e^x + C$ for some constant $C$ and every function of the form $e^x + C$ is an antiderivative of $e^x$.

### Note: Breaks in the Domain and Our Choice of $C$

Consider the function $f(x) = \frac{1}{x}$. In Example 5.1.1*b*, we claimed that the antiderivative of $f(x)$ was $F(x) = \ln(|x|) + C$. In truth, however, because $F(x)$ has breaks in its domain, this antiderivative *could* technically be written as

$$F(x) = \begin{cases} \ln(x) + C_1, & \text{if } x > 0 \\ \ln(-x) + C_2, & \text{if } x < 0 \end{cases}$$

Likewise, if we consider the antiderivative of $g(x) = -\csc^2(x)$, rather than writing $G(x) = \cot(x) + C$ (I leave it to the reader to verify that $G(x)$ is the antiderivative of $g(x)$), we *could* write $G$ (with some slightly abusive index notation) as

$$G(x) = \begin{cases} \cot(x) + C_1, & \text{if } 0 < x < \pi \\ \cot(x) + C_{-1}, & \text{if } -\pi < x < 0 \\ \cot(x) + C_2, & \text{if } \pi < x < 2\pi \\ \cot(x) + C_{-2}, & \text{if } -2\pi < x < -\pi \\ \vdots & \vdots \\ \cot(x) + C_n, & \text{if } (n-1)\pi < x < n\pi \\ \cot(x) + C_{-n}, & \text{if } n\pi < x < (n+1)\pi \\ \vdots & \vdots \end{cases}$$

While both of these piecewise versions of the antiderivatives of $f(x)$ and $g(x)$ are correct, I hope the reader would agree, they are incredibly bulky. The convention adopted in this text (and all others I have encountered on the subject) is to collapse these down to $F(x) = \ln(|x|) + C$ and $G(x) = \cot(x) + C$, respectively, with the understanding that these are valid on all disjoint intervals in their domains.

### Checkpoint 5.1.1

Find all antiderivatives of $f(x) = \sin x$.

**Answer**

$F(x) = -\cos x + C$

## Indefinite Integrals

We now look at the formal notation used to represent antiderivatives and examine some of their properties. These properties allow us to find antiderivatives of more complicated functions. Given a function $f$, we use the notation $f'(x)$ or $\frac{df}{dx}$ to denote the derivative of $f$. Here, we introduce notation for antiderivatives. If $F$ is an antiderivative of $f$, we say that $F(x) + C$ is the most general antiderivative of $f$ and write

$$\int f(x)\,dx = F(x) + C.$$

The symbol $\int$ is called an **integral sign**, and $\int f(x)\,dx$ is called the **indefinite integral** of $f$.

### Definition: Indefinite Integrals

Given a function $f$, the **indefinite integral** of $f$, denoted

$$\int f(x)\,dx,$$

is the most general antiderivative of $f$. If $F$ is an antiderivative of $f$, then

$$\int f(x)\,dx = F(x) + C.$$

The expression $f(x)$ is called the **integrand** and the variable $x$ is the **variable of integration**.

Given the terminology introduced in this definition, the act of finding the antiderivatives of a function $f$ is usually referred to as **integrating** $f$.

For a function $f$ and an antiderivative $F$, the set of functions $F(x) + C$, where $C$ is any real number, is often referred to as the **family of antiderivatives** of $f$. For example, since $x^2$ is an antiderivative of $2x$ and any antiderivative of $2x$ is of the form $x^2 + C$, we write

$$\int 2x\,dx = x^2 + C.$$

The collection of all functions of the form $x^2 + C$, where $C$ is any real number, is known as the family of antiderivatives of $2x$. Figure 5.1.1 shows a graph of this family of antiderivatives.

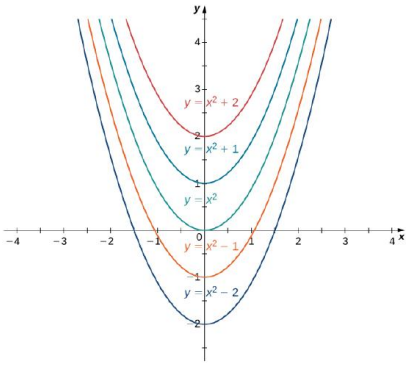

*Figure 5.1.1: The family of antiderivatives of $2x$ consists of all functions of the form $x^2 + C$, where $C$ is any real number.*

For some functions, evaluating indefinite integrals follows directly from properties of derivatives. For example, for $n \neq -1$,

$$\int x^n\,dx = \frac{x^{n+1}}{n+1} + C,$$

which comes directly from

$$\frac{d}{dx}\left(\frac{x^{n+1}}{n+1}\right) = (n+1)\frac{x^n}{n+1} = x^n.$$

This fact is known as the Power Rule for integrals.

**Theorem: Power Rule for Integrals**

For $n \neq -1$,

$$\int x^n\,dx = \frac{x^{n+1}}{n+1} + C.$$

Evaluating indefinite integrals for some other functions is also a straightforward calculation. The following table lists the indefinite integrals for several common functions.

**Table 5.1.1: Integration Formulas**

| Differentiation Formula | Indefinite Integral |
|---|---|
| $\frac{d}{dx}(k) = 0$ | $\int k\,dx = \int kx^0\,dx = kx + C$ |
| $\frac{d}{dx}(x^n) = nx^{n-1}$ | $\int x^n\,dx = \frac{x^{n+1}}{n+1} + C$ for $n \neq -1$ |
| $\frac{d}{dx}(\ln\lvert x\rvert) = \frac{1}{x}$ | $\int \frac{1}{x}\,dx = \ln\lvert x\rvert + C$ |
| $\frac{d}{dx}(e^x) = e^x$ | $\int e^x\,dx = e^x + C$ |
| $\frac{d}{dx}(b^x) = b^x \ln(b)$ | $\int b^x\,dx = \frac{b^x}{\ln(b)} + C$ |
| $\frac{d}{dx}(\sin x) = \cos x$ | $\int \cos x\,dx = \sin x + C$ |
| $\frac{d}{dx}(\cos x) = -\sin x$ | $\int \sin x\,dx = -\cos x + C$ |
| $\frac{d}{dx}(\tan x) = \sec^2 x$ | $\int \sec^2 x\,dx = \tan x + C$ |
| $\frac{d}{dx}(\csc x) = -\csc x \cot x$ | $\int \csc x \cot x\,dx = -\csc x + C$ |
| $\frac{d}{dx}(\sec x) = \sec x \tan x$ | $\int \sec x \tan x\,dx = \sec x + C$ |
| $\frac{d}{dx}(\cot x) = -\csc^2 x$ | $\int \csc^2 x\,dx = -\cot x + C$ |
| $\frac{d}{dx}(\sin^{-1} x) = \frac{1}{\sqrt{1-x^2}}$ | $\int \frac{1}{\sqrt{1-x^2}}\,dx = \sin^{-1} x + C$ |
| $\frac{d}{dx}(\tan^{-1} x) = \frac{1}{1+x^2}$ | $\int \frac{1}{1+x^2}\,dx = \tan^{-1} x + C$ |
| $\frac{d}{dx}(\sec^{-1} x) = \frac{1}{x\sqrt{x^2-1}}$ | $\int \frac{1}{x\sqrt{x^2-1}}\,dx = \sec^{-1} x + C$ |
| $\frac{d}{dx}(\sinh(x)) = \cosh(x)$ | $\int \cosh(x)\,dx = \sinh(x) + C$ |
| $\frac{d}{dx}(\cosh(x)) = \sinh(x)$ | $\int \sinh(x)\,dx = \cosh(x) + C$ |

Notice that not all derivatives we have learned are represented in this table. For example, we learned $\frac{d}{dx}(\log_b(x)) = \frac{1}{x\ln(b)}$, however, the related indefinite integral is not listed. Moreover, most of the inverse trigonometric and hyperbolic functions are missing. This is because indefinite integrals involving these forms are rare. In the case of the inverse hyperbolic functions, if you find the antiderivative, you must convert that to a logarithm. This is not a pleasant process, but you will find a more efficient way to integrate these styles of functions in Calculus II. Rather than making an already long table even longer, we leave it to the reader to reference the relevant sections in Chapter 3 to determine the antiderivatives of those functions, if needed.

From the definition of indefinite integral of $f$, we know

$$\int f(x)\,dx = F(x) + C$$

if and only if $F$ is an antiderivative of $f$.

Therefore, when claiming that

$$\int f(x)\,dx = F(x) + C,$$

it is essential to check whether this statement is correct by verifying that $F'(x) = f(x)$.

### Example 5.1.2: Verifying an Indefinite Integral

Each of the following statements is of the form $\int f(x)\,dx = F(x) + C$. Verify that each statement is correct by showing that $F'(x) = f(x)$.

a. $\int (x + e^x)\,dx = \frac{x^2}{2} + e^x + C$

b. $\int xe^x\,dx = xe^x - e^x + C$

**Solution**

a. Since

$$\frac{d}{dx}\left(\frac{x^2}{2} + e^x + C\right) = x + e^x,$$

the statement

$$\int (x + e^x)\,dx = \frac{x^2}{2} + e^x + C$$

is correct.

Note that we are verifying an indefinite integral for a sum. Furthermore, $\frac{x^2}{2}$ and $e^x$ are antiderivatives of $x$ and $e^x$, respectively, and the sum of the antiderivatives is an antiderivative of the sum. We discuss this fact again later in this section.

b. Using the Product Rule, we see that

$$\frac{d}{dx}(xe^x - e^x + C) = e^x + xe^x - e^x = xe^x.$$

Therefore, the statement

$$\int xe^x\,dx = xe^x - e^x + C$$

is correct.

Note that we are verifying an indefinite integral for a product. The antiderivative $xe^x - e^x$ is not a product of the antiderivatives. Furthermore, the product of antiderivatives, $x^2e^x/2$ is not an antiderivative of $xe^x$ since

$$\frac{d}{dx}\left(\frac{x^2e^x}{2}\right) = xe^x + \frac{x^2e^x}{2} \neq xe^x.$$

Generally, the product of antiderivatives is not an antiderivative of a product.

### Checkpoint 5.1.2

Verify that $\int x\cos x\,dx = x\sin x + \cos x + C$.

**Answer**

$\frac{d}{dx}(x\sin x + \cos x + C) = \sin x + x\cos x - \sin x = x\cos x$

In Table 5.1.1, we listed the indefinite integrals for many elementary functions. Let's now consider evaluating indefinite integrals for more complicated functions. For example, consider finding an antiderivative of a sum $f + g$. In Example 5.1.2a, we showed that an antiderivative of the sum $x + e^x$ is given by the sum $\frac{x^2}{2} + e^x$ - that is, an antiderivative of a sum is given by a sum of antiderivatives. This result was not specific to this example. In general, if $F$ and $G$ are antiderivatives of any functions $f$ and $g$, respectively, then

$$\frac{d}{dx}\left(F(x)+G(x)\right)=F'(x)+G'(x)=f(x)+g(x).$$

Therefore, $F(x)+G(x)$ is an antiderivative of $f(x)+g(x)$ and we have

$$\int \left(f(x)+g(x)\right)\,dx=F(x)+G(x)+C.$$

Similarly,

$$\int \left(f(x)-g(x)\right)\,dx=F(x)-G(x)+C.$$

In addition, consider the task of finding an antiderivative of $kf(x)$, where $k$ is any real number. Since

$$\frac{d}{dx}\left(kF(x)\right)=k\frac{d}{dx}\left(F(x)\right)=kF'(x)$$

for any real number $k$, we conclude that

$$\int kf(x)\,dx=kF(x)+C.$$

These properties are summarized next.

**Theorem: Properties of Indefinite Integrals**

Let $F$ and $G$ be antiderivatives of $f$ and $g$, respectively, and let $k$ be any real number.

**Sums and Differences**

$$\int \left(f(x)\pm g(x)\right)\,dx=F(x)\pm G(x)+C$$

**Constant Multiples**

$$\int kf(x)\,dx=kF(x)+C$$

From this theorem, we can evaluate any integral involving a sum, difference, or constant multiple of functions with known antiderivatives. Evaluating integrals involving products, quotients, or compositions is more complicated. (See Example **5.1.2*b*** for an example involving an antiderivative of a product.) We address integrals involving these more complicated functions in Integral Calculus (Calculus II). In the next example, we examine how to use this theorem to calculate the indefinite integrals of several functions.

**Example 5.1.3: Evaluating Indefinite Integrals**

Evaluate each of the following indefinite integrals:

a. $\int \left(5x^3-7x^2+3x+4\right)\,dx$

b. $\int \dfrac{x^2+4\sqrt[3]{x}}{x}\,dx$

c. $\int \dfrac{4}{1+x^2}\,dx$

d. $\int \tan x\cos x\,dx$

**Solutions**

a. Using Properties of Indefinite Integrals, we can integrate the four terms in the integrand separately. We obtain

$$\int \left(5x^3-7x^2+3x+4\right)\,dx=\int 5x^3\,dx-\int 7x^2\,dx+\int 3x\,dx+\int 4\,dx.$$

From the second part of Properties of Indefinite Integrals, each coefficient can be written in front of the integral sign, which gives

$$\int 5x^3\,dx - \int 7x^2\,dx + \int 3x\,dx + \int 4\,dx = 5\int x^3\,dx - 7\int x^2\,dx + 3\int x\,dx + 4\int 1\,dx.$$

Using the Power Rule for integrals, we conclude that

$$\int \left(5x^3 - 7x^2 + 3x + 4\right)\,dx = \frac{5}{4}x^4 - \frac{7}{3}x^3 + \frac{3}{2}x^2 + 4x + C.$$

b. Rewrite the integrand as

$$\frac{x^2 + 4\sqrt[3]{x}}{x} = \frac{x^2}{x} + \frac{4\sqrt[3]{x}}{x}.$$

Then, to evaluate the integral, integrate each of these terms separately. Using the Power Rule, we have

$$\begin{aligned}\int \left(x + \frac{4}{x^{2/3}}\right)\,dx &= \int x\,dx + 4\int x^{-2/3}\,dx \\ &= \frac{1}{2}x^2 + 4\frac{1}{\left(\frac{-2}{3}\right)+1}x^{(-2/3)+1} + C \\ &= \frac{1}{2}x^2 + 12x^{1/3} + C.\end{aligned}$$

c. Using Properties of Indefinite Integrals, write the integral as

$$4\int \frac{1}{1+x^2}\,dx.$$

Then, use the fact that $\tan^{-1}(x)$ is an antiderivative of $\frac{1}{1+x^2}$ to conclude that

$$\int \frac{4}{1+x^2}\,dx = 4\tan^{-1}(x) + C.$$

d. Rewrite the integrand as

$$\tan x \cos x = \frac{\sin x}{\cos x}\cdot \cos x = \sin x.$$

Therefore,

$$\int \tan x \cos x\,dx = \int \sin x\,dx = -\cos x + C.$$

**? Checkpoint 5.1.3**

Evaluate $\int \left(4x^3 - 5x^2 + x - 7\right)\,dx$.

**Answer**

$$\int \left(4x^3 - 5x^2 + x - 7\right)\,dx = x^4 - \frac{5}{3}x^3 + \frac{1}{2}x^2 - 7x + C$$

## Initial-Value Problems

We look at techniques for integrating functions involving products, quotients, and compositions later in the text. Here, we turn to one everyday use for antiderivatives that arises often in many applications: solving differential equations.

A **differential equation** is an equation that relates an unknown function and one or more of its derivatives. The equation

$$\frac{dy}{dx} = f(x) \tag{5.1.1}$$

is a simple example of a differential equation. Solving this equation means finding a function $y$ with a derivative $f$. Therefore, the solutions of Equation 5.1.1 are the antiderivatives of $f$. If $F$ is one antiderivative of $f$, every function of the form $y = F(x) + C$ is a solution of that differential equation. For example, the solutions of

$$\frac{dy}{dx} = 6x^2$$

are given by

$$y = \int 6x^2\,dx = 2x^3 + C.$$

Sometimes we are interested in determining whether a **particular solution curve** passes through a certain point $(x_0, y_0)$ - that is, $y(x_0) = y_0$. The problem of finding a function $y$ that satisfies a differential equation

$$\frac{dy}{dx} = f(x)$$

with the additional condition $y(x_0) = y_0$ is an example of an **initial-value problem**. The condition $y(x_0) = y_0$ is known as an **initial condition**. For example, looking for a function $y$ that satisfies the differential equation

$$\frac{dy}{dx} = 6x^2$$

and the initial condition $y(1) = 5$ is an example of an initial-value problem. Since the solutions of the differential equation are $y = 2x^3 + C$, to find a function $y$ that also satisfies the initial condition, we need to find $C$ such that $y(1) = 2(1)^3 + C = 5$. This equation shows that $C = 3$, and we conclude that $y = 2x^3 + 3$ solves this initial-value problem, as shown in the following graph.

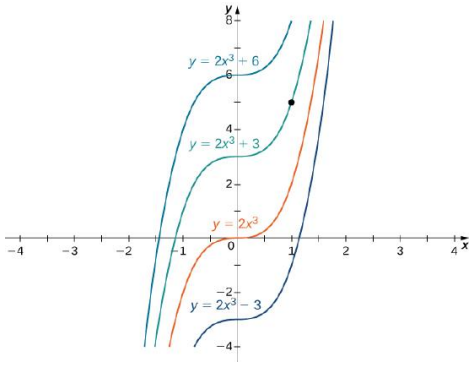

*Figure 5.1.2: Some of the solution curves of the differential equation $\frac{dy}{dx} = 6x^2$ are displayed. The function $y = 2x^3 + 3$ satisfies the differential equation and the initial condition $y(1) = 5$.*

### Example 5.1.4: Solving an Initial-Value Problem

Solve the initial-value problem

$$\frac{dy}{dx} = \sin x, \quad y(0) = 5.$$

**Solution**

First, we need to solve the differential equation. If $\frac{dy}{dx} = \sin x$, then

$$y = \int \sin(x)\,dx = -\cos x + C.$$

Next we need to look for a solution $y$ that satisfies the initial condition. The initial condition $y(0) = 5$ means we need a constant $C$ such that $-\cos x + C = 5$. Therefore,

$$C = 5 + \cos(0) = 6.$$

The solution of the initial-value problem is $y = -\cos x + 6$.

**? Checkpoint 5.1.4**

Solve the initial value problem $\frac{dy}{dx} = 3x^{-2}, \quad y(1) = 2.$

**Answer**

$y = -\frac{3}{x} + 5$

Initial-value problems arise in many applications. Next, we consider a situation where a driver applies brakes to a car. We are interested in how long it takes for the vehicle to stop. Recall that the velocity function $v(t)$ is the derivative of a position function $s(t)$, and the acceleration $a(t)$ is the derivative of the velocity function. In earlier examples in the text, we could calculate the velocity from the position and then compute the acceleration from the velocity. In the following example, we work the other way around. Given an acceleration function, we calculate the velocity function. We then use the velocity function to determine the position function.

**✓ Example 5.1.5:**

A car is traveling at the rate of $88$ ft/sec ($60$ mph) when the brakes are applied. The car begins decelerating at a constant rate of $15$ ft/sec$^2$.

a. How many seconds elapse before the car stops?
b. How far does the car travel during that time?

**Solutions**

a. First, we introduce variables for this problem. Let $t$ be the time (in seconds) after the brakes are applied. Let $a(t)$ be the acceleration of the car (in feet per second squared) at time $t$. Let $v(t)$ be the velocity of the car (in feet per second) at time $t$. Let $s(t)$ be the car's position (in feet) beyond the point where the brakes are applied at time $t$.

The car travels at a rate of $88$ ft/sec. Therefore, the initial velocity is $v(0) = 88$ ft/sec. Since the car is decelerating, the acceleration is

$$a(t) = -15 \text{ ft/sec}^2.$$

The acceleration is the derivative of the velocity,

$$v'(t) = -15.$$

Therefore, we have an initial-value problem to solve:

$$v'(t) = -15, \quad v(0) = 88.$$

Integrating, we find that

$$v(t) = -15t + C.$$

Since $v(0) = 88, C = 88$. Thus, the velocity function is

$$v(t) = -15t + 88.$$

To find how long it takes for the car to stop, we need to find the time $t$ such that the velocity is zero. Solving $-15t + 88 = 0$, we obtain $t = \frac{88}{15}$ sec.

b. To find how far the car travels during this time, we need to find the position of the car after $\frac{88}{15}$ sec. We know the velocity $v(t)$ is the derivative of the position $s(t)$. Consider the initial position as $s(0) = 0$. Therefore, we need to solve the initial-value problem

$$s'(t) = -15t + 88, \quad s(0) = 0.$$

Integrating, we have

$$s(t) = -\frac{15}{2}t^2 + 88t + C.$$

Since $s(0) = 0$, the constant is $C = 0$. Therefore, the position function is

$$s(t) = -\frac{15}{2}t^2 + 88t.$$

After $t = \frac{88}{15}$ sec, the position is $s\left(\frac{88}{15}\right) \approx 258.133$ ft.

**? Checkpoint 5.1.5**

Suppose the car is traveling at the rate of $44$ ft/sec. How long does it take for the car to stop? How far will the car travel?

**Answer**

$2.93$ sec, $64.5$ ft

# 5.2: Approximating Areas

**Learning Objectives**

- Use sigma (summation) notation to calculate sums and powers of integers.
- Use the sum of rectangular areas to approximate the area under a curve.
- Use Riemann sums to approximate area.
- Determine the precise area under polynomial curves of degree at most 3 using limits of Riemann sums.

Hawk A.I. Section-Specific Tutor

Please note that, to access the Hawk A.I. Tutor, you will need a (free) OpenAI account.

Archimedes was fascinated with calculating the areas of various shapes - in other words, the amount of space enclosed by the shape. He used a process that has come to be known as the **method of exhaustion**, which used smaller and smaller shapes, the areas of which could be calculated exactly, to fill an irregular region and thereby obtain closer and closer approximations to the total area. In this process, an area bounded by curves is filled with rectangles, triangles, and shapes with exact area formulas. These areas are then summed to approximate the area of the curved region.

In this section, we develop techniques to approximate the area between a curve, defined by a function $f(x)$, and the $x$-axis on a closed interval $[a, b]$. Like Archimedes, we first approximate the area under the curve using shapes of known area (namely, rectangles). By using smaller and smaller rectangles, we get closer and closer approximations to the area. Taking a limit allows us to calculate the exact area under the curve.

Let's start by introducing some notation to simplify calculations. We consider the case when $f(x)$ is continuous and nonnegative. Later in the chapter, we relax some of these restrictions and develop techniques that apply in more general cases.

## Sigma (Summation) Notation

As mentioned, we will use shapes of known area to approximate the area of an irregular region bounded by curves. This process often requires adding up long strings of numbers. To make it easier to write down these lengthy sums, we look at some new notation here, called **sigma notation** (also known as **summation notation**). The Greek capital letter $\Sigma$, Sigma, is used to express long sums of values in a compact form. For example, if we want to add all the integers from 1 to 20 without sigma notation, we have to write

$$1+2+3+4+5+6+7+8+9+10+11+12+13+14+15+16+17+18+19+20.$$

We could probably skip writing a couple of terms and write

$$1+2+3+4+\cdots+19+20,$$

which is better but still cumbersome. With sigma notation, we write this sum as

$$\sum_{i=1}^{20} i,$$

which is much more compact. Typically, sigma notation is presented in the form

$$\sum_{i=1}^{n} a_i,$$

where $a_i$ describes the terms to be added, and the $i$ is called the **index**. Each term is evaluated, then we sum all the values, beginning with the value when $i=1$ and ending with the value when $i=n$. For example, an expression like $\sum_{i=2}^{7} s_i$ is interpreted as $s_2+s_3+s_4+s_5+s_6+s_7$. Note that the index is used only to keep track of the terms to be added; it does not factor into calculating the sum itself. The index is, therefore, called a **dummy variable**. We can use any letter we like for the index. Typically, mathematicians use $i$, $j$, $k$, $m$, and $n$ for indices.

Let's try a couple of examples of using sigma notation.

### Example 5.2.1: Using Sigma Notation

a. Write in sigma notation and evaluate the sum of terms $3^i$ for $i = 1, 2, 3, 4, 5$.

b. Write the sum in sigma notation:

$$1 + \frac{1}{4} + \frac{1}{9} + \frac{1}{16} + \frac{1}{25}.$$

**Solutions**

a. $$\sum_{i=1}^{5} 3^i = 3 + 3^2 + 3^3 + 3^4 + 3^5 = 363.$$

b. The denominator of each term is a perfect square. Using sigma notation, this sum can be written as $\sum_{i=1}^{5} \frac{1}{i^2}$.

### Checkpoint 5.2.1

Write in sigma notation and evaluate the sum of terms $2^i$ for $i = 3, 4, 5, 6$.

**Answer**

$$\sum_{i=3}^{6} 2^i = 2^3 + 2^4 + 2^5 + 2^6 = 120$$

The properties associated with the summation process are given in the following rule.

### Theorem: Properties of Sigma Notation

Let $a_1, a_2, \ldots, a_n$ and $b_1, b_2, \ldots, b_n$ represent two sequences of terms and let $c$ be a constant. The following properties hold for all positive integers $n$ and for integers $m$, with $1 \leq m \leq n$.

i. $\sum_{i=1}^{n} c = nc$

ii. $\sum_{i=1}^{n} ca_i = c\sum_{i=1}^{n} a_i$

iii. $\sum_{i=1}^{n} (a_i + b_i) = \sum_{i=1}^{n} a_i + \sum_{i=1}^{n} b_i$

iv. $\sum_{i=1}^{n} (a_i - b_i) = \sum_{i=1}^{n} a_i - \sum_{i=1}^{n} b_i$

v. $\sum_{i=1}^{n} a_i = \sum_{i=1}^{m} a_i + \sum_{i=m+1}^{n} a_i$

**Proof**

We prove properties (ii.) and (iii.) here and leave proof of the other properties to the Exercises.

(ii.) We have

$$\sum_{i=1}^{n} ca_i = ca_1 + ca_2 + ca_3 + \cdots + ca_n = c(a_1 + a_2 + a_3 + \cdots + a_n) = c\sum_{i=1}^{n} a_i.$$

(iii.) We have

$$\begin{aligned}\sum_{i=1}^{n}(a_i+b_i) &= (a_1+b_1)+(a_2+b_2)+(a_3+b_3)+\cdots+(a_n+b_n)\\ &= (a_1+a_2+a_3+\cdots+a_n)+(b_1+b_2+b_3+\cdots+b_n)\\ &= \sum_{i=1}^{n}a_i+\sum_{i=1}^{n}b_i.\end{aligned}$$

*Q.E.D.*

A few more formulas for frequently found functions simplify the summation process further. These were (hopefully) covered in your Precalculus course and are shown in the next rule for **sums and powers of integers**.

### Theorem: Sums and Powers of Integers

1. The sum of $n$ integers is given by

$$\sum_{i=1}^{n} i = 1+2+\cdots+n = \frac{n(n+1)}{2}. \tag{5.2.1}$$

2. The sum of consecutive integers squared is given by

$$\sum_{i=1}^{n} i^2 = 1^2+2^2+\cdots+n^2 = \frac{n(n+1)(2n+1)}{6}. \tag{5.2.2}$$

3. The sum of consecutive integers cubed is given by

$$\sum_{i=1}^{n} i^3 = 1^3+2^3+\cdots+n^3 = \frac{n^2(n+1)^2}{4}. \tag{5.2.3}$$

### Example 5.2.2: Evaluation Using Sigma Notation

Write using sigma notation and evaluate:

a. The sum of the terms $(i-3)^2$ for $i = 1, 2, \ldots, 200$.
b. The sum of the terms $(i^3 - i^2)$ for $i = 1, 2, 3, 4, 5, 6$

**Solutions**

a. Multiplying out $(i-3)^2$, we can break the expression into three terms.

$$\begin{aligned}\sum_{i=1}^{200}(i-3)^2 &= \sum_{i=1}^{200}(i^2-6i+9)\\ &= \sum_{i=1}^{200}i^2-\sum_{i=1}^{200}6i+\sum_{i=1}^{200}9\\ &= \sum_{i=1}^{200}i^2-6\sum_{i=1}^{200}i+\sum_{i=1}^{200}9\\ &= \frac{200(200+1)(400+1)}{6}-6\left[\frac{200(200+1)}{2}\right]+9(200)\\ &= 2,686,700-120,600+1800\\ &= 2,567,900\end{aligned}$$

b. Use sigma notation property iv. and the rules for the sum of squared and cubed terms.

$$\begin{aligned}\sum_{i=1}^{6}(i^3-i^2) &= \sum_{i=1}^{6}i^3-\sum_{i=1}^{6}i^2\\ &= \frac{6^2(6+1)^2}{4}-\frac{6(6+1)(2(6)+1)}{6}\\ &= \frac{1764}{4}-\frac{546}{6}\\ &= 350\end{aligned}$$

**Checkpoint 5.2.2**

Find the sum of the values of $4+3i$ for $i=1,2,\ldots,100$.

**Answer**

$15,550$

**Example 5.2.3: Finding the Sum of the Function Values**

Find the sum of the values of $f(x)=x^3$ over the integers $1,2,3,\ldots,10$.

**Solution**

Using Equation 5.2.3, we have

$$\sum_{i=0}^{10}i^3=\frac{(10)^2(10+1)^2}{4}=\frac{100(121)}{4}=3025.$$

**Checkpoint 5.2.3**

Evaluate the sum indicated by the notation $\sum_{k=1}^{20}(2k+1)$.

**Answer**

$440$

## Approximating Area

Now that we have the necessary notation, we return to the problem: approximating the area under a curve. Let $f(x)$ be a continuous, nonnegative function defined on the closed interval $[a,b]$. We want to approximate the area $A$ bounded by $f(x)$ above, the $x$-axis below, the line $x=a$ on the left, and the line $x=b$ on the right (Figure 5.2.1).

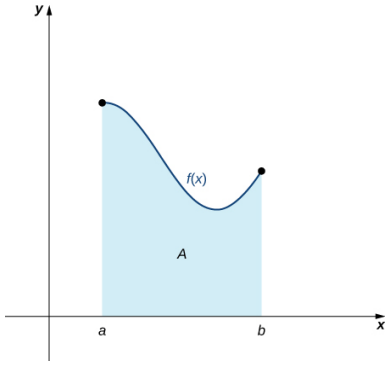

*Figure 5.2.1: An area (shaded region) bounded by the curve $f(x)$ at the top, the $x$-axis at the bottom, the line $x=a$ to the left, and the line $x=b$ at right.*

How do we approximate the area under this curve? The approach is a geometric one. By dividing a region into many small shapes with known area formulas, we can sum these areas and obtain a reasonable estimate of the true area. We begin by dividing the interval $[a, b]$ into $n$ subintervals of equal width, $\frac{b-a}{n}$. We do this by selecting equally spaced points $x_0, x_1, x_2, \ldots, x_n$ with $x_0 = a$, $x_n = b$, and

$$x_i - x_{i-1} = \frac{b-a}{n}$$

for $i = 1, 2, 3, \ldots, n$.

We denote the width of each subinterval with the notation $\Delta x$, so $\Delta x = \frac{b-a}{n}$ and

$$x_i = x_0 + i\Delta x$$

for $i = 1, 2, 3, \ldots, n$. This notion of dividing an interval $[a, b]$ into subintervals by selecting points from within the interval approximates the area under a curve, so let's define some relevant terminology.

### Definition: Partitions

A set of points $P = \{x_i\}$ for $i = 0, 1, 2, \ldots, n$ with $a = x_0 < x_1 < x_2 < \ldots < x_n = b$, which divides the interval $[a, b]$ into subintervals of the form $[x_0, x_1]$, $[x_1, x_2]$, $\ldots$, $[x_{n-1}, x_n]$ is called a **partition** of $[a, b]$. If the subintervals all have the same width, the set of points forms a **regular partition** (or uniform partition) of the interval $[a, b]$.

We can use this regular partition as the basis of a method for estimating the area under the curve. We next examine two methods: the **left-endpoint approximation** and the **right-endpoint approximation**.

### Theorem: Left-Endpoint Approximation

On each subinterval $[x_{i-1}, x_i]$ (for $i = 1, 2, 3, \ldots, n$), construct a rectangle with width $\Delta x$ and height equal to $f(x_{i-1})$, which is the function value at the left endpoint of the subinterval. Then the area of this rectangle is $f(x_{i-1})\Delta x$. Adding the areas of all these rectangles, we get an approximate value for $A$ (Figure 5.2.2). We use the notation $L_n$ to denote that this is a **left-endpoint approximation** of $A$ using $n$ subintervals.

$$A \approx L_n = f(x_0)\Delta x + f(x_1)\Delta x + \cdots + f(x_{n-1})\Delta x = \sum_{i=1}^{n} f(x_{i-1})\Delta x$$

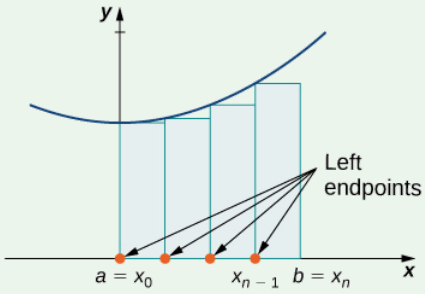

*Figure 5.2.2: In the left-endpoint approximation of the area under a curve, the height of each rectangle is determined by the function value at the left of each subinterval.*

The second method for approximating the area under a curve is the right-endpoint approximation. It is almost the same as the left-endpoint approximation, but now the heights of the rectangles are determined by the function values at the right of each subinterval.

### Theorem: Right-Endpoint Approximation

Construct a rectangle on each subinterval $[x_{i-1}, x_i]$, only this time the height of the rectangle is determined by the function value $f(x_i)$ at the right endpoint of the subinterval. Then, the area of each rectangle is $f(x_i)\,\Delta x$ and the approximation for $A$ is given by

$$A \approx R_n = f(x_1)\Delta x + f(x_2)\Delta x + \cdots + f(x_n)\Delta x = \sum_{i=1}^{n} f(x_i)\Delta x.$$

The notation $R_n$ indicates this is a **right-endpoint approximation** for $A$ (Figure 5.2.3).

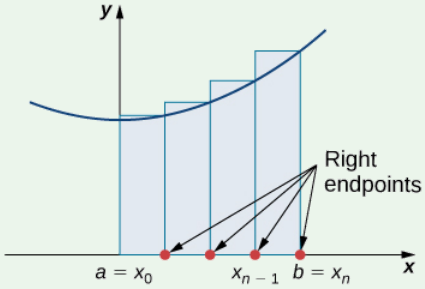

*Figure 5.2.3: In the right-endpoint approximation of the area under a curve, the height of each rectangle is determined by the function value at the right of each subinterval. Note that the right-endpoint approximation differs from the left-endpoint approximation in Figure 5.2.2.*

The graphs in Figure 5.2.4 represent the curve $f(x) = \frac{x^2}{2}$. In Figure 5.2.4*a*, we divide the region represented by the interval $[0, 3]$ into six subintervals, each of width 0.5. Thus, $\Delta x = 0.5$. We then form six rectangles by drawing vertical lines perpendicular to $x_{i-1}$, the left endpoint of each subinterval. We determine the height of each rectangle by calculating $f(x_{i-1})$ for $i = 1, 2, 3, 4, 5, 6$. The intervals are $[0, 0.5]$, $[0.5, 1]$, $[1, 1.5]$, $[1.5, 2]$, $[2, 2.5]$, $[2.5, 3]$. We find the area of each rectangle by multiplying the height by the width. Then, the sum of the rectangular areas approximates the area between $f(x)$ and the $x$-axis. When the left endpoints are used to calculate height, we have a left-endpoint approximation. Thus,

$$\begin{aligned} A &\approx L_6 \\ &= \sum_{i=1}^{6} f(x_{i-1})\Delta x \\ &= f(x_0)\Delta x + f(x_1)\Delta x + f(x_2)\Delta x + f(x_3)\Delta x + f(x_4)\Delta x + f(x_5)\Delta x \\ &= f(0)0.5 + f(0.5)0.5 + f(1)0.5 + f(1.5)0.5 + f(2)0.5 + f(2.5)0.5 \\ &= (0)0.5 + (0.125)0.5 + (0.5)0.5 + (1.125)0.5 + (2)0.5 + (3.125)0.5 \\ &= 0 + 0.0625 + 0.25 + 0.5625 + 1 + 1.5625 \\ &= 3.4375 \text{ units}^2 \end{aligned}$$

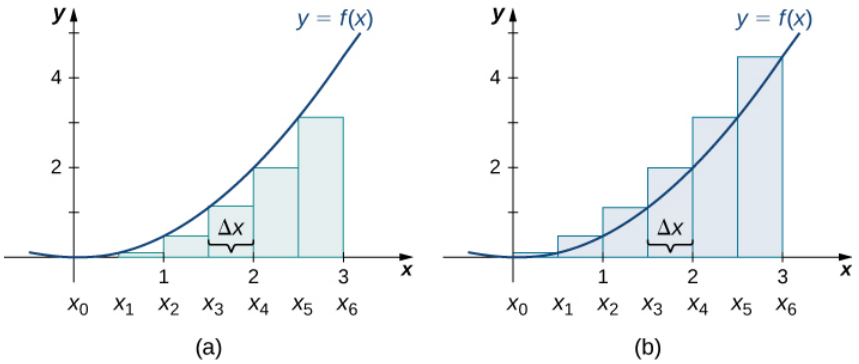

*Figure 5.2.4: Methods of approximating the area under a curve by using (a) the left endpoints and (b) the right endpoints.*

In Figure 5.2.4*b*, we draw vertical lines perpendicular to $x_i$ such that $x_i$ is the right endpoint of each subinterval, and calculate $f(x_i)$ for $i = 1, 2, 3, 4, 5, 6$. We multiply each $f(x_i)$ by $\Delta x$ to find the rectangular areas and then add them. This is a right-endpoint approximation of the area under $f(x)$. Thus,

$$
\begin{aligned}
A &\approx R_6 \\
&= \sum_{i=1}^{6} f(x_i)\Delta x \\
&= f(x_1)\Delta x + f(x_2)\Delta x + f(x_3)\Delta x + f(x_4)\Delta x + f(x_5)\Delta x + f(x_6)\Delta x \\
&= f(0.5)0.5 + f(1)0.5 + f(1.5)0.5 + f(2)0.5 + f(2.5)0.5 + f(3)0.5 \\
&= (0.125)0.5 + (0.5)0.5 + (1.125)0.5 + (2)0.5 + (3.125)0.5 + (4.5)0.5 \\
&= 0.0625 + 0.25 + 0.5625 + 1 + 1.5625 + 2.25 \\
&= 5.6875 \text{ units}^2.
\end{aligned}
$$

### Example 5.2.4: Approximating the Area Under a Curve

Use both left-endpoint and right-endpoint approximations to approximate the area under the curve of $f(x) = x^2$ on the interval $[0, 2]$; use $n = 4$.

**Solution**

First, divide the interval $[0, 2]$ into $n$ equal subintervals. Using $n = 4$, $\Delta x = \frac{(2-0)}{4} = 0.5$. This is the width of each rectangle. The intervals $[0, 0.5]$, $[0.5, 1]$, $[1, 1.5]$, $[1.5, 2]$ are shown in Figure 5.2.5. Using a left-endpoint approximation, the heights are $f(0) = 0$, $f(0.5) = 0.25$, $f(1) = 1$, and $f(1.5) = 2.25$. Then,

$$
\begin{aligned}
L_4 &= f(x_0)\Delta x + f(x_1)\Delta x + f(x_2)\Delta x + f(x_3)\Delta x \\
&= 0(0.5) + 0.25(0.5) + 1(0.5) + 2.25(0.5) \\
&= 1.75 \text{ units}^2
\end{aligned}
$$

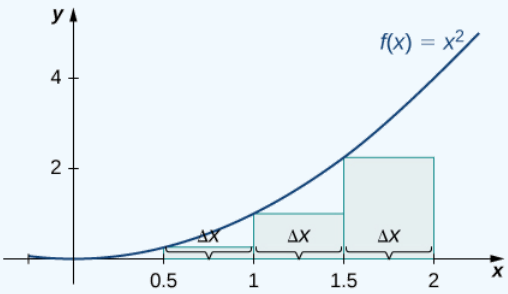

*Figure 5.2.5: The graph shows the left-endpoint approximation of the area under $f(x) = x^2$ from 0 to 2.*

The right-endpoint approximation is shown in Figure 5.2.6. The intervals are the same, $\Delta x = 0.5$, but now use the right endpoint to calculate the height of the rectangles. We have

$$
\begin{aligned}
R_4 &= f(x_1)\Delta x + f(x_2)\Delta x + f(x_3)\Delta x + f(x_4)\Delta x \\
&= 0.25(0.5) + 1(0.5) + 2.25(0.5) + 4(0.5) \\
&= 3.75 \text{ units}^2
\end{aligned}
$$

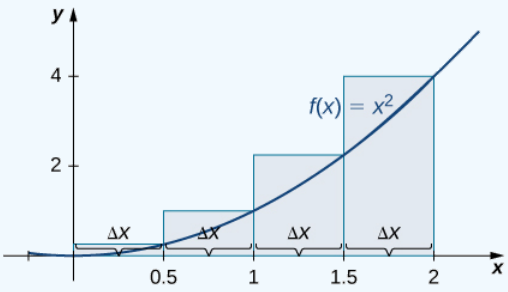

*Figure 5.2.6: The graph shows the right-endpoint approximation of the area under $f(x) = x^2$ from 0 to 2.*

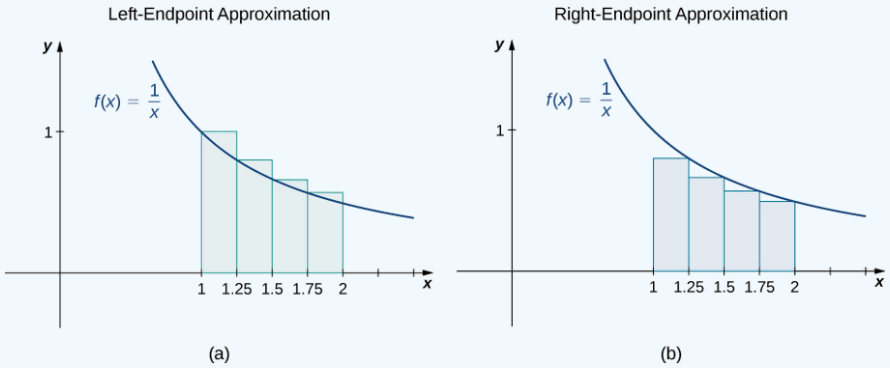
The left-endpoint approximation is $1.75\ \text{units}^2$; the right-endpoint approximation is $3.75\ \text{units}^2$.

**Checkpoint 5.2.4**

Sketch left-endpoint and right-endpoint approximations for $f(x) = \frac{1}{x}$ on $[1, 2]$; use $n = 4$. Approximate the area using both methods.

**Answer**

The left-endpoint approximation is $0.7595\ \text{units}^2$. The right-endpoint approximation is $0.6345\ \text{units}^2$. See the figures below.



Looking at Figure 5.2.4 and the graphs in Example 5.2.4, we can see that when we use a small number of intervals, neither the left-endpoint approximation nor the right-endpoint approximation is a particularly accurate estimate of the area under the curve. However, increasing the number of points in our partition will improve our estimate of $A$. We will have more rectangles, but each rectangle will be thinner so we can fit the rectangles to the curve more precisely.

We can demonstrate the improved approximation obtained through smaller intervals with an example. Let's explore the idea of increasing $n$, first in a left-endpoint approximation with four rectangles, then eight rectangles, and finally 32 rectangles. Then, let's do the same thing in a right-endpoint approximation, using the same sets of intervals of the same curved region. Figure 5.2.7 shows the area of the region under the curve $f(x) = (x-1)^3 + 4$ on the interval $[0, 2]$ using a left-endpoint approximation where $n = 4$. The width of each rectangle is

$$\Delta x = \frac{2-0}{4} = \frac{1}{2}.$$

The summed areas of the rectangles approximate the area, or

$$L_4 = f(0)(0.5) + f(0.5)(0.5) + f(1)(0.5) + f(1.5)0.5 = 7.5\ \text{units}^2$$

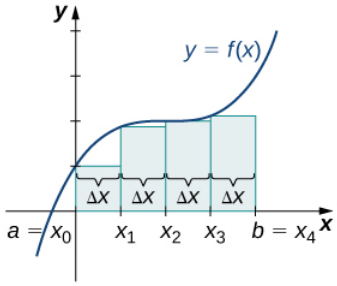


*Figure 5.2.7: With a left-endpoint approximation and dividing the region from $a$ to $b$ into four equal intervals, the area under the curve is approximately equal to the sum of the areas of the rectangles.*

Figure 5.2.8 shows the same curve divided into eight subintervals. Comparing the graph with four rectangles in Figure 5.2.7 with this graph with eight rectangles, we can see there appears to be less white space under the curve when $n = 8$. This white space is the area under the curve we cannot include using our approximation. The area of the rectangles is

$$L_8 = f(0)(0.25) + f(0.25)(0.25) + f(0.5)(0.25) + f(0.75)(0.25) + f(1)(0.25) + f(1.25)(0.25) + f(1.5)(0.25) + f(1.75)(0.25) = 7.75 \text{ units}^2$$

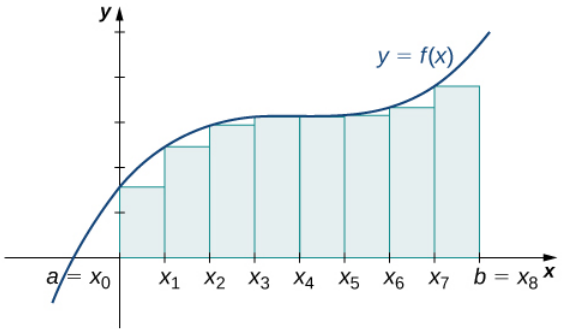

*Figure* **5.2.8***: The region under the curve is divided into* $n = 8$ *rectangular areas of equal width for a left-endpoint approximation.*

The graph in Figure **5.2.9** shows the same function with **32** rectangles inscribed under the curve. There appears to be little white space left. The area occupied by the rectangles is

$$L_{32} = f(0)(0.0625) + f(0.0625)(0.0625) + f(0.125)(0.0625) + \cdots + f(1.9375)(0.0625) = 7.9375 \text{ units}^2.$$

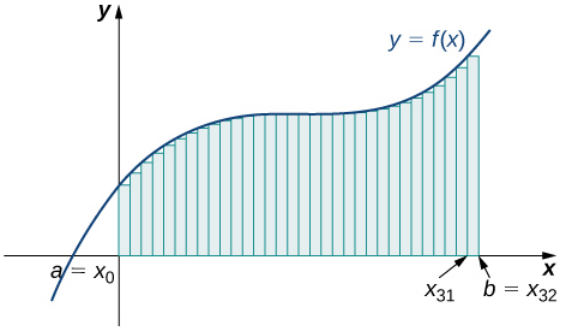

*Figure* **5.2.9***: Here,* **32** *rectangles are inscribed under the curve for a left-endpoint approximation.*

We can perform a similar process for the right-endpoint approximation method. A right-endpoint approximation of the same curve, using four rectangles (Figure **5.2.10**), yields an area

$$R_4 = f(0.5)(0.5) + f(1)(0.5) + f(1.5)(0.5) + f(2)(0.5) = 8.5 \text{ units}^2.$$

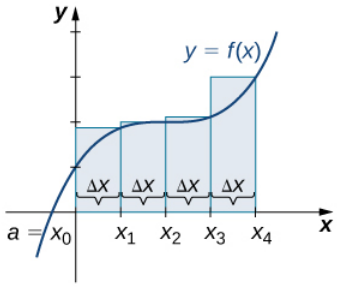

*Figure* **5.2.10***: Now, we divide the area under the curve into four equal subintervals for a right-endpoint approximation.*

Dividing the region over the interval $[0, 2]$ into eight rectangles results in $\Delta x = \frac{2-0}{8} = 0.25$. The graph is shown in Figure **5.2.11**. The area is

$$R_8 = f(0.25)(0.25) + f(0.5)(0.25) + f(0.75)(0.25) + f(1)(0.25) + f(1.25)(0.25) + f(1.5)(0.25) + f(1.75)(0.25) + f(2)(0.25) = 8.25 \text{ units}^2$$

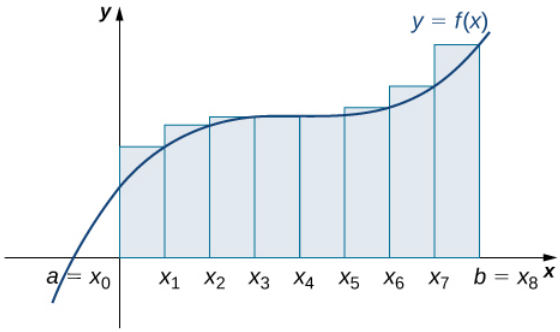

*Figure* **5.2.11***: Here, we use a right-endpoint approximation for a region divided into eight equal subintervals.*

Last, the right-endpoint approximation with $n = 32$ is close to the actual area (Figure **5.2.12**). The area is approximately

$$R_{32} = f(0.0625)(0.0625) + f(0.125)(0.0625) + f(0.1875)(0.0625) + \cdots + f(2)(0.0625) = 8.0625 \text{ units}^2$$

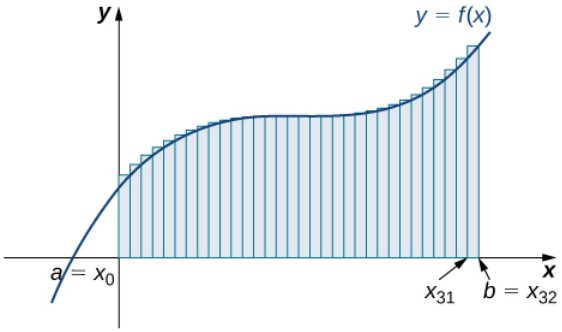

*Figure* **5.2.12***: The region is divided into* **32** *equal subintervals for a right-endpoint approximation.*

Based on these figures and calculations, we are on the right track; the rectangles better approximate the area under the curve as $n$ gets larger. Furthermore, as $n$ increases, both the left-end and right-endpoint approximations approach an area of 8 square units. Table **5.2.1** shows a numerical comparison of the left- and right-endpoint methods. The idea that the approximations of the area under the curve get better and better as $n$ gets larger and larger is very important, and we now explore this idea in more detail.

**Table 5.2.1: Converging Values of Left- and Right-Endpoint Approximations as $n$ Increases**

| Value of $n$ | Approximate Area $L_n$ | Approximate Area $R_n$ |
|---|---|---|
| $n = 4$ | 7.5 | 8.5 |
| $n = 8$ | 7.75 | 8.25 |
| $n = 32$ | 7.94 | 8.06 |

## Forming Riemann Sums

So far, we have been using rectangles to approximate the area under a curve. The heights of these rectangles have been determined by evaluating the function at either the right or left endpoints of the subinterval $[x_{i-1}, x_i]$. In reality, there is no reason to restrict the evaluation of the function to only one of these two points. We could evaluate the function at any point $x_i^*$ in the subinterval $[x_{i-1}, x_i]$, and use $f(x_i^*)$ as the height of our rectangle. This gives us an estimate for the area of the form

$$A \approx \sum_{i=1}^{n} f(x_i^*)\,\Delta x.$$

A sum of this form is called a **Riemann sum**, named for the 19th-century mathematician Bernhard Riemann, who developed the idea.

### Definition: Riemann sum

Let $f(x)$ be defined on a closed interval $[a,b]$ and let $P$ be any partition of $[a,b]$. Let $\Delta x_i$ be the width of each subinterval $[x_{i-1}, x_i]$ and for each $i$, let $x_i^*$ be any point in $[x_{i-1}, x_i]$. A **Riemann sum** is defined for $f(x)$ as

$$\sum_{i=1}^{n} f(x_i^*)\,\Delta x_i.$$

At this point, we'll choose a regular partition $P$, as we have in our examples above. This forces all $\Delta x_i$ to be equal to $\Delta x = \frac{b-a}{n}$ for any natural number of intervals $n$.

Recall that with the left- and right-endpoint approximations, the estimates get better and better as $n$ get larger and larger. The same thing happens with Riemann sums. Riemann sums give better approximations for larger values of $n$. We are now ready to define the area under a curve in terms of Riemann sums.

### Definition: Area Under the Curve

Let $f(x)$ be a continuous, nonnegative function on an interval $[a,b]$, and let $\sum_{i=1}^{n} f(x_i^*)\,\Delta x$ be a Riemann sum for $f(x)$ with a regular partition $P$. Then, the **area under the curve** $y = f(x)$ on $[a,b]$ is given by

$$A = \lim_{n\to\infty} \sum_{i=1}^{n} f(x_i^*)\,\Delta x.$$

Some subtleties here are worth discussing. First, taking the limit of a sum is different from taking the limit of a function $f(x)$ as $x$ goes to infinity. Limits of sums are discussed in Calculus II; however, we can assume that the computational techniques we used to compute the limits of functions can also be used to calculate the limits of sums.

Second, we must consider what to do if the expression converges to different limits for different choices of $x_i^*$. Fortunately, this does not happen. Although the proof is beyond the scope of this text, it can be shown that if $f(x)$ is continuous on the closed interval $[a,b]$, then $\lim_{n\to\infty} \sum_{i=1}^{n} f(x_i^*)\Delta x$ exists and is unique (in other words, it does not depend on the choice of $x_i^*$).

We look at some examples shortly. But, before we do, let's take a moment and talk about some specific choices for $x_i^*$. Although any choice for $x_i^*$ gives us an estimate of the area under the curve, we don't necessarily know whether that estimate is too high (overestimate) or too low (underestimate). If it is important to know whether our estimate is high or low, we can select our value for $x_i^*$ to guarantee one result or the other.

If we want an overestimate, for example, we can choose $x_i^*$ such that for $i = 1, 2, 3, \ldots, n$, $f(x_i^*) \geq f(x)$ for all $x \in [x_i - 1, x_i]$. In other words, we choose $x_i^*$ so that for $i = 1, 2, 3, \ldots, n$, $f(x_i^*)$ is the maximum function value on the interval $[x_{i-1}, x_i]$. If we select $x_i^*$ in this way, then the Riemann sum $\sum_{i=1}^{n} f(x_i^*)\Delta x$ is called an **upper sum**. Similarly, if we want an underestimate, we can choose $x_i^*$ so that for $i = 1, 2, 3, \ldots, n$, $f(x_i^*)$ is the minimum function value on the interval $[x_{i-1}, x_i]$. The associated Riemann sum is called a **lower sum**. Note that if $f(x)$ is either increasing or decreasing throughout the interval $[a,b]$, then the maximum and minimum values of the function occur at the endpoints of the subintervals, so the upper and lower sums are just the same as the left- and right-endpoint approximations.

### Example 5.2.5: Finding Lower and Upper Sums

Find a lower sum for $f(x) = 10 - x^2$ on $[1,2]$; let $n = 4$ subintervals.

**Solution**

With $n = 4$ over the interval $[1,2]$, $\Delta x = \frac{1}{4}$. We can list the intervals as $[1, 1.25]$, $[1.25, 1.5]$, $[1.5, 1.75]$, and $[1.75, 2]$. Because the function is decreasing over the interval $[1,2]$, Figure 5.2.13 shows that a lower sum is obtained by using the right endpoints.

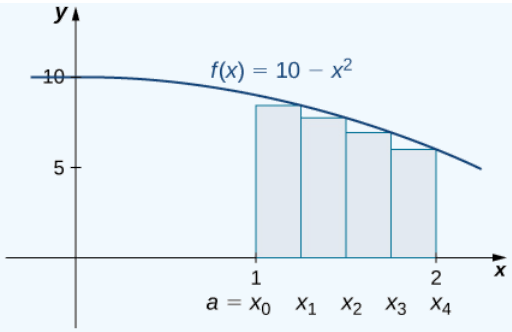

*Figure* **5.2.13**: *The graph of* $f(x) = 10 - x^2$ *is set up for a right-endpoint approximation of the area bounded by the curve and the* $x$*-axis on* $[1, 2]$*, and it shows a lower sum.*

The Riemann sum is

$$\begin{aligned} \sum_{k=1}^{4}(10 - x^2)(0.25) &= 0.25[10 - (1.25)^2 + 10 - (1.5)^2 + 10 - (1.75)^2 + 10 - (2)^2] \\ &= 0.25[8.4375 + 7.75 + 6.9375 + 6] \\ &= 7.28 \text{ units}^2. \end{aligned}$$

The area of $7.28 \text{ units}^2$ is a lower sum and an underestimate.

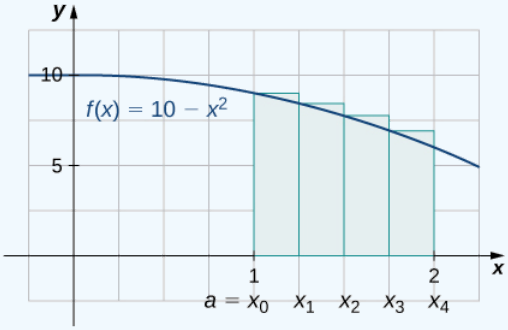
## Checkpoint 5.2.5

a. Find an upper sum for $f(x) = 10 - x^2$ on $[1, 2]$; let $n = 4$.
b. Sketch the approximation.

**Answer**

a. Upper sum=$8.0313 \text{ units}^2$.

b.



## Example 5.2.6: Finding Lower and Upper Sums for $f(x) = \sin x$

Find a lower sum for $f(x) = \sin x$ over the interval $[a, b] = [0, \frac{\pi}{2}]$; let $n = 6$.

**Solution**

Let's first look at the graph in Figure **5.2.14** to get a better idea of the area of interest.

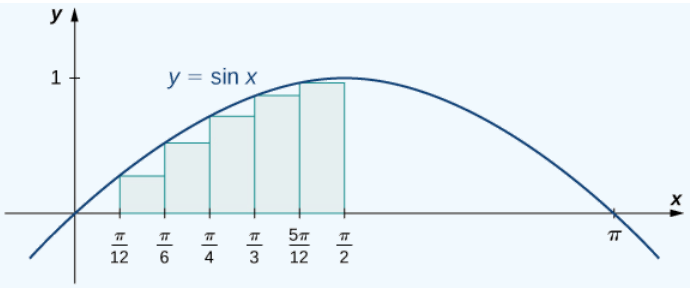


*Figure* **5.2.14**: *The graph of* $y = \sin x$ *is divided into six regions:* $\Delta x = \frac{\pi/2}{6} = \frac{\pi}{12}$.

The intervals are $[0, \frac{\pi}{12}]$, $[\frac{\pi}{12}, \frac{\pi}{6}]$, $[\frac{\pi}{6}, \frac{\pi}{4}]$, $[\frac{\pi}{4}, \frac{\pi}{3}]$, $[\frac{\pi}{3}, \frac{5\pi}{12}]$, and $[\frac{5\pi}{12}, \frac{\pi}{2}]$. Note that $f(x) = \sin x$ is increasing on the interval $[0, \frac{\pi}{2}]$, so a left-endpoint approximation gives us the lower sum. A left-endpoint approximation is the Riemann sum $\sum_{i=0}^{5} \sin x_i \left(\frac{\pi}{12}\right)$.We have

$$A \approx \sin(0)\left(\tfrac{\pi}{12}\right) + \sin\left(\tfrac{\pi}{12}\right)\left(\tfrac{\pi}{12}\right) + \sin\left(\tfrac{\pi}{6}\right)\left(\tfrac{\pi}{12}\right) + \sin\left(\tfrac{\pi}{4}\right)\left(\tfrac{\pi}{12}\right) + \sin\left(\tfrac{\pi}{3}\right)\left(\tfrac{\pi}{12}\right) + \sin\left(\tfrac{5\pi}{12}\right)\left(\tfrac{\pi}{12}\right) \approx 0.863 \text{ units}^2.$$

**? Checkpoint 5.2.6**

Using the function $f(x) = \sin x$ over the interval $[0, \frac{\pi}{2}]$, find an upper sum; let $n = 6$.

**Answer**

$A \approx 1.125 \text{ units}^2$

# 5.2E: EXERCISES

This page is a draft and is under active development.

## READING QUESTIONS

1. What is sigma notation (or summation notation) used for? Explain the meaning of the components in $\sum_{i=1}^{n} a_i$.
2. What is a regular partition of an interval $[a, b]$? How is the width $\Delta x$ of each subinterval calculated if there are $n$ subintervals?
3. Describe the left-endpoint approximation method for estimating the area under a curve. How is the height of each rectangle determined?
4. Describe the right-endpoint approximation method. How does it differ from the left-endpoint method in determining rectangle height?
5. What is a Riemann sum? How does it generalize the left- and right-endpoint approximations?
6. What is an upper sum? What is a lower sum?
7. How is the exact area under a continuous, non-negative function $f(x)$ on an interval $[a, b]$ defined using Riemann sums?
8. What is the formula for the sum of the first $n$ integers, $\sum_{i=1}^{n} i$?
9. What is the formula for the sum of the first $n$ squares, $\sum_{i=1}^{n} i^2$?
10. Does the choice of sample points $x_i^*$ in a Riemann sum affect the value of the limit $\lim_{n\to\infty} \sum_{i=1}^{n} f(x_i^*)\Delta x$ if $f(x)$ is continuous?

## HOMEWORK

1.) State whether the given sums are equal or unequal.

a. $\sum_{i=1}^{10} i$ and $\sum_{k=1}^{10} k$

b. $\sum_{i=1}^{10} i$ and $\sum_{i=6}^{15} (i-5)$

c. $\sum_{i=1}^{10} i(i-1)$ and $\sum_{j=0}^{9} (j+1)j$

d. $\sum_{i=1}^{10} i(i-1)$ and $\sum_{k=1}^{10} (k^2-k)$

**Answer**

a. They are equal; both represent the sum of the first 10 whole numbers.

b. They are equal; both represent the sum of the first 10 whole numbers.

c. They are equal by substituting $j = i - 1$.

d. They are equal; the first sum factors the terms of the second.

**In exercises 2 - 3, use the rules for sums of powers of integers to compute the sums.**

2) $\sum_{i=5}^{10} i$

3) $\sum_{i=5}^{10} i^2$

**Answer**

$$\sum_{i=5}^{10} i^2 = 385 - 30 = 355$$

**Suppose that $\sum_{i=1}^{100} a_i = 15$ and $\sum_{i=1}^{100} b_i = -12$.**

**In exercises 4 - 7, compute the sums.**

4) $\sum_{i=1}^{100} (a_i + b_i)$

5) $\sum_{i=1}^{100} (a_i - b_i)$

**Answer**

$$\sum_{i=1}^{100}(a_i - b_i) = 15 - (-12) = 27$$

6) $\sum_{i=1}^{100}(3a_i - 4b_i)$

7) $\sum_{i=1}^{100}(5a_i + 4b_i)$

**Answer**

$$\sum_{i=1}^{100}(5a_i + 4b_i) = 5(15) + 4(-12) = 27$$

**In exercises 8 - 11, use summation properties and formulas to rewrite and evaluate the sums.**

8) $\sum_{k=1}^{20} 100(k^2 - 5k + 1)$

9) $\sum_{j=1}^{50}(j^2 - 2j)$

**Answer**

$$\sum_{j=1}^{50} j^2 - 2\sum_{j=1}^{50} j = \frac{(50)(51)(101)}{6} - \frac{2(50)(51)}{2} = 40,375$$

10) $\sum_{j=11}^{20}(j^2 - 10j)$

11) $\sum_{k=1}^{25}[(2k)^2 - 100k]$

**Answer**

$$4\sum_{k=1}^{25} k^2 - 100\sum_{k=1}^{25} k = \frac{4(25)(26)(51)}{9} - 50(25)(26) = -10,400$$

**Let $L_n$ denote the left-endpoint sum using n subintervals and let $R_n$ denote the corresponding right-endpoint sum.**

**In exercises 12 - 19, compute the indicated left and right sums for the given functions on the indicated interval.**

12) $L_4$ for $f(x) = \dfrac{1}{x-1}$ on $[2, 3]$

13) $R_4$ for $g(x) = \cos(\pi x)$ on $[0, 1]$

**Answer**

$R_4 = 0.25$

14) $L_6$ for $f(x) = \dfrac{1}{x(x-1)}$ on $[2, 5]$

15) $R_6$ for $f(x) = \dfrac{1}{x(x-1)}$ on $[2, 5]$

**Answer**

$R_6 = 0.372$

16) $R_4$ for $\dfrac{1}{x^2+1}$ on $[-2, 2]$

17) $L_4$ for $\dfrac{1}{x^2+1}$ on $[-2, 2]$

**Answer**

$L_4 = 2.20$

18) $R_4$ for $x^2 - 2x + 1$ on $[0, 2]$

19) $L_8$ for $x^2 - 2x + 1$ on $[0, 2]$

**Answer**

$L_8 = 0.6875$

20) Compute the left and right Riemann sums— $L_4$ and $R_4$, respectively—for $f(x) = (2 - |x|)$ on $[-2, 2]$. Compute their average value and compare it with the area under the graph of $f$.

21) Compute the left and right Riemann sums— $L_6$ and $R_6$, respectively—for $f(x) = (3 - |3 - x|)$ on $[0, 6]$. Compute their average value and compare it with the area under the graph of $f$.

**Answer**

$L_6 = 9.000 = R_6$. The graph of $f$ is a triangle with area $9\ \text{units}^2$.

22) Compute the left and right Riemann sums— $L_4$ and $R_4$, respectively—for $f(x) = \sqrt{4 - x^2}$ on $[-2, 2]$ and compare their values.

23) Compute the left and right Riemann sums— $L_6$ and $R_6$, respectively—for $f(x) = \sqrt{9 - (x - 3)^2}$ on $[0, 6]$ and compare their values.

**Answer**

$L_6 = 13.12899 = R_6$. They are equal.

**For exercises 24 - 27, express the following endpoint sums in sigma notation but do not evaluate them.**

24) $L_{30}$ for $f(x) = x^2$ on $[1, 2]$

25) $L_{10}$ for $f(x) = \sqrt{4 - x^2}$ on $[-2, 2]$

**Answer**

$$L_{10} = \frac{4}{10} \sum_{i=1}^{10} \sqrt{4 - (-2 + 4\frac{(i-1)}{10})}$$

26) $R_{20}$ for $f(x) = \sin x$ on $[0, \pi]$

27) $R_{100}$ for $\ln x$ on $[1, e]$

**Answer**

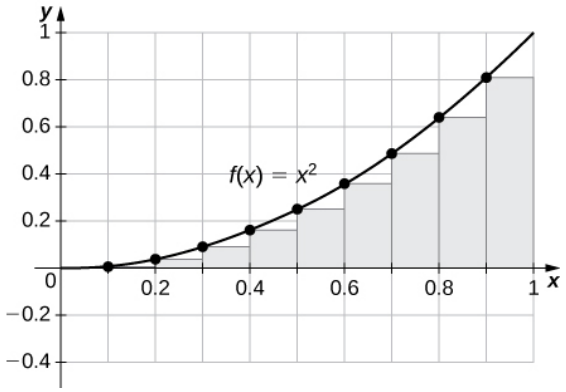
$$R_{100} = \frac{e-1}{100} \sum_{i=1}^{100} ln(1 + (e-1)\frac{i}{100})$$

**In exercises 28 - 33, graph the function then use a calculator or a computer program to evaluate the following left and right endpoint sums. Is the area under the curve between the left and right endpoint sums?**

28) [Technology Required] $L_{100}$ and $R_{100}$ for $y = x^2 - 3x + 1$ on the interval $[-1, 1]$

29) [Technology Required] $L_{100}$ and $R_{100}$ for $y = x^2$ on the interval $[0, 1]$

**Answer**



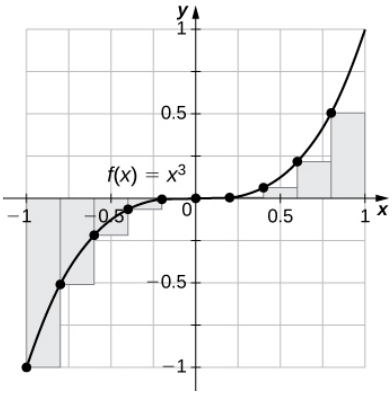
$R_{100} = 0.33835, \quad L_{100} = 0.32835.$

The plot shows that the left Riemann sum is an underestimate because the function is increasing. Similarly, the right Riemann sum is an overestimate. The area lies between the left and right Riemann sums. Ten rectangles are shown for visual clarity. This behavior persists for more rectangles.

30) [Technology Required] $L_{50}$ and $R_{50}$ for $y = \dfrac{x+1}{x^2-1}$ on the interval $[2, 4]$

31) [Technology Required] $L_{100}$ and $R_{100}$ for $y = x^3$ on the interval $[-1, 1]$

**Answer**



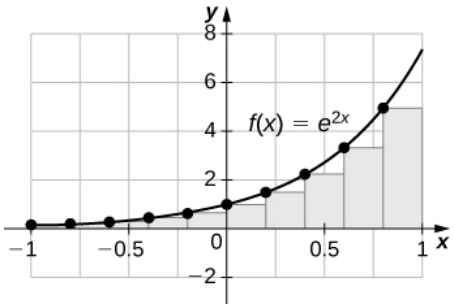
$L_{100} = -0.02, \quad R_{100} = 0.02.$

The left endpoint sum is an underestimate because the function is increasing. Similarly, a right endpoint approximation is an overestimate. The area lies between the left and right endpoint estimates.

32) [Technology Required] $L_{50}$ and $R_{50}$ for $y = \tan(x)$ on the interval $[0, \frac{\pi}{4}]$

33) [Technology Required] $L_{100}$ and $R_{100}$ for $y = e^{2x}$ on the interval $[-1, 1]$

**Answer**



$L_{100} = 3.555, \quad R_{100} = 3.670.$

The plot shows that the left Riemann sum is an underestimate because the function is increasing. Ten rectangles are shown for visual clarity. This behavior persists for more rectangles.

34) Let $t_j$ denote the time that it took Tejay van Garteren to ride the $j^{\text{th}}$ stage of the Tour de France in 2014. If there were a total of 21 stages, interpret $\sum_{j=1}^{21} t_j$.

35) Let $r_j$ denote the total rainfall in Portland on the $j^{\text{th}}$ day of the year in 2009. Interpret $\sum_{j=1}^{31} r_j$.

**Answer**

The sum represents the cumulative rainfall in January 2009.

36) Let $d_j$ denote the hours of daylight and $\delta_j$ denote the increase in the hours of daylight from day $j-1$ to day $j$ in Fargo, North Dakota, on the $j^{\text{th}}$ day of the year. Interpret $d1 + \sum_{j=2}^{365} \delta_j$.

37) To help get in shape, Joe gets a new pair of running shoes. If Joe runs 1 mi each day in week 1 and adds $\frac{1}{10}$ mi to his daily routine each week, what is the total mileage on Joe's shoes after 25 weeks?

**Answer**

The total mileage is $7 \times \sum_{i=1}^{25}(1+\frac{(i-1)}{10}) = 7 \times 25 + \frac{7}{10} \times 12 \times 25 = 385$ mi.

38) The following table gives approximate values of the average annual atmospheric rate of increase in carbon dioxide ($CO_2$) each decade since 1960, in parts per million (ppm). Estimate the total increase in atmospheric $CO_2$ between 1964 and 2013.

| Decade | Ppm/y |
|---|---|
| 1964-1973 | 1.07 |
| 1976-1983 | 1.34 |
| 1984-1993 | 1.40 |
| 1994-2003 | 1.87 |
| 2004-2013 | 2.07 |

Average Annual Atmospheric CO2 Increase, 1964–2013 Source: http://www.esrl.noaa.gov/gmd/ccgg/trends/.

39) The following table gives the approximate increase in sea level in inches over 20 years starting in the given year. Estimate the net change in mean sea level from 1870 to 2010.

| Starting Year | 20- Year Change |
|---|---|
| 1870 | 0.3 |
| 1890 | 1.5 |
| 1910 | 0.2 |
| 1930 | 2.8 |
| 1950 | 0.7 |
| 1970 | 1.1 |
| 1990 | 1.5 |

Approximate 20-Year Sea Level Increases, 1870–1990

Source: http://link.springer.com/article/10....712-011-9119-1

**Answer**

Add the numbers to get 8.1-in. net increase.

40) The following table gives the approximate increase in dollars in the average price of a gallon of gas per decade since 1950. If the average price of a gallon of gas in 2010 was $2.60, what was the average price of a gallon of gas in 1950?

| Starting Year | 10- Year Change |
|---|---|
| 1950 | 0.03 |
| 1960 | 0.05 |
| 1970 | 0.86 |
| 1980 | −0.03 |
| 1990 | 0.29 |

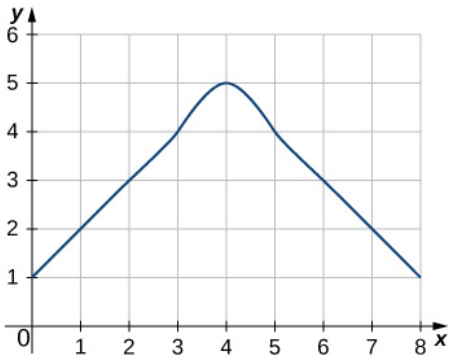
(Hint: To obtain the population in July 2001, multiply the population in July 2000 by 1.0112 to get 284,573,831.)

**Answer**

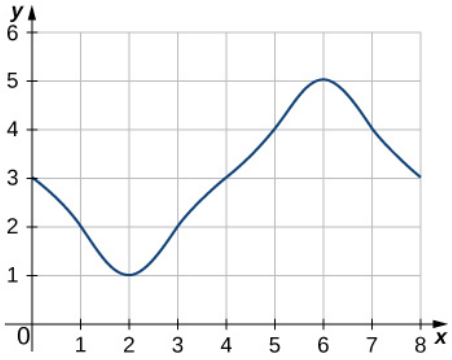
309,389,957

**In exercises 42 - 45, estimate the areas under the curves by computing the left Riemann sums, $L_8$.**

42)



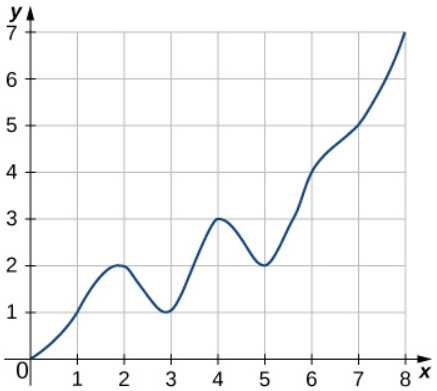
43)



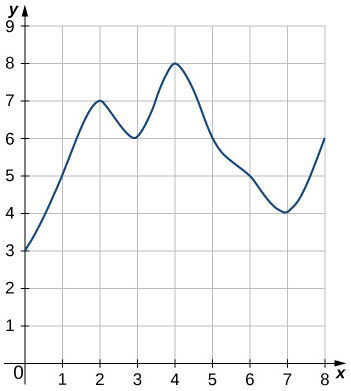
**Answer**

$L_8 = 3+2+1+2+3+4+5+4 = 24$

44)



45)



**Answer**

$L_8 = 3+5+7+6+8+6+5+4 = 44$

46) [Technology Required] Use a computer algebra system to compute the Riemann sum, $L_N$, for $N = 10, 30, 50$ for $f(x) = \sqrt{1-x^2}$ on $[-1, 1]$.

47) [Technology Required] Use a computer algebra system to compute the Riemann sum, $L_N$, for $N = 10, 30, 50$ for $f(x) = \dfrac{1}{\sqrt{1+x^2}}$ on $[-1, 1]$.

**Answer**

$L_{10} \approx 1.7604, \quad L_{30} \approx 1.7625, \quad L_{50} \approx 1.76265$

48) [Technology Required] Use a computer algebra system to compute the Riemann sum, $L_N$, for $N = 10, 30, 50$ for $f(x) = \sin^2 x$ on $[0, 2\pi]$. Compare these estimates with $\pi$.

**In exercises 49-50, use a calculator or a computer program to evaluate the endpoint sums $R_N$ and $L_N$ for $N = 1, 10, 100$. How do these estimates compare with the exact answers, which you can find via geometry?**

49) [Technology Required] $y = \cos(\pi x)$ on the interval $[0, 1]$

**Answer**

$R_1 = -1, \quad L_1 = 1,$
$R_{10} = -0.1, \quad L_{10} = 0.1,$
$L_{100} = 0.01, \quad R_{100} = -0.01.$
By symmetry of the graph, the exact area is zero.

50) [Technology Required] $y = 3x + 2$ on the interval $[3, 5]$

**In exercises 51 - 52, use a calculator or a computer program to evaluate the endpoint sums $R_N$ and $L_N$ for $N = 1, 10, 100$.**

51) [Technology Required] $y = x^4 - 5x^2 + 4$ on the interval $[-2, 2]$, which has an exact area of $\frac{32}{15}$

**Answer**

$R_1 = 0, \quad L_1 = 0,$
$R_{10} = 2.4499, \quad L_{10} = 2.4499,$
$R_{100} = 2.1365, \quad L_{100} = 2.1365$

52) [Technology Required] $y = \ln x$ on the interval $[1, 2]$, which has an exact area of $2\ln(2) - 1$

53) Explain why, if $f(a) \geq 0$ and $f$ is increasing on $[a, b]$, that the left endpoint estimate is a lower bound for the area below the graph of $f$ on $[a, b]$.

**Answer**

If $[c, d]$is a subinterval of $[a, b]$ under one of the left-endpoint sum rectangles, then the area of the rectangle contributing to the left-endpoint estimate is $f(c)(d - c)$. But, $f(c) \leq f(x)$ for $c \leq x \leq d$, so the area under the graph of $f$ between $c$ and $d$ is $f(c)(d - c)$ plus the area below the graph of $f$ but above the horizontal line segment at height $f(c)$, which is positive. As this is true for each left-endpoint sum interval, it follows that the left Riemann sum is less than or equal to the area below the graph of $f$ on $[a, b]$.

54) Explain why, if $f(b) \geq 0$ and f is decreasing on $[a, b]$, that the left endpoint estimate is an upper bound for the area below the graph of $f$ on $[a, b]$.

55) Show that, in general, $R_N - L_N = (b - a) \times \dfrac{f(b) - f(a)}{N}$.

**Answer**

$$\begin{aligned} L_N &= \frac{b-a}{N}\sum_{i=1}^{N} f\left(a + (b-a)\frac{i-1}{N}\right) \\ &= \frac{b-a}{N}\sum_{i=0}^{N-1} f\left(a + (b-a)\frac{i}{N}\right) \end{aligned}$$

and

$$R_N = \frac{b-a}{N}\sum_{i=1}^{N} f\left(a + (b-a)\frac{i}{N}\right)$$

The left sum has a term corresponding to $i = 0$ and the right sum has a term corresponding to $i = N$. In $R_N - L_N$, any term corresponding to $i = 1, 2, \ldots, N - 1$ occurs once with a plus sign and once with a minus sign, so each such term cancels and one is left with

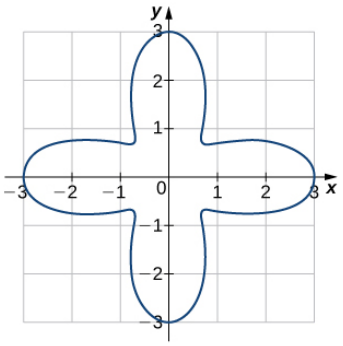
$$\begin{aligned} R_N - L_N &= \frac{b-a}{N} \cdot f\left(a + (b-a)\frac{N}{N}\right) - f\left(a + (b-a)\cdot\frac{0}{N}\right) \\ &= \frac{b-a}{N}(f(b) - f(a)) \end{aligned}$$

56) Explain why, if $f$ is increasing on $[a, b]$, the error between either $L_N$ or $R_N$ and the area $A$ below the graph of $f$ is at most $(b - a)\dfrac{f(b) - f(a)}{N}$.

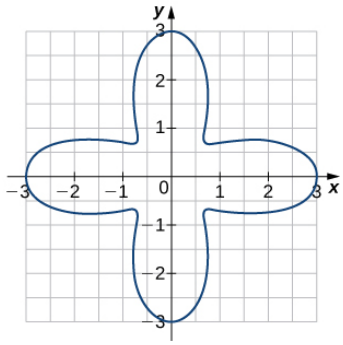
57) For each of the three graphs:

a. Obtain a lower bound $L(A)$ for the area enclosed by the curve by adding the areas of the squares enclosed completely by the curve.

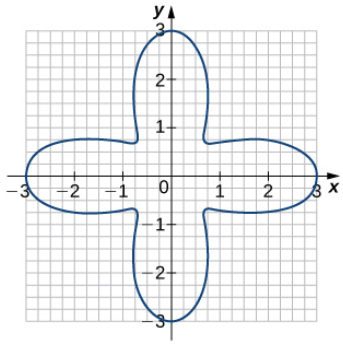
b. Obtain an upper bound $U(A)$ for the area by adding to $L(A)$ the areas $B(A)$ of the squares enclosed partially by the curve.



Graph 1



Graph 2



Graph 3

**Answer**

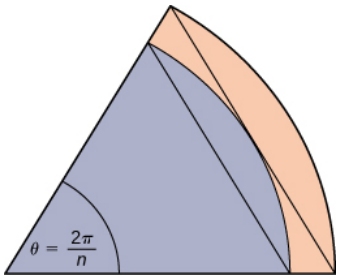
Graph 1: a. $L(A) = 0, \quad B(A) = 20; \quad b. U(A) = 20.$

Graph 2: $a. L(A) = 9; \quad b. B(A) = 11, \quad U(A) = 20.$

Graph 3: a. $L(A) = 11.0; \quad b. B(A) = 4.5, \quad U(A) = 15.5.$

58) In the previous exercise, explain why $L(A)$ gets no smaller while $U(A)$ gets no larger as the squares are subdivided into four boxes of equal area.

59) A unit circle is made up of n wedges equivalent to the inner wedge in the figure. The base of the inner triangle is 1 unit and its height is $\sin(\frac{\pi}{n})$. The base of the outer triangle is $B = \cos(\frac{\pi}{n}) + \sin(\frac{\pi}{n}) \tan(\frac{\pi}{n})$ and the height is $H = B \sin(\frac{2\pi}{n})$. Use this information to argue that the area of a unit circle is equal to $\pi$.



**Answer**

Let $A$ be the area of the unit circle. The circle encloses $n$ congruent triangles each of area $\frac{\sin(\frac{2\pi}{n})}{2}$, so $\frac{n}{2}\sin(\frac{2\pi}{n}) \leq A$. Similarly, the circle is contained inside $n$ congruent triangles each of area $\frac{BH}{2} = \frac{1}{2}(\cos(\frac{\pi}{n}) + \sin(\frac{\pi}{n})\tan(\frac{\pi}{n}))\sin(\frac{2\pi}{n})$, so $A \leq \frac{n}{2}\sin(\frac{2\pi}{n})(\cos(\frac{\pi}{n})) + \sin(\frac{\pi}{n})\tan(\frac{\pi}{n}))$. As $n \to \infty, \quad \frac{n}{2}\sin(\frac{2\pi}{n}) = \frac{\pi\sin(\frac{2\pi}{n})}{(\frac{2\pi}{n})} \to \pi$, so we conclude $\pi \leq A$. Also, as $n \to \infty, \quad \cos(\frac{\pi}{n}) + \sin(\frac{\pi}{n})\tan(\frac{\pi}{n}) \to 1$, so we also have $A \leq \pi$. By the squeeze theorem for limits, we conclude that $A = \pi$.

# 5.3: The Definite Integral

**Learning Objectives**

- State the definition of the definite integral.
- Explain the terms integrand, limits of integration, and variable of integration.
- Explain when a function is integrable.
- Describe the relationship between the definite integral and net area.
- Use Geometry and the properties of definite integrals to evaluate them.

Hawk A.I. Section-Specific Tutor

Please note that, to access the Hawk A.I. Tutor, you will need a (free) OpenAI account.

In the preceding section, we defined the area under a curve in terms of Riemann sums:

$$A = \lim_{n\to\infty} \sum_{i=1}^{n} f(x_i^*)\Delta x.$$

However, this definition came with restrictions. We required $f(x)$ to be continuous and nonnegative. Unfortunately, real-world problems don't always meet these restrictions. In this section, we look at applying the concept of the area under the curve to a broader set of functions using the definite integral.

## Definition and Notation

The **definite integral** generalizes the concept of the area under a curve. We lift the requirements that $f(x)$ be continuous and nonnegative, and define the definite integral as follows.

**Definition: Definite Integral**

If $f(x)$ is a function defined on an interval $[a, b]$, the **definite integral** of $f$ from $a$ to $b$ is given by

$$\int_a^b f(x)\,dx = \lim_{n\to\infty} \sum_{i=1}^{n} f(x_i^*)\Delta x,$$

provided the limit exists. If this limit exists, the function $f(x)$ is said to be **integrable** on $[a, b]$, or is an **integrable function**.

The integral symbol in the previous definition should look familiar. We have seen a similar notation in a previous section, where we used the indefinite integral symbol (without the $a$ and $b$ above and below) to represent an antiderivative. Although the notation for indefinite integrals may look similar to that of a definite integral, they are not the same. A definite integral is a number. An indefinite integral is a family of functions. Later in this chapter, we examine how these concepts are related. However, close attention should always be paid to notation so we know whether we're working with a definite integral or an indefinite integral.

Integral notation goes back to the late seventeenth century. It is one of the contributions of Gottfried Wilhelm Leibniz, who is often considered the co-discoverer of Calculus, along with Isaac Newton. The integration symbol $\int$ is an elongated $S$, suggesting sigma or summation. On a definite integral, above and below the summation symbol are the boundaries of the interval, $[a, b]$. The numbers $a$ and $b$ are $x$-values and are called the **limits of integration**; specifically, $a$ is the **lower limit** and $b$ is the **upper limit**. To clarify, we use the word limit in two different ways in the context of the definite integral. First, we talk about the limit of a sum as $n \to \infty$. Second, the boundaries of the region are called the limits of integration.

We call the function $f(x)$ the **integrand**, and the $dx$ indicates that $f(x)$ is a function with respect to $x$, called the **variable of integration**. Note that, like the index in a sum, the variable of integration is a **dummy variable** and has no impact on the computation of the integral. We could use any variable we like as the variable of integration:

$$\int_a^b f(x)\,dx = \int_a^b f(t)\,dt = \int_a^b f(u)\,du$$

Previously, we discussed the fact that if $f(x)$ is continuous on $[a, b]$, then the limit $\lim_{n\to\infty} \sum_{i=1}^{n} f(x_i^*)\Delta x$ exists and is unique. This leads to the following theorem, which we state without proof.

**Theorem: Continuous Functions Are Integrable**

If $f(x)$ is continuous on $[a, b]$, then $f$ is integrable on $[a, b]$.

Functions that are not continuous on $[a, b]$ may still be integrable, depending on the nature of the discontinuities. For example, functions with a finite number of jump discontinuities or removable discontinuities on a closed interval are integrable.

It is also worth noting that we are using a regular partition in the Riemann sums. This is not strictly necessary. Any partition can be used to form a Riemann sum. However, if a non-regular partition defines the definite integral, it is not sufficient to take the limit as the number of subintervals goes to infinity. Instead, we must take the limit as the width of the largest subinterval goes to zero. This introduces a more complex notation in our limits and makes the calculations more difficult without really gaining much additional insight, so we stick with regular partitions for the Riemann sums.

**Example 5.3.1: Evaluating an Integral Using the Definition**

Use the definition of the definite integral to evaluate $\int_0^2 x^2\,dx$. Use a right-endpoint approximation to generate the Riemann sum.

**Solution**

We first want to set up a Riemann sum. Based on the limits of integration, we have $a = 0$ and $b = 2$. For $i = 0, 1, 2, \ldots, n$, let $P = x_i$ be a regular partition of $[0, 2]$. Then

$$\Delta x = \frac{b-a}{n} = \frac{2}{n}.$$

Since we are using a right-endpoint approximation to generate Riemann sums, for each $i$, we need to calculate the function value at the right endpoint of the interval $[x_{i-1}, x_i]$. The right endpoint of the interval is $x_i$, and since $P$ is a regular partition,

$$x_i = x_0 + i\Delta x = 0 + i\left[\frac{2}{n}\right] = \frac{2i}{n}.$$

Thus, the function value at the right endpoint of the interval is

$$f(x_i) = x_i^2 = \left(\frac{2i}{n}\right)^2 = \frac{4i^2}{n^2}.$$

Then the Riemann sum takes the form

$$\sum_{i=1}^{n} f(x_i)\Delta x = \sum_{i=1}^{n} \left(\frac{4i^2}{n^2}\right)\frac{2}{n} = \sum_{i=1}^{n} \frac{8i^2}{n^3} = \frac{8}{n^3}\sum_{i=1}^{n} i^2.$$

Using the summation formula for $\sum_{i=1}^{n} i^2$, we have

$$\begin{aligned}\sum_{i=1}^{n} f(x_i)\Delta x &= \frac{8}{n^3}\sum_{i=1}^{n} i^2 \\ &= \frac{8}{n^3}\left[\frac{n(n+1)(2n+1)}{6}\right] \\ &= \frac{8}{n^3}\left[\frac{2n^3+3n^2+n}{6}\right] \\ &= \frac{16n^3+24n^2+8n}{6n^3} \\ &= \frac{8}{3}+\frac{4}{n}+\frac{4}{3n^2}.\end{aligned}$$

Now, to calculate the definite integral, we need to take the limit as $n \to \infty$. We get

$$\begin{aligned}\int_0^2 x^2 dx &= \lim_{n\to\infty}\sum_{i=1}^{n} f(x_i)\Delta x \\ &= \lim_{n\to\infty}\left(\frac{8}{3}+\frac{4}{n}+\frac{4}{3n^2}\right) \\ &= \lim_{n\to\infty}\left(\frac{8}{3}\right)+\lim_{n\to\infty}\left(\frac{4}{n}\right)+\lim_{n\to\infty}\left(\frac{4}{3n^2}\right) \\ &= \frac{8}{3}+0+0 \\ &= \frac{8}{3}.\end{aligned}$$

**? Checkpoint 5.3.1**

Use the definition of the definite integral to evaluate $\int_0^3 (2x-1)\,dx$. Use a right-endpoint approximation to generate the Riemann sum.

**Answer**

6

## Evaluating Definite Integrals Using Geometry

Evaluating definite integrals this way can be tedious because of the complexity of the calculations. Later in this chapter, we develop techniques for evaluating definite integrals *without* taking limits of Riemann sums. However, for now, we can rely on the fact that definite integrals represent the area under the curve, and we can evaluate definite integrals by using geometric formulas to calculate that area. We do this to confirm that definite integrals do, indeed, represent areas, so we can then discuss what to do in the case of a curve of a function dropping below the $x$-axis.

**✔ Example 5.3.2: Using Geometric Formulas to Calculate Definite Integrals**

Use the formula for the area of a circle to evaluate $\int_3^6 \sqrt{9-(x-3)^2}\,dx$.

**Solution**

The function describes a semicircle with radius 3. To find

$$\int_3^6 \sqrt{9-(x-3)^2}\,dx$$

we want to find the area under the curve over the interval $[3,6]$. The formula for the area of a circle is $A=\pi r^2$. The area of a semicircle is just one-half the area of a circle, or $A=\frac{1}{2}\pi r^2$. The shaded area in Figure 5.3.1 covers one-half of the semicircle, or $A=\frac{1}{4}\pi r^2$. Thus,

$$\int_3^6 \sqrt{9-(x-3)^2}\,dx = \frac{1}{4}\pi(3)^2 = \frac{9}{4}\pi \approx 7.069.$$

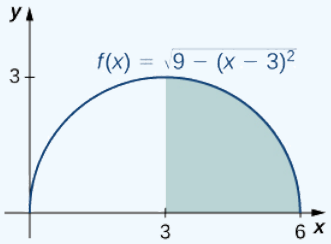


*Figure* **5.3.1**: *The value of the integral of the function* $f(x)$ *over the interval* $[3, 6]$ *is the area of the shaded region.*

**? Checkpoint 5.3.2**

Use the formula for the area of a trapezoid to evaluate $\int_2^4 (2x+3)\,dx$.

**Answer**

18 square units

The ability to think geometrically can be *very* useful when it comes to evaluating definite integrals. It's always a good idea to see if the integrand represents a simple geometric curve for which you have an area formula. This will often be circles and lines.

## Area and the Definite Integral

When we defined the definite integral, we lifted the requirement that $f(x)$ be nonnegative. But how do we interpret "the area under the curve" when $f(x)$ is negative?

Let us return to the Riemann sum. Consider, for example, the function $f(x) = 2 - 2x^2$ (shown in Figure **5.3.2**) on the interval $[0, 2]$. Use $n = 8$ and choose $x_i^*$ as the left-endpoint of each interval. Construct a rectangle on each subinterval of height $f(x_i^*)$ and width $\Delta x$. When $f(x_i^*)$ is positive, the product $f(x_i^*)\Delta x$ represents the area of the rectangle, as before. When $f(x_i^*)$ is negative, however, the product $f(x_i^*)\Delta x$ represents the negative of the area of the rectangle. The Riemann sum then becomes

$$\sum_{i=1}^{8} f(x_i^*)\Delta x = (\text{Area of rectangles above the } x\text{-axis}) - (\text{Area of rectangles below the } x\text{-axis})$$

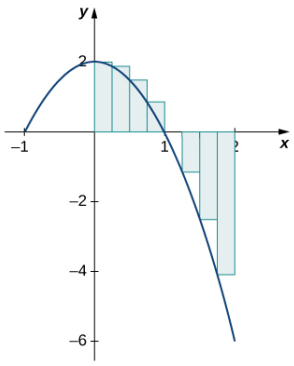

*Figure* **5.3.2**: *For a function that is partly negative, the Riemann sum is the area of the rectangles above the* $x$*-axis less the area of the rectangles below the* $x$*-axis.*

Taking the limit as $n \to \infty$, the Riemann sum approaches the area between the curve above the $x$-axis and the $x$-axis, less the area between the curve below the $x$-axis and the $x$-axis, as shown in Figure **5.3.3**. Then,

$$\int_0^2 f(x)\,dx = \lim_{n\to\infty} \sum_{i=1}^{n} f(c_i)\Delta x = A_1 - A_2.$$

The quantity $A_1 - A_2$ is called the **net signed area.**

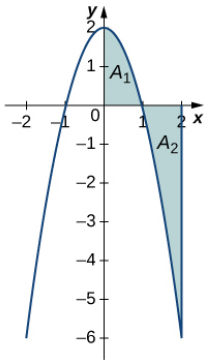

*Figure 5.3.3: In the limit, the definite integral equals area $A_1$ less area $A_2$, or the net signed area.*

Notice that the net signed area can be positive, negative, or zero. The net signed area is positive if the area above the $x$-axis is larger. The net signed area is negative if the area below the $x$-axis is larger. The net signed area is zero if the areas above and below the $x$-axis are equal.

### Example 5.3.3: Finding the Net Signed Area

Find the net signed area between the curve of the function $f(x) = 2x$ and the $x$-axis over the interval $[-3, 3]$.

**Solution**

The function produces a straight line that forms two triangles: one from $x = -3$ to $x = 0$ and the other from $x = 0$ to $x = 3$ (Figure 5.3.4). Using the geometric formula for the area of a triangle, $A = \frac{1}{2}bh$, the area of triangle $A_1$, above the axis, is

$$A_1 = \frac{1}{2}3(6) = 9,$$

where $3$ is the base and $2(3) = 6$ is the height. The area of triangle $A_2$, below the axis, is

$$A_2 = \frac{1}{2}(3)(6) = 9,$$

where $3$ is the base and $6$ is the height. Thus, the net area is

$$\int_{-3}^{3} 2x\,dx = A_1 - A_2 = 9 - 9 = 0.$$

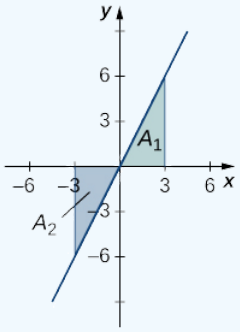

*Figure 5.3.4: The area above the curve and below the $x$-axis equals the area below the curve and above the $x$-axis.*

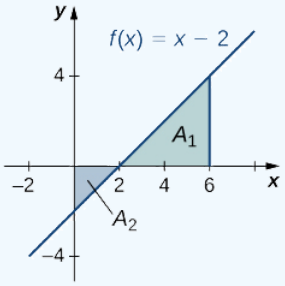
#### Analysis

If $A_1$ is the area above the $x$-axis and $A_2$ is the area below the $x$-axis, then the net area is $A_1 - A_2$. Since the areas of the two triangles are equal, the net area is zero.

**? Checkpoint 5.3.3**

Find the net signed area of $f(x) = x - 2$ over the interval $[0, 6]$, illustrated in the following image.



**Answer**

6

One application of the definite integral is finding **displacement** when given a velocity function. If $v(t)$ represents the velocity of an object as a function of time, then the area under the curve tells us how far the object is from its original position. This is an essential application of the definite integral, and we examine it in more detail later in the chapter. We will look at some basic examples involving constant velocities to understand how this works.

When velocity is a constant, the area under the curve is just velocity times time. This idea is already very familiar. If a car travels away from its starting position in a straight line at a speed of $70$ mph for $2$ hours, then it is $140$ miles away from its original position (Figure $5.3.5$). Using integral notation, we have

$$\int_0^2 70\,dt = 140 \text{ miles.}$$

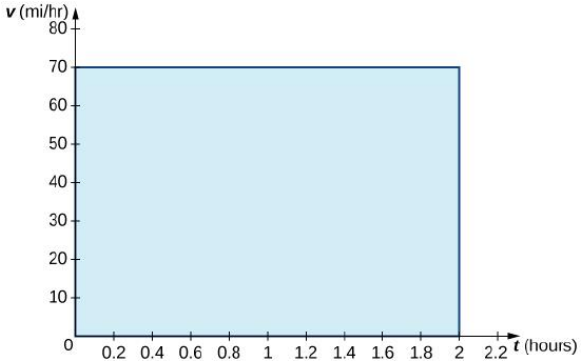


*Figure $5.3.5$: The area under the curve $v(t) = 70$ tells us how far the car is from its starting point at a given time.*

In the context of displacement, the net signed area allows us to consider direction. If a car travels straight north at 60 mph for 2 hours, it is 120 miles north of its starting position. If the car then turns around and travels south at a speed of 40 mph for 3 hours, it will be back at its starting position (Figure $5.3.6$). Again, using integral notation, we have

$$\int_0^2 60\,dt + \int_2^5 -40\,dt = 120 - 120 = 0.$$

In this case, the displacement is zero.

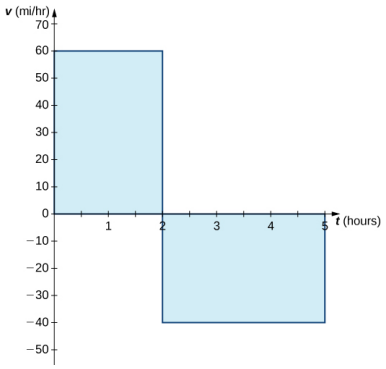

*Figure* **5.3.6***: The area above and below the axis is equal, so the net signed area is zero.*

Suppose we want to know how far the car travels, regardless of direction. In this case, we want to know the area between the curve and the $t$-axis, regardless of whether that area is above or below the axis. This is called the **total area.**

Graphically, it is easiest to calculate the total area by adding the areas above and below the axis (rather than subtracting the areas below the axis, as we did with the net signed area). To accomplish this mathematically, we use the absolute value function. Thus, the total distance traveled by the car is

$$\int_0^2 |60|\,dt + \int_2^5 |-40|\,dt = \int_0^2 60\,dt + \int_2^5 40\,dt = 120 + 120 = 240.$$

Bringing these ideas together formally, we state the following definitions.

### Definition: Net Signed Area

Let $f(x)$ be an integrable function defined on an interval $[a, b]$. Let $A_1$ represent the area between $f(x)$ and the $x$-axis that lies above the axis, and let $A_2$ represent the area between $f(x)$ and the $x$-axis that lies below the axis. Then, the **net signed area** between $f(x)$ and the $x$-axis is given by

$$\int_a^b f(x)\,dx = A_1 - A_2.$$

The total area between $f(x)$ and the $x$-axis is given by

$$\int_a^b |f(x)|\,dx = A_1 + A_2.$$

### Example 5.3.4: Finding the Total Area

Find the total area between $f(x) = x - 2$ and the $x$-axis over the interval $[0, 6]$.

**Solution**

Calculate the $x$-intercept as $(2, 0)$ (set $y = 0$, solve for $x$). To find the total area, take the area below the $x$-axis over the subinterval $[0, 2]$ and add it to the area above the $x$-axis on the subinterval $[2, 6]$ (Figure 5.3.7).

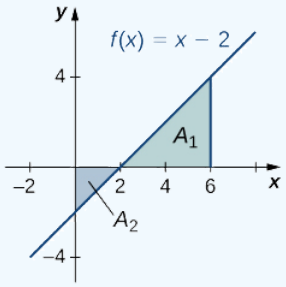

*Figure* **5.3.7***: The total area between the line and the $x$-axis over $[0, 6]$ is $A_2$ plus $A_1$.*

We have

$$\int_0^6 |x-2|\,dx = A_2 + A_1.$$

Then, using the formula for the area of a triangle, we obtain

$$A_2 = \frac{1}{2}bh = \frac{1}{2}\cdot 2\cdot 2 = 2$$

$$A_1 = \frac{1}{2}bh = \frac{1}{2}\cdot 4\cdot 4 = 8.$$

The total area, then, is

$$A_1 + A_2 = 8 + 2 = 10\,\text{units}^2.$$

**Checkpoint 5.3.4**

Find the total area between the function $f(x) = 2x$ and the $x$-axis over the interval $[-3, 3]$.

**Answer**

$18\,\text{units}^2$

## Properties of the Definite Integral

The properties of indefinite integrals also apply to definite integrals. Definite integrals also have properties that relate to the limits of integration. These properties, along with the rules of integration that we examine later in this chapter, help us manipulate expressions to evaluate definite integrals.

**Theorem: Properties of the Definite Integral**

1. If the limits of integration are the same, the integral is just a vertical line and contains no area. That is,

$$\int_a^a f(x)\,dx = 0.$$

2. If the limits are reversed, place a negative sign before the integral. That is,

$$\int_b^a f(x)\,dx = -\int_a^b f(x)\,dx.$$

3. The integral of a sum is the sum of the integrals. That is,

$$\int_a^b [f(x) + g(x)]\,dx = \int_a^b f(x)\,dx + \int_a^b g(x)\,dx.$$

4. The integral of a difference is the difference of the integrals. That is,

$$\int_a^b [f(x) - g(x)]\,dx = \int_a^b f(x)\,dx - \int_a^b g(x)\,dx.$$

5. The integral of the product of a constant and a function is equal to the constant multiplied by the integral of the function. That is, for a constant $c$,

$$\int_a^b cf(x)\,dx = c\int_a^b f(x)\,dx.$$

6. An integral can be split into pieces. That is,

$$\int_a^b f(x)\,dx = \int_a^c f(x)\,dx + \int_c^b f(x)\,dx.$$

Although this formula normally applies when $c$ is between $a$ and $b$, the formula holds for all values of $a$, $b$, and $c$, provided $f(x)$ is integrable on the largest interval.

### Example 5.3.5: Using the Properties of the Definite Integral

Use the properties of the definite integral to express the definite integral of $f(x) = -3x^3 + 2x + 2$ over the interval $[-2, 1]$ as the sum of three definite integrals.

**Solution**

Using integral notation, we have $\int_{-2}^{1} (-3x^3 + 2x + 2)\, dx$. We apply properties 3. and 5. to get

$$\begin{aligned} \int_{-2}^{1}(-3x^3 + 2x + 2)\, dx &= \int_{-2}^{1} -3x^3\, dx + \int_{-2}^{1} 2x\, dx + \int_{-2}^{1} 2\, dx \\ &= -3\int_{-2}^{1} x^3\, dx + 2\int_{-2}^{1} x\, dx + \int_{-2}^{1} 2\, dx. \end{aligned}$$

### Checkpoint 5.3.5

Use the properties of the definite integral to express the definite integral of $f(x) = 6x^3 - 4x^2 + 2x - 3$ over the interval $[1, 3]$ as the sum of four definite integrals.

**Answer**

$$6\int_1^3 x^3\, dx - 4\int_1^3 x^2\, dx + 2\int_1^3 x\, dx - \int_1^3 3\, dx$$

### Example 5.3.6: Using the Properties of the Definite Integral

If it is known that $\int_0^8 f(x)\, dx = 10$ and $\int_0^5 f(x)\, dx = 5$, find the value of $\int_5^8 f(x)\, dx$.

**Solution**

By property 6,

$$\int_a^b f(x)\, dx = \int_a^c f(x)\, dx + \int_c^b f(x)\, dx.$$

Thus,

$$\begin{aligned} \int_0^8 f(x)\, dx &= \int_0^5 f(x)\, dx + \int_5^8 f(x)\, dx \\ 10 &= 5 + \int_5^8 f(x)\, dx \\ 5 &= \int_5^8 f(x)\, dx. \end{aligned}$$

### Checkpoint 5.3.6

If it is known that $\int_1^5 f(x)\, dx = -3$ and $\int_2^5 f(x)\, dx = 4$, find the value of $\int_1^2 f(x)\, dx$.

**Answer**

$-7$

## Comparison Properties of Integrals

A picture can sometimes tell us more about a function than the results of computations. Comparing functions by their graphs and algebraic expressions can give new insight into the process of integration. Intuitively, we might say that if a function $f(x)$ is above another function $g(x)$, then the area between $f(x)$ and the $x$-axis is greater than the area between $g(x)$ and the $x$-axis. This is true depending on the interval over which the comparison is made. The properties of definite integrals are valid whether $a < b$, $a = b$, or $a > b$. The following properties, however, concern only the case $a \leq b$ and are used when we want to compare the sizes of integrals.

### Theorem: Comparison Theorem

i. If $f(x) \geq 0$ for $a \leq x \leq b$, then

$$\int_a^b f(x)\,dx \geq 0.$$

ii. If $f(x) \geq g(x)$ for $a \leq x \leq b$, then

$$\int_a^b f(x)\,dx \geq \int_a^b g(x)\,dx.$$

iii. If $m$ and $M$ are constants such that $m \leq f(x) \leq M$ for $a \leq x \leq b$, then

$$m(b-a) \leq \int_a^b f(x)\,dx \leq M(b-a).$$

### Example 5.3.7: Comparing Two Functions over a Given Interval

Compare $f(x) = \sqrt{1+x^2}$ and $g(x) = \sqrt{1+x}$ over the interval $[0,1]$.

**Solution**

Graphing these functions is necessary to understand how they compare over the interval $[0,1]$. Initially, when graphed on a graphing calculator, $f(x)$ appears to be above $g(x)$ everywhere. However, the graphs appear the same on the interval $[0,1]$. We need to zoom in to see that $g(x)$ is above $f(x)$ on the given interval. The two functions intersect at $x = 0$ and $x = 1$ (Figure 5.3.8).

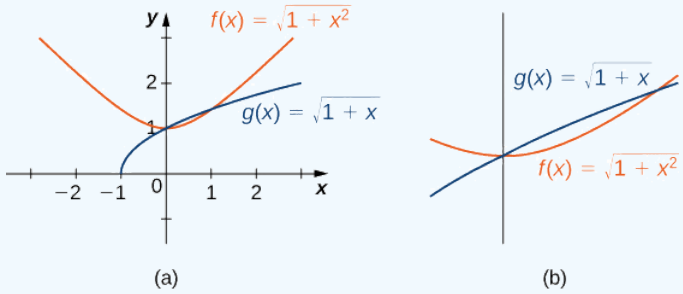

*Figure 5.3.8a: The function $f(x)$ appears above the function $g(x)$ except over the interval $[0,1]$.*
*Figure 5.3.8b: Viewing the same graph with a greater zoom shows this more clearly.*

We can see from the graph that over the interval $[0,1]$, $g(x) \geq f(x)$. Comparing the integrals over the specified interval $[0,1]$, we also see that $\int_0^1 g(x)\,dx \geq \int_0^1 f(x)\,dx$ (Figure 5.3.9). The thin, red-shaded area shows just how much difference there is between these two integrals over the interval $[0,1]$.

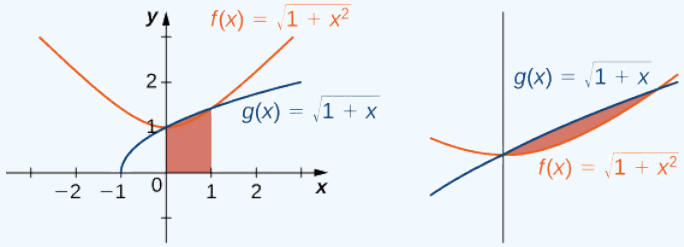

*Figure* **5.3.9a**: *The graph shows that over the interval* $[0, 1], g(x) \geq f(x)$, *where equality holds only at the endpoints of the interval.*

*Figure* **5.3.9b**: *Viewing the same graph with a greater zoom shows this more clearly.*

# 5.3E: EXERCISES

This page is a draft and is under active development.

## READING QUESTIONS

1. How is the definite integral $\int_a^b f(x)\,dx$ defined in terms of a limit of Riemann sums?
2. What are the "limits of integration" in a definite integral? What do $a$ and $b$ represent?
3. What is the difference between a definite integral and an indefinite integral?
4. What does it mean for a function to be "integrable" on an interval $[a,b]$? Are all continuous functions on $[a,b]$ integrable?
5. How does the definite integral relate to the concept of "net signed area"? Explain what happens to areas below the $x$-axis.
6. How can you find the "total area" between a curve $y=f(x)$ and the $x$-axis over $[a,b]$ using a definite integral?
7. If $v(t)$ is a velocity function, what does $\int_a^b v(t)\,dt$ represent?
8. State the property of definite integrals: $\int_a^a f(x)\,dx =$?
9. State the property of definite integrals: $\int_a^b f(x)\,dx =? \cdot \int_b^a f(x)\,dx$
10. State the property of definite integrals regarding the integral of a sum: $\int_a^b [f(x)+g(x)]\,dx =$?
11. State the property of definite integrals: $\int_a^b cf(x)\,dx =$? (where $c$ is a constant).
12. State the additivity property of definite integrals: $\int_a^b f(x)\,dx = \int_a^c f(x)\,dx +$?
13. What does the Comparison Theorem state about $\int_a^b f(x)\,dx$ if $f(x) \geq 0$ on $[a,b]$?

## HOMEWORK

**In exercises 1 - 4, express the limits as integrals.**

1) $\lim\limits_{n\to\infty} \sum\limits_{i=1}^{n} (x_i^*)\Delta x$ over $[1,3]$

2) $\lim\limits_{n\to\infty} \sum\limits_{i=1}^{n} (5(x_i^*)^2 - 3(x_i^*)^3)\Delta x$ over $[0,2]$

**Answer**

$$\int_0^2 (5x^2 - 3x^3)\,dx$$

3) $\lim\limits_{n\to\infty} \sum\limits_{i=1}^{n} \sin^2(2\pi x_i^*)\Delta x$ over $[0,1]$

4) $\lim\limits_{n\to\infty} \sum\limits_{i=1}^{n} \cos^2(2\pi x_i^*)\Delta x$ over $[0,1]$

**Answer**

$$\int_0^1 \cos^2(2\pi x)\,dx$$

**In exercises 5 - 10, given $L_n$ or $R_n$ as indicated, express their limits as $n\to\infty$ as definite integrals, identifying the correct intervals.**

5) $L_n = \dfrac{1}{n}\sum\limits_{i=1}^{n} \dfrac{i-1}{n}$

6) $R_n = \dfrac{1}{n}\sum\limits_{i=1}^{n} \dfrac{i}{n}$

**Answer**

$$\int_0^1 x\,dx$$

7) $Ln = \dfrac{2}{n}\sum\limits_{i=1}^{n} (1 + 2\dfrac{i-1}{n})$

8) $R_n = \frac{3}{n}\sum_{i=1}^{n}(3+3\frac{i}{n})$

**Answer**

$\int_3^6 x\,dx$

9) $L_n = \frac{2\pi}{n}\sum_{i=1}^{n} 2\pi\frac{i-1}{n}\cos(2\pi\frac{i-1}{n})$

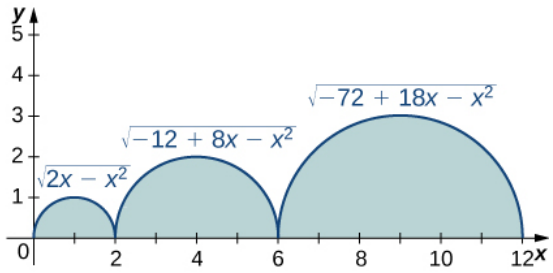
10 $R_n = \frac{1}{n}\sum_{i=1}^{n}(1+\frac{i}{n})\log((1+\frac{i}{n})^2)$

**Answer**

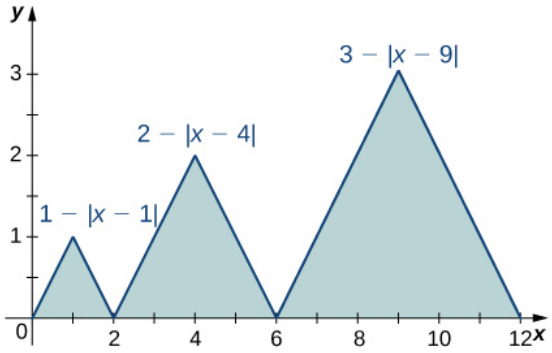
$\int_1^2 x\log(x^2)\,dx$

**In exercises 11 - 16, evaluate the integrals of the functions graphed using the formulas for areas of triangles and circles, and subtracting the areas below the $x$-axis.**

11)



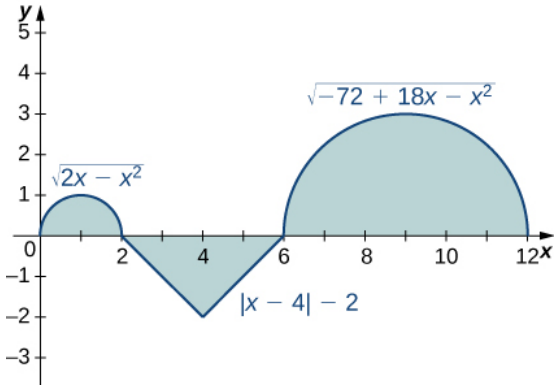
12)



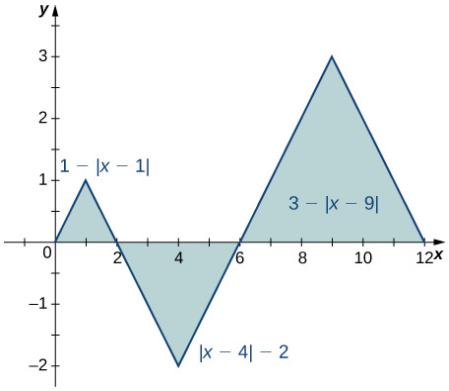
**Answer**

$1+2\cdot 2+3\cdot 3=14$

13)



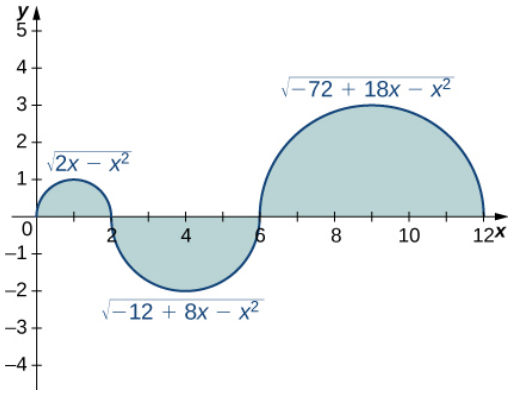
14)



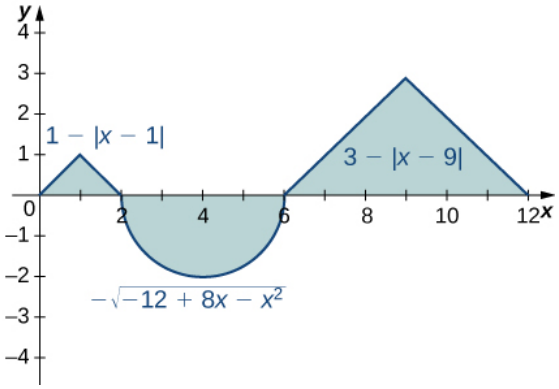
**Answer**

$1 - 4 + 9 = 6$

15)



16)



**Answer**

$1-2\pi+9=10-2\pi$

**In exercises 17 - 24, evaluate the integral using area formulas.**

17) $\int_0^3 (3-x)\,dx$

18) $\int_2^3 (3-x)\,dx$

**Answer**

The integral is the area of the triangle, $\frac{1}{2}$.

19) $\int_{-3}^3 (3-|x|)\,dx$

20) $\int_0^6 (3-|x-3|)\,dx$

**Answer**

The integral is the area of the triangle, $9$.

21) $\int_{-2}^2 \sqrt{4-x^2}\,dx$

22) $\int_1^5 \sqrt{4-(x-3)^2}\,dx$

**Answer**

The integral is the area $\frac{1}{2}\pi r^2=2\pi$.

23) $\int_0^{12} \sqrt{36-(x-6)^2}\,dx$

24) $\int_{-2}^3 (3-|x|)\,dx$

**Answer**

The integral is the area of the "big" triangle less the "missing" triangle, $9-\frac{1}{2}$.

**Suppose that $\int_0^4 f(x)\,dx=5$ and $\int_0^2 f(x)\,dx=-3$, and $\int_0^4 g(x)\,dx=-1$ and $\int_0^2 g(x)\,dx=2$. In exercises 25 - 30, compute the integrals.**

25) $\int_0^4 (f(x)+g(x))\,dx$

26) $\int_2^4 (f(x)+g(x))\,dx$

**Answer**

$\int_2^4 f(x)\,dx+\int_2^4 g(x)\,dx=8-3=5$

27) $\int_0^2 (f(x)-g(x))\,dx$

28) $\int_2^4 (f(x)-g(x))\,dx$

**Answer**

$\int_2^4 f(x)\,dx - \int_2^4 g(x)\,dx = 8+3=11$

29) $\int_0^2 (3f(x)-4g(x))\,dx$

30) $\int_2^4 (4f(x)-3g(x))\,dx$

**Answer**

$4\int_2^4 f(x)\,dx - 3\int_2^4 g(x)\,dx = 32+9=41$

**In exercises 31 - 34, use the identity $\int_{-A}^{A} f(x)\,dx = \int_{-A}^{0} f(x)\,dx + \int_0^A f(x)\,dx$ to compute the integrals.**

31) $\int_{-\pi}^{\pi} \frac{\sin t}{1+t^2}dt$ (Hint: $\sin(-t) = -\sin(t)$)

32) $\int_{\sqrt{-\pi}}^{\sqrt{\pi}} \frac{t}{1+\cos t}dt$

**Answer**

The integrand is odd; the integral is zero.

33) $\int_1^3 (2-x)\,dx$ (Hint: Look at the graph of $f$.)

34) $\int_2^4 (x-3)^3\,dx$ (Hint: Look at the graph of $f$.)

**Answer**

The integrand is antisymmetric with respect to $x=3$. The integral is zero.

**In exercises 35 - 40, given that $\int_0^1 x\,dx = \frac{1}{2}$, $\int_0^1 x^2\,dx = \frac{1}{3}$, and $\int_0^1 x^3\,dx = \frac{1}{4}$, compute the integrals.**

35) $\int_0^1 (1+x+x^2+x^3)\,dx$

36) $\int_0^1 (1-x+x^2-x^3)\,dx$

**Answer**

$1-\frac{1}{2}+\frac{1}{3}-\frac{1}{4}=\frac{7}{12}$

37) $\int_0^1 (1-x)^2\,dx$

38) $\int_0^1 (1-2x)^3\,dx$

**Answer**

$\int_0^1 (1-6x+12x^2-8x^3)\,dx = 1-6\left(\frac{1}{2}\right)+12\left(\frac{1}{3}\right)-8\left(\frac{1}{4}\right)=1-3+4-2=0$

39) $\int_0^1 \left(6x-\frac{4}{3}x^2\right)\,dx$

40) $\int_0^1 (7-5x^3)\,dx$

**Answer**

$7-\frac{5}{4}=\frac{23}{4}$

**In exercises 41 - 46, use the comparison theorem.**

41) Show that $\int_0^3 (x^2 - 6x + 9)\,dx \geq 0$.

42) Show that $\int_{-2}^3 (x-3)(x+2)\,dx \leq 0$.

**Answer**

The integrand is negative over $[-2, 3]$.

43) Show that $\int_0^1 \sqrt{1+x^3}\,dx \leq \int_0^1 \sqrt{1+x^2}\,dx$.

44) Show that $\int_1^2 \sqrt{1+x}\,dx \leq \int_1^2 \sqrt{1+x^2}\,dx$.

**Answer**

$x \leq x^2$ over $[1, 2]$, so $\sqrt{1+x} \leq \sqrt{1+x^2}$ over $[1, 2]$.

45) Show that $\int_0^{\pi/2} \sin t dt \geq \frac{\pi}{4}$ (Hint: $\sin t \geq \frac{2t}{\pi}$ over $[0, \frac{\pi}{2}]$)

46) Show that $\int_{-\pi/4}^{\pi/4} \cos t\,dt \geq \pi\sqrt{2}/4$.

**Answer**

$\cos(t) \geq \frac{\sqrt{2}}{2}$. Multiply by the length of the interval to get the inequality.

47) Suppose that $A = \int_0^{2\pi} \sin^2 t\,dt$ and $B = \int_0^{2\pi} \cos^2 t\,dt$. Show that $A + B = 2\pi$ and $A = B$.

48) Suppose that $A = \int_{-\pi/4}^{\pi/4} \sec^2 t\,dt = \pi$ and $B = \int_{-\pi/}^{\pi/4} 4\tan^2 t\,dt$. Show that $A - B = \frac{\pi}{2}$.

**Answer**

Use $\tan^2\theta + 1 = \sec^2\theta$. Then, $B - A = \int_{-\pi/4}^{\pi/4} 1\,dx = \frac{\pi}{2}$.

49) Explain why the graphs of a quadratic function (parabola) $p(x)$ and a linear function $\ell(x)$ can intersect in at most two points. Suppose that $p(a) = \ell(a)$ and $p(b) = \ell(b)$, and that $\int_a^b p(t)\,dt > \int_a^b \ell(t)dt$. Explain why $\int_c^d p(t) > \int_c^d \ell(t)\,dt$ whenever $a \leq c < d \leq b$.

50) Suppose that parabola $p(x) = ax^2 + bx + c$ opens downward $(a < 0)$ and has a vertex of $y = \frac{-b}{2a} > 0$. For which interval $[A, B]$ is $\int_A^B (ax^2 + bx + c)\,dx$ as large as possible?

**Answer**

The integral is maximized when one uses the largest interval on which $p$ is nonnegative. Thus, $A = \frac{-b-\sqrt{b^2-4ac}}{2a}$ and $B = \frac{-b+\sqrt{b^2-4ac}}{2a}$.

51) Suppose $[a, b]$ can be subdivided into subintervals $a = a_0 < a_1 < a_2 < \cdots < a_N = b$ such that either $f \geq 0$ over $[a_{i-1}, a_i]$ or $f \leq 0$ over $[a_{i-1}, a_i]$. Set $A_i = \int_{a_{i-1}}^{a_i} f(t)\,dt$.

a. Explain why $\int_a^b f(t)\,dt = A_1 + A_2 + \cdots + A_N$.

b. Then, explain why $\int_a^b f(t)\,dt \leq \int_a^b |f(t)|\,dt$.

52) Suppose $f$ and $g$ are continuous functions such that $\int_c^d f(t)\,dt \leq \int_c^d g(t)\,dt$ for every subinterval $[c, d]$ of $[a, b]$. Explain why $f(x) \leq g(x)$ for all values of $x$.

**Answer**

If $f(t_0) > g(t_0)$ for some $t_0 \in [a, b]$, then since $f - g$ is continuous, there is an interval containing $t_0$ such that $f(t) > g(t)$ over the interval $[c, d]$, and then $\int_d^d f(t)\,dt > \int_c^d g(t)\,dt$over this interval.

53) Suppose that for each $i$ such that $1 \le i \le N$ one has $\int_{i-1}^{i} f(t)\,dt = i$. Show that $\int_0^N f(t)\,dt = \dfrac{N(N+1)}{2}$.

54) Suppose that for each $i$ such that $1 \le i \le N$ one has $\int_{i-1}^{i} f(t)\,dt = i^2$. Show that $\int_0^N f(t)\,dt = \dfrac{N(N+1)(2N+1)}{6}$.

**Answer**

$$\begin{aligned}\int_0^N f(t)\,dt &= \sum_{i=1}^{N}\int_{i-1}^{i} f(t)\,dt \\ &= \sum_{i=1}^{N} i^2 \\ &= \frac{N(N+1)(2N+1)}{6}\end{aligned}$$

55) If $\int_1^5 \sqrt{1+t^4}\,dt = 41.7133...$, what is $\int_1^5 \sqrt{1+u^4}\,du$?

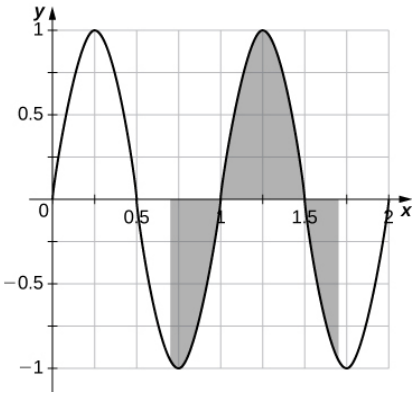
56) Estimate $\int_0^1 t\,dt$ by comparison with the area of a single rectangle with height equal to the value of $t$ at the midpoint $t = \dfrac{1}{2}$. How does this midpoint estimate compare with the actual value $\int_0^1 t\,dt$?

57) From the graph of $\sin(2\pi x)$ shown:

a. Explain why $\int_0^1 \sin(2\pi t)\,dt = 0$.

b. Explain why, in general, $\int_a^{a+1} \sin(2\pi t)\,dt = 0$ for any value of $a$.

**Answer**



a. The graph is antisymmetric with respect to $t = \frac{1}{2}$ over $[0,1]$, so the average value is zero.

b. For any value of $a$, the graph between $[a, a+1]$ is a shift of the graph over $[0,1]$, so the net areas above and below the axis do not change and the average remains zero.

58) If f is 1-periodic $(f(t+1) = f(t))$, odd, and integrable over $[0,1]$, is it always true that $\int_0^1 f(t)\,dt = 0$?

59) If f is 1-periodic and $\int 10 f(t)\,dt = A$, is it necessarily true that $\int_a^{1+a} f(t)\,dt = A$ for all $A$?

**Answer**

Yes, the integral over any interval of length 1 is the same.

# 5.4: The Fundamental Theorem of Calculus

**Learning Objectives**

- State the meaning of the Fundamental Theorem of Calculus, Part 1.
- Use the Fundamental Theorem of Calculus, Part 1, to evaluate derivatives of integrals.
- State the meaning of the Fundamental Theorem of Calculus, Part 2.
- Use the Fundamental Theorem of Calculus, Part 2, to evaluate definite integrals.
- Explain the relationship between differentiation and integration.

Hawk A.I. Section-Specific Tutor

Please note that, to access the Hawk A.I. Tutor, you will need a (free) OpenAI account.

In the previous section, we looked at the definite integral and its relationship to the area under the curve of a function. Unfortunately, the only tools available to calculate the value of a definite integral up to this point are geometric area formulas and limits of Riemann sums - both extremely cumbersome methods. In this section, we look at some more powerful and practical techniques for evaluating definite integrals.

These new techniques rely on the relationship between differentiation and integration. This relationship was discovered and explored by Sir Isaac Newton and Gottfried Wilhelm Leibniz (among others) during the late 1600s and early 1700s. It is codified in what we now call the Fundamental Theorem of Calculus, which has two parts that we examine in this section. Its very name indicates how central this theorem is to the entire development of Calculus.

Isaac Newton's contributions to Mathematics and Physics changed how we view the world. The relationships he discovered, codified as **Newton's Laws** and the **Law of Universal Gravitation**, are still taught as foundational material in Physics, and his Calculus has spawned entire fields of Mathematics.

## Fundamental Theorem of Calculus Part 1: Integrals and Antiderivatives

As mentioned earlier, the Fundamental Theorem of Calculus is an extremely powerful theorem that establishes the relationship between differentiation and integration. It allows us to evaluate definite integrals without using Riemann sums or calculating areas. The theorem comprises two parts, the first of which, the **Fundamental Theorem of Calculus, Part 1** , is stated here. Part 1 establishes the relationship between differentiation and integration.

**Theorem: The Fundamental Theorem of Calculus, Part 1 (FTC1)**

If $f(x)$ is continuous over an interval $[a, b]$, and the function $F(x)$ is defined by

$$F(x) = \int_a^x f(t)\,dt,$$

then $F'(x) = f(x)$ over $[a, b]$.

**Proof**

Applying the definition of the derivative, we have

$$\begin{aligned} F'(x) &= \lim_{h\to 0}\frac{F(x+h)-F(x)}{h} \\ &= \lim_{h\to 0}\frac{1}{h}\left[\int_a^{x+h} f(t)dt - \int_a^x f(t)\,dt\right] \\ &= \lim_{h\to 0}\frac{1}{h}\left[\int_a^{x+h} f(t)\,dt + \int_x^a f(t)\,dt\right] \\ &= \lim_{h\to 0}\frac{1}{h}\int_x^{x+h} f(t)\,dt. \end{aligned}$$

Before taking this limit, notice that we have shown, for $h \neq 0$,

$$\frac{F(x+h)-F(x)}{h} = \frac{1}{h}\int_x^{x+h} f(t)dt.$$

Suppose $h > 0$. Since $f(x)$ is continuous on $[a,b]$ and both $x$ and $x+h$ are in $[a,b]$, $f(x)$ is continuous on $[x, x+h]$. By the Extreme Value Theorem, there must exist numbers $c_1, c_2 \in [x, x+h]$ such that $f(c_1) = m$ is the absolute minimum of $f$ on $[x, x+h]$ and $f(c_2) = M$ is the absolute maximum of $f$ on $[x, x+h]$. Therefore,

$$m \leq f(t) \leq M, \text{ for all } t \in [x, x+h].$$

By the Comparison Theorem,

$$\begin{aligned} & m[(x+h)-x] \leq \int_x^{x+h} f(t)dt \leq M[(x+h)-x] \\ \Longrightarrow\quad & mh \leq \int_x^{x+h} f(t)dt \leq Mh \\ \Longrightarrow\quad & f(c_1)h \leq \int_x^{x+h} f(t)dt \leq f(c_2)h \\ \Longrightarrow\quad & f(c_1) \leq \frac{1}{h}\int_x^{x+h} f(t)dt \leq f(c_2) \\ \Longrightarrow\quad & f(c_1) \leq \frac{F(x+h)-F(x)}{h} \leq f(c_2) \end{aligned}$$

However,

$$\begin{aligned} \lim_{h\to 0} f(c_1) &= \lim_{c_1\to x} f(c_1) \quad (\text{Since } c_1 \in [x, x+h], c_1 \to x \text{ as } h \to 0) \\ &= f(x) \end{aligned}$$

A similar argument shows $\lim_{h\to 0} f(c_2) = f(x)$. Since $f$ is continuous, the Squeeze Theorem shows us that

$$f(x) \leq \lim_{h\to 0}\frac{F(x+h)-F(x)}{h} \leq f(x).$$

That is,

$$\begin{aligned} F'(x) &= \lim_{h\to 0}\frac{F(x+h)-F(x)}{h} \\ &= f(x) \end{aligned}$$

The proof is done similarly if we had assumed $h < 0$.

*Q.E.D.*

$F(x)$ is called an **integral function** (also known as an **area function**) because it represents the definite integral of a function, $f(t)$, over an interval determined by the argument of $F$. That is, $F(x)$ is the area under the curve $f(t)$ from $t = a$ to some, yet to be determined value, $t = x$.

A couple of subtleties are worth mentioning here. First, a comment on the notation. Note that we have defined a function, $F(x)$, as the definite integral of another function, $f(t)$, from the number $a$ to the number $x$. At first glance, this is confusing because we have

said several times that a definite integral is a *number*, and here it looks like it's a function. The key here is to notice that for any particular value of $x$, the definite integral *is* a number. So, the function $F(x)$ returns a number (the value of the definite integral) for each value of $x$.

Second, it is worth commenting on some of the key implications of this theorem. There is a reason it is called the Fundamental Theorem of Calculus. Not only does it establish a relationship between integration and differentiation, but it also guarantees that any integrable function has an antiderivative. Specifically, it guarantees that any continuous function has an antiderivative.

### Example 5.4.1: Finding a Derivative with the Fundamental Theorem of Calculus

Use the Fundamental Theorem of Calculus, Part 1 to find the derivative of

$$g(x) = \int_1^x \frac{1}{t^3+1}\,dt.$$

**Solution**

According to the Fundamental Theorem of Calculus, Part 1, the derivative is given by

$$g'(x) = \frac{1}{x^3+1}.$$

### Checkpoint 5.4.1

Use the Fundamental Theorem of Calculus, Part 1 to find the derivative of $g(r) = \int_0^r \sqrt{x^2+4}\,dx$.

**Answer**

$g'(r) = \sqrt{r^2+4}$

### Example 5.4.2: Using the Fundamental Theorem and the Chain Rule to Calculate Derivatives

Let $F(x) = \int_1^{\sqrt{x}} \sin t\,dt$. Find $F'(x)$.

**Solution**

Letting $u(x) = \sqrt{x}$, we have

$$F(x) = \int_1^{u(x)} \sin t\,dt.$$

Thus, by the Fundamental Theorem of Calculus and the Chain Rule,

$$F'(x) = \sin(u(x))\frac{du}{dx} = \sin(u(x)) \cdot \left(\frac{1}{2}x^{-1/2}\right) = \frac{\sin\sqrt{x}}{2\sqrt{x}}.$$

### Checkpoint 5.4.2

Let $F(x) = \int_1^{x^3} \cos t\,dt$. Find $F'(x)$.

**Answer**

$F'(x) = 3x^2 \cos x^3$

### Example 5.4.3: Using the Fundamental Theorem of Calculus with Two Variable Limits of Integration

Let $F(x) = \int_x^{2x} t^3\,dt$. Find $F'(x)$.

**Solution**

We have $F(x) = \int_x^{2x} t^3\,dt$. Both limits of integration are variable, so we need to split this into two integrals. We get

$$\begin{aligned} F(x) &= \textstyle\int_x^{2x} t^3\,dt \\ &= \textstyle\int_x^0 t^3\,dt + \int_0^{2x} t^3\,dt \\ &= \textstyle -\int_0^x t^3\,dt + \int_0^{2x} t^3\,dt. \end{aligned}$$

Differentiating the first term, we obtain

$$\frac{d}{dx}\left[-\int_0^x t^3\,dt\right] = -x^3.$$

Differentiating the second term, we first let $(x) = 2x$. Then,

$$\begin{aligned} \frac{d}{dx}\left[\textstyle\int_0^{2x} t^3\,dt\right] &= \frac{d}{dx}\left[\textstyle\int_0^{u(x)} t^3\,dt\right] \\ &= (u(x))^3\,du\,dx \\ &= (2x)^3 \cdot 2 = 16x^3. \end{aligned}$$

Thus,

$$\begin{aligned} F'(x) &= \frac{d}{dx}\left[-\textstyle\int_0^x t^3\,dt\right] + \frac{d}{dx}\left[\textstyle\int_0^{2x} t^3\,dt\right] \\ &= -x^3 + 16x^3 \\ &= 15x^3 \end{aligned}$$

### Checkpoint 5.4.3

Let $F(x) = \int_x^{x^2} \cos t\,dt$. Find $F'(x)$.

**Answer**

$F'(x) = 2x\cos x^2 - \cos x$

If you study Example **5.4.3** in detail, it implies a more general form of the FTC1.

### Corollary: General Form of the FTC1

If $f(x)$, $U(x)$, and $L(x)$ are continuous over an interval $[a, b]$, and the function $F(x)$ is defined by

$$F(x) = \int_{L(x)}^{U(x)} f(t)\,dt,$$

then

$$F'(x) = f(U(x))U'(x) - f(L(x))L'(x)$$

over $[a, b]$.

**Proof**

$$\begin{aligned}\int_{L(x)}^{U(x)} f(t)\,dt &= \int_{L(x)}^{a} f(t)\,dt + \int_{a}^{U(x)} f(t)\,dt \quad \text{(Properties of the Definite Integral)}\\ &= -\int_{a}^{L(x)} f(t)\,dt + \int_{a}^{U(x)} f(t)\,dt \quad \text{(Properties of the Definite Integral)}\\ &= \int_{a}^{U(x)} f(t)\,dt - \int_{a}^{L(x)} f(t)\,dt\end{aligned}$$

Therefore,

$$\begin{aligned}\frac{d}{dx}\left(\int_{L(x)}^{U(x)} f(t)\,dt\right) &= \frac{d}{dx}\left(\int_{a}^{U(x)} f(t)\,dt - \int_{a}^{L(x)} f(t)\,dt\right)\\ &= \frac{d}{dx}\left(\int_{a}^{U(x)} f(t)\,dt\right) - \frac{d}{dx}\left(\int_{a}^{L(x)} f(t)\,dt\right) \quad \text{(Properties of the Definite Integral)}\\ &= f(U(x))U'(x) - f(L(x))L'(x) \quad \text{(FTC1 and the Chain Rule)}\end{aligned}$$

*Q.E.D.*

I encourage you to go back through Examples **5.4.1** through **5.4.3** applying this General Form of the FTC1 to verify it works in all cases. It is a wonderful preview of the structure of the Fundamental Theorem of Calculus, Part 2.

## Fundamental Theorem of Calculus, Part 2: The Evaluation Theorem

The **Fundamental Theorem of Calculus, Part 2**, is perhaps the most important theorem in Calculus. After tireless efforts by mathematicians for approximately 500 years, new techniques emerged that provided scientists with the necessary tools to explain many phenomena. Using Calculus, astronomers could finally determine distances in space and map planetary orbits. Everyday financial problems such as calculating marginal costs or predicting total profit could now be handled with simplicity and accuracy. Engineers could calculate materials' bending strength or objects' three-dimensional motion. Our view of the world was forever changed with Calculus.

After finding approximate areas by adding the areas of $n$ rectangles, applying this theorem is straightforward by comparison. It seems too simple that the area of an entire curved region can be calculated by just evaluating an antiderivative at the first and last endpoints of an interval.

### Theorem: The Fundamental Theorem of Calculus, Part 2

If $f(x)$ is continuous over the interval $[a, b]$ and $F(x)$ is any antiderivative of $f(x)$, then

$$\int_a^b f(x)\,dx = F(b) - F(a). \tag{5.4.1}$$

**Proof**

Let $P = x_i, i = 0, 1, \ldots, n$ be a regular partition of $[a, b]$. Then, we can write

$$\begin{aligned}F(b) - F(a) &= F(x_n) - F(x_0)\\ &= [F(x_n) - F(x_{n-1})] + [F(x_{n-1}) - F(x_{n-2})] + \ldots + [F(x_1) - F(x_0)]\\ &= \textstyle\sum_{i=1}^{n} [F(x_i) - F(x_{i-1})].\end{aligned}$$

Now, we know $F$ is an antiderivative of $f$ over $[a, b]$, so, by the Mean Value Theorem, for $i = 0, 1, \ldots, n$ we can find $c_i$ in $[x_{i-1}, x_i]$ such that

$$F(x_i) - F(x_{i-1}) = F'(c_i)(x_i - x_{i-1}) = f(c_i)\,\Delta x.$$

Then, substituting into the previous equation, we have

$$F(b) - F(a) = \sum_{i=1}^{n} f(c_i)\,\Delta x.$$

Taking the limit of both sides as $n \to \infty$, we obtain

$$F(b) - F(a) = \lim_{n \to \infty} \sum_{i=1}^{n} f(c_i) \Delta x = \int_a^b f(x)\, dx.$$

*Q.E.D.*

We often see the notation $F(x)\,|_a^b$ to denote the expression $F(b) - F(a)$. We use this vertical bar and associated limits $a$ and $b$ to indicate that we should evaluate the function $F(x)$ at the upper limit (in this case, $b$), and subtract the value of the function $F(x)$ evaluated at the lower limit (in this case, $a$).

The Fundamental Theorem of Calculus, Part 2 (also known as the **Evaluation Theorem**) states that if we can find an antiderivative for the integrand, then we can evaluate the definite integral by evaluating the antiderivative at the endpoints of the interval and subtracting.

### Example 5.4.4: Evaluating an Integral with the Fundamental Theorem of Calculus

Use Equation 5.4.1 to evaluate

$$\int_{-2}^{2} (t^2 - 4)\, dt.$$

**Solution**

Recall the Power Rule for Antiderivatives:

If $y = x^n$,

$$\int x^n\, dx = \frac{x^{n+1}}{n+1} + C.$$

Use this rule to find the antiderivative of the function and then apply the theorem. We have

$$\begin{aligned} \int_{-2}^{2} (t^2 - 4) dt &= \left( \frac{t^3}{3} - 4t \right) |_{-2}^{2} \\ &= \left[ \frac{(2)^3}{3} - 4(2) \right] - \left[ \frac{(-2)^3}{3} - 4(-2) \right] \\ &= \left[ \frac{8}{3} - 8 \right] - \left[ -\frac{8}{3} + 8 \right] \\ &= \frac{8}{3} - 8 + \frac{8}{3} - 8 \\ &= \frac{16}{3} - 16 \\ &= -\frac{32}{3}. \end{aligned}$$

#### Analysis

Notice that we did not include the "$+C$" term when we wrote the antiderivative. The reason is that, according to the Fundamental Theorem of Calculus, Part 2 (Equation 5.4.1), any antiderivative works. So, for convenience, we chose the antiderivative with $C = 0$. If we had chosen another antiderivative, the constant term would have been canceled. This always happens when evaluating a definite integral.

The region of the area we just calculated is depicted in Figure 5.4.1. Note that the region between the curve and the $x$-axis is all below the $x$-axis. Area is always positive, but a definite integral can still produce a negative number (a net signed area). For example, if this were a profit function, a negative number indicates the company is operating at a loss over the given interval.

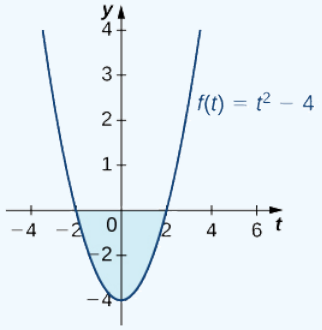

*Figure* **5.4.1***: The evaluation of a definite integral can produce a negative value, even though area is always positive.*

### Example 5.4.5: Evaluating a Definite Integral Using the Fundamental Theorem of Calculus, Part 2

Evaluate the following integral using the Fundamental Theorem of Calculus, Part 2 (Equation 5.4.1):

$$\int_1^9 \frac{x-1}{\sqrt{x}}dx.$$

**Solution**

First, eliminate the radical by rewriting the integral using rational exponents. Then, separate the numerator terms by writing each one over the denominator:

$$\int_1^9 \frac{x-1}{x^{1/2}}\,dx = \int_1^9 \left(\frac{x}{x^{1/2}} - \frac{1}{x^{1/2}}\right)\,dx.$$

Use the properties of exponents to simplify:

$$\int_1^9 \left(\frac{x}{x^{1/2}} - \frac{1}{x^{1/2}}\right)\,dx = \int_1^9 (x^{1/2} - x^{-1/2})\,dx.$$

Now, integrate using the Power Rule:

$$\begin{aligned}
\textstyle\int_1^9 (x^{1/2} - x^{-1/2})\,dx &= \left(\frac{x^{3/2}}{\frac{3}{2}} - \frac{x^{1/2}}{\frac{1}{2}}\right)\Big|_1^9 \\
&= \left[\frac{(9)^{3/2}}{\frac{3}{2}} - \frac{(9)^{1/2}}{\frac{1}{2}}\right] - \left[\frac{(1)^{3/2}}{\frac{3}{2}} - \frac{(1)^{1/2}}{\frac{1}{2}}\right] \\
&= \left[\frac{2}{3}(27) - 2(3)\right] - \left[\frac{2}{3}(1) - 2(1)\right] \\
&= 18 - 6 - \frac{2}{3} + 2 \\
&= \frac{40}{3}.
\end{aligned}$$

See Figure 5.4.2.

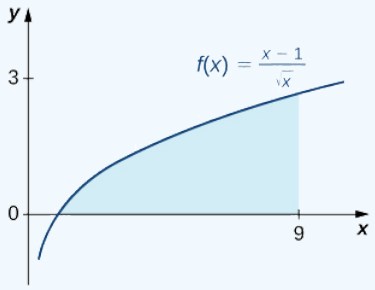

*Figure* **5.4.2***: The area under the curve from* $x = 1$ *to* $x = 9$ *can be calculated by evaluating a definite integral.*

## Checkpoint 5.4.5

Evaluate $\int_1^2 x^{-4}\,dx$.

**Answer**

$\frac{7}{24}$

## A Parachutist in Free Fall

Julie is an avid skydiver with more than 300 jumps under her belt and has mastered the art of adjusting her body position in the air to control how fast she falls. If she arches her back and points her belly toward the ground, she reaches a terminal velocity of approximately 120 mph (176 ft/sec). If, instead, she orients her body with her head straight down, she falls faster, reaching a terminal velocity of 150 mph (220 ft/sec).

*Figure* **5.4.3***: Skydivers can adjust the velocity of their dive by changing the position of their body during the free fall. (credit: Jeremy T. Lock)*

Since Julie will be moving (falling) downward, we assume the downward direction is positive to simplify our calculations. Julie executes her jumps from an altitude of 12,500 ft. After she exits the aircraft, she immediately starts falling at a velocity given by $v(t) = 32t$.

She continues accelerating according to this velocity function until she reaches terminal velocity. After she reaches terminal velocity, her speed remains constant until she pulls her ripcord and slows down to land.

On her first jump of the day, Julie orients herself in the slower "belly down" position (terminal velocity is 176 ft/sec). Using this information, answer the following questions.

1. How long after she exits the aircraft does Julie reach terminal velocity?
2. Based on your answer to question 1, set up an expression involving one or more integrals that represents the distance Julie falls after 30 sec.
3. If Julie pulls her ripcord at an altitude of 3000 ft, how long does she spend in a free fall?

4. Julie pulls her ripcord at 3000 ft. It takes 5 sec for her parachute to open completely and for her to slow down, during which time she falls another 400 ft. After her canopy is fully open, her speed is reduced to 16 ft/sec. Find the total time Julie spends in the air, from when she leaves the airplane to when her feet touch the ground. On Julie's second jump of the day, she decides she wants to fall a little faster and orients herself in the "head down" position. Her terminal velocity in this position is 220 ft/sec. Answer these questions based on this velocity:
5. How long does it take Julie to reach terminal velocity in this case?
6. Before pulling her ripcord, Julie reorients her body in the "belly down" position so she is not moving quite as fast when her parachute opens. If she begins this maneuver at an altitude of 4000 ft, how long does she spend in a free fall before beginning the reorientation?

Some jumpers wear "**wingsuits**" (Figure 5.4.4). These suits have fabric panels between the arms and legs, allowing the wearer to glide in a free fall, much like a flying squirrel. (Indeed, the suits are sometimes called "flying squirrel suits.") When wearing these suits, terminal velocity can be reduced to about 30 mph (44 ft/sec), allowing the wearers a much longer time in the air. Wingsuit flyers still use parachutes to land; although the vertical velocities are within the margin of safety, horizontal velocities can exceed 70 mph, much too fast to land safely.

*Figure 5.4.4: The fabric panels on the arms and legs of a wingsuit work to reduce the vertical velocity of a skydiver's fall. (credit: Richard Schneider)*

Answer the following question based on the velocity in a wingsuit.

7. If Julie dons a wingsuit before her third jump of the day, and she pulls her ripcord at an altitude of 3000 ft, how long does she get to spend gliding around in the air?

## READING QUESTIONS

1. What does the Fundamental Theorem of Calculus, Part 1 (FTC1) state about the derivative of an integral function $F(x) = \int_a^x f(t)\,dt$?
2. If $g(x) = \int_1^x \frac{1}{t^3+1}dt$, what is $g'(x)$ according to FTC1?
3. How is the Chain Rule incorporated into FTC1 when the upper limit of integration is a function $u(x)$, i.e., for $F(x) = \int_a^{u(x)} f(t)\,dt$?
4. What is the general form of FTC1 when both limits of integration are functions, $F(x) = \int_{L(x)}^{U(x)} f(t)\,dt$?
5. What does the Fundamental Theorem of Calculus, Part 2 (FTC2), also known as the Evaluation Theorem, state?
6. What is an "antiderivative" of a function $f(x)$?
7. To evaluate $\int_a^b f(x)dx$ using FTC2, what are the two main steps?
8. When using FTC2, does it matter which antiderivative of $f(x)$ you choose? Explain why or why not regarding the constant of integration $C$.
9. How does FTC2 provide a more powerful and practical technique for evaluating definite integrals compared to using the limit of Riemann sums?
10. What is the relationship between differentiation and integration as established by the Fundamental Theorem of Calculus (both parts considered)?

## HOMEWORK

**In exercises 1 - 12, use the Fundamental Theorem of Calculus, Part 1, to find each derivative.**

1) $\frac{d}{dx}\left[\int_1^x e^{-t^2}\,dt\right]$

2) $\frac{d}{dx}\left[\int_1^x e^{\cos t}\,dt\right]$

**Answer**

$\frac{d}{dx}\left[\int_1^x e^{\cos t}\,dt\right] = e^{\cos t}$

3) $\frac{d}{dx}\left[\int_3^x \sqrt{9-y^2}\,dy\right]$

4) $\frac{d}{dx}\left[\int_3^x \frac{ds}{\sqrt{16-s^2}}\right]$

**Answer**

$\frac{d}{dx}\left[\int_3^x \frac{ds}{\sqrt{16-s^2}}\right] = \frac{1}{\sqrt{16-x^2}}$

5) $\frac{d}{dx}\left[\int^{2x} x_t\,dt\right]$

6) $\frac{d}{dx}\left[\int_0^{\sqrt{x}} t\,dt\right]$

**Answer**

$\frac{d}{dx}\left[\int_0^{\sqrt{x}} t\,dt\right] = \sqrt{x}\frac{d}{dx}\left(\sqrt{x}\right) = \frac{1}{2}$

7) $\frac{d}{dx}\left[\int_0^{\sin x} \sqrt{1-t^2}\,dt\right]$

8) $\frac{d}{dx}\left[\int_{\cos x}^1 \sqrt{1-t^2}\,dt\right]$

**Answer**

$$\frac{d}{dx}\left[\int_{\cos x}^{1}\sqrt{1-t^2}\,dt\right]=-\sqrt{1-\cos^2 x}\,\frac{d}{dx}\left(\cos x\right)=|\sin x|\sin x$$

9) $\frac{d}{dx}\left[\int_{1}^{\sqrt{x}}\frac{t^2}{1+t^4}\,dt\right]$

10) $\frac{d}{dx}\left[\int_{1}^{x^2}\frac{\sqrt{t}}{1+t}\,dt\right]$

**Answer**

$$\frac{d}{dx}\left[\int_{1}^{x^2}\frac{\sqrt{t}}{1+t}\,dt\right]=2x\frac{|x|}{1+x^2}$$

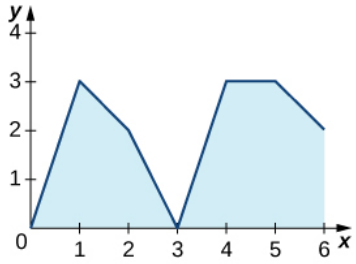
11) $\frac{d}{dx}\left[\int_{0}^{\ln x}e^t\,dt\right]$

12) $\frac{d}{dx}\left[\int_{1}^{e^x}\ln u^2\,du\right]$

**Answer**

$$\frac{d}{dx}\left[\int_{1}^{e^x}\ln u^2\,du\right]=\ln(e^{2x})\frac{d}{dx}\left(e^x\right)=2xe^x$$

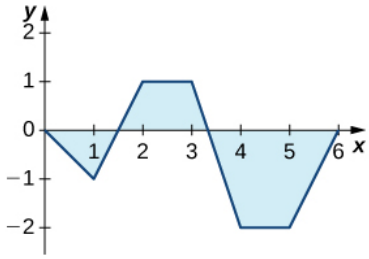
13) The graph of $y=\int_{0}^{x}f(t)\,dt$, where $f$ is a piecewise constant function, is shown here.



a. Over which intervals is $f$ positive? Over which intervals is it negative? Over which intervals, if any, is it equal to zero?

b. What are the maximum and minimum values of $f$?

14) The graph of $y=\int_{0}^{x}f(t)\,dt$, where $f$ is a piecewise constant function, is shown here.



a. Over which intervals is $f$ positive? Over which intervals is it negative? Over which intervals, if any, is it equal to zero?

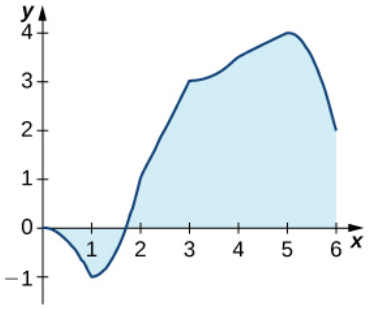
b. What are the maximum and minimum values of $f$?

**Answer**

a. $f$ is positive over $[1,2]$ and $[5,6]$, negative over $[0,1]$ and $[3,4]$, and zero over $[2,3]$ and $[4,5]$.

b. The maximum value is $2$ and the minimum is $-3$.

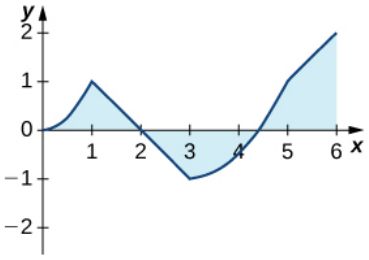
15) The graph of $y=\int_{0}^{x}\ell(t)\,dt$, where $\ell$ is a piecewise linear function, is shown here.



a. Over which intervals is $\ell$ positive? Over which intervals is it negative? Over which, if any, is it zero?

b. Over which intervals is $\ell$ increasing? Over which is it decreasing? Over which, if any, is it constant?

16) The graph of $y = \int_0^x \ell(t)\,dt$, where $\ell$ is a piecewise linear function, is shown here.



a. Over which intervals is $\ell$ positive? Over which intervals is it negative? Over which, if any, is it zero?

b. Over which intervals is $\ell$ increasing? Over which is it decreasing? Over which intervals, if any, is it constant?

**Answer**

a. $\ell$ is positive over $[0,1]$ and $[3,6]$, and negative over $[1,3]$.

b. It is increasing over $[0,1]$ and $[3,5]$, and it is constant over $[1,3]$ and $[5,6]$.

**In exercises 17 - 36, evaluate each definite integral using the Fundamental Theorem of Calculus, Part 2.**

17) $\int_{-1}^{2} (x^2 - 3x)\,dx$

18) $\int_{-2}^{3} (x^2 + 3x - 5)\,dx$

**Answer**

$$F(x) = \frac{x^3}{3} + \frac{3x^2}{2} - 5x, \quad F(3) - F(-2) = -\frac{35}{6}$$

19) $\int_{-2}^{3} (t+2)(t-3)dt$

20) $\int_{2}^{3} (t^2 - 9)(4 - t^2)dt$

**Answer**

$$F(x) = -\frac{t^5}{5} + \frac{13t^3}{3} - 36t, \quad F(3) - F(2) = \tfrac{62}{15}$$

21) $\int_{1}^{2} x^9\,dx$

22) $\int_{0}^{1} x^{99}\,dx$

**Answer**

$$F(x) = \frac{x^{100}}{100}, \quad F(1) - F(0) = \frac{1}{100}$$

23) $\int_4^8 (4t^{5/2} - 3t^{3/2})dt$

24) $\int_{1/4}^4 \left(x^2 - \frac{1}{x^2}\right) dx$

**Answer**

$F(x) = \frac{x^3}{3} + \frac{1}{x}, \quad F(4) - F\left(\frac{1}{4}\right) = \frac{1125}{64}$

25) $\int_1^2 \frac{2}{x^3}\, dx$

26) $\int_1^4 \frac{1}{2\sqrt{x}}\, dx$

**Answer**

$F(x) = \sqrt{x}, \quad F(4) - F(1) = 1$

27) $\int_1^4 \frac{2 - \sqrt{t}}{t^2}\, dt$

28) $\int_1^{16} \frac{dt}{t^{1/4}}$

**Answer**

$F(t) = \frac{4}{3}t^{3/4}, \quad F(16) - F(1) = \frac{28}{3}$

29) $\int_0^{2\pi} \cos\theta\, d\theta$

30) $\int_0^{\pi/2} \sin\theta\, d\theta$

**Answer**

$F(\theta) = -\cos\theta, \quad F(\frac{\pi}{2}) - F(0) = 1$

31) $\int_0^{\pi/4} \sec^2\theta\, d\theta$

32) $\int_0^{\pi/4} \sec\theta\tan\theta\, d\theta$

**Answer**

$F(\theta) = \sec\theta, \quad F(\frac{\pi}{4}) - F(0) = \sqrt{2} - 1$

33) $\int_{\pi/3}^{\pi/4} \csc\theta\cot\theta\, d\theta$

34) $\int_{\pi/4}^{\pi/2} \csc^2\theta\, d\theta$

**Answer**

$F(\theta) = -\cot\theta, \quad F(\frac{\pi}{2}) - F(\frac{\pi}{4}) = 1$

35) $\int_1^2 \left(\frac{1}{t^2} - \frac{1}{t^3}\right) dt$

36) $\int_{-2}^{-1} \left(\frac{1}{t^2} - \frac{1}{t^3}\right) dt$

**Answer**

$F(t) = -\frac{1}{t} + \frac{1}{2t^2}, \quad F(-1) - F(-2) = \frac{7}{8}$

**In exercises 37 - 40, use the evaluation theorem to express the integral as a function $F(x)$.**

37) $\int_a^x t^2\, dt$

38) $\int_1^x e^t\, dt$

**Answer**

$F(x) = e^x - e$

39) $\int_0^x \cos t \, dt$

40) $\int_{-x}^x \sin t \, dt$

**Answer**

$F(x) = 0$

**In exercises 41 - 44, identify the roots of the integrand to remove absolute values, then evaluate using the Fundamental Theorem of Calculus, Part 2.**

41) $\int_{-2}^3 |x| \, dx$

42) $\int_{-2}^4 | \, t^2 - 2t - 3 \, | \, dt$

**Answer**

$\int_{-2}^{-1} (t^2 - 2t - 3) \, dt - \int_{-1}^3 (t^2 - 2t - 3) \, dt + \int_3^4 (t^2 - 2t - 3) \, dt = \frac{46}{3}$

43) $\int_0^{\pi} |\cos t| \, dt$

44) $\int_{-\pi/2}^{\pi/2} |\sin t| \, dt$

**Answer**

$-\int_{-\pi/2}^0 \sin t \, dt + \int_0^{\pi/2} \sin t \, dt = 2$

# 5.5: The Net Change Theorem, Distances, and Symmetry

**Learning Objectives**

- Apply the basic integration formulas.
- Explain the significance of the Net Change Theorem.
- Use the Net Change Theorem to solve applied problems.
- Apply the integrals of odd and even functions.

Hawk A.I. Section-Specific Tutor

Please note that, to access the Hawk A.I. Tutor, you will need a (free) OpenAI account.

In this section, we use some basic integration formulas previously studied to solve key applied problems. It is important to note that these formulas are presented in terms of indefinite integrals. Although definite and indefinite integrals are closely related, there are some key differences to remember. A definite integral is either a number (when the limits of integration are constants) or a single function (when one or both of the limits of integration are variables). An indefinite integral represents a family of functions, all of which differ by a constant. As you become more familiar with integration, you will get a feel for when to use definite and indefinite integrals. You will naturally select the correct approach for a given problem without overthinking. However, until these concepts are cemented in your mind, think carefully about whether you need a definite or an indefinite integral and ensure you are using the proper notation based on your choice.

## The Net Change Theorem

The **Net Change Theorem** considers the integral of a rate of change. It says that when a quantity changes, the new value equals the initial value plus the integral of the rate of change of that quantity. The formula can be expressed in two ways. The second is more familiar; it is simply the definite integral.

**Theorem: Net Change Theorem**

The new value of a changing quantity equals the initial value plus the integral of the rate of change:

$$F(b) = F(a) + \int_a^b F'(x)dx \tag{5.5.1}$$

or

$$\int_a^b F'(x)dx = F(b) - F(a). \tag{5.5.2}$$

Subtracting $F(a)$ from both sides of the Equation 5.5.1 yields Equation 5.5.2. Since they are equivalent formulas, which one we use depends on the application.

The significance of the Net Change Theorem lies in the results. Net change can be applied to area, distance, and volume, to name only a few applications. Net change accounts for negative quantities automatically without having to write more than one integral. To illustrate, let's apply the Net Change Theorem to a **velocity** function in which the result is **displacement**.

We looked at a simple example of this in a previous section. Suppose a car moves due north (the positive direction) at 40 mph between 2 p.m. and 4 p.m., then the car moves south at 30 mph between 4 p.m. and 5 p.m. We can graph this motion as shown in Figure 5.5.1.

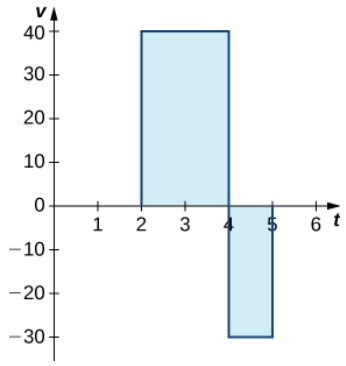


*Figure* **5.5.1***: The graph shows speed versus time for the given motion of a car.*

As before, we can use definite integrals to calculate the net displacement and the total distance traveled. The **net displacement** is given by

$$\int_2^5 v(t)\,dt = \int_2^4 40\,dt + \int_4^5 -30\,dt = 80 - 30 = 50.$$

Thus, at 5 p.m., the car is 50 mi north of its starting position. The **total distance** traveled is given by

$$\int_2^5 |v(t)|\,dt = \int_2^4 40\,dt + \int_4^5 30\,dt = 80 + 30 = 110.$$

Therefore, between 2 p.m. and 5 p.m., the car traveled a total of 110 mi.

To summarize, net displacement may include positive and negative values. In other words, the velocity function accounts for both forward and backward distances. To find net displacement, integrate the velocity function over the interval. Total distance traveled, on the other hand, is always positive. To find the total distance traveled by an object, regardless of direction, we need to integrate the absolute value of the velocity function.

### Example 5.5.1: Finding Net Displacement

Given a velocity function $v(t) = 3t - 5$ (in meters per second) for a particle in motion from time $t = 0$ to time $t = 3$, find the net displacement of the particle.

**Solution**

Applying the Net Change Theorem, we have

$$\int_0^3 (3t - 5)\,dt = \left(\frac{3t^2}{2} - 5t\right)\Big|_0^3 = \left[\frac{3(3)^2}{2} - 5(3)\right] - 0 = \frac{27}{2} - 15 = \frac{27}{2} - \frac{30}{2} = -\frac{3}{2}.$$

The net displacement is $-\frac{3}{2}$ m (Figure 5.5.2).

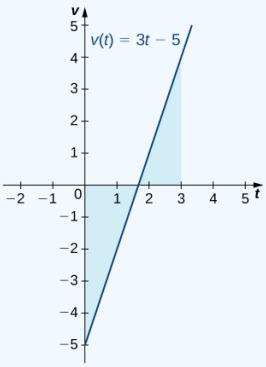

*Figure* **5.5.2***: The graph shows velocity versus time for a particle moving with a linear velocity function.*

### Example 5.5.2: Finding the Total Distance Traveled

Use Example 5.5.1 to find the total distance traveled by a particle according to the velocity function $v(t) = 3t - 5$ m/sec over a time interval $[0, 3]$.

**Solution**

The total distance traveled includes both the positive and the negative values. Therefore, we must integrate the absolute value of the velocity function to find the total distance traveled.

To continue with the example, use two integrals to find the total distance. First, find the $t$-intercept of the function since that is where the division of the interval occurs. Set the equation equal to zero and solve for $t$. Thus,

$$\begin{aligned} 3t - 5 &= 0 \\ 3t &= 5 \\ t &= \frac{5}{3}. \end{aligned}$$

The two subintervals are $[0, \frac{5}{3}]$ and $[\frac{5}{3}, 3]$. To find the total distance traveled, integrate the absolute value of the function. Since the function is negative over the interval $[0, \frac{5}{3}]$, we have $|v(t)| = -v(t)$ over that interval. Over $[\frac{5}{3}, 3]$, the function is positive, so $|v(t)| = v(t)$. Thus, we have

$$\begin{aligned} \int_0^3 |v(t)|\,dt &= \int_0^{5/3} -v(t)\,dt + \int_{5/3}^3 v(t)\,dt \\ &= \int_0^{5/3} 5 - 3t\,dt + \int_{5/3}^3 3t - 5\,dt \\ &= \left(5t - \frac{3t^2}{2}\right)\Big|_0^{5/3} + \left(\frac{3t^2}{2} - 5t\right)\Big|_{5/3}^3 \\ &= \left[5(\frac{5}{3}) - \frac{3(5/3)^2}{2}\right] - 0 + \left[\frac{27}{2} - 15\right] - \left[\frac{3(5/3)^2}{2} - \frac{25}{3}\right] \\ &= \frac{25}{3} - \frac{25}{6} + \frac{27}{2} - 15 - \frac{25}{6} + \frac{25}{3} \\ &= \frac{41}{6} \end{aligned}$$

So, the total distance traveled is $\frac{14}{6}$ m.

### Checkpoint 5.5.2

Find the net displacement and total distance traveled in meters given the velocity function $f(t) = \frac{1}{2}e^t - 2$ over the interval $[0, 2]$.

**Answer**

Net displacement: $\frac{e^2-9}{2} \approx -0.8055$ m; total distance traveled: $4\ln 4 - 7.5 + \frac{e^2}{2} \approx 1.740$ m.

## Applying the Net Change Theorem

The Net Change Theorem can be applied to the flow and consumption of fluids, as shown in Example 5.5.3.

### Example 5.5.3: How Many Gallons of Gasoline Are Consumed?

If the motor on a motorboat is started at $t = 0$ and the boat consumes gasoline at the rate of $5 - t^3$ gal/hr, how much gasoline is used in the first hour?

**Solution**

Express the problem as a definite integral, integrate, and evaluate using the Fundamental Theorem of Calculus. The limits of integration are the endpoints of the interval $[0, 1]$. We have

$$\begin{aligned}\int_0^1 (5-t^3)\,dt &= \left(5t-\frac{t^4}{4}\right)\Big|_0^1 \\ &= \left[5(1)-\frac{(1)^4}{4}\right]-0 \\ &= 5-\frac{1}{4} \\ &= 4.75.\end{aligned}$$

Thus, the motorboat uses $4.75$ gallons of gas in the first hour.

### Example 5.5.4: Iceboats

Top **iceboat** racers can attain speeds of up to five times the wind speed. Andrew is an intermediate iceboater, though, so he attains speeds equal to only twice the wind speed.

*Figure 5.5.3: (credit: modification of work by Carter Brown, Flickr)*

Suppose Andrew takes his iceboat out one morning when a light $5$-mph breeze has been blowing all morning. As Andrew sets up his iceboat, though, the wind picks up. During his first half hour of iceboating, the wind speed increases according to the function $v(t)=20t+5$. The wind remains steady at $15$ mph for the second half hour of Andrew's outing. In other words, the wind speed is given by

$$v(t)=\begin{cases}20t+5, & \text{for } 0\le t\le \frac{1}{2}\\ 15, & \text{for } \frac{1}{2}\le t\le 1\end{cases}$$

Recalling that Andrew's iceboat travels at twice the wind speed, and assuming he moves in a straight line away from his starting point, how far is Andrew from his starting point after $1$ hour?

**Solution**

To determine how far Andrew has traveled, we need to integrate his velocity, which is twice the wind speed. Then

$$\text{Distance}=\int_0^1 2v(t)\,dt.$$

Substituting the expressions we were given for $v(t)$, we get

$$\begin{aligned}\int_0^1 2v(t)\,dt &= \int_0^{1/2} 2v(t)\,dt + \int_{1/2}^1 2v(t)\,dt \\ &= \int_0^{1/2} 2(20t+5)\,dt + \int_{1/3}^1 2(15)\,dt \\ &= \int_0^{1/2} (40t+10)\,dt + \int_{1/2}^1 30\,dt \\ &= \left[20t^2+10t\right]\Big|_0^{1/2} + \left[30t\right]\Big|_{1/2}^1 \\ &= \left(\frac{20}{4}+5\right) - 0 + (30-15) \\ &= 25.\end{aligned}$$

Andrew is 25 mi from his starting point after 1 hour.

**? Checkpoint 5.5.4**

Suppose that, instead of remaining steady during the second half-hour of Andrew's outing, the wind starts to die down according to the function $v(t) = -10t + 15$. In other words, the wind speed is given by

$$v(t) = \begin{cases} 20t+5, & \text{for } 0 \le t \le \frac{1}{2} \\ -10t+15, & \text{for } \frac{1}{2} \le t \le 1 \end{cases}.$$

Under these conditions, how far from his starting point is Andrew after 1 hour?

**Answer**

17.5 mi

## Integrating Even and Odd Functions

We know that an **even function** is a function in which $f(-x) = f(x)$ for all $x$ in the domain—that is, the graph of the curve is unchanged when $x$ is replaced with $-x$. The graphs of even functions are symmetric about the $y$-axis. An **odd function** is one in which $f(-x) = -f(x)$ for all $x$ in the domain, and the graph of the function is symmetric about the origin.

Integrals of even functions, when the limits of integration are from $-a$ to $a$, involve two equal areas because they are symmetric about the $y$-axis. Integrals of odd functions, when the limits of integration are similarly $[-a, a]$, evaluate to zero because the areas above and below the $x$-axis are equal.

**Theorem: Integrals of Even and Odd Functions**

For continuous even functions such that $f(-x) = f(x)$,

$$\int_{-a}^{a} f(x)\,dx = 2\int_0^a f(x)\,dx.$$

For continuous odd functions such that $f(-x) = -f(x)$,

$$\int_{-a}^{a} f(x)\,dx = 0.$$

**Example 5.5.5: Integrating an Even Function**

Integrate the even function $\int_{-2}^{2} (3x^8 - 2)\,dx$ and verify that the integration formula for even functions holds.

**Solution**

The symmetry appears in the graphs in Figure 5.5.4. Graph (a) shows the region below the curve and above the $x$-axis. We have to zoom in on this graph by a huge amount to see the region. Graph (b) shows the region above the curve and below the $x$-axis. The signed area of this region is negative. Both views illustrate the symmetry about the $y$-axis of an even function. We have

$$\begin{aligned}\int_{-2}^{2}(3x^8-2)\,dx &= \left(\frac{x^9}{3}-2x\right)\Big|_{-2}^{2}\\ &= \left[\frac{(2)^9}{3}-2(2)\right]-\left[\frac{(-2)^9}{3}-2(-2)\right]\\ &= \left(\frac{512}{3}-4\right)-\left(-\frac{512}{3}+4\right)\\ &= \frac{1000}{3}.\end{aligned}$$

To verify the integration formula for even functions, we can calculate the integral from $0$ to $2$ and double it, then check to make sure we get the same answer.

$$\int_0^2(3x^8-2)\,dx=\left(\frac{x^9}{3}-2x\right)\Big|_0^2=\frac{512}{3}-4=\frac{500}{3}$$

Since $2\cdot\frac{500}{3}=\frac{1000}{3}$, we have verified the formula for even functions in this particular example.

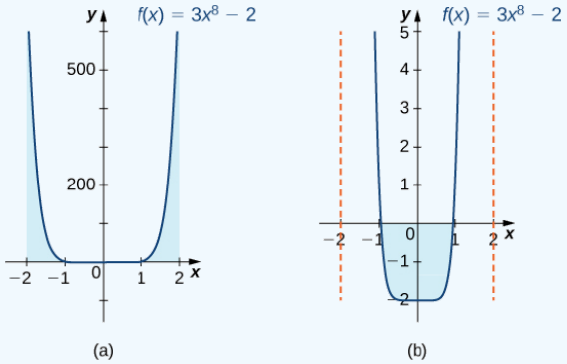

*Figure 5.5.4: Graph (a) shows the positive area between the curve and the $x$-axis, whereas graph (b) shows the negative area between the curve and the $x$-axis. Both views show the symmetry about the $y$-axis.*

## Example 5.5.6: Integrating an Odd Function

Evaluate the definite integral of the odd function $-5\sin x$ over the interval $[-\pi,\pi]$.

**Solution**

The graph is shown in Figure 5.5.5. We can see the symmetry about the origin by the positive area above the $x$-axis over $[-\pi,0]$, and the negative area below the $x$-axis over $[0,\pi]$. we have

$$\begin{aligned}\int_{-\pi}^{\pi}-5\sin x\,dx &= -5(-\cos x)\Big|_{-\pi}^{\pi}\\ &= 5\cos x\Big|_{-\pi}^{\pi}\\ &= [5\cos\pi]-[5\cos(-\pi)]\\ &= -5-(-5)\\ &= 0.\end{aligned}$$

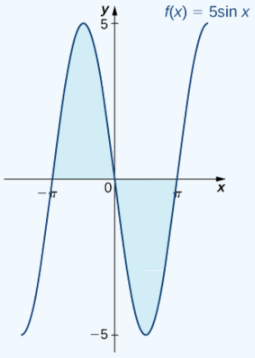

*Figure* **5.5.5***:The graph shows areas between a curve and the* $x$*-axis for an odd function.*

**? Checkpoint 5.5.6**

Integrate the function $\int_{-2}^{2} x^4\,dx$.

**Answer**

$\frac{64}{5}$

# 5.5E: EXERCISES

This page is a draft and is under active development.

## READING QUESTIONS

1. State the Net Change Theorem in its two common forms. How does the second form relate to the Fundamental Theorem of Calculus, Part 2?
2. If $v(t)$ is the velocity of a particle, what does $\int_a^b v(t)\,dt$ represent? What does $\int_a^b |v(t)|\,dt$ represent?
3. When calculating total distance traveled, why might it be necessary to split the integral into multiple parts?
4. What is an even function? Describe its symmetry.
5. What is an odd function? Describe its symmetry.
6. What is the value of $\int_{-a}^{a} f(x)\,dx$ if $f(x)$ is a continuous odd function? Explain geometrically.
7. How can the integral $\int_{-a}^{a} f(x)\,dx$ be simplified if $f(x)$ is a continuous even function? Explain geometrically.
8. In Example 3 (gasoline consumption), how was the Net Change Theorem applied to find the total amount of gasoline used?
9. If $F'(x)$ represents the rate of change of a quantity $F(x)$, what does the definite integral $\int_a^b F'(x)\,dx$ tell you about the quantity $F(x)$?

## HOMEWORK

1) Write an integral that expresses the increase in the perimeter $P(s)$ of a square when its side length $s$ increases from 2 units to 4 units and evaluate the integral.

**Answer**

$P(s) = 4s$, so $\frac{dP}{ds} = 4$ and $\int_2^4 4\,ds = 8$.

2) Write an integral that quantifies the change in the area $A(s) = s^2$ of a square when the side length doubles from $S$ units to $2S$ units and evaluate the integral.

3) A regular $N$-gon (an $N$-sided polygon with sides that have equal length $s$, such as a pentagon or hexagon) has perimeter $Ns$. Write an integral that expresses the increase in perimeter of a regular $N$-gon when the length of each side increases from 1 unit to 2 units and evaluate the integral.

**Answer**

$\int_1^2 N\,ds = N$

4) The area of a regular pentagon with side length $a > 0$ is $pa^2$ with $p = \frac{1}{4}\sqrt{5+\sqrt{5+2\sqrt{5}}}$. The Pentagon in Washington, DC, has inner sides of length 360 ft and outer sides of length 920 ft. Write an integral to express the area of the roof of the Pentagon according to these dimensions and evaluate this area.

5) A dodecahedron is a Platonic solid with a surface that consists of 12 pentagons, each of equal area. By how much does the surface area of a dodecahedron increase as the side length of each pentagon doubles from 1 unit to 2 units?

**Answer**

With $p$ as in the previous exercise, each of the 12 pentagons increases in area from $2p$ to $4p$ units so the net increase in the area of the dodecahedron is $36p$ units.

6) An icosahedron is a Platonic solid with a surface that consists of 20 equilateral triangles. By how much does the surface area of an icosahedron increase as the side length of each triangle doubles from a unit to $2a$ units?

7) Write an integral that quantifies the change in the area of the surface of a cube when its side length doubles from $s$ unit to $2s$ units and evaluate the integral.

**Answer**

$18s^2 = 6\int_s^{2s} 2x\,dx$

8) Write an integral that quantifies the increase in the volume of a cube when the side length doubles from $s$ unit to $2s$ units and evaluate the integral.

9) Write an integral that quantifies the increase in the surface area of a sphere as its radius doubles from $R$ unit to $2R$ units and evaluate the integral.

**Answer**

$12\pi R^2 = 8\pi \int_R^{2R} r\,dr$

10) Write an integral that quantifies the increase in the volume of a sphere as its radius doubles from $R$ unit to $2R$ units and evaluate the integral.

11) Suppose that a particle moves along a straight line with velocity $v(t) = 4 - 2t$, where $0 \le t \le 2$ (in meters per second). Find the displacement at time $t$ and the total distance traveled up to $t = 2$.

**Answer**

$d(t) = \int_0^t v(s)\,ds = 4t - t^2$. The total distance is $d(2) = 4$ m.

12) Suppose that a particle moves along a straight line with velocity defined by $v(t) = t^2 - 3t - 18$, where $0 \le t \le 6$ (in meters per second). Find the displacement at time $t$ and the total distance traveled up to $t = 6$.

13) Suppose that a particle moves along a straight line with velocity defined by $v(t) = |2t - 6|$, where $0 \le t \le 6$ (in meters per second). Find the displacement at time $t$ and the total distance traveled up to $t = 6$.

**Answer**

$d(t) = \int_0^t v(s)\,ds$. For $t < 3,\ d(t) = \int_0^t (6 - 2t)\,dt = 6t - t^2$. For $t > 3,\ d(t) = d(3) + \int_3^t (2t - 6)\,dt = 9 + (t^2 - 6t)$. The total distance is $d(6) = 9$ m.

14) Suppose that a particle moves along a straight line with acceleration defined by $a(t) = t - 3$, where $0 \le t \le 6$ (in meters per second). Find the velocity and displacement at time $t$ and the total distance traveled up to $t = 6$ if $v(0) = 3$ and $d(0) = 0$.

15) A ball is thrown upward from a height of 1.5 m at an initial speed of 40 m/sec. Acceleration resulting from gravity is $-9.8\ \text{m/sec}^2$. Neglecting air resistance, solve for the velocity $v(t)$ and the height $h(t)$ of the ball $t$ seconds after it is thrown and before it returns to the ground.

**Answer**

$v(t) = 40 - 9.8t;\ h(t) = 1.5 + 40t - 4.9t^2$ m/s

16) A ball is thrown upward from a height of 3 m at an initial speed of 60 m/sec. Acceleration resulting from gravity is $-9.8\ \text{m/sec}^2$. Neglecting air resistance, solve for the velocity $v(t)$ and the height $h(t)$ of the ball $t$ seconds after it is thrown and before it returns to the ground.

17) The area $A(t)$ of a circular shape is growing at a constant rate. If the area increases from $4\pi$ units to $9\pi$ units between times $t = 2$ and $t = 3$, find the net change in the radius during that time.

**Answer**

The net increase is 1 unit.

18) A spherical balloon is being inflated at a constant rate. If the volume of the balloon changes from $36\pi\ \text{in}^3$ to $288\pi\ \text{in}^3$ between time $t = 30$ and $t = 60$ seconds, find the net change in the radius of the balloon during that time.

19) Water flows into a conical tank with cross-sectional area $\pi x^2$ at height $x$ and volume $\frac{\pi x^3}{3}$ up to height $x$. If water flows into the tank at a rate of 1 $\text{m}^3/\text{min}$, find the height of water in the tank after 5 min. Find the change in height between 5 min and 10 min.

**Answer**

At $t = 5$, the height of water is $x = \left(\frac{15}{\pi}\right)^{1/3}$ m. The net change in height from $t = 5$ to $t = 10$ is $\left(\left(\frac{30}{\pi}\right)^{1/3} - \left(\frac{15}{\pi}\right)^{1/3}\right)$ m.

20) A horizontal cylindrical tank has cross-sectional area $A(x) = 4(6x - x^2)\ \text{m}^2$ at height $x$ meters above the bottom when $x \le 3$.

a. The volume $V$ between heights $a$ and $b$ is $\int_a^b A(x)\,dx$. Find the volume at heights between 2 m and 3 m.

b. Suppose that oil is being pumped into the tank at a rate of 50 L/min. Using the chain rule, $\frac{dx}{dt} = \frac{dx}{dV}\frac{dV}{dt}$, at how many meters per minute is the height of oil in the tank changing, expressed in terms of $x$, when the height is at $x$ meters?

c. How long does it take to fill the tank to 3 m starting from a fill level of 2 m?

21) The following table lists the electrical power in gigawatts—the rate at which energy is consumed—used in a certain city for different hours of the day, in a typical 24-hour period, with hour 1 corresponding to midnight to 1 a.m.

| Hour | Power | Hour | Power |
|---|---|---|---|
| 1 | 28 | 13 | 48 |
| 2 | 25 | 14 | 49 |
| 3 | 24 | 15 | 49 |
| 4 | 23 | 16 | 50 |
| 5 | 24 | 17 | 50 |
| 6 | 27 | 18 | 50 |
| 7 | 29 | 19 | 46 |
| 8 | 32 | 20 | 43 |
| 9 | 34 | 21 | 42 |
| 10 | 39 | 22 | 40 |
| 11 | 42 | 23 | 37 |
| 12 | 46 | 24 | 34 |

Find the total amount of power in gigawatt-hours (gW-h) consumed by the city in a typical 24-hour period.

**Answer**

The total daily power consumption is estimated as the sum of the hourly power rates, or 911 gW-h.

22) The average residential electrical power use (in hundreds of watts) per hour is given in the following table.

| Hour | Power | Hour | Power |
|---|---|---|---|
| 1 | 8 | 13 | 12 |
| 2 | 6 | 14 | 13 |
| 3 | 5 | 15 | 14 |
| 4 | 4 | 16 | 15 |
| 5 | 5 | 17 | 17 |
| 6 | 6 | 18 | 19 |
| 7 | 7 | 19 | 18 |
| 8 | 8 | 20 | 17 |
| 9 | 9 | 21 | 16 |
| 10 | 10 | 22 | 16 |
| 11 | 10 | 23 | 13 |
| 12 | 11 | 24 | 11 |

a. Compute the average total energy used in a day in kilowatt-hours (kWh).

b. If a ton of coal generates 1842 kWh, how long does it take for an average residence to burn a ton of coal?

c. Explain why the data might fit a plot of the form $p(t) = 11.5 - 7.5\sin\left(\frac{\pi t}{12}\right)$.

23) The data in the following table are used to estimate the average power output produced by Peter Sagan for each of the last 18 sec of Stage 1 of the 2012 **Tour de France.**

| Second | Watts | Second | Watts |
|---|---|---|---|
| 1 | 600 | 10 | 1200 |
| 2 | 500 | 11 | 1170 |
| 3 | 575 | 12 | 1125 |
| 4 | 1050 | 13 | 1100 |
| 5 | 925 | 14 | 1075 |
| 6 | 950 | 15 | 1000 |
| 7 | 1050 | 16 | 950 |
| 8 | 950 | 17 | 900 |
| 9 | 1100 | 18 | 780 |

Average Power Output Source: sportsexercisengineering.com

Estimate the net energy used in kilojoules (kJ), noting that 1W = 1 J/s, and the average power output by Sagan during this time interval.

**Answer**

**17** kJ

24) The data in the following table are used to estimate the average power output produced by Peter Sagan for each 15-min interval of Stage 1 of the 2012 Tour de France.

| Minutes | Watts | Minutes | Watts |
|---|---|---|---|
| 15 | 200 | 165 | 170 |
| 30 | 180 | 180 | 220 |
| 45 | 190 | 195 | 140 |
| 60 | 230 | 210 | 225 |
| 75 | 240 | 225 | 170 |
| 90 | 210 | 240 | 10 |
| 105 | 210 | 255 | 200 |
| 1120 | 220 | 270 | 220 |
| 135 | 210 | 285 | 250 |
| 150 | 150 | 300 | 400 |

Average Power Output *Source*: sportsexercisengineering.com

Estimate the net energy used in kilojoules, noting that 1W = 1 J/s.

25) The distribution of incomes as of 2012 in the United States in $5000 increments is given in the following table. The kth row denotes the percentage of households with incomes between $\$5000xk$ and $5000xk + 4999$. The row $k = 40$ contains all households with income between $200,000 and $250,000 and $k = 41$ accounts for all households with income exceeding $250,000.

| | | | |
|---|---|---|---|
| 0 | 3.5 | 21 | 1.5 |
| 1 | 4.1 | 22 | 1.4 |

Income Distributions Source: http://www.census.gov/prod/2013pubs/p60-245.pdf

a. Estimate the percentage of U.S. households in 2012 with incomes less than $55,000.

b. What percentage of households had incomes exceeding $85,000?

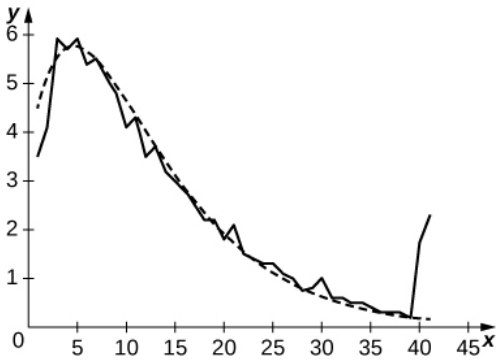
c. Plot the data and try to fit its shape to that of a graph of the form $a(x+c)e^{-b(x+e)}$ for suitable $a, b, c$.

**Answer**

a. 54.3%;

b. 27.00%;

c. The curve in the following plot is $2.35(t+3)e^{-0.15(t+3)}$.



26) Newton's law of gravity states that the gravitational force exerted by an object of mass $M$ and one of mass $m$ with centers that are separated by a distance r is $F = G\frac{mM}{r^2}$, with $G$ an empirical constant $G = 6.67x10^{-11}\ \mathrm{m}^3/(\mathrm{kg}\cdot\mathrm{s}^2)$. The work done by a variable force over an interval $[a,b]$ is defined as $W = \int_a^b F(x)\,dx$. If Earth has mass $5.97219 \times 10^{24}$ and radius 6371 km, compute the amount of work to elevate a polar weather satellite of mass 1400 kg to its orbiting altitude of 850 km above Earth.

27) For a given motor vehicle, the maximum achievable **deceleration** from braking is approximately $7\ \mathrm{m/sec}^2$ on dry concrete. On wet asphalt, it is approximately $2.5\ \mathrm{m/sec}^2$. Given that 1 mph corresponds to 0.447 m/sec, find the total distance that a car travels in meters on

dry concrete after the brakes are applied until it comes to a complete stop if the initial velocity is 67 mph (30 m/sec) or if the initial braking velocity is 56 mph (25 m/sec). Find the corresponding distances if the surface is slippery wet asphalt.

**Answer**

In dry conditions, with initial velocity $v_0 = 30$ m/s, $D = 64.3$ and, if $v_0 = 25,\ D = 44.64$. In wet conditions, if $v_0 = 30$, and $D = 180$ and if $v_0 = 25,\ D = 125$.

28) John is a 25-year old man who weighs 160 lb. He burns $500 - 50t$ calories/hr while riding his bike for $t$ hours. If an oatmeal cookie has 55 cal and John eats $4t$ cookies during the $t^{\text{th}}$ hour, how many net calories has he lost after 3 hours riding his bike?

29) Sandra is a 25-year old woman who weighs 120 lb. She burns $300 - 50t$ cal/hr while walking on her treadmill for $t$ hours. Her caloric intake from drinking Gatorade is $100t$ calories during the $t^{\text{th}}$ hour. What is her net decrease in calories after walking for 3 hours?

**Answer**

225 cal

30) A motor vehicle has a maximum efficiency of 33 mpg at a cruising speed of 40 mph. The efficiency drops at a rate of 0.1 mpg/mph between 40 mph and 50 mph, and at a rate of 0.4 mpg/mph between 50 mph and 80 mph. What is the efficiency in miles per gallon if the car is cruising at 50 mph? What is the efficiency in miles per gallon if the car is cruising at 80 mph? If gasoline costs $3.50/gal, what is the cost of fuel to drive 50 mi at 40 mph, at 50 mph, and at 80 mph?

31) Although some engines are more efficient at given a horsepower than others, on average, fuel efficiency decreases with horsepower at a rate of $1/25$ mpg/horsepower. If a typical 50-horsepower engine has an average fuel efficiency of 32 mpg, what is the average fuel efficiency of an engine with the following horsepower: 150, 300, 450?

**Answer**

$E(150) = 28,\ E(300) = 22,\ E(450) = 16$

32) [Technology Required] The following table lists the 2013 schedule of **federal income tax** versus taxable income.

| Taxable Income Range | The Tax Is ... | ... Of the Amount Over |
|---|---|---|
| $0–$8925 | 10% | $0 |
| $8925–$36,250 | $892.50 + 15% | $8925 |
| $36,250–$87,850 | $4,991.25 + 25% | $36,250 |
| $87,850–$183,250 | $17,891.25 + 28% | $87,850 |
| $183,250–$398,350 | $44,603.25 + 33% | $183,250 |
| $398,350–$400,000 | $115,586.25 + 35% | $398,350 |
| > $400,000 | $116,163.75 + 39.6% | $400,000 |

Federal Income Tax Versus Taxable Income Source: http://www.irs.gov/pub/irs-prior/i1040tt--2013.pdf.

Suppose that Steve just received a $10,000 raise. How much of this raise is left after federal taxes if Steve's salary before receiving the raise was $40,000? If it was $90,000? If it was $385,000?

33) [Technology Required] The following table provides hypothetical data regarding the level of service for a certain highway.

| Highway Speed Range (mph) | Vehicles per Hour per Lane | Density Range (vehicles/mi) |
|---|---|---|
| >60 | <600 | <10 |
| 60-57 | 300-1000 | 10-20 |
| 57-54 | 1000-1500 | 20-30 |
| 57-54 | 1500-1900 | 30-45 |
| 46-30 | 1900-2100 | 48-70 |
| <30 | Unstable | 70-200 |

a. Plot vehicles per hour per lane on the $x$-axis and highway speed on the $y$-axis.

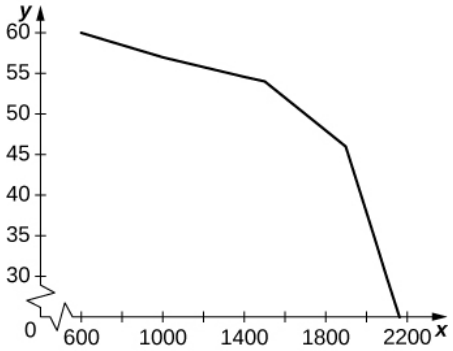
b. Compute the average decrease in speed (in miles per hour) per unit increase in congestion (vehicles per hour per lane) as the latter increases from 600 to 1000, from 1000 to 1500, and from 1500 to 2100. Does the decrease in miles per hour depend linearly on the increase

in vehicles per hour per lane?

c. Plot minutes per mile (60 times the reciprocal of miles per hour) as a function of vehicles per hour per lane. Is this function linear?

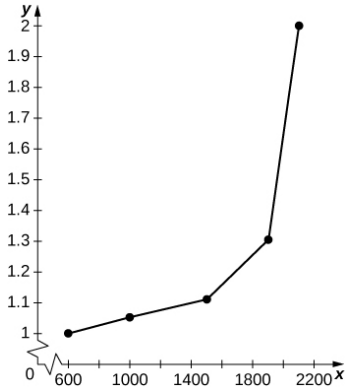
**Answer**

a.



b. Between 600 and 1000 the average decrease in vehicles per hour per lane is −0.0075. Between 1000 and 1500 it is −0.006 per vehicles per hour per lane, and between 1500 and 2100 it is −0.04 vehicles per hour per lane.

c.



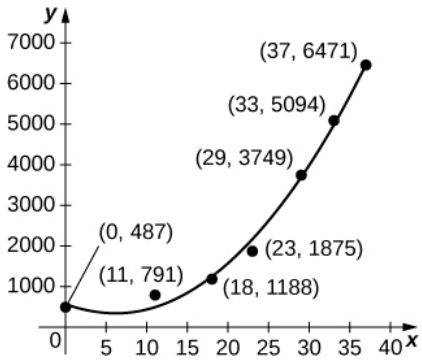
The graph is nonlinear, with minutes per mile increasing dramatically as vehicles per hour per lane reach 2000.

**For the next two exercises use the data in the following table, which displays bald eagle populations from 1963 to 2000 in the continental United States.**

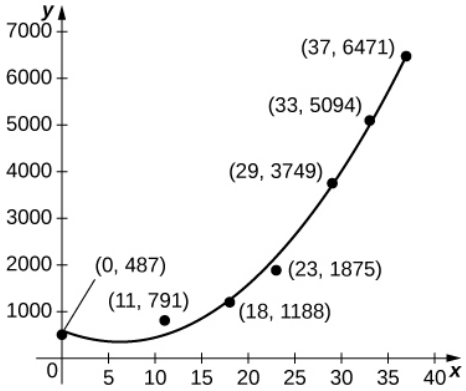
| Year | Population of Breeding Pairs of Bald Eagles |
|---|---|
| 1963 | 487 |
| 1974 | 791 |
| 1981 | 1188 |
| 1986 | 1875 |
| 1992 | 3749 |
| 1996 | 5094 |
| 2000 | 6471 |

Population of Breeding Bald Eagle Pairs *Source*: http://www.fws.gov/Midwest/eagle/pop.../chtofprs.html.

34) [Technology Required] The graph below plots the quadratic $p(t) = 6.48t^2 - 80.31t + 585.69$ against the data in preceding table, normalized so that $t = 0$ corresponds to 1963. Estimate the average number of bald eagles per year present for the 37 years by computing the average value of $p$ over $[0, 37]$.



35) [Technology Required] The graph below plots the cubic $p(t) = 0.07t^3 + 2.42t^2 - 25.63t + 521.23$ against the data in the preceding table, normalized so that $t = 0$ corresponds to 1963. Estimate the average number of bald eagles per year present for the 37 years by computing the average value of $p$ over $[0, 37]$.



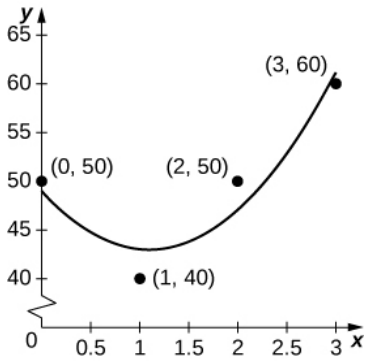
**Answer**

$$\frac{1}{37}\int_0^{37} p(t)\,dt = \frac{0.07(37)^3}{4} + \frac{2.42(37)^2}{3} - \frac{25.63(37)}{2} + 521.23 \approx 2037$$

Solution:

36) [Technology Required] Suppose you go on a road trip and record your speed at every half hour, as compiled in the following table. The best quadratic fit to the data is $q(t) = 5x^2 - 11x + 49$, shown in the accompanying graph. Integrate $q$ to estimate the total distance driven over the 3 hours.

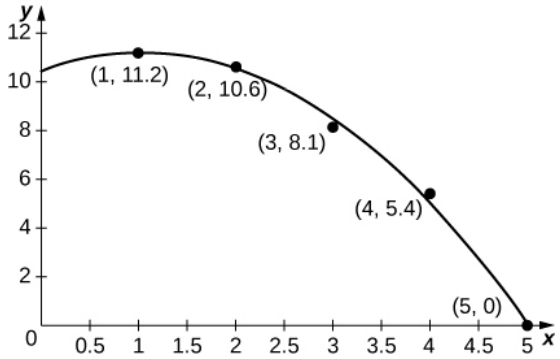
| Time (hr) | Speed (m[h) |
|---|---|
| 0 (start) | 50 |
| 1 | 40 |
| 2 | 50 |
| 3 | 60 |



**As a car accelerates, it does not accelerate at a constant rate; rather, the acceleration is variable. For the following exercises, use the following table, which contains the acceleration measured at every second as a driver merges onto a freeway.**

| Time (sec) | Acceleration (mph/sec) |
|---|---|
| 1 | 11.2 |
| 2 | 10.6 |
| 3 | 8.1 |
| 4 | 5.4 |
| 5 | 0 |

37) [Technology Required] The accompanying graph plots the best quadratic fit, $a(t) = -0.70t^2 + 1.44t + 10.44$, to the data from the preceding table. Compute the average value of $a(t)$ to estimate the average acceleration between $t = 0$ and $t = 5$.



**Answer**

Average acceleration is $A = \frac{1}{5}\int_0^5 a(t)\,dt = -\frac{0.7(5^2)}{3} + \frac{1.44(5)}{2} + 10.44 \approx 8.2$ mph/s

38) [Technology Required] Using your acceleration equation from the previous exercise, find the corresponding velocity equation. Assuming the final velocity is 0 mph, find the velocity at time $t = 0$.

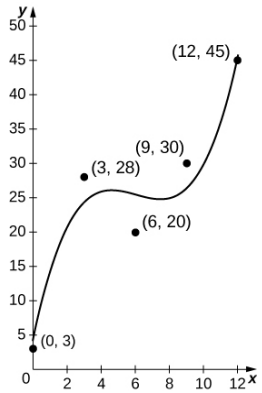
39) [Technology Required] Using your velocity equation from the previous exercise, find the corresponding distance equation, assuming your initial distance is 0 mi. How far did you travel while you accelerated your car? (Hint: You will need to convert time units.)

**Answer**

$d(t) = \int_0^1 |v(t)|\,dt = \int_0^t \left(\frac{7}{30}t^3 - 0.72t^2 - 10.44t + 41.033\right)\,dt = \frac{7}{120}t^4 - 0.24t^3 - 5.22t^3 + 41.033t$. Then, $d(5) \approx 81.12\,\text{mph} \times \text{sec} \approx 119$ feet.

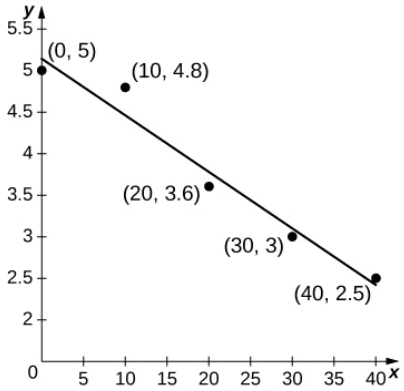
40) [Technology Required] The number of hamburgers sold at a restaurant throughout the day is given in the following table, with the accompanying graph plotting the best cubic fit to the data, $b(t) = 0.12t^3 - 2.13t^3 + 12.13t + 3.91$, with $t = 0$ corresponding to 9 a.m. and $t = 12$ corresponding to 9 p.m. Compute the average value of $b(t)$ to estimate the average number of hamburgers sold per hour.

| Hours Past Midnight | No. of Burgers Sold |
|---|---|
| 9 | 3 |
| 12 | 28 |
| 15 | 20 |
| 18 | 30 |
| 21 | 45 |



41) [Technology Required] An athlete runs by a motion detector, which records her speed, as displayed in the following table. The best linear fit to this data, $\ell(t) = -0.068t + 5.14$, is shown in the accompanying graph. Use the average value of $\ell(t)$ between $t = 0$ and $t = 40$ to estimate the runner's average speed.

| Minutes | Speed (m/sec) |
|---|---|
| 0 | 5 |
| 10 | 4.8 |
| 20 | 3.6 |
| 30 | 3.0 |
| 40 | 2.5 |



**Answer**

$\frac{1}{40}\int_0^{40}(-0.068t + 5.14)\,dt = -\frac{0.068(40)}{2} + 5.14 = 3.78$ m/sec

# 5.6: Integration by Substitution

**Learning Objectives**

- Use substitution to evaluate indefinite integrals.
- Use substitution to evaluate definite integrals.

Hawk A.I. Section-Specific Tutor

Please note that, to access the Hawk A.I. Tutor, you will need a (free) OpenAI account.

The Fundamental Theorem of Calculus allows us to evaluate integrals without using Riemann sums. The drawback of this method is that we must be able to find an antiderivative, which can be challenging. This section examines **integration by substitution** - a technique to help us find antiderivatives. Specifically, this method allows us to find antiderivatives when the integrand is the result of a Chain Rule derivative.

At first, the approach to the substitution procedure may appear obscure. However, it is primarily a visual task - that is, the integrand shows you what to do; it is a matter of recognizing the form of the function. So, what are we supposed to see?

We are looking for an integrand of the form $f\,(g(x))\,g'(x)\,dx$. For example, in the integral

$$\int (x^2-3)^3\,2x\,dx. \tag{5.6.1}$$

we have

$$f(x)=x^3$$

and

$$g(x)=x^2-3.$$

Then

$$g'(x)=2x.$$

Therefore,

$$f(g(x))g'(x)=(x^2-3)^3(2x),$$

and we see that our integrand is in the correct form. The method is called substitution, or the **Substitution Method**, because we substitute part of the integrand with the variable $u$ and part of the integrand with $du$. It is also referred to as **change of variables** because we are changing variables to obtain an easier expression to work with for applying the integration rules.

**Theorem: Substitution Method with Indefinite Integrals**

Let $u=g(x)$, where $g'(x)$ is continuous over an interval, let $f(x)$ be continuous over the corresponding range of $g$, and let $F(x)$ be an antiderivative of $f(x)$. Then,

$$\begin{aligned}\int f\,(g(x))\,g'(x)\,dx &= \int f(u)\,du\\ &= F(u)+C\\ &= F(g(x))+C\end{aligned}$$

**Proof**

Let $f$, $g$, $u$, and $F$ be as specified in the theorem. Then

$$\frac{d}{dx}\left[F(g(x))\right] = F'(g(x))g'(x) = f[g(x)]g'(x).$$

Integrating both sides with respect to $x$, we see that

$$\int f\left(g(x)\right) g'(x)\, dx = F(g(x)) + C.$$

If we now substitute $u = g(x)$, and $du = g'(x)\, dx$, we get

$$\int f\left(g(x)\right) g'(x)\, dx = \int f(u)\, du = F(u) + C = F(g(x)) + C.$$

*Q.E.D.*

Returning to the problem we looked at originally, we let $u = x^2 - 3$ and then $du = 2x\, dx$.

Rewrite the integral (Equation 5.6.1) in terms of $u$:

$$\int (x^2 - 3)^3 (2x\, dx) = \int u^3\, du.$$

Using the Power Rule for integrals, we have

$$\int u^3\, du = \frac{u^4}{4} + C.$$

Substitute the original expression for $x$ back into the solution:

$$\frac{u^4}{4} + C = \frac{(x^2 - 3)^4}{4} + C.$$

At this point, it is important to note that integration is mostly a heuristic method. That is, integration is approached more often by using a "calculated guess" derived from previous experiences. As you move through the middle part of Calculus (also known as Calculus II, or Integral Calculus), you will learn many different integration techniques. You must practice as many problems as possible to get a "natural feel" for what method to use and when to use it.

In the case of Integration by Substitution, you are often (but not always) looking for an integrand involving a function, $g(x)$, and its *approximate* derivative, $g'(x)$. You let $u(x) = g(x)$ so that $du = g'(x)dx$. At that point, you will have rewritten your original integral into a form that (hopefully) looks like

$$\int u\, du.$$

### Example 5.6.1: Using Substitution to Find an Antiderivative

Use substitution to find the antiderivative of $\int 6x(3x^2 + 4)^4\, dx$.

**Solution**

The first step is to choose an expression for $u$. We choose $u = 3x^2 + 4$ because then $du = 6x\, dx$ and we already have $du$ in the integrand. Write the integral in terms of $u$:

$$\int 6x(3x^2 + 4)^4\, dx = \int u^4\, du.$$

Remember that $du$ is the derivative of the expression chosen for $u$, regardless of what is inside the integrand. Now we can evaluate the integral with respect to $u$:

$$\int u^4\, du = \frac{u^5}{5} + C = \frac{(3x^2 + 4)^5}{5} + C.$$

### Analysis

We can check our answer by taking the derivative of the result of integration. We should obtain the integrand. Picking a value for $C$ of 1, we let $y = \frac{1}{5}(3x^2+4)^5+1$. We have

$$y = \frac{1}{5}(3x^2+4)^5+1,$$

so

$$\begin{aligned} y' &= \left(\frac{1}{5}\right)5(3x^2+4)^4 6x \\ &= 6x(3x^2+4)^4. \end{aligned}$$

This is exactly the expression we started with inside the integrand.

**? Checkpoint 5.6.1**

Use substitution to find the antiderivative of $\int 3x^2(x^3-3)^2\,dx$.

**Answer**

$$\int 3x^2(x^3-3)^2\,dx = \frac{1}{3}(x^3-3)^3+C$$

Sometimes, we need to adjust the constants in our integral if they don't match up exactly with the expressions we are substituting.

**✓ Example 5.6.2: Using Substitution with Alteration**

Use substitution to find the antiderivative of

$$\int z\sqrt{z^2-5}\,dz.$$

**Solution**

Rewrite the integral as $\int z(z^2-5)^{1/2}\,dz$. Let $u = z^2-5$ and $du = 2z\,dz$. We have a problem because $du = 2z\,dz$ and the original expression has only $z\,dz$. We must alter our expression for $du$, or the integral in $u$ will be twice as large as it should be. If we multiply both sides of the $du$ equation by $\frac{1}{2}$. we can solve this problem. Thus,

$$u = z^2-5$$

$$du = 2z\,dz$$

$$\frac{1}{2}du = \frac{1}{2}(2z)\,dz = z\,dz.$$

Write the integral in terms of $u$, but pull the $\frac{1}{2}$ outside the integration symbol:

$$\int z(z^2-5)^{1/2}\,dz = \frac{1}{2}\int u^{1/2}\,du.$$

Integrate the expression in $u$:

$$\begin{aligned}\frac{1}{2}\int u^{1/2}\,du &= \left(\frac{1}{2}\right)\frac{u^{3/2}}{\frac{3}{2}}+C\\ &= \left(\frac{1}{2}\right)\left(\frac{2}{3}\right)u^{3/2}+C\\ &= \frac{1}{3}u^{3/2}+C\\ &= \frac{1}{3}(z^2-5)^{3/2}+C\end{aligned}$$

**? Checkpoint 5.6.2**

Use substitution to find the antiderivative of $\int x^2(x^3+5)^9\,dx$.

**Answer**

$$\int x^2(x^3+5)^9\,dx = \frac{(x^3+5)^{10}}{30}+C$$

**✔ Example 5.6.3: Using Substitution with Integrals of Trigonometric Functions**

Use substitution to evaluate the integral $\int \frac{\sin t}{\cos^3 t}\,dt$.

**Solution**

We know the derivative of $\cos t$ is $-\sin t$, so we set $u=\cos t$. Then $du=-\sin t\,dt$.

Substituting into the integral, we have

$$\int \frac{\sin t}{\cos^3 t}\,dt = -\int \frac{du}{u^3}.$$

Evaluating the integral, we get

$$-\int \frac{du}{u^3} = -\int u^{-3}\,du = -\left(-\frac{1}{2}\right)u^{-2}+C.$$

Putting the answer back in terms of t, we get

$$\int \frac{\sin t}{\cos^3 t}\,dt = \frac{1}{2u^2}+C = \frac{1}{2\cos^2 t}+C.$$

Example 5.6.3 needs a little more explanation. How did we know to let $u=\cos(t)$ rather than the sine function? To be honest, this is something that becomes more of an instinct after a while; however, there is a science to it - it's the science of *considering ramifications*.

If we let $u=\sin(t)$, then $du=\cos(t)dt$. This might not jump off the page to you and scream, "This is bad," so let's see the ramifications of this choice.

The original integrand was $\frac{\sin(t)}{\cos^3(t)}$. Since this does not have a $\cos(t)$ to "steal" in the numerator, we need to solve $du=\cos(t)dt$ for $dt$. Doing so yields $dt=\frac{1}{\cos(t)}du$. If we make this substitution, the integrand would become

$$\frac{\sin(t)}{\cos^3(t)}\,dt = \frac{u}{\cos^3(t)}\cdot\frac{1}{\cos(t)}\,du = \frac{u}{\cos^4(t)}\,du.$$

There are two major issues here:

1. the integrand would have a mixture of variables, so we cannot leave it this way, and
2. the integrand would become *more* complex - not less.

The first issue can be overcome by using our Trigonometry knowledge.

$$\begin{aligned}\frac{u}{\cos^4(t)}\,du &= \frac{u}{(\cos^2(t))^2}\,du \\ &= \frac{u}{(1-\sin^2(t))^2}\,du \\ &= \frac{u}{(1-u^2)^2}\,du \qquad \text{(Substitution: Recall } u=\sin(t)\text{)}\end{aligned}$$

However, the second issue (complexity) still exists. Instead of

$$\int \frac{\sin(t)}{\cos^3(t)}\,dt,$$

we are now faced with

$$\int \frac{u}{(1-u^2)^2}\,du.$$

In either case, we do not immediately know of an appropriate antiderivative.

**? Checkpoint 5.6.3**

Use substitution to evaluate each integral

a. $\int \frac{\cos t}{\sin^2 t}\,dt$

b. $\int \cos^3 t \sin t\,dt$

**Answers**

a. $\int \frac{\cos t}{\sin^2 t}\,dt = -\frac{1}{\sin t} + C$

b. $\int \cos^3 t \sin t\,dt = -\frac{\cos^4 t}{4} + C$

Sometimes, we need to manipulate an integral in more complicated ways than just multiplying or dividing by a constant. We need to eliminate all the expressions within the integrand that are in terms of the original variable. When done, $u$ should be the only variable in the integrand. This sometimes means solving for the original variable in terms of $u$. This technique should become clear in the next example.

**✓ Example 5.6.4: Finding an Antiderivative Using $u$-Substitution**

Use substitution to find the antiderivative of

$$\int \frac{x}{\sqrt{x-1}}\,dx.$$

**Solution**

If we let $u = x-1$, then $du = dx$. But this does not account for the $x$ in the numerator of the integrand. We must express $x$ in terms of $u$. If $u = x-1$, then $x = u+1$. Now we can rewrite the integral in terms of $u$:

$$\int \frac{x}{\sqrt{x-1}}\,dx = \int \frac{u+1}{\sqrt{u}}\,du = \int \left(\sqrt{u} + \frac{1}{\sqrt{u}}\right)du = \int \left(u^{1/2} + u^{-1/2}\right)du.$$

Then we integrate in the usual way, replace $u$ with the original expression, and factor and simplify the result. Thus,

$$\begin{aligned}\int (u^{1/2}+u^{-1/2})\,du &= \frac{2}{3}u^{3/2}+2u^{1/2}+C\\ &= \frac{2}{3}(x-1)^{3/2}+2(x-1)^{1/2}+C\\ &= (x-1)^{1/2}\left[\frac{2}{3}(x-1)+2\right]+C\\ &= (x-1)^{1/2}\left(\frac{2}{3}x-\frac{2}{3}+\frac{6}{3}\right)\\ &= (x-1)^{1/2}\left(\frac{2}{3}x+\frac{4}{3}\right)\\ &= \frac{2}{3}(x-1)^{1/2}(x+2)+C.\end{aligned}$$

The final example in this subsection illustrates a common tripping point for students - the dreaded substitution with resubstitution.

### Example 5.6.5: Using Substitution with a Resubstitution

Evaluate.

$$\int 3x^{17}\sqrt[4]{4x^9+8}\,dx$$

**Solution**

On first inspection, there doesn't seem to be an expression whose exact derivative (or constant multiple of the derivative) is contained within the integrand. However, practicing some faith, let's try the $u$-substitution, $u=4x^9+8$. This would imply that $du=36x^8\,dx$. Looking at the integrand, we don't have a $36x^8\,dx$ to "steal," but we *do* have $3x^8\,dx$. Thus, we let $\frac{1}{12}\,du = 3x^8\,dx$. Therefore,

$$\begin{aligned}\int 3x^{17}\sqrt[4]{4x^9+8}\,dx &= \int x^9\sqrt[4]{4x^9+8}\cdot 3x^8\,dx\\ &= \frac{1}{12}\int x^9\sqrt[4]{u}\,du\end{aligned}$$

At this point, I want to be clear that the notation in that final line is not traditionally acceptable. Our original integral was in terms of the variable $x$ (and only that variable). The integral we arrived at in the last line *should* be in terms of only $u$; however, we have a pesky $x^9$ in there. Luckily, we know that $u=4x^9+8$. Hence, $\frac{u-8}{4}=x^9$. Substituting (also known as resubstituting) this into the last line of the computation above, we get the following.

$$\begin{aligned}\int 3x^{17}\sqrt[4]{4x^9+8}\,dx &= \frac{1}{12}\int x^9\sqrt[4]{u}\,du\\ &= \frac{1}{12}\int \frac{u-8}{4}u^{1/4}\,du\\ &= \frac{1}{48}\int (u-8)u^{1/4}\,du\\ &= \frac{1}{48}\int u^{5/4}-8u^{1/4}\,du\\ &= \frac{1}{48}\left(\frac{4}{9}u^{9/4}-\frac{32}{5}u^{5/4}\right)+C\\ &= \frac{1}{12}\left(\frac{1}{9}u^{9/4}-\frac{8}{5}u^{5/4}\right)+C\\ &= \frac{1}{12}\left(\frac{1}{9}(4x^9+8)^{9/4}-\frac{8}{5}(4x^9+8)^{5/4}\right)+C\end{aligned}$$

Before moving away from Example 5.6.5, it's worthwhile to mention that we should simplify expressions when possible. Unfortunately, factoring out common expressions from the answer in Example 5.6.5 does not improve the look and feel of the solution.

$$\begin{aligned}\frac{1}{12}\left(\frac{1}{9}(4x^9+8)^{9/4}-\frac{8}{5}(4x^9+8)^{5/4}\right)+C &= \frac{1}{12\cdot 9\cdot 5}(4x^9+8)^{5/4}\left(5(4x^9+8)-9\cdot 8\right)+C\\ &= \frac{1}{540}(4x^9+8)^{5/4}\left(20x^9+40-72\right)+C\\ &= \frac{1}{540}(4x^9+8)^{5/4}\left(20x^9-32\right)+C\\ &= \frac{4}{540}(4x^9+8)^{5/4}\left(5x^9-8\right)+C\\ &= \frac{1}{135}(4x^9+8)^{5/4}\left(5x^9-8\right)+C\end{aligned}$$

## Substitution for Definite Integrals

Substitution can be used with definite integrals, too. However, using substitution to evaluate a definite integral requires changing the limits of integration. If we change variables in the integrand, the limits of integration change as well.

**Theorem: Substitution with Definite Integrals**

Let $u=g(x)$ and let $g'$ be continuous over an interval $[a,b]$, and let $f$ be continuous over the range of $u=g(x)$. Then,

$$\int_a^b f(g(x))g'(x)\,dx=\int_{g(a)}^{g(b)} f(u)\,du.$$

Although we will not formally prove this theorem, we justify it with some calculations. From the Substitution Method for indefinite integrals, if $F(x)$ is an antiderivative of $f(x)$, we have

$$\int f(g(x))g'(x)\,dx=F(g(x))+C.$$

Then

$$\begin{aligned}\textstyle\int_a^b f[g(x)]g'(x)\,dx &= F(g(x))\Big|_{x=a}^{x=b}\\ &= F(g(b))-F(g(a))\\ &= F(u)\Big|_{u=g(a)}^{u=g(b)}\\ &= \textstyle\int_{g(a)}^{g(b)} f(u)\,du\end{aligned}$$

and we have the desired result.

**Example 5.6.6: Using Substitution to Evaluate a Definite Integral**

Use substitution to evaluate

$$\int_0^1 x^2(1+2x^3)^5\,dx.$$

**Solution**

Let $u=1+2x^3$, so $du=6x^2\,dx$. Since the original function includes one factor of $x^2$ and $du=6x^2\,dx$, multiply both sides of the $du$ equation by $1/6$. Then,

$$du = 6x^2\,dx$$
$$\Rightarrow \quad \frac{1}{6}du = x^2\,dx.$$

To adjust the limits of integration, note that when $x = 0, u = 1 + 2(0) = 1$, and when $x = 1,\ u = 1 + 2(1) = 3$.

Then

$$\int_0^1 x^2(1 + 2x^3)^5 dx = \frac{1}{6}\int_1^3 u^5\,du.$$

Evaluating this expression, we get

$$\begin{aligned} \frac{1}{6}\int_1^3 u^5\,du &= \left(\frac{1}{6}\right)\left(\frac{u^6}{6}\right)\Big|_{u=1}^{u=3} \\ &= \frac{1}{36}\left[(3)^6 - (1)^6\right] \\ &= \frac{182}{9}. \end{aligned}$$

## Checkpoint 5.6.6

Use substitution to evaluate the definite integral.

a. $\int_{-1}^{0} y(2y^2 - 3)^5\,dy$

b. $\int_0^1 x^2 \cos\left(\frac{\pi}{2}x^3\right)\,dx$

**Answers**

a. $\int_{-1}^{0} y(2y^2 - 3)^5\,dy = \frac{91}{3}$

b. $\int_0^1 x^2 \cos\left(\frac{\pi}{2}x^3\right)\,dx = \frac{2}{3\pi} \approx 0.2122$

## Example 5.6.7: Using Substitution with an Exponential Function

Use substitution to evaluate

$$\int_0^1 xe^{4x^2+3}\,dx.$$

**Solution**

Let $u = 4x^3 + 3$. Then, $du = 8x\,dx$. To adjust the limits of integration, we note that when $x = 0,\ u = 3$, and when $x = 1,\ u = 7$. So our substitution gives

$$\begin{aligned} \int_0^1 xe^{4x^2+3}\,dx &= \frac{1}{8}\int_3^7 e^u\,du \\ &= \frac{1}{8}e^u\Big|_{u=3}^{u=7} \\ &= \frac{e^7 - e^3}{8} \\ &\approx 134.568 \end{aligned}$$

**Caution: Change Limits of Integration!**

When performing a substitution on a definite integral, it is critical that you *immediately* change the limits of integration as well.

Substitution may be only one of the techniques needed to evaluate a definite integral. All of the properties and rules of integration apply independently, and trigonometric functions may need to be rewritten using a trigonometric identity before we can apply substitution.

**Example 5.6.8: Using Substitution to Evaluate a Trigonometric Integral**

Use substitution to evaluate

$$\int_0^{\pi/2} \cos^2\theta\, d\theta.$$

**Solution**

First, use a trigonometric identity to rewrite the integral. The trigonometric identity $\cos^2\theta = \frac{1+\cos 2\theta}{2}$ allows us to rewrite the integral as

$$\int_0^{\pi/2} \cos^2\theta\, d\theta = \int_0^{\pi/2} \frac{1+\cos 2\theta}{2}\, d\theta.$$

Then,

$$\begin{aligned} \int_0^{\pi/2} \left(\frac{1+\cos 2\theta}{2}\right) d\theta &= \int_0^{\pi/2} \left(\frac{1}{2}+\frac{1}{2}\cos 2\theta\right) d\theta \\ &= \frac{1}{2}\int_0^{\pi/2} d\theta + \int_0^{\pi/2} \cos 2\theta\, d\theta. \end{aligned}$$

We can evaluate the first integral as it is. Still, we need to make a substitution to evaluate the second integral. Let $u = 2\theta$. Then, $du = 2\, d\theta$, or $\frac{1}{2}\, du = d\theta$. Also, when $\theta = 0$, $u = 0$, and when $\theta = \pi/2$, $u = \pi$. Expressing the second integral in terms of $u$, we have

$$\begin{aligned} \frac{1}{2}\int_0^{\pi/2} d\theta + \frac{1}{2}\int_0^{\pi/2} \cos 2\theta\, d\theta &= \frac{1}{2}\int_0^{\pi/2} d\theta + \frac{1}{2}\left(\frac{1}{2}\right)\int_0^{\pi} \cos u\, du \\ &= \frac{\theta}{2}\Big|_{\theta=0}^{\theta=\pi/2} + \frac{1}{4}\sin u\Big|_{u=0}^{u=\theta} \\ &= \left(\frac{\pi}{4}-0\right)+(0-0) \\ &= \frac{\pi}{4} \end{aligned}$$

# 5.6E: EXERCISES

This page is a draft and is under active development.

## READING QUESTIONS

1. What is the main goal of the integration by substitution method?
2. If we choose $u = g(x)$ for a substitution, what is $du$ equal to?
3. When is integration by substitution particularly useful? What form of integrand are we often looking for?
4. After performing a $u$-substitution for an indefinite integral and finding the antiderivative in terms of $u$, what is the final step?
5. When performing a $u$-substitution for a definite integral $\int_a^b f(g(x))g'(x)\,dx$, what must be done to the limits of integration $a$ and $b$?
6. In Example 2, where $u = z^2 - 5$ and $du = 2z\,dz$, but the integral had $z\,dz$, what "alteration" was made?
7. Is it permissible to have both $x$ and $u$ (or $dx$ and $du$) in the integrand after making a substitution?
8. If, after choosing $u = g(x)$, there are still terms involving $x$ in the integrand that are not part of $du$, what algebraic step might be necessary?
9. What is meant by "substitution with resubstitution" as illustrated in Example 5?
10. Why is it critical to change the limits of integration immediately when performing a substitution on a definite integral?

## HOMEWORK

**In exercises 1 - 10, find the antiderivatives for the given functions.**

1) $\cosh(2x+1)$

**Answer**

$\frac{1}{2}\sinh(2x+1)+C$

2) $\tanh(3x+2)$

3) $x\cosh(x^2)$

**Answer**

$\frac{1}{2}\sinh^2(x^2)+C$

4) $3x^3\tanh(x^4)$

5) $\cosh^2(x)\sinh(x)$

**Answer**

$\frac{1}{3}\cosh^3(x)+C$

6) $\tanh^2(x)\text{sech}^2(x)$

7) $\dfrac{\sinh(x)}{1+\cosh(x)}$

**Answer**

$\ln(1+\cosh(x))+C$

8) $\coth(x)$

9) $\cosh(x)+\sinh(x)$

**Answer**

$\cosh(x)+\sinh(x)+C$

10) $(\cosh(x)+\sinh(x))^n$

**In exercises 11 - 17, find the antiderivatives for the functions.**

11) $\int \dfrac{dx}{4-x^2}$

12) $\int \frac{dx}{a^2 - x^2}$

**Answer**

$\frac{1}{a}\tanh^{-1}\left(\frac{x}{a}\right) + C$

13) $\int \frac{dx}{\sqrt{x^2+1}}$

14) $\int \frac{x\,dx}{\sqrt{x^2+1}}$

**Answer**

$\sqrt{x^2+1} + C$

15) $\int -\frac{dx}{x\sqrt{1-x^2}}$

16) $\int \frac{e^x\,dx}{\sqrt{e^{2x}-1}}$

**Answer**

$\cosh^{-1}(e^x) + C$

17) $\int -\frac{2x}{x^4-1}\,dx$

18) Why is $u$-substitution referred to as a *change of variable*?

19) If $f = g \circ h$, when reversing the chain rule, $\frac{d}{dx}(g \circ h)(x) = g'(h(x))h'(x)$, should you take $u = g(x)$ or $u = h(x)$?

**Answer**

$u = h(x)$

**In exercises 20 - 24, verify each identity using differentiation. Then, using the indicated $u$-substitution, identify $f$ such that the integral takes the form $\int f(u)\,du$.**

20) $\int x\sqrt{x+1}\,dx = \frac{2}{15}(x+1)^{3/2}(3x-2) + C; \quad u = x+1$

21) $\int \frac{x^2}{\sqrt{x-1}}\,dx = \frac{2}{15}\sqrt{x-1}(3x^2+4x+8) + C, \quad (x>1); \quad u = x-1$

**Answer**

$f(u) = \frac{(u+1)^2}{\sqrt{u}}$

22) $\int x\sqrt{4x^2+9}\,dx = \frac{1}{12}(4x^2+9)^{3/2} + C; \quad u = 4x^2+9$

23) $\int \frac{x}{\sqrt{4x^2+9}}\,dx = \frac{1}{4}\sqrt{4x^2+9} + C; \quad u = 4x^2+9$

**Answer**

$du = 8x\,dx; \quad f(u) = \frac{1}{8\sqrt{u}}$

24) $\int \frac{x}{(4x^2+9)^2}\,dx = -\frac{1}{8(4x^2+9)} + C; \quad u = 4x^2+9$

**In exercises 25 - 34, find the antiderivative using the indicated substitution.**

25) $\int (x+1)^4\,dx; \quad u = x+1$

**Answer**

$\int (x+1)^4\,dx = \frac{1}{5}(x+1)^5 + C$

26) $\int (x-1)^5\,dx; \quad u = x-1$

27) $\int (2x-3)^{-7}\,dx; \quad u=2x-3$

**Answer**

$$\int (2x-3)^{-7}\,dx = -\frac{1}{12(2x-3)^6}+C$$

28) $\int (3x-2)^{-11}\,dx; \quad u=3x-2$

29) $\int \frac{x}{\sqrt{x^2+1}}\,dx; \quad u=x^2+1$

**Answer**

$$\int \frac{x}{\sqrt{x^2+1}}\,dx = \sqrt{x^2+1}+C$$

30) $\int \frac{x}{\sqrt{1-x^2}}\,dx; \quad u=1-x^2$

31) $\int (x-1)(x^2-2x)^3\,dx; \quad u=x^2-2x$

**Answer**

$$\int (x-1)(x^2-2x)^3\,dx = \frac{1}{8}(x^2-2x)^4+C$$

32) $\int (x^2-2x)(x^3-3x^2)^2\,dx; \quad u=x^3=3x^2$

33) $\int \cos^3\theta\,d\theta; \quad u=\sin\theta$ (Hint: $\cos^2\theta=1-\sin^2\theta$)

**Answer**

$$\int \cos^3\theta\,d\theta = \sin\theta-\frac{\sin^3\theta}{3}+C$$

34) $\int \sin^3\theta\,d\theta; \quad u=\cos\theta$ (Hint: $\sin^2\theta=1-\cos^2\theta$)

**In exercises 35 - 51, use a suitable change of variables to determine the indefinite integral.**

35) $\int x(1-x)^{99}\,dx$

**Answer**

$$\begin{aligned}\int x(1-x)^{99}\,dx &= \frac{(1-x)^{101}}{101}-\frac{(1-x)^{100}}{100}+C\\ &= -\frac{(1-x)^{100}}{10100}\left[100x+1\right]+C\end{aligned}$$

36) $\int t(1-t^2)^{10}\,dt$

37) $\int (11x-7)^{-3}\,dx$

**Answer**

$$\int (11x-7)^{-3}\,dx = -\frac{1}{22(11x-7)^2}+C$$

38) $\int (7x-11)^4\,dx$

39) $\int \cos^3\theta\sin\theta\,d\theta$

**Answer**

$$\int \cos^3\theta\sin\theta\,d\theta = -\frac{\cos^4\theta}{4}+C$$

40) $\int \sin^7\theta\cos\theta\,d\theta$

41) $\int \cos^2(\pi t)\sin(\pi t)\,dt$

**Answer**

$$\int \cos^2(\pi t)\sin(\pi t)\,dt = -\frac{cos^3(\pi t)}{3\pi} + C$$

42) $\int \sin^2 x \cos^3 x\,dx$ (Hint: $\sin^2 x + \cos^2 x = 1$)

43) $\int t\sin(t^2)\cos(t^2)\,dt$

**Answer**

$$\int t\sin(t^2)\cos(t^2)\,dt = -\frac{1}{4}\cos^2(t^2) + C$$

44) $\int t^2\cos^2(t^3)\sin(t^3)\,dt$

45) $\int \frac{x^2}{(x^3-3)^2}\,dx$

**Answer**

$$\int \frac{x^2}{(x^3-3)^2}\,dx = -\frac{1}{3(x^3-3)} + C$$

46) $\int \frac{x^3}{\sqrt{1-x^2}}\,dx$

47) $\int \frac{y^5}{(1-y^3)^{3/2}}\,dy$

**Answer**

$$\int \frac{y^5}{(1-y^3)^{3/2}}\,dy = -\frac{2(y^3-2)}{3\sqrt{1-y^3}} + C$$

48) $\int \cos\theta(1-\cos\theta)^{99}\sin\theta\,d\theta$

49) $\int (1-\cos^3\theta)^{10}\cos^2\theta\sin\theta\,d\theta$

**Answer**

$$\int (1-\cos^3\theta)^{10}\cos^2\theta\sin\theta\,d\theta = \frac{1}{33}(1-\cos^3\theta)^{11} + C$$

50) $\int (\cos\theta - 1)(\cos^2\theta - 2\cos\theta)^3\sin\theta\,d\theta$

51) $\int (\sin^2\theta - 2\sin\theta)(\sin^3\theta - 3\sin^2\theta)^3\cos\theta\,d\theta$

**Answer**

$$\int (\sin^2\theta - 2\sin\theta)(\sin^3\theta - 3\sin^2\theta)^3\cos\theta\,d\theta = \frac{1}{12}(\sin^3\theta - 3\sin^2\theta)^4 + C$$

**In exercises 52 - 55, use a calculator to estimate the area under the curve using left Riemann sums with 50 terms, then use substitution to solve for the exact answer.**

52) [Technology Required] $y = 3(1-x)^2$ over $[0, 2]$

53) [Technology Required] $y = x(1-x^2)^3$ over $[-1, 2]$

**Answer**

$L_{50} = -8.5779$. The exact area is $\frac{-81}{8}$ units$^2$.

54) [Technology Required] $y = \sin x(1-\cos x)^2$ over $[0, \pi]$

55) [Technology Required] $y = \frac{x}{(x^2+1)^2}$ over $[-1, 1]$

**Answer**

$L_{50} = -0.006399$. The exact area is 0.

**In exercises 56 - 61, use a change of variables to evaluate the definite integral.**

56) $\int_0^1 x\sqrt{1-x^2}\,dx$

57) $\int_0^1 \dfrac{x}{\sqrt{1+x^2}}\,dx$

**Answer**

$u = 1+x^2, \quad du = 2x\,dx, \quad \int_0^1 \dfrac{x}{\sqrt{1+x^2}}\,dx = \dfrac{1}{2}\int_1^2 u^{-1/2}du = \sqrt{2}-1$

58) $\int_0^2 \dfrac{t}{\sqrt{5+t^2}}\,dt$

59) $\int_0^1 \dfrac{t^2}{\sqrt{1+t^3}}\,dt$

**Answer**

$u = 1+t^3, \quad du = 3t^2, \quad \int_0^1 \dfrac{t^2}{\sqrt{1+t^3}}\,dt = \dfrac{1}{3}\int_1^2 u^{-1/2}du = \dfrac{2}{3}(\sqrt{2}-1)$

60) $\int_0^{\pi/4} \sec^2\theta\tan\theta\,d\theta$

61) $\int_0^{\pi/4} \dfrac{\sin\theta}{\cos^4\theta}\,d\theta$

**Answer**

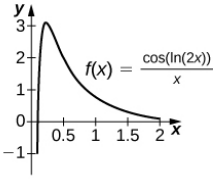
$u = \cos\theta, \quad du = -\sin\theta\,d\theta, \quad \int_0^{\pi/4} \dfrac{\sin\theta}{\cos^4\theta}\,d\theta = -\int_1^{\sqrt{2}/2} u^{-4}\,du = \int_{\sqrt{2}/2}^1 u^{-4}\,du = \dfrac{1}{3}(2\sqrt{2}-1)$

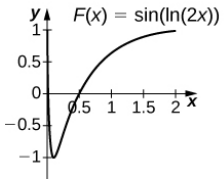
**In exercises 62 - 67, evaluate the indefinite integral $\int f(x)\,dx$ with constant $C = 0$ using $u$-substitution. Then, graph the function and the antiderivative over the indicated interval. If possible, estimate a value of $C$ that would need to be added to the antiderivative to make it equal to the definite integral $F(x) = \int_a^x f(t)\,dt$, with a the left endpoint of the given interval.**

62) [Technology Required] $\int (2x+1)e^{x^2+x-6}\,dx$ over $[-3, 2]$

63) [Technology Required] $\int \dfrac{\cos(\ln(2x))}{x}\,dx$ on $[0, 2]$

**Answer**



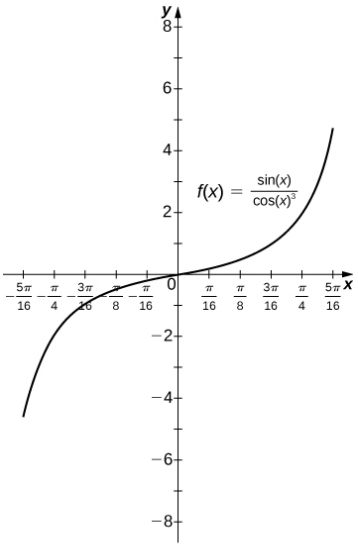


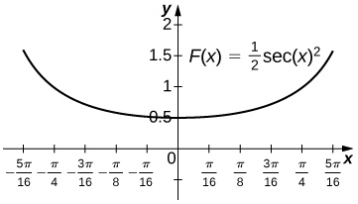
The antiderivative is $y = \sin(\ln(2x))$. Since the antiderivative is not continuous at $x = 0$, one cannot find a value of C that would make $y = \sin(\ln(2x)) - C$ work as a definite integral.

64) [Technology Required] $\int \dfrac{3x^2+2x+1}{\sqrt{x^3+x^2+x+4}}\,dx$ over $[-1, 2]$

65) [Technology Required] $\int \dfrac{\sin x}{\cos^3 x}\,dx$ over $[-\frac{\pi}{3}, \frac{\pi}{3}]$

**Answer**



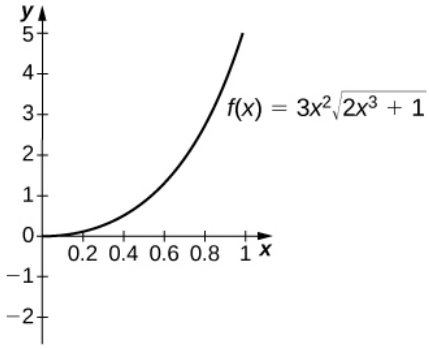


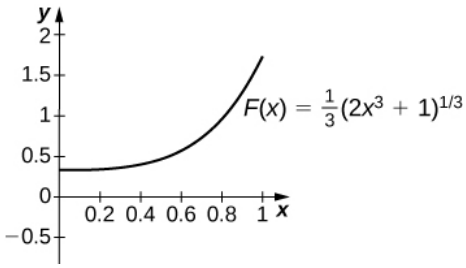
The antiderivative is $y = \frac{1}{2}\sec^2 x$. You should take $C = -2$ so that $F(-\frac{\pi}{3}) = 0$.

66) [Technology Required] $\int (x+2)e^{-x^2-4x+3}\,dx$ over $[-5, 1]$

67) [Technology Required] $\int 3x^2\sqrt{2x^3+1}\,dx$ over $[0, 1]$

**Answer**





The antiderivative is $y = \frac{1}{3}(2x^3+1)^{3/2}$. One should take $C = -\frac{1}{3}$.

68) If $h(a) = h(b)$ in $\int_a^b g'(h(x))h(x)\,dx$, what can you say about the value of the integral?

69) Is the substitution $u = 1 - x^2$ in the definite integral $\int_0^2 \frac{x}{1-x^2}\,dx$ okay? If not, why not?

**Answer**

No, because the integrand is discontinuous at $x = 1$.

**In exercises 70 - 76, use a change of variables to show that each definite integral is equal to zero.**

70) $\int_0^{\pi} \cos^2(2\theta)\sin(2\theta)\,d\theta$

71) $\int_0^{\sqrt{\pi}} t\cos(t^2)\sin(t^2)\,dt$

**Answer**

$u = \sin(t^2)$; the integral becomes $\frac{1}{2}\int_0^0 u\,du$.

72) $\int_0^1 (1-2t)\,dt$

73) $\int_0^1 \frac{1-2t}{1+(t-\frac{1}{2})^2}\,dt$

**Answer**

$u = 1 + (t - \frac{1}{2})^2$; the integral becomes $-\int_{5/4}^{5/4} \frac{1}{u}\,du$.

74) $\int_0^{\pi} \sin\left((t-\frac{\pi}{2})^3\right)\cos\left(t-\frac{\pi}{2}\right)\,dt$

75) $\int_0^2 (1-t)\cos(\pi t)\,dt$

**Answer**

$u = 1 - t$; Since the integrand is odd, the integral becomes

$$\int_1^{-1} u\cos\left(\pi(1-u)\right)du = \int_1^{-1} u[\cos\pi\cos u - \sin\pi\sin u]\,du = -\int_1^{-1} u\cos u\,du = \int_{-1}^{1} u\cos u\,du = 0$$

76) $\int_{\pi/4}^{3\pi/4} \sin^2 t\cos t\,dt$

77) Show that the average value of $f(x)$ over an interval $[a, b]$ is the same as the average value of $f(cx)$ over the interval $[\frac{a}{c}, \frac{b}{c}]$ for $c > 0$.

**Answer**

Setting $u = cx$ and $du = c\,dx$ gets you $\frac{1}{\frac{b}{c}-\frac{a}{c}}\int_{a/c}^{b/c} f(cx)\,dx = \frac{c}{b-a}\int_{u=a}^{u=b} f(u)\frac{du}{c} = \frac{1}{b-a}\int_a^b f(u)\,du$.

78) Find the area under the graph of $f(t) = \frac{t}{(1+t^2)^a}$ between $t = 0$ and $t = x$ where $a > 0$ and $a \neq 1$ is fixed, and evaluate the limit as $x \to \infty$.

79) Find the area under the graph of $g(t) = \frac{t}{(1-t^2)^a}$ between $t = 0$ and $t = x$, where $0 < x < 1$ and $a > 0$ is fixed. Evaluate the limit as $x \to 1$.

**Answer**

$\int_0^x g(t)\,dt = \frac{1}{2}\int_{u=1-x^2}^{1} \frac{du}{u^a} = \frac{1}{2(1-a)}u^{1-a}\,|\,1u = \frac{1}{2(1-a)}(1-(1-x^2)^{1-a})$ As $x \to 1$ the limit is $\frac{1}{2(1-a)}$ if $a < 1$, and the limit diverges to $+\infty$ if $a > 1$.

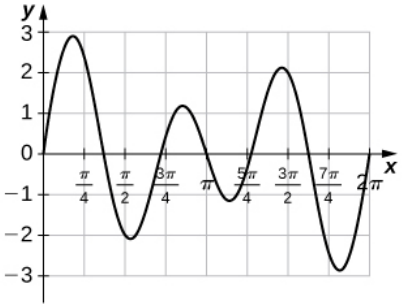
80) The area of a semicircle of radius $1$ can be expressed as $\int_{-1}^{1} \sqrt{1-x^2}\,dx$. Use the substitution $x = \cos t$ to express the area of a semicircle as the integral of a trigonometric function. You do not need to compute the integral.

81) The area of the top half of an ellipse with a major axis that is the $x$-axis from $x = -1$ to a and with a minor axis that is the $y$-axis from $y = -b$ to $y = b$ can be written as $\int_{-a}^{a} b\sqrt{1 - \frac{x^2}{a^2}}\, dx$. Use the substitution $x = a\cos t$ to express this area in terms of an integral of a trigonometric function. You do not need to compute the integral.

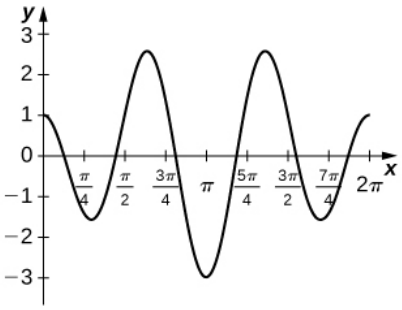
**Answer**

$$\int_{t=\pi}^{t=0} b\sqrt{1-\cos^2 t} \times (-a\sin t)\, dt = \int_{t=0}^{t=\pi} ab\sin^2 t\, dt$$

82) [Technology Required] The following graph is of a function of the form $f(t) = a\sin(nt) + b\sin(mt)$. Estimate the coefficients $a$ and $b$ and the frequency parameters $n$ and $m$. Use these estimates to approximate $\int_0^{\pi} f(t)\, dt$.



83) [Technology Required] The following graph is of a function of the form $f(x) = a\cos(nt) + b\cos(mt)$. Estimate the coefficients $a$ and $b$ and the frequency parameters $n$ and $m$. Use these estimates to approximate $\int_0^{\pi} f(t)\, dt$.



**Answer**

$$f(t) = 2\cos(3t) - \cos(2t); \quad \int_0^{\pi/2} (2\cos(3t) - \cos(2t))\, dt = -\frac{2}{3}$$

# CHAPTER OVERVIEW

## 6: Applications of Integration

In this chapter, we use definite integrals to calculate the force exerted on the dam when the reservoir is full and we examine how changing water levels affect that force. Hydrostatic force is only one of the many applications of definite integrals we explore in this chapter. From geometric applications such as surface area and volume, to physical applications such as mass and work, to growth and decay models, definite integrals are a powerful tool to help us understand and model the world around us.

# 6.1: Volumes of Revolution - The Disk and Washer Methods

**Note to the Instructor (click to expand)**

This sections deals solely with the Disk and Washer methods for finding the volume of rotation.

---

The following is a list of learning objectives for this section.

**Learning Objectives (click to expand)**

- Find the volume of a solid of revolution using the disk method.
- Find the volume of a solid of revolution with a cavity using the washer method.

Hawk A.I. Section-Specific Tutor

To access the Hawk A.I. Tutor, you will need to be logged into your campus Gmail account.

Now that we have the basic idea of how to compute the volume of a solid using slices, we venture into rotational solids.

## Solids of Revolution

If a region in a plane is revolved around a line in that plane, the resulting solid is called a **solid of revolution**, as shown in the following figure.

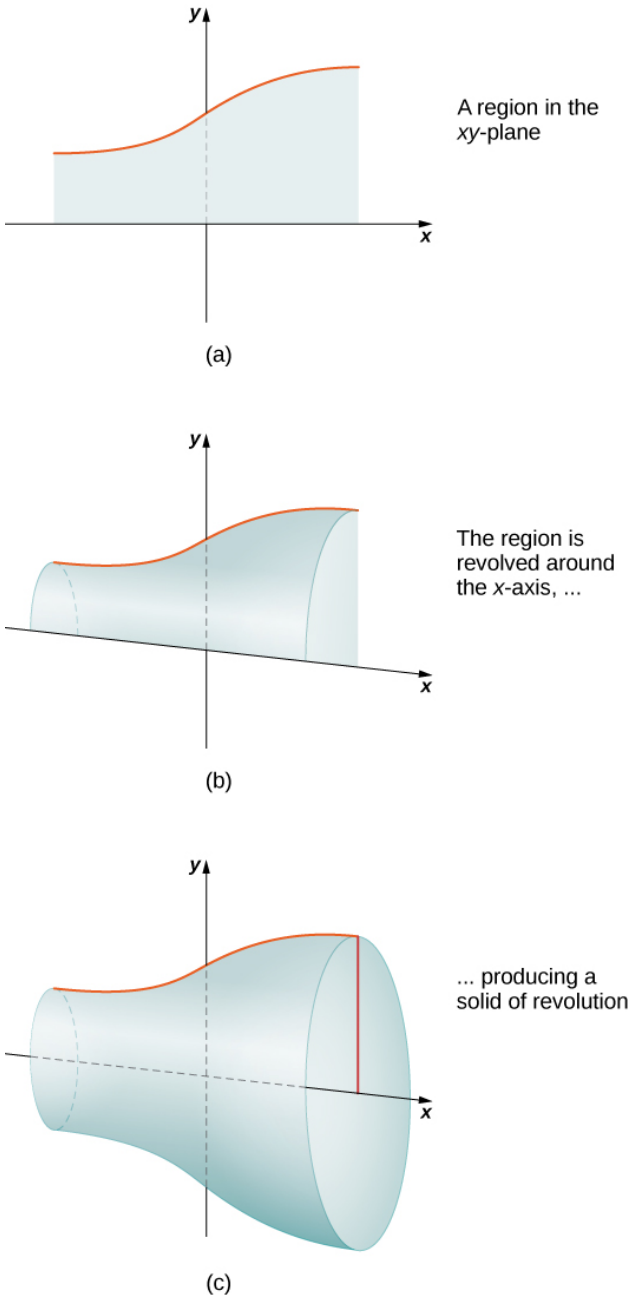

Figure **6.1.1***a*: This is the region that is revolved around the $x$-axis.
Figure **6.1.1***b*: As the region begins to revolve around the axis, it sweeps out a solid of revolution.
Figure **6.1.1***c*: This is the solid that results when the revolution is complete.

Solids of revolution are common in mechanical applications, such as machine parts produced by a lathe. We spend the rest of this section looking at solids of this type. The following example uses the slicing method to calculate the volume of a solid of revolution.

### Example 6.1.1

Use the slicing method to find the volume of the solid of revolution bounded by the graphs of $f(x) = x^2 - 4x + 5$, $x = 1$, and $x = 4$, and rotated about the $x$-axis.

**Solution**

Using the problem-solving strategy, we first sketch the graph of the quadratic function over the interval $[1, 4]$ as shown in the following figure.

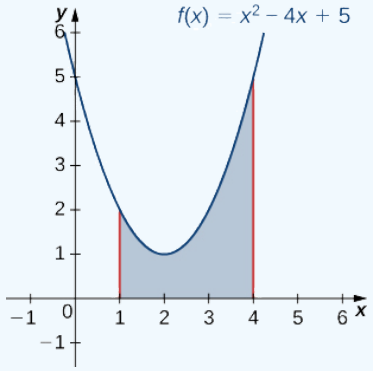

Figure 6.1.2: A region used to produce a solid of revolution.

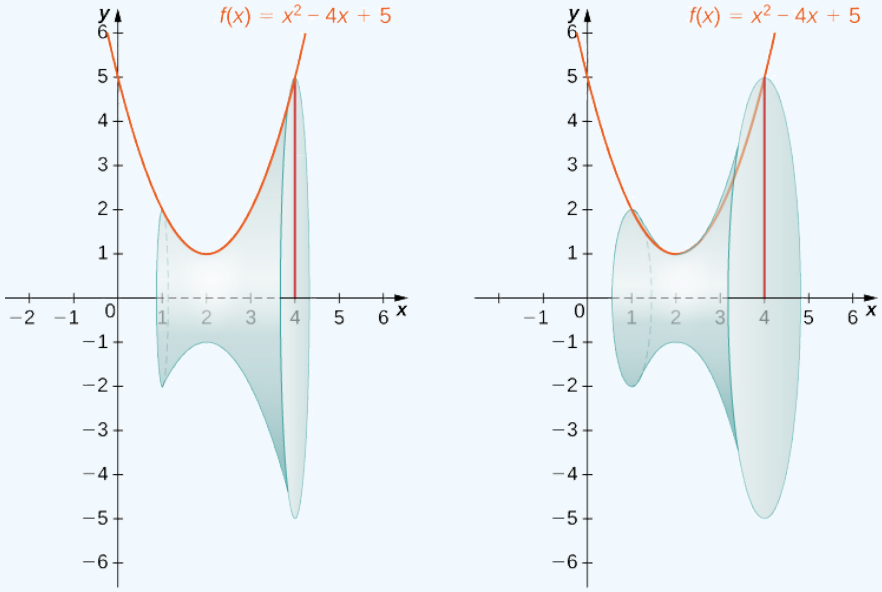
Next, revolve the region around the $x$-axis, as shown in the following figure.



(a) (b)

Figure 6.1.3: Two views, (a) and (b), of the solid of revolution produced by revolving the region in Figure 6.1.2 about the $x$-axis.

The cross-sections are circles since the solid was formed by revolving the region around the $x$-axis. The area of the cross-section, then, is the area of a circle, and the radius of the circle is given by $f(x)$. Use the formula for the area of the circle:

$$A(x) = \pi r^2 = \pi[f(x)]^2 = \pi(x^2 - 4x + 5)^2.$$

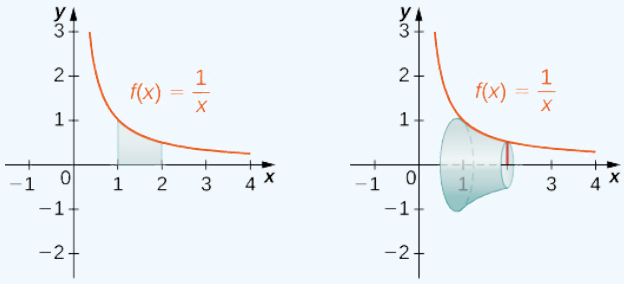
The volume, then, is

$$\begin{aligned} V &= \int_a^b A(x)\,dx \\ &= \int_1^4 \pi(x^2-4x+5)^2\,dx \\ &= \pi\int_1^4 (x^4-8x^3+26x^2-40x+25)\,dx \\ &= \pi\left(\frac{x^5}{5}-2x^4+\frac{26x^3}{3}-20x^2+25x\right)\Big|_1^4 \\ &= \frac{78}{5}\pi \end{aligned}$$

The volume is $\frac{78\pi}{5}$ $\text{units}^3$.

**? Checkpoint 6.1.1**

Use the method of slicing to find the volume of the solid of revolution formed by revolving the region between the graph of the function $f(x)=\frac{1}{x}$ and the $x$-axis over the interval $[1,2]$ around the $x$-axis. See the following figure.



(a) (b)

**Answer**

$\frac{\pi}{2}$ $\text{units}^3$

## The Disk Method

When we use the slicing method with solids of revolution, it is often called the **Disk Method** because, for solids of revolution, the slices used to approximate the volume of the solid are disks. To see this, consider the solid of revolution generated by revolving the region between the graph of the function $f(x)=(x-1)^2+1$ and the $x$-axis over the interval $[-1,3]$ around the $x$-axis (called the **axis of rotation**). The graph of the function and a representative disk are shown in Figure 6.1.11 (a) and (b). The region of revolution and the resulting solid are shown in Figure 6.1.4 (c) and (d).

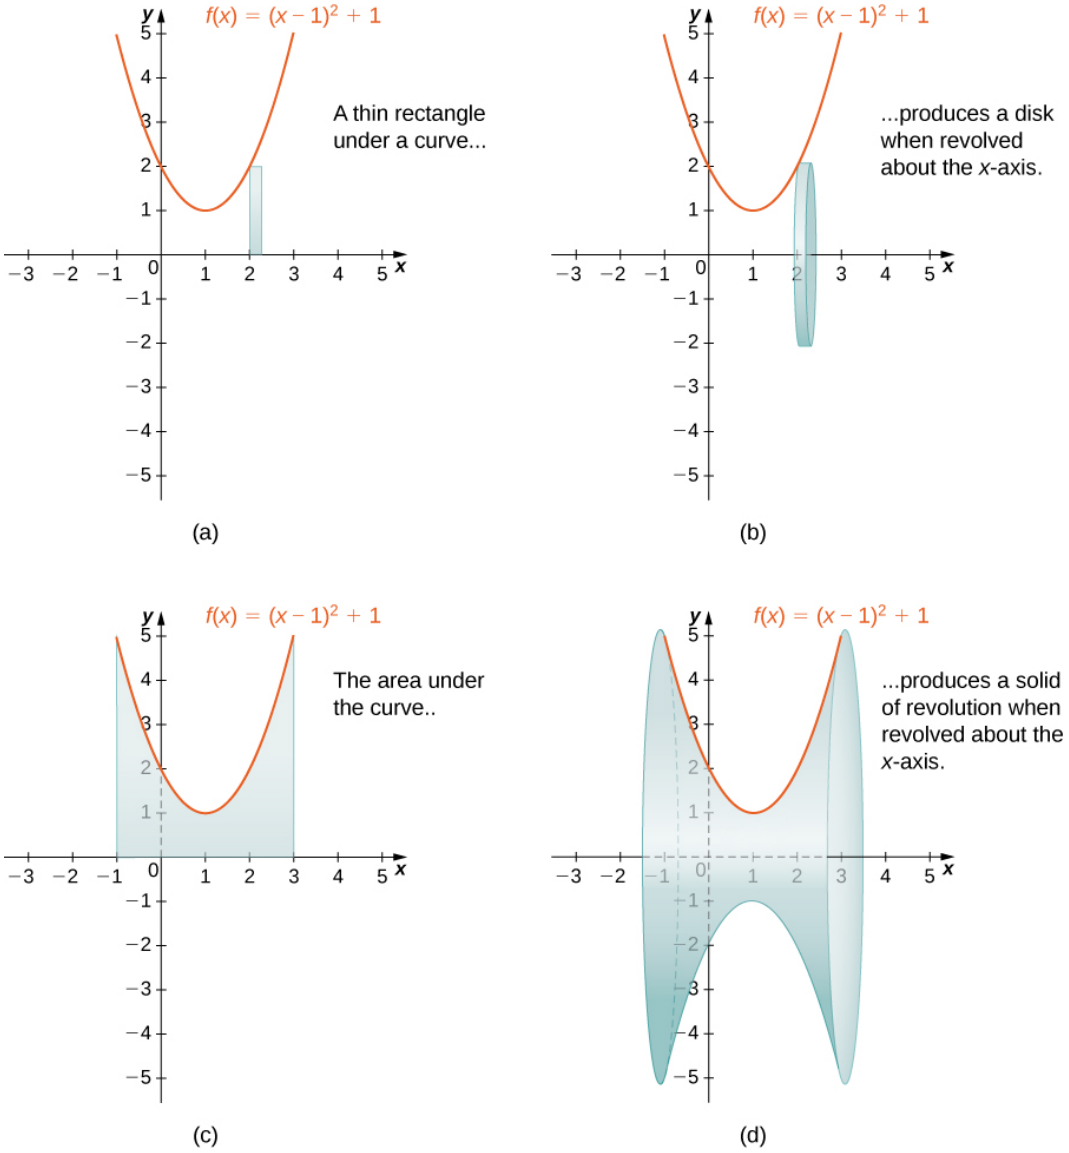


Figure 6.1.4a: A thin rectangle for approximating the area under a curve. The height of this rectangle is the **radius of rotation** and it is denoted $r_i$.

Figure 6.1.4b: A representative disk formed by revolving the rectangle about the $x$-axis.

Figure 6.1.4c: The region under the curve is revolved around the $x$-axis, resulting in Figure 6.1.4d the solid of revolution.

We already used the formal Riemann sum development of the volume formula when we developed the slicing method. We know that

$$V = \lim_{n\to\infty} \sum_{i=1}^{n} A(x_i^*)\Delta x = \int_a^b A(x)\,dx.$$

The only difference with the Disk Method is that we know the formula for the cross-sectional area ahead of time; it is the area of a circle. That is,

$$V = \lim_{n\to\infty} \sum_{i=1}^{n} \pi\,[r(x_i^*)]^2\,\Delta x = \int_a^b \pi\,[r(x)]^2\,dx,$$

where $r(x)$ is the **radius of rotation** (and $r(x_i^*)$ is the radius of rotation for the $i^{\text{th}}$ slice).[1] For the Disk and Washer (see below) Methods, the radius of rotation is the distance between the axis of rotation and the function. If the axis of rotation is the $x$-axis, then our discussion of measuring distances in Section 1.1 reveals that

$$r(x) = \begin{cases} f(x) - 0 = f(x) & \text{if} \quad f(x) \geq 0 \\ 0 - f(x) = -f(x) & \text{if} \quad f(x) < 0 \end{cases}$$

In either case, *and only if the axis of rotation is the $x$-axis*, we get

$$[r(x)]^2 = [f(x)]^2$$

This leads to the following theorem.

**Theorem: The Volume of a Rotational Solid About the $x$-axis Using the Disk Method**

Let $f(x)$ be continuous. Define $\mathbf{R}$ as the region bounded by the graph of $f(x)$, the $x$-axis, on the left by the line $x = a$, and on the right by the line $x = b$. Then, the volume of the solid of revolution formed by revolving $R$ around the $x$-axis is given by

$$V = \int_a^b \pi [f(x)]^2 \, dx. \tag{6.1.1}$$

While Equation 6.1.1 is simple to memorize, doing so will result in a massive lack of understanding of how rotational volumes are computed and inevitably will lead to mistakes. It is best to truly understand the underpinnings of the development of Equation 6.1.1 so that you can compute the volume of a rotational solid in more general situations. For example, Equation 6.1.1 does not work if you are rotating a region about the $y$-axis, the line $y = -2$, or the region bounded between two curves about the line $x = 7$.

In general, when needing to compute the volume of a rotational solid, you should fall back to the development of the corresponding Riemann sum

$$V = \lim_{n \to \infty} \sum_{i=1}^{n} K(x_i^*) \Delta x, \tag{6.1.2}$$

where $K(x_i^*)\Delta x$ is the volume of the $i^{\text{th}}$ slice found using logic from our previous Geometry course.[2] To compute this volume, we will *always* start by focusing on the volume of the $i^{\text{th}}$ slice,

$$V_i = K(x_i^*)\Delta x.$$

**Example 6.1.2**

Compute the volume of the rotational solid from Figure 6.1.4*d*.

**Solution**

Just as we said we should, we start by considering the volume of the $i^{\text{th}}$ slice,

$$V_i = K(x_i^*)\Delta x.$$

Since a representative slice of this solid of revolution is a disk (a circle with a thickness), we know the volume of the $i^{\text{th}}$ slice is

$$V_i = \pi \left[r(x_i^*)\right]^2 \Delta x.$$

Moreover, since $r(x_i^*)$ is the radius of revolution, and the axis of revolution is the $x$-axis, we know $r(x_i^*) = f(x_i^*)$ (remember, $f(x) \geq 0$ on the given interval). Therefore,

$$V_i = \pi \left[f(x_i^*)\right]^2 \Delta x.$$

Hence,

$$
\begin{aligned}
V &= \int_a^b \pi [f(x)]^2 \, dx \\
&= \int_{-1}^3 \pi \left[(x-1)^2+1\right]^2 dx \\
&= \pi \int_{-1}^3 \left[(x-1)^4+2(x-1)^2+1\right]^2 dx \\
&= \pi \left[\frac{1}{5}(x-1)^5+\frac{2}{3}(x-1)^3+x\right]\Big|_{-1}^3 \\
&= \pi \left[\left(\frac{32}{5}+\frac{16}{3}+3\right)-\left(-\frac{32}{5}-\frac{16}{3}-1\right)\right] \\
&= \tfrac{412\pi}{15} \text{ units}^3.
\end{aligned}
$$

Again, it cannot be overstated that starting our computation of the volume for a solid of revolution by considering the volume of the $i^{\text{th}}$ slice is incredibly helpful.[3]

Let's look at some other examples.

**Example 6.1.3**

Use the Disk Method to find the volume of the solid of revolution generated by rotating the region bounded by the graph of $f(x) = \sqrt{x}$ and the $x$-axis over the interval $[1, 4]$ around the $x$-axis.

**Solution**

The graphs of the function and the solid of revolution are shown in the following figure.

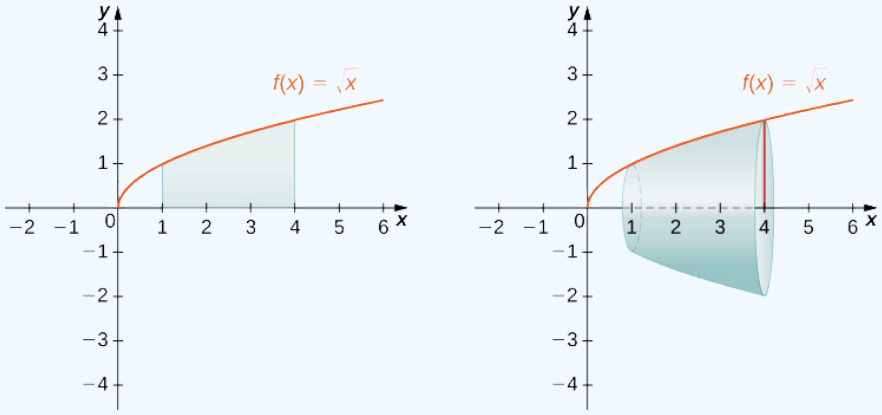

Figure 6.1.5*a*: The function $f(x) = \sqrt{x}$ over the interval $[1, 4]$.

Figure 6.1.5*b*: The solid of revolution obtained by revolving the region under the graph of $f(x)$ about the $x$-axis.

We have the volume of the $i^{\text{th}}$ slice as

$$V_i = K(x_i^*)\Delta x;$$

however, we can see that a drawing of this representative slice would be a disk. Using the fact that the axis of rotation is the $x$-axis and $f(x) \geq 0$, we get

$$V_i = \pi [r(x_i^*)]^2 \Delta x = \pi [f(x_i^*)]^2 \Delta x = \pi \left[\sqrt{x_i^*}\right]^2 \Delta x = \pi x_i^* \Delta x.$$

Hence,

$$\begin{aligned} V &= \int_a^b \pi [f(x)]^2 \, dx \\ &= \int_1^4 \pi x \, dx \\ &= \pi \int_1^4 x \, dx \\ &= \frac{\pi}{2} x^2 \Big|_1^4 \\ &= \frac{15\pi}{2} \end{aligned}$$

The volume is $\frac{15\pi}{2}$ $\text{units}^3$.

**Checkpoint 6.1.3**

Use the Disk Method to find the volume of the solid of revolution generated by rotating the region between the graph of $f(x) = \sqrt{4-x}$ and the $x$-axis over the interval $[0, 4]$ around the $x$-axis.

**Answer**

$8\pi$ $\text{units}^3$

So far, our examples have all concerned regions revolved around the $x$-axis, but we can generate a solid of revolution by revolving a plane region around any horizontal or vertical line. In the following example, we look at a solid of revolution that has been generated by rotating a region around the $y$-axis. The mechanics of the Disk Method are nearly the same as when the $x$-axis is the axis of revolution, but we express the function in terms of $y$ and we integrate with respect to $y$ as well. This is summarized in the following theorem.

**Theorem: The Volume of a Rotational Solid about the $y$-axis Using the Disk Method**

Let $g(y)$ be continuous. Define $\mathbf{Q}$ as the region bounded by the graph of $g(y)$, the $y$-axis, below by the line $y = c$, and above by the line $y = d$. Then, the volume of the solid of revolution formed by revolving $\mathbf{Q}$ around the $y$-axis is given by

$$V = \int_c^d \pi [g(y)]^2 \, dy. \tag{6.1.3}$$

Again, memorizing Equation 6.1.3 is a terrible idea. An example showcases that this formula is a result of our theoretical derivation of the volume of the $i^{\text{th}}$ slice.

**Example 6.1.4**

Let $\mathbf{R}$ be the region bounded by the graph of $g(y) = \sqrt{4-y}$ and the $y$-axis over the $y$-axis interval $[0, 4]$. Use the Disk Method to find the volume of the solid of revolution generated by rotating $\mathbf{R}$ about the $y$-axis.

**Solution**

Figure **6.1.13** shows the function and a representative disk that can be used to estimate the volume. Notice that since we are revolving the function around the $y$-axis, the disks are horizontal, rather than vertical.

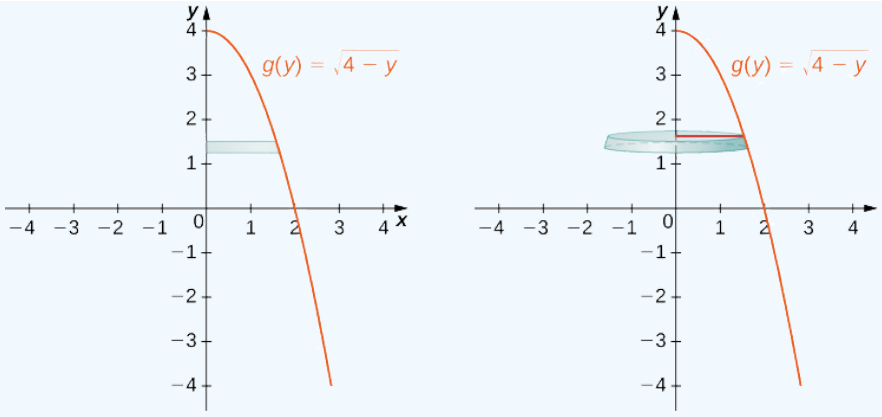

Figure 6.1.6*a*: Shown is a thin rectangle between the curve of the function $g(y) = \sqrt{4-y}$ and the $y$-axis.
Figure 6.1.6*b*: The rectangle forms a representative disk after revolving around the $y$-axis.

The region to be revolved and the full solid of revolution are depicted in the following figure.

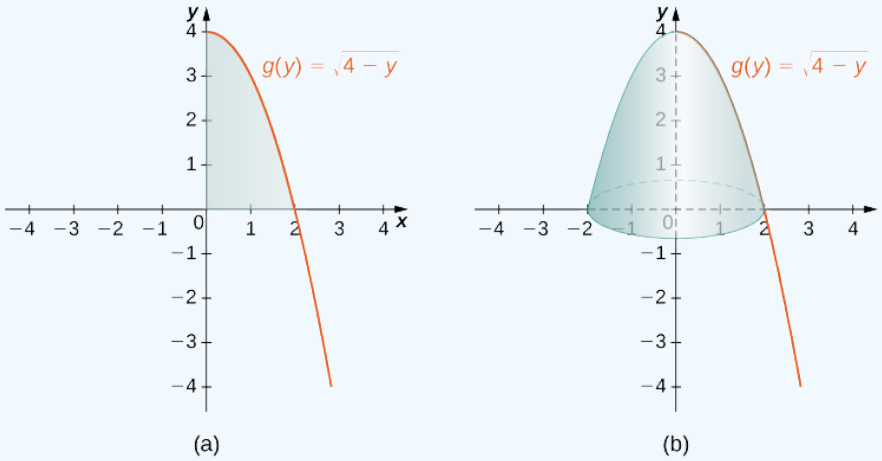

Figure 6.1.7*a*: The region to the left of the function $g(y) = \sqrt{4-y}$ over the $y$-axis interval $[0, 4]$.
Figure 6.1.7*b*: The solid of revolution formed by revolving the region about the $y$-axis.

We can see from Figure 6.1.7*b* that the $i^{\text{th}}$ slice is a disk. Hence, its volume is

$$V_i = \pi\,[r(y_i^*)]^2\,\Delta y,$$

where the thickness, $\Delta y$, is a small "wiggle" in $y$. The axis of rotation is the $y$-axis and the radius of rotation is $r(y_i^*) = x_R - x_L = g(y_i^*) - 0 = g(y_i^*)$.[4] Hence,

$$V_i = \pi\,[g(y_i^*)]^2\,\Delta y = \pi\left[\sqrt{4-y_i^*}\right]^2\Delta y = \pi\,(4-y_i^*)\,\Delta y.$$

Therefore, we obtain

$$V = \int_c^d \pi\,[g(y)]^2\,dy = \pi\int_0^4 (4-y)\,dy = \pi\left[4y - \frac{y^2}{2}\right]\Big|_0^4 = 8\pi.$$

The volume is $8\pi$ units$^3$.

## ? Checkpoint 6.1.4

Use the Disk Method to find the volume of the solid of revolution generated by rotating the region between the graph of $g(y) = y$ and the $y$-axis over the interval $[1, 4]$ around the $y$-axis.

https://math.libretexts.org/@go/page/175577

**Answer**

$21\pi$ units$^3$

We now showcase how to compute the volume of a solid of revolution if the axis of rotation is off an axis.[5]

**Example 6.1.5**

Find the volume of the solid of revolution generated by rotating the region bounded by $f(x) = \sin\left(\frac{x}{4}\right)$, $y = -1$, $x = 0$, and $x = 2\pi$ about the line $y = -1$.

**Solution**

As always, we begin by sketching the curve, the axis of rotation, and a representative slice.

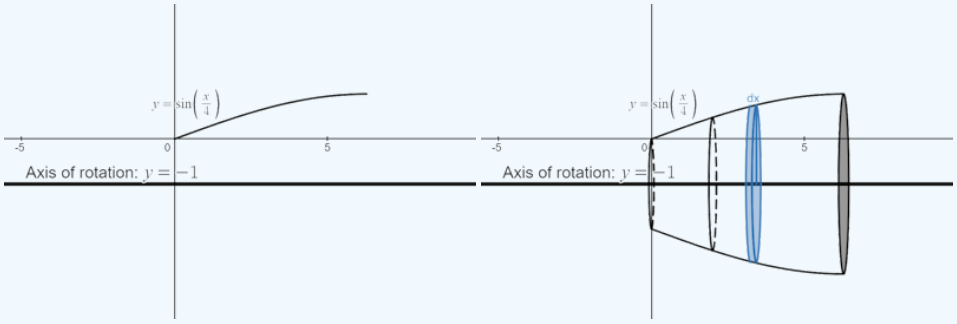

Figure 6.1.8: A sketch of $f(x) = \sin\left(\frac{x}{4}\right)$, the axis of rotation ($y = -1$), and a representative slice.

The volume of the $i^{\text{th}}$ slice is

$$V_i = K(x_i^*)\Delta x,$$

and we can see that this slice is a disk. Hence,

$$V_i = \pi\left[r(x_i^*)\right]^2 \Delta x.$$

The difference between this problem and the previous problems is that the radius of rotation involves a little more thought. The distance from the function to the axis of rotation is $y_T - y_B = \sin\left(\frac{x_i^*}{4}\right) - (-1) = \sin\left(\frac{x_i^*}{4}\right) + 1$. Hence, the radius of rotation is $r(x_i^*) = \sin\left(\frac{x_i^*}{4}\right) + 1$. Thus, the volume of the $i^{\text{th}}$ slice is

$$V_i = \pi\left[\sin\left(\frac{x_i^*}{4}\right) + 1\right]^2 \Delta x = \pi\left[\sin^2\left(\frac{x_i^*}{4}\right) + 2\sin\left(\frac{x_i^*}{4}\right) + 1\right]\Delta x.$$

We are now ready to find this volume.

$$
\begin{aligned}
V &= \int_a^b \pi [r(x)]^2\,dx \\
&= \int_0^{2\pi} \pi\left[\sin^2\left(\frac{x}{4}\right)+2\sin\left(\frac{x}{4}\right)+1\right]dx \\
&= \pi\int_0^{2\pi} \frac{1-\cos\left(\frac{x}{2}\right)}{2}+2\sin\left(\frac{x}{4}\right)+1dx && \text{(Power reduction formula)} \\
&= \frac{\pi}{2}\int_0^{2\pi} 1-\cos\left(\frac{x}{2}\right)dx+2\pi\int_0^{2\pi}\sin\left(\frac{x}{4}\right)dx+\pi\int_0^{2\pi}dx \\
&= \frac{\pi}{2}\int_0^{2\pi} dx-\frac{\pi}{2}\int_0^{2\pi}\cos\left(\frac{x}{2}\right)dx+2\pi\int_0^{2\pi}\sin\left(\frac{x}{4}\right)dx+\pi\int_0^{2\pi}dx \\
&= \pi^2-\frac{\pi}{2}\int_0^{2\pi}\cos\left(\frac{x}{2}\right)dx+2\pi\int_0^{2\pi}\sin\left(\frac{x}{4}\right)dx+2\pi^2 \\
&= 3\pi^2-\frac{\pi}{2}\int_0^{2\pi}\cos\left(\frac{x}{2}\right)dx+2\pi\int_0^{2\pi}\sin\left(\frac{x}{4}\right)dx \\
&= 3\pi^2-\pi\int_{u=0}^{u=\pi}\cos(u)\,du+2\pi\int_0^{2\pi}\sin\left(\frac{x}{4}\right)dx && \left(\text{Let } u=\tfrac{x}{2} \implies du=\tfrac{1}{2}dx\right) \\
&= 3\pi^2-\pi\Big(\sin(u)\Big)_{u=0}^{u=\pi}+2\pi\int_0^{2\pi}\sin\left(\frac{x}{4}\right)dx \\
&= 3\pi^2-\pi\left(\sin(\pi)-\sin(0)\right)+2\pi\int_0^{2\pi}\sin\left(\frac{x}{4}\right)dx \\
&= 3\pi^2+2\pi\int_0^{2\pi}\sin\left(\frac{x}{4}\right)dx \\
&= 3\pi^2+8\pi\int_{u=0}^{u=\pi/2}\sin(u)\,du && \left(\text{Let } u=\tfrac{x}{4} \implies du=\tfrac{1}{4}dx\right) \\
&= 3\pi^2-8\pi\Big(\cos(u)\Big)_{u=0}^{u=\pi/2} \\
&= 3\pi^2-8\pi\left(\cos\left(\tfrac{\pi}{2}\right)-\cos(0)\right) \\
&= 3\pi^2-8\pi\left(0-1\right) \\
&= 3\pi^2+8\pi
\end{aligned}
$$

Thus, the volume is $3\pi^2+8\pi$ units$^3$.[6]

## The Washer Method

Some solids of revolution have cavities in the middle; they are not solid near to the axis of revolution. Sometimes, this is just a result of how the region of revolution is shaped with respect to the axis of revolution. In other cases, cavities arise when the region of revolution is defined as the region between the graphs of two functions. A third way this can happen is when an axis of revolution other than the $x$-axis or $y$-axis is selected.

When the solid of revolution has a cavity in the middle, the slices used to approximate the volume are not disks, but washers (disks with holes in the center). For example, consider the region bounded above by the graph of the function $f(x)=\sqrt{x}$ and below by the graph of the function $g(x)=1$ over the interval $[1,4]$. When this region is revolved around the $x$-axis, the result is a solid with a cavity

in the middle, and the slices are washers. The graph of the function and a representative washer are shown in Figure **6.1.9** (a) and (b). The region of revolution and the resulting solid are shown in Figure **6.1.9** (c) and (d).

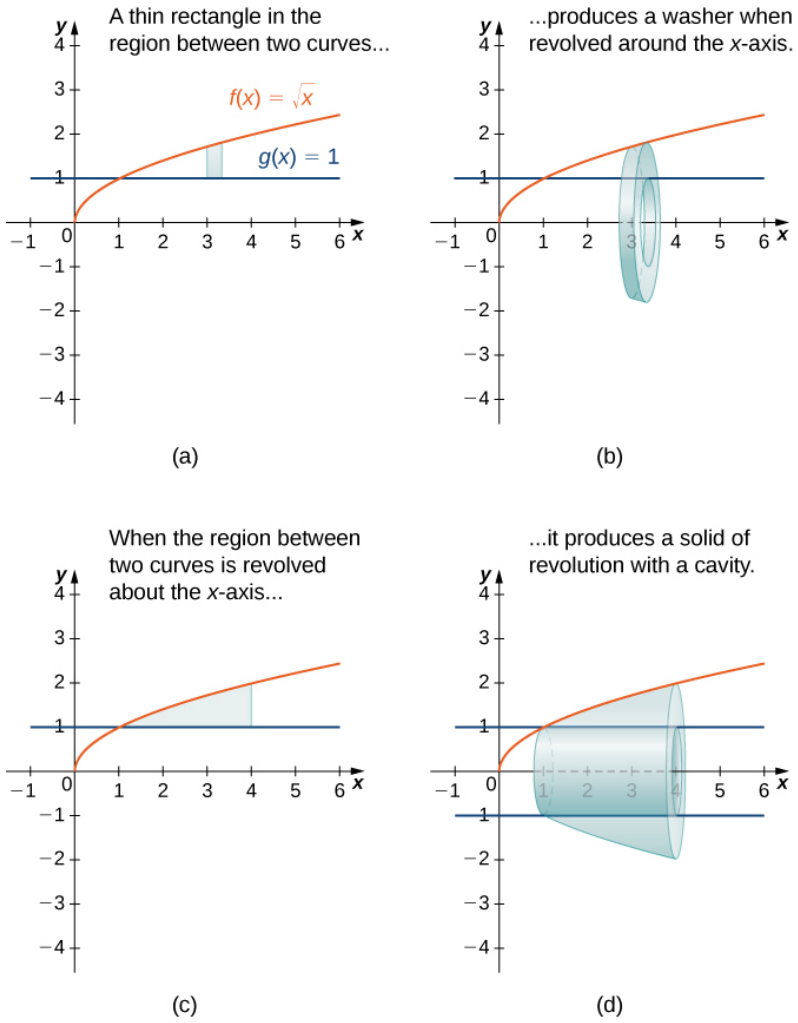

Figure **6.1.9***a*: A thin rectangle in the region between two curves.
Figure **6.1.9***b*: A representative disk formed by revolving the rectangle about the $x$-axis.
Figure **6.1.9***c*: The region between the curves over the given interval.
Figure **6.1.9***d*: The resulting solid of revolution.

The volume of the $i^{\text{th}}$ slice is still represented by

$$V_i = K(x_i^*)\Delta x;$$

however, we can see that this slice is a disk with a central disk removed. That is,

$$V_i = \pi\left[r_O(x_i^*)\right]^2 \Delta x - \pi\left[r_I(x_i^*)\right]^2 \Delta x,$$

where $r_O$ is the radius of rotation to the outer function and $r_I$ is the radius of rotation to the inner function. In both cases, the axis of rotation is the $x$-axis, so its easily found that $r_O(x_i^*) = f(x_i^*) = \sqrt{x_i^*}$ and $r_I(x_i^*) = g(x_i^*) = 1$. Hence,

$$V_i = \pi\left[\sqrt{x_i^*}\right]^2 \Delta x - \pi\left[1\right]^2 \Delta x = \pi x_i^* \Delta x - \pi \Delta x.$$

From this formula, we have the option to use two integrals or one to find the volume of the solid of revolution. That is, we could use

$$V = \int_1^4 \pi x\, dx - \int_1^4 \pi\, dx \quad \text{or} \quad V = \int_1^4 \pi(x-1)\, dx.$$

Both are acceptable, but while the second form looks simpler, it can lead to mistakes (see the Caution below). Computing the volume, we get

$$V = \pi \int_1^4 x\,dx - \pi \int_1^4 dx = \pi\left(\frac{x^2}{2}\right)_1^4 - \pi(4-1) = \frac{9}{2}\pi \text{ units}^3.$$

Generalizing this process gives the **Washer Method**. Again, you should "strive to derive" this formula rather than memorize it (this formula can cause issues if you just try to memorize it).

### Theorem: The Washer Method About the $x$-axis

Suppose $f(x)$ and $g(x)$ are continuous, nonnegative functions such that $f(x) \geq g(x)$ over $[a,b]$. Let $\mathbf{R}$ denote the region bounded above by the graph of $f(x)$, below by the graph of $g(x)$, on the left by the line $x = a$, and on the right by the line $x = b$. Then, the volume of the solid of revolution formed by revolving $\mathbf{R}$ around the $x$-axis is given by

$$V = \int_a^b \pi\left[(f(x))^2 - (g(x))^2\right]\,dx.$$

### Caution

A prevalent mistake is to think that the volume in the previous theorem is

$$\int_a^b \pi\left[f(x) - g(x)\right]^2\,dx.$$

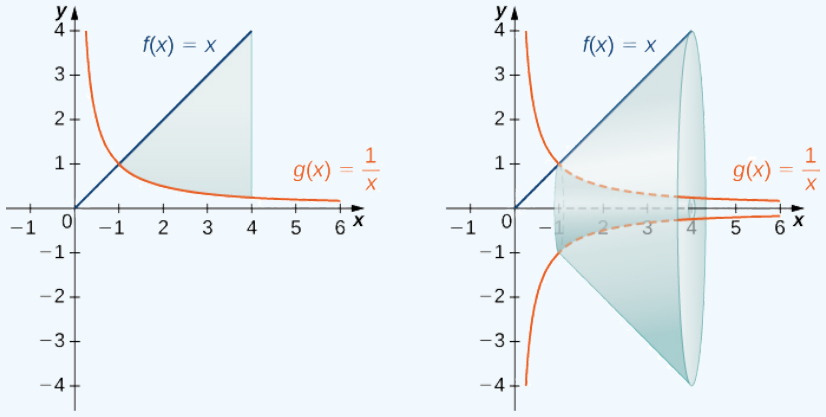
This is why I strongly encourage my students to *not* memorize that formula, but instead to derive it until it makes sense. I will demonstrate this process with each remaining problem.

### Example 6.1.6

Find the volume of a solid of revolution formed by revolving the region bounded above by the graph of $f(x) = x$ and below by the graph of $g(x) = 1/x$ over the interval $[1,4]$ around the $x$-axis.

**Solution**

We start by graphing the functions, the axis of rotation, the solid, and a representative slice (Figure 6.1.10c).



(a) (b)

Figure 6.1.10a: The region between the graphs of the functions $f(x) = x$ and $g(x) = 1/x$ over the interval $[1,4]$.
Figure 6.1.10b: Revolving the region about the $x$-axis generates a solid of revolution with a cavity in the middle.

The slice is a disk with an inner disk removed. Therefore, the volume of this slice is

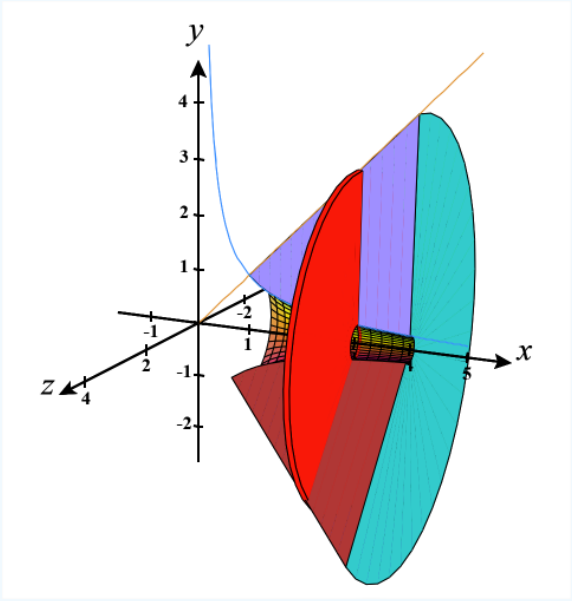
$$V_i = \pi\left[r_O(x_i^*)\right]^2 \Delta x - \pi\left[r_I(x_i^*)\right]^2 \Delta x,$$

where the outer radius is the distance between the axis of rotation (the $x$-axis) and $f(x) = x$, and the inner radius is the distance between the axis of rotation and $g(x) = \frac{1}{x}$. Thus,

$$V_i = \pi [f(x_i^*)]^2 \Delta x - \pi [g(x_i^*)]^2 \Delta x = \pi [x_i^*]^2 \Delta x - \pi \left[\frac{1}{x_i^*}\right]^2 \Delta x = \pi (x_i^*)^2 \Delta x - \frac{\pi}{(x_i^*)^2} \Delta x = \pi \left[(x_i^*)^2 - \frac{1}{(x_i^*)^2}\right] \Delta x.$$

Finally, we get

$$\begin{aligned} V &= \pi \int_1^4 \left[x^2 - \left(\frac{1}{x}\right)^2\right] dx \\ &= \pi \left[\frac{x^3}{3} + \frac{1}{x}\right]\Big|_1^4 \\ &= \frac{81\pi}{4} \text{ units}^3. \end{aligned}$$



**? Checkpoint 6.1.6**

Find the volume of a solid of revolution formed by revolving the region bounded by the graphs of $f(x) = \sqrt{x}$ and $g(x) = 1/x$ over the interval $[1, 3]$ around the $x$-axis.

**Answer**

$\frac{10\pi}{3}$ units$^3$

As with the Disk Method, we can also apply the Washer Method to solids of revolution that result from revolving a region around the $y$-axis. In this case, the following rule applies (again, you need to understand how this is derived).

**Theorem: The Washer Method About the $y$-axis**

Suppose $u(y)$ and $v(y)$ are continuous, nonnegative functions such that $v(y) \leq u(y)$ for $y \in [c, d]$. Let $\mathbf{Q}$ denote the region bounded on the right by the graph of $u(y)$, on the left by the graph of $v(y)$, below by the line $y = c$, and above by the line $y = d$. Then, the volume of the solid of revolution formed by revolving $\mathbf{Q}$ around the $y$-axis is given by

$$V = \int_c^d \pi \left[(u(y))^2 - (v(y))^2\right] dy.$$

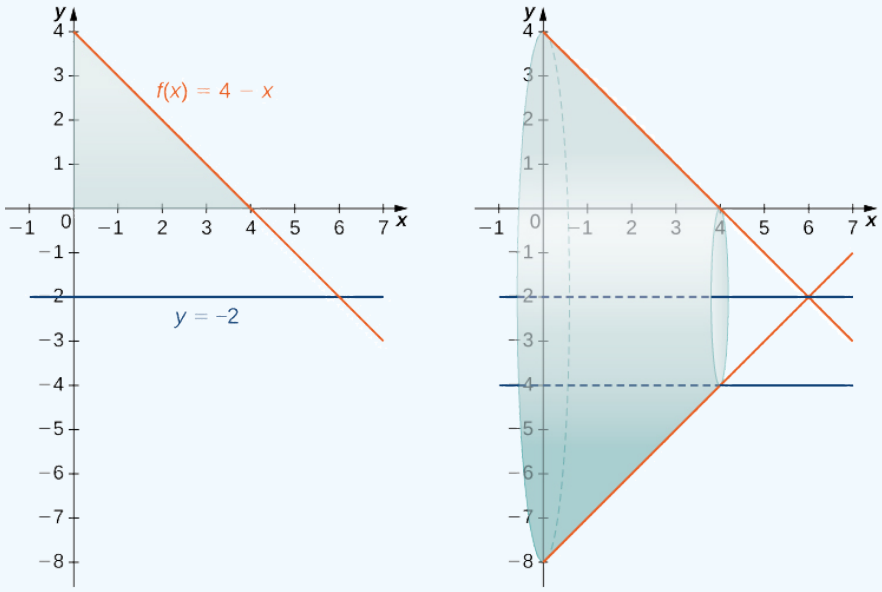
Rather than looking at an example of the Washer Method with the $y$-axis as the axis of revolution, we now consider an example in which the axis of revolution is a line other than one of the two coordinate axes. The same general method applies, but you may have to visualize just how to describe the cross-sectional area of the volume.

**Example 6.1.7**

Find the volume of a solid of revolution formed by revolving the region bounded above by $f(x) = 4 - x$ and below by the $x$-axis over the interval $[0, 4]$ around the line $y = -2$.

**Solution**

We graph the functions, the axis of rotation, the solid of revolution, and a representative slice (not shown).



(a) (b)

Figure 6.1.11$a$: The region between the graph of the function $f(x) = 4 - x$ and the $x$-axis over the interval $[0, 4]$.
Figure 6.1.11$b$: Revolving the region about the line $y = -2$ generates a solid of revolution with a cylindrical hole through its middle.

A representative slice is a disk with an inner disk removed. Therefore, the volume of this slice is

$$V_i = \pi [r_O(x_i^*)]^2 \, \Delta x - \pi [r_I(x_i^*)]^2 \, \Delta x,$$

where the outer radius is the distance between the axis of rotation, $y = -2$, and $f(x) = 4 - x$, and the inner radius is the distance between the axis of rotation and the $x$-axis ($y = 0$). Thus,

$$V_i = \pi [f(x_i^*) - (-2)]^2 \, \Delta x - \pi [0 - (-2)]^2 \, \Delta x = \pi [4 - x_i^* + 2]^2 \, \Delta x - \pi (2)^2 \Delta x = \pi (6 - x_i^*)^2 \, \Delta x - 4\pi \Delta x = \pi \left(32 - 12x_i^* + (x_i^*)^2\right) \Delta x.$$

Therefore, we have

$$\begin{aligned} V &= \int_0^4 \pi \left(x^2 - 12x + 32\right) \, dx \\ &= \pi \left[\frac{x^3}{3} - 6x^2 + 32x\right]\Big|_0^4 \\ &= \frac{160\pi}{3} \text{ units}^3. \end{aligned}$$

**? Checkpoint 6.1.7**

Find the volume of a solid of revolution formed by revolving the region bounded above by the graph of $f(x) = x + 2$ and below by the $x$-axis over the interval $[0, 3]$ around the line $y = -1$.

**Answer**

$60\pi$ units$^3$

## Footnotes

[1] For the remainder of this course, I will be using $r_i$ to denote the radius of rotation for the $i^{\text{th}}$ slice of a rotational solid, and $r(x)$ for the "radius function." The distinction between the two should be evident within the context of the discussion.

[2] The use of $K(x_i^*)$ instead of $\pi[f(x_i^*)]^2$ here is purposeful. As you will see in Section 1.4, we have choices as to the shapes of our slices. The formula for $K(x_i^*)$ will change accordingly.

[3] If you haven't noticed, you will perform a lot of fractional arithmetic in Integral Calculus. This is unavoidable. When doing homework, try to use technology sparingly (also, trust that your professor will give you something manageable on an exam).

[4] Since we are computing a horizontal distance, we use our discussion of measuring distances in Section 1.1 to compute the horizontal distance $x_R - x_L$.

[5] The axes of rotation of rotation for this course will be restricted to horizontal or vertical lines.

[6] This example showcases your need to be very familiar with Trigonometry in Integral Calculus. If you struggle with Trigonometry, please take the time to review the main topics by referencing Section 1.6 of Differential Calculus.

# 6.1E: Exercises

## Reading Questions

1. What is a solid of revolution?
2. What is the geometric shape of a cross-sectional slice in the disk method?
3. What is the key difference between a slice in the disk method and a slice in the washer method?
4. When using the washer method for a region between $y = f(x)$ and $y = g(x)$ revolved around the x-axis, what is the correct integrand: $\pi(f(x) - g(x))^2$ or $\pi((f(x))^2 - (g(x))^2)$?
5. If a region is bounded by $x = g(y)$ and revolved around the y-axis, what is the variable of integration?
6. How do you determine the outer radius ($r_o$) and inner radius ($r_i$) when revolving the region bounded by $f(x) = 4 - x$ and the x-axis over $[0, 4]$ around the line $y = -2$?

1) Use the disk method to derive the formula for the volume of a trapezoidal cylinder.

2) Explain when you would use the disk method versus the washer method. When are they interchangeable?

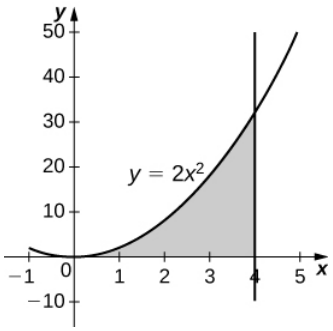
## Disk and Washer Method

**For exercises 3 - 10, draw the region bounded by the curves. Then, use the disk or washer method to find the volume when the region is rotated around the $x$-axis.**

3) $x + y = 8$, $x = 0$, and $y = 0$

4) $y = 2x^2$, $x = 0$, $x = 4$, and $y = 0$

**Answer**

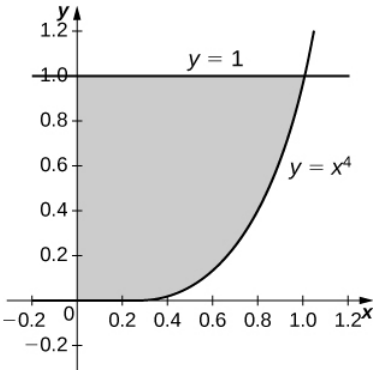


$$V = \int_0^4 4\pi x^4 \, dx = \frac{4096\pi}{5} \text{ units}^3$$

5) $y = e^x + 1$, $x = 0$, $x = 1$, and $y = 0$

6) $y = x^4$, $x = 0$, and $y = 1$

**Answer**

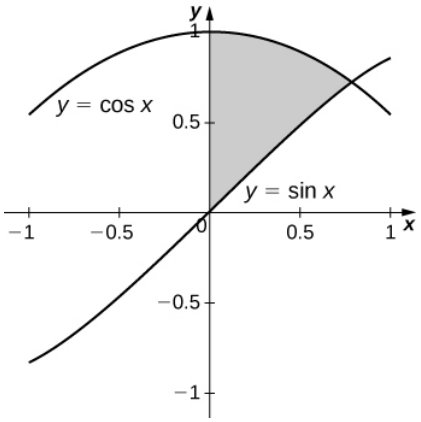


$$V = \int_0^1 \pi\left(1^2 - \left(x^4\right)^2\right)\,dx = \int_0^1 \pi\left(1 - x^8\right)\,dx \quad = \quad \frac{8\pi}{9} \text{ units}^3$$

7) $y = \sqrt{x}, \quad x = 0, \quad x = 4$, and $y = 0$

8) $y = \sin x, \quad y = \cos x$, and $x = 0$

**Answer**

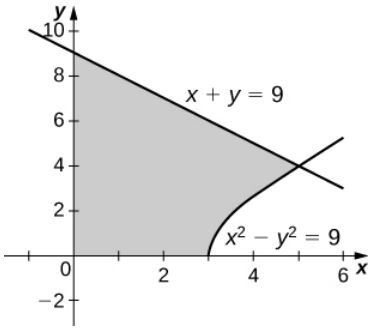


$$V = \int_0^{\pi/4} \pi\left(\cos^2 x - \sin^2 x\right)\,dx = \int_0^{\pi/4} \pi \cos 2x\,dx \quad = \quad \frac{\pi}{2} \text{ units}^3$$

9) $y = \frac{1}{x}, \quad x = 2$, and $y = 3$

10) $x^2 - y^2 = 9$ and $x + y = 9, \quad y = 0$ and $x = 0$

**Answer**



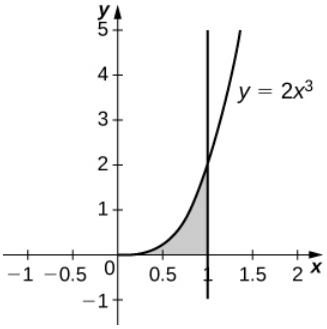
$V = 207\pi$ units$^3$

**For exercises 11 - 18, draw the region bounded by the curves. Then, find the volume when the region is rotated around the $y$ -axis.**

11) $y = 4 - \frac{1}{2}x, \quad x = 0$, and $y = 0$

12) $y = 2x^3, \quad x = 0, \quad x = 1$, and $y = 0$

**Answer**

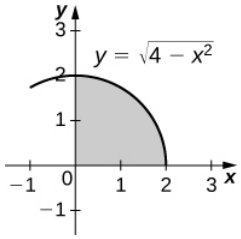


$V = \frac{4\pi}{5}$ units$^3$

13) $y = 3x^2$, $x = 0$, and $y = 3$

14) $y = \sqrt{4 - x^2}$, $y = 0$, and $x = 0$

**Answer**

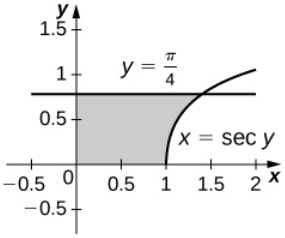


$V = \frac{16\pi}{3}$ units$^3$

15) $y = \dfrac{1}{\sqrt{x+1}}$, $x = 0$, and $x = 3$

16) $x = \sec(y)$ and $y = \dfrac{\pi}{4}$, $y = 0$ and $x = 0$

**Answer**

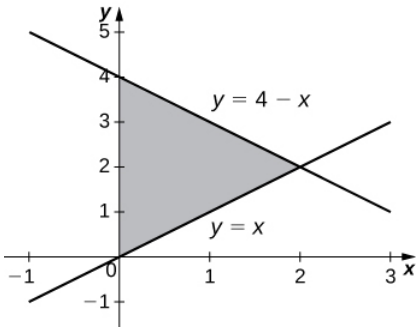


$V = \pi$ units$^3$

17) $y = \dfrac{1}{x+1}$, $x = 0$, and $x = 2$

18) $y = 4 - x$, $y = x$, and $x = 0$

**Answer**



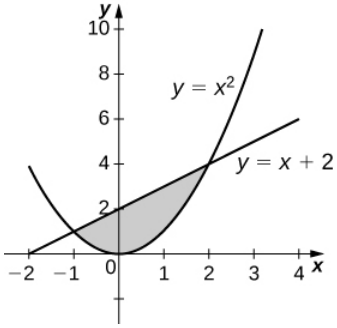
$V = \frac{16\pi}{3}$ units$^3$

**For exercises 19 - 26, draw the region bounded by the curves. Then, find the volume when the region is rotated around the $x$ -axis.**

19) $y = x + 2, \quad y = x + 6, \quad x = 0$, and $x = 5$

20) $y = x^2$ and $y = x + 2$

**Answer**

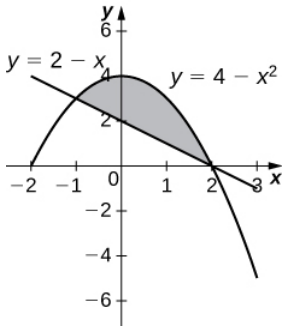


$V = \frac{72\pi}{5}$ units$^3$

21) $x^2 = y^3$ and $x^3 = y^2$

22) $y = 4 - x^2$ and $y = 2 - x$

**Answer**

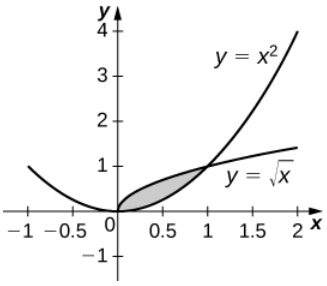


$V = \frac{108\pi}{5}$ units$^3$

23) [Technology Required] $y = \cos x, \quad y = e^{-x}, \quad x = 0$, and $x = 1.2927$

24) $y = \sqrt{x}$ and $y = x^2$

**Answer**

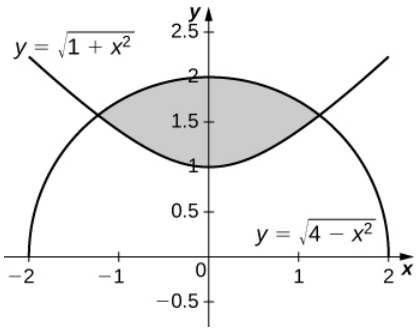


$V = \frac{3\pi}{10}$ units$^3$

25) $y = \sin x, \quad y = 5\sin x, \quad x = 0$ and $x = \pi$

26) $y = \sqrt{1 + x^2}$ and $y = \sqrt{4 - x^2}$

**Answer**



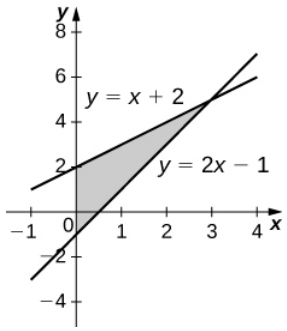
$V = 2\sqrt{6}\pi$ units$^3$

**For exercises 27 - 31, draw the region bounded by the curves. Then, use the washer method to find the volume when the region is revolved around the $y$-axis.**

27) $y = \sqrt{x}, \quad x = 4$, and $y = 0$

28) $y = x + 2, \quad y = 2x - 1$, and $x = 0$

**Answer**

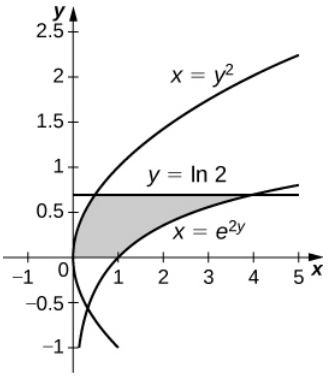


$V = 9\pi$ units$^3$

29) $y = \frac{3}{x}$ and $y = x^3$

30) $x = e^{2y}, \quad x = y^2, \quad y = 0$, and $y = \ln(2)$

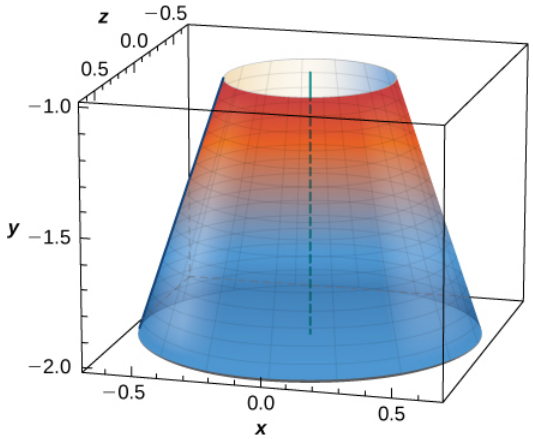
**Answer**



$V = \frac{\pi}{20}(75 - 4\ln^5(2))$ units$^3$

31) $x = \sqrt{9 - y^2}$, $x = e^{-y}$, $y = 0$, and $y = 3$

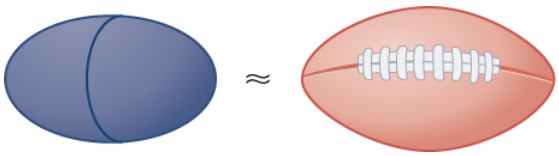
32) Yogurt containers can be shaped like frustums. Rotate the line $y = \left(\frac{1}{m}\right)x$ around the $y$-axis to find the volume between $y = a$ and $y = b$.



**Answer**

$V = \frac{m^2\pi}{3}(b^3 - a^3)$ units$^3$

33) Rotate the ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ around the $x$-axis to approximate the volume of a football, as seen here.

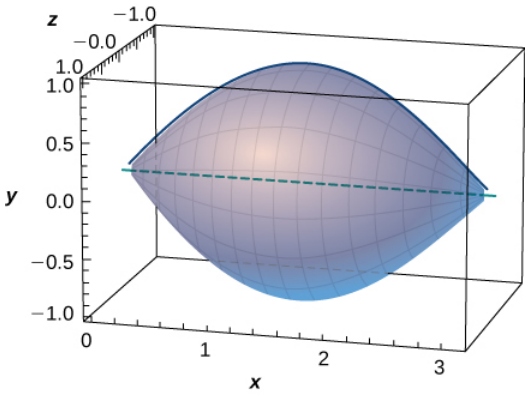


34) Rotate the ellipse $\frac{x^2}{a^2}+\frac{y^2}{b^2}=1$ around the $y$-axis to approximate the volume of a football.

**Answer**

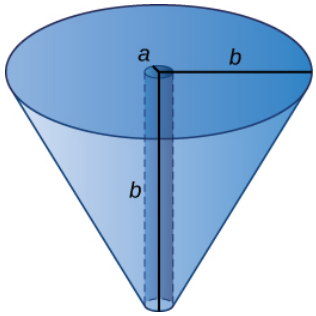
$V=\frac{4a^2b\pi}{3}$ units$^3$

35) A better approximation of the volume of a football is given by the solid that comes from rotating $y=\sin x$ around the $x$-axis from $x=0$ to $x=\pi$. What is the volume of this football approximation, as seen here?

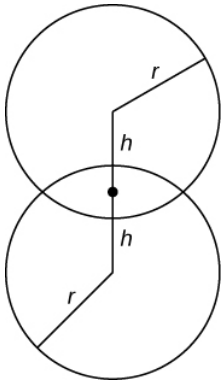


**For exercises 36 - 39, find the volume of the solid described.**

36) Bore a hole of radius a down the axis of $a$ right cone and through the base of radius $b$, as seen here.



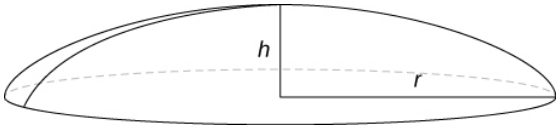
37) Find the volume common to two spheres of radius $r$ with centers that are $2h$ apart, as shown here.



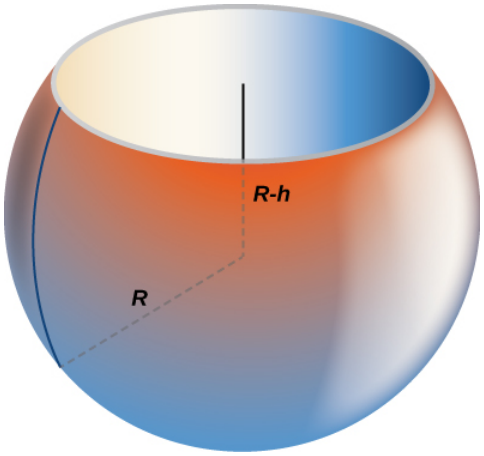
**Answer**

$V=\frac{\pi}{12}(r+h)^2(6r-h)$ units$^3$

38) Find the volume of a spherical cap of height $h$ and radius $r$ where $h<r$, as seen here.



39) Find the volume of a sphere of radius $R$ with a cap of height $h$ removed from the top, as seen here.



**Answer**

$V = \frac{\pi}{3}(h+R)(h-2R)^2$ units$^3$

# 6.2: Volumes of Revolution - Cylindrical Shells

**Note to the Instructor (click to expand)**

This is the typical "cylindrical shells" topic.

---

To succeed in this section, you'll need to use some skills from previous courses. While you should already know them, this is the first time they've been required. You can review these skills in CRC's Corequisite Codex. If you have a support class, it might cover some, **but not all**, of these topics.

**Prerequisite Skills and Support Topics (click to expand)**

- **Geometry**
  - Common Volumes: The volume of a cylindrical shell is derived by considering it as a cylinder whose height is the height of the function and whose base is an annulus. The "unrolling" analogy uses the volume of a rectangular prism (a flat plate).

---

The following is a list of learning objectives for this section.

**Learning Objectives (click to expand)**

- Calculate the volume of a solid of revolution using the Method of Cylindrical Shells.
- Compare the different methods for calculating the volume of revolution.

Hawk A.I. Section-Specific Tutor

To access the Hawk A.I. Tutor, you will need to be logged into your campus Gmail account.

In this section, we examine the Method of Cylindrical Shells, the final method for finding the volume of a solid of revolution. We can use this method on the same kinds of solids as the Disk Method or the Washer Method; however, with the Disk and Washer Methods, we integrate along the coordinate axis parallel to the axis of revolution. With the Method of Cylindrical Shells, we integrate along the coordinate axis *perpendicular* to the axis of revolution. The ability to choose which variable of integration we want to use can be a significant advantage with more complicated functions. Also, the specific geometry of the solid sometimes makes the method of using cylindrical shells more appealing than using the Washer Method.

## The Method of Cylindrical Shells

Again, we are working with a solid of revolution. As before, we define a region $\mathbf{R}$, bounded above by the graph of a function $y = f(x)$, below by the $x$-axis, and on the left and right by the lines $x = a$ and $x = b$, respectively, as shown in Figure $\mathbf{6.2.1}(a)$. We then revolve this region around the $y$-axis, as shown in Figure $\mathbf{6.2.1}(b)$. Note that this is different from what we have done before. Previously, regions defined in terms of functions of $x$ were revolved around the $x$-axis or a line parallel to it.

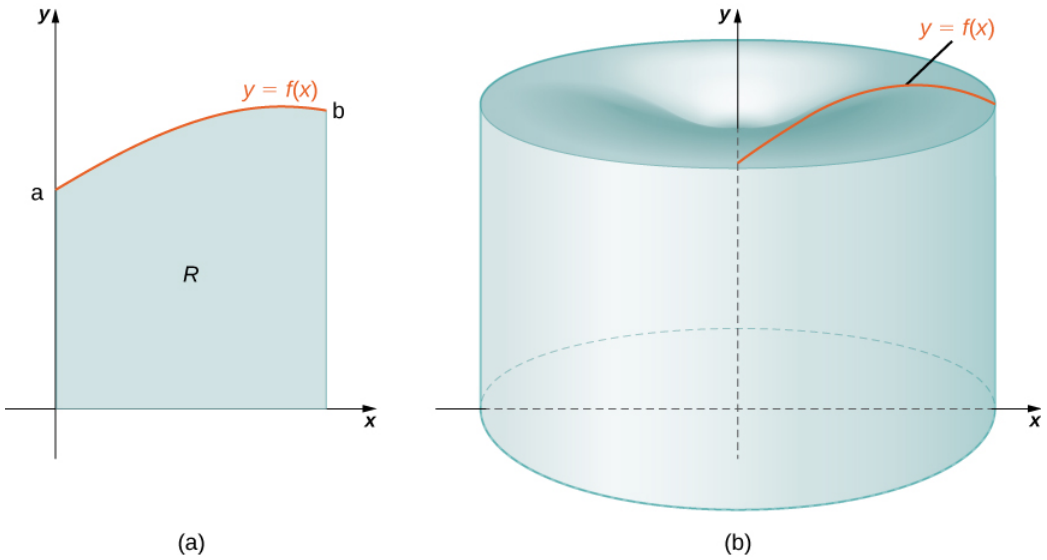

Figure 6.2.1(a): A region bounded by the graph of a function of $x$.
Figure 6.2.1(b): The solid of revolution formed when the region revolves around the $y$-axis.

As we have done many times before, partition the interval $[a, b]$ using a regular partition, $P = \{x_0, x_1, \ldots, x_n\}$ and, for $i = 1, 2, \ldots, n$, choose a point $x_i^* \in [x_{i-1}, x_i]$. Then, construct a rectangle over the interval $[x_{i-1}, x_i]$ of height $f(x_i^*)$ and width $\Delta x$. A representative rectangle is shown in Figure 6.2.2(a). When that rectangle is revolved around the $y$-axis, instead of a disk or a washer, we get a **cylindrical shell**, as shown in Figure 6.2.2(b).

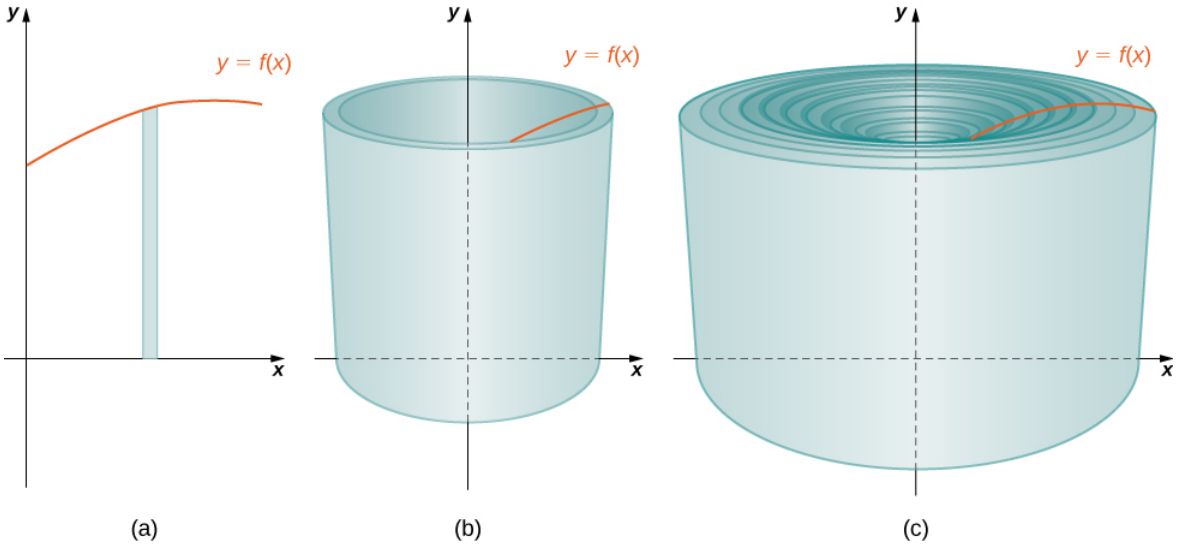

Figure 6.2.2(a): A representative rectangle.
Figure 6.2.2(b): When this rectangle revolves around the $y$-axis, the result is a cylindrical shell.
Figure 6.2.2(c): When we put all the shells together, we get an approximation of the original solid.

To calculate the volume of this shell, consider Figure 6.2.3.

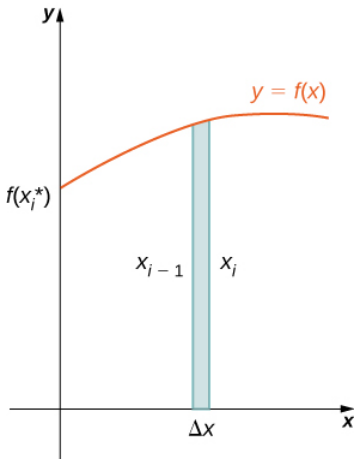

Figure **6.2.3**: Calculating the volume of the shell.

The shell is a cylinder, so its volume is the cross-sectional area multiplied by the height of the cylinder. The cross-sections are **annuli** (ring-shaped regions - essentially, circles with a hole in the center), with outer radius $x_i$ and inner radius $x_{i-1}$. Thus, the cross-sectional area is $\pi x_i^2 - \pi x_{i-1}^2$. The height of the cylinder is $f(x_i^*)$. Then the volume of the shell is

$$\begin{aligned} V_{\text{shell}} &= f(x_i^*)(\pi x_i^2 - \pi x_{i-1}^2) \\ &= \pi f(x_i^*)(x_i^2 - x_{i-1}^2) \\ &= \pi f(x_i^*)(x_i + x_{i-1})(x_i - x_{i-1}) \\ &= 2\pi f(x_i^*)\left(\frac{x_i + x_{i-1}}{2}\right)(x_i - x_{i-1}). \end{aligned}$$

Note that $x_i - x_{i-1} = \Delta x$, so we have

$$V_{\text{shell}} = 2\pi f(x_i^*)\left(\frac{x_i + x_{i-1}}{2}\right)\Delta x.$$

Furthermore, $\frac{x_i + x_{i-1}}{2}$ is both the midpoint of the interval $[x_{i-1}, x_i]$ and the average radius of the shell. We can approximate this by $x_i^*$. We then have

$$V_{\text{shell}} \approx 2\pi f(x_i^*)x_i^* \Delta x.$$

Another way to think of this is to think of making a vertical cut in the shell and then opening it up to form a flat plate (Figure **6.2.4**).

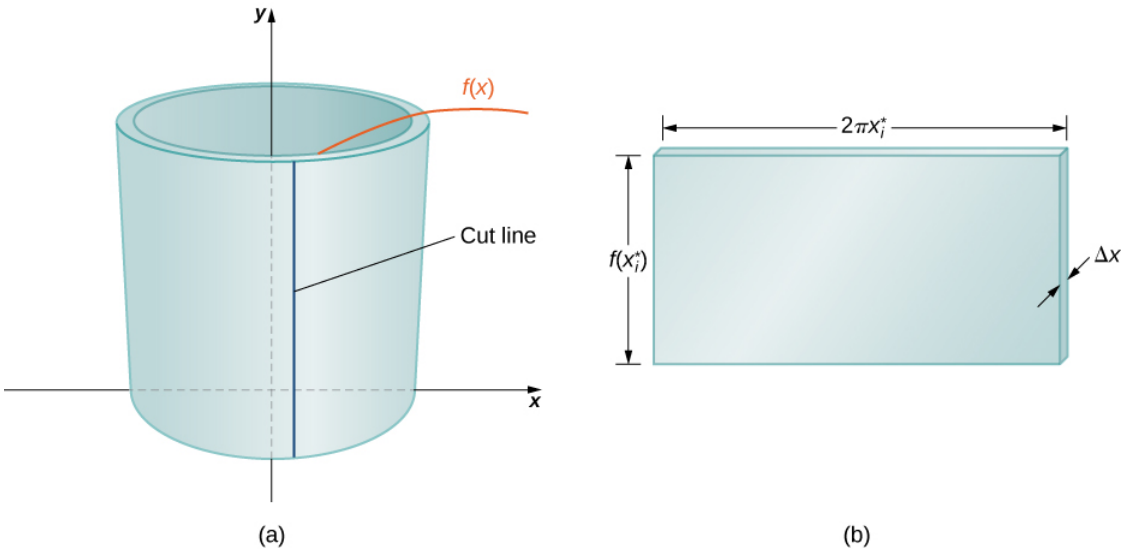

Figure 6.2.4($a$): Make a vertical cut in a representative shell.
Figure 6.2.4($b$): Open the shell up to form a flat plate.

In reality, the outer radius of the shell is greater than the inner radius. Hence, the back edge of the plate would be slightly longer than the front edge of the plate. However, we can approximate the flattened shell by a flat plate of height $f(x_i^*)$, width $2\pi x_i^*$, and thickness $\Delta x$ (Figure 6.2.4($b$)). Then, the shell's volume is approximately the volume of the flat plate. Multiplying the height, width, and depth of the plate, we get

$$V_{\text{shell}} \approx f(x_i^*)(2\pi x_i^*)\,\Delta x,$$

which is the same formula we had before.

To calculate the volume of the entire solid, we then add the volumes of all the shells and obtain

$$V \approx \sum_{i=1}^{n} (2\pi x_i^* f(x_i^*)\,\Delta x).$$

Here we have another Riemann sum, this time for the function $2\pi x\, f(x)$. Taking the limit as $n \to \infty$ gives us

$$V = \lim_{n\to\infty} \sum_{i=1}^{n} (2\pi x_i^* f(x_i^*)\,\Delta x) = \int_a^b (2\pi x\, f(x))\,dx.$$

This leads to the following rule for the **Method of Cylindrical Shells**.

**Theorem: The Method of Cylindrical Shells About the $y$-axis**

Let $f(x)$ be continuous and nonnegative. Define $\mathbf{R}$ as the region bounded above by the graph of $f(x)$, below by the $x$-axis, on the left by the line $x = a$, and on the right by the line $x = b$. Then the volume of the solid of revolution formed by revolving $\mathbf{R}$ around the $y$-axis is given by

$$V = \int_a^b (2\pi x\, f(x))\,dx.$$

As stated in the previous section, you want to understand how this works rather than memorizing the formula. We will work hard to showcase the thought process you should follow when using the Method of Cylindrical Shells.

**Example 6.2.1**

Define $\mathbf{R}$ as the region bounded above by the graph of $f(x) = 1/x$ and below by the $x$-axis over the interval $[1, 3]$. Find the volume of the solid of revolution formed by revolving $\mathbf{R}$ around the $y$-axis.

**Solution**

First, we must graph the region $\mathbf{R}$ and the associated solid of revolution, as shown in Figure 6.2.5. You should also get used to graphing a representative shell (use the CalcPlot3D applet below to visualize this for this example).

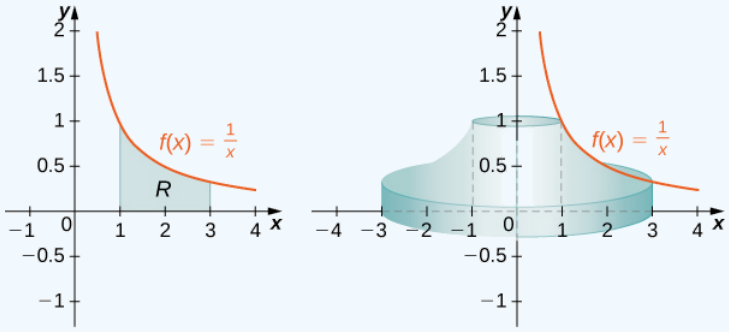

Figure 6.2.5($a$): The region $\mathbf{R}$ under the graph of $f(x) = 1/x$ over the interval $[1, 3]$.
Figure 6.2.5($b$): The solid of revolution generated by revolving $\mathbf{R}$ about the $y$-axis.

If we had not been told to use the Method of Cylindrical Shells, we would have a choice to make. If you can visualize horizontal slices being rotated about the $y$-axis, you would see that the outer radius changes functions at $y = 1/3$. This means that you would need two groups of integrals (one for the bottom set of washers, and one for the washers starting at a height of $y = 1/3$). This is highly inefficient.

On the other hand, choosing to make vertical slices and rotating those about the $y$-axis shows that the top function of each slice is always $f(x) = 1/x$ and the bottom function is always $y = 0$. Therefore, vertical slicing is a more attractive option.

The volume of the $i^{\text{th}}$ slice is given *in words* by

$$V_i = (\text{Circumference of the rotated slice})\,(\text{Height of the rotated slice})\,(\text{Thickness of the rotated slice}).$$

As per our usual approach, we let $r(x_i^*)$ be the radius of rotation. We will also let $h(x_i^*)$ be the height of the slice and naturally select $\Delta x$ as the thickness. Then our language formula transforms to

$$\begin{array}{rcccc} & & \text{Circumference} & \text{Height} & \text{Thickness} \\ V_i & = & 2\pi r(x_i^*) & h(x_i^*) & \Delta x. \end{array}$$

The radius of rotation is the distance between the slice and the axis of rotation (the $y$-axis). Since this is a horizontal distance, we measure it as $x_R - x_L$. In this case, $x_R = x_i^*$ and $x_L$ is the $y$-axis. That is, or $x_L = 0$. The height of the slice is a vertical distance, so this should be $y_T - y_B$. The top of the slice is $f(x_i^*) = \frac{1}{x_i^*}$ and the bottom is $y = 0$. Putting this altogether, we get

$$\begin{array}{rcccc} & & \text{Circumference} & \text{Height} & \text{Thickness} \\ V_i & = & 2\pi r(x_i^*) & h(x_i^*) & \Delta x \\ & = & 2\pi x_i^* & \frac{1}{x_i^*} & \Delta x. \end{array}$$

Hence, the true volume is

$$\begin{aligned} V &= \int_{x=1}^{x=3} \left(2\pi x \left(\frac{1}{x}\right)\right) dx \\ &= \int_{x=1}^{x=3} 2\pi \, dx \\ &= 2\pi x \Big|_{x=1}^{x=3} \\ &= 4\pi \text{ units}^3. \end{aligned}$$

## Checkpoint 6.2.1

Define $\mathbf{R}$ as the region bounded above by the graph of $f(x) = x^2$ and below by the $x$-axis over the interval $[1, 2]$. Find the volume of the solid of revolution formed by revolving $\mathbf{R}$ around the $y$-axis.

**Answer**

$\frac{15\pi}{2}$ units$^3$

## Example 6.2.2

Define $\mathbf{R}$ as the region bounded above by the graph of $f(x) = 2x - x^2$ and below by the $x$-axis over the interval $[0, 2]$. Find the volume of the solid of revolution formed by revolving $\mathbf{R}$ around the $y$-axis.

**Solution**

First graph the region $\mathbf{R}$ and the associated solid of revolution, as shown in Figure 6.2.6.

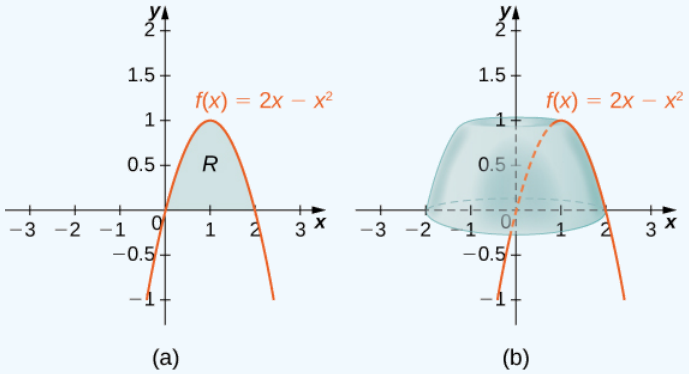

Figure 6.2.6($a$): The region $\mathbf{R}$ under the graph of $f(x) = 2x - x^2$ over the interval $[0, 2]$.
Figure 6.2.6($b$): The volume of revolution obtained by revolving $\mathbf{R}$ about the $y$-axis.

If we chose horizontal slices, we would get washers; however, each washer's outer and inner edges would be described by the same function. While we *could* find a way to get the volume of this washer, there are more efficient methods than this one. Instead, let's try slicing vertically.

Figure 6.2.6 shows that vertical slices would result in cylindrical shells. From Example 6.2.1, we know the volume of the $i^{\text{th}}$ such shell would be

$$\begin{array}{rcccc} & & \textbf{Circumference} & \textbf{Height} & \textbf{Thickness} \\ V_i & = & 2\pi r(x_i^*) & h(x_i^*) & \Delta x, \end{array}$$

where $r(x_i^*) = x_i^*$ and $h(x_i^*) = 2x_i^* - (x_i^*)^2$. Hence,

$$\begin{array}{rcccc} & & \textbf{Circumference} & \textbf{Height} & \textbf{Thickness} \\ V_i & = & 2\pi r(x_i^*) & h(x_i^*) & \Delta x \\ & = & 2\pi x_i^* & (2x_i^* - (x_i^*)^2) & \Delta x. \end{array}$$

Thus,

$$\begin{aligned} V &= \int_0^2 (2\pi x(2x - x^2))\, dx \\ &= 2\pi \int_0^2 (2x^2 - x^3)\, dx \\ &= 2\pi \left[ \frac{2x^3}{3} - \frac{x^4}{4} \right] \Big|_0^2 \\ &= \frac{8\pi}{3} \text{ units}^3 \end{aligned}$$

**? Checkpoint 6.2.2**

Define $\mathbf{R}$ as the region bounded above by the graph of $f(x) = 3x - x^2$ and below by the $x$-axis over the interval $[0, 2]$. Find the volume of the solid of revolution formed by revolving $\mathbf{R}$ around the $y$-axis.

**Answer**

$8\pi$ units$^3$

As with the Disk Method and the Washer Method, we can use the Method of Cylindrical Shells with solids of revolution, revolved around the $x$-axis, when we want to integrate with respect to $y$. The analogous rule for this type of solid is given here. To be clear, you should not memorize this formula without truly understanding how to derive it yourself. Committing this formula to memory is worthless if you genuinely understand the derivation of the process.

**Theorem: The Method of Cylindrical Shells About the $x$-axis**

Let $g(y)$ be continuous and nonnegative. Define $\mathbf{Q}$ as the region bounded on the right by the graph of $g(y)$, on the left by the $y$-axis, below by the line $y = c$, and above by the line $y = d$. Then, the volume of the solid of revolution formed by revolving $\mathbf{Q}$ around the $x$-axis is given by

$$V = \int_c^d (2\pi y\, g(y))\, dy.$$

**✓ Example 6.2.3**

Define $\mathbf{Q}$ as the region bounded on the right by the graph of $g(y) = 2\sqrt{y}$ and on the left by the $y$-axis for $y \in [0, 4]$. Find the volume of the solid of revolution formed by revolving $\mathbf{Q}$ around the $x$-axis.

**Solution**

First, we need to graph the region $\mathbf{Q}$ and the associated solid of revolution, as shown in Figure 6.2.7.

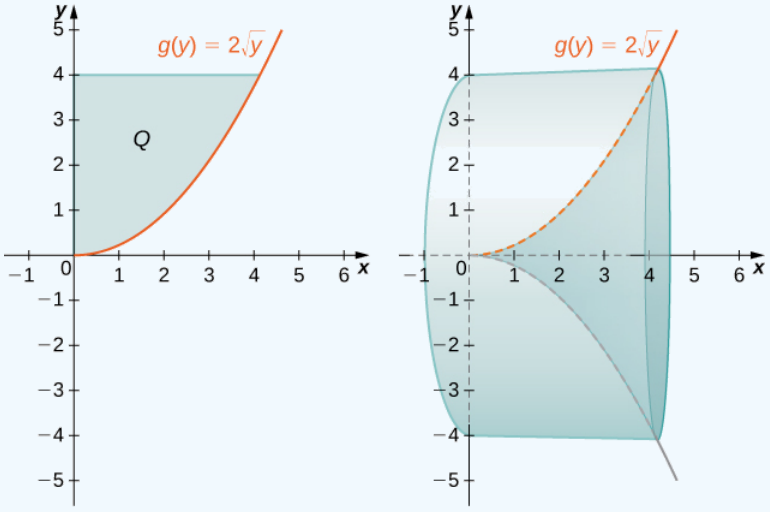

Figure 6.2.7($a$): The region $\mathbf{Q}$ to the left of the function $g(y)$ over the interval $[0, 4]$.
Figure 6.2.7($b$): The solid of revolution generated by revolving $\mathbf{Q}$ around the $x$-axis.

This is an excellent example of how we could easily use *either* the Washer Method or the Method of Cylindrical Shells. It's advisable to set up both integrals for practice and to see which one looks easier to evaluate.

**VERTICAL SLICES:** If we choose vertical slices, we will get washers, which implies the Washer Method. Moreover, each washer will have width $\Delta x$. This informs us that all of our work should eventually be in terms of $x$. Let's state the required information first.

$$r_O(x_i^*) = y_T - y_B = 4 - 0 = 4.$$

Finding $r_I(x_i^*)$ requires us to solve $x = 2\sqrt{y}$ for $y$. This gives $\frac{x^2}{4} = y$. Therefore,

$$r_I(x_i^*) = y_T - y_B = \frac{x^2}{4} - 0 = \frac{x^2}{4}.$$

The volume of the $i^{\text{th}}$ slice is

$$\begin{aligned} V_i &= \pi \left[r_O(x_i^*)\right]^2 \Delta x - \pi \left[r_I(x_i^*)\right]^2 \Delta x \\ &= \pi \left(16 - \frac{x^4}{16}\right) \Delta x \end{aligned}$$

Thus,

$$V = \pi \int_{x=0}^{x=4} 16 - \frac{x^4}{16}\, dx.$$

**HORIZONTAL SLICES:** If, on the other hand, we decide on horizontal slices, the rotation will result in shells. Hence, we will use the Method of Cylindrical Shells. The thickness of each shell will be $\Delta y$. This informs us that all of our work should eventually be only in terms of $y$.

The radius of rotation is $y_i^*$ and the "height" of each shell is $x_R - x_L = 2\sqrt{y_i^*} - 0 = 2\sqrt{y_i^*}$. Therefore, the volume of the $i^{\text{th}}$ slice is

| | | Circumference | Height | Thickness |
|---|---|---|---|---|
| $V_i$ | $=$ | $2\pi r(y_i^*)$ | $h(y_i^*)$ | $\Delta y$ |
| | $=$ | $2\pi y_i^*$ | $\left(2\sqrt{y_i^*}\right)$ | $\Delta y.$ |

Then the volume of the solid is given by

$$V = 4\pi \int_{y=0}^{y=4} y^{3/2} dy.$$

You be the judge of which integral looks nicer. While they will both yield the same result, I am choosing the second because... well, it's nicer.

$$\begin{aligned} V &= 4\pi \int_{y=0}^{y=4} y^{3/2}\, dy \\ &= 4\pi \left[ \frac{2y^{5/2}}{5} \right] \Big|_0^4 \\ &= \frac{256\pi}{5} \text{ units}^3 \end{aligned}$$

Example **6.2.3** showcases two fundamental concepts. First, you should refrain from getting married to a method. That is, always be willing to try *both* horizontal *and* vertical slices. This takes little time once you get used to things and can make an impossible problem simple. The second important concept is based on notation. If you look back through Example **6.2.3**, you will notice that I wrote the limits of integration as $x = 0$ or $y = 0$, and $x = 4$ or $y = 4$, accordingly. While the limits didn't change in this example, they often are not the same, and writing $x =$ or $y =$ will keep your work "honest" and remind you that, yes, you already changed those limits into the proper variable.

**? Checkpoint 6.2.3**

Define $\mathbf{Q}$ as the region bounded on the right by the graph of $g(y) = 3/y$ and on the left by the $y$-axis for $y \in [1, 3]$. Find the volume of the solid of revolution formed by revolving $\mathbf{Q}$ around the $x$-axis.

**Answer**

$12\pi$ units$^3$

**✓ Example 6.2.4**

Define $\mathbf{R}$ as the region bounded above by the graph of $f(x) = x$ and below by the $x$-axis over the interval $[1, 2]$. Find the volume of the solid of revolution formed by revolving $\mathbf{R}$ around the line $x = -1$.

**Solution**

First, graph the region $\mathbf{R}$ and the associated solid of revolution, as shown in Figure **6.2.8**.

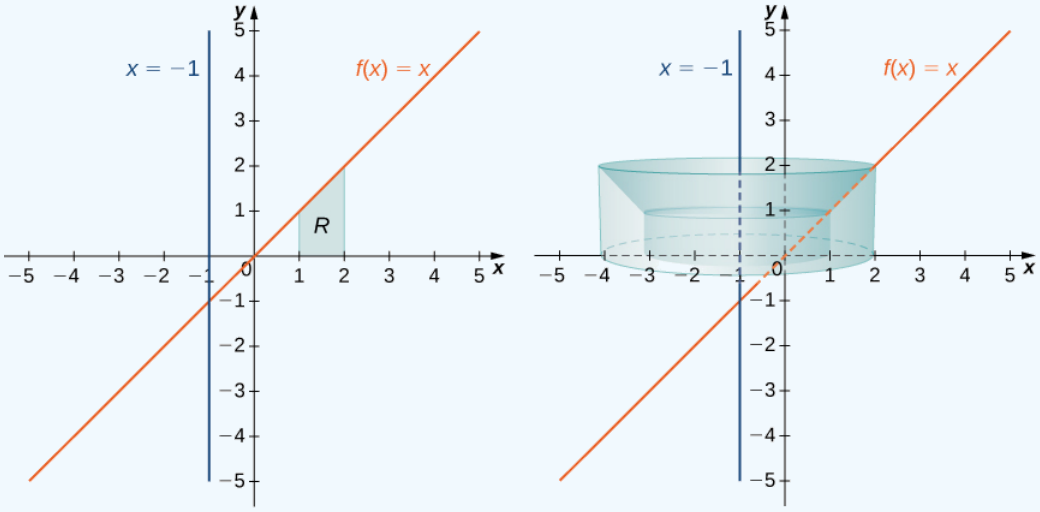

Figure 6.2.8($a$): The region $\mathbf{R}$ between the graph of $f(x)$ and the $x$-axis over the interval $[1, 2]$.
Figure 6.2.8($b$): The solid of revolution generated by revolving $\mathbf{R}$ around the line $x = -1$.

**HORIZONTAL SLICES:** If we chose to slice $\mathbf{R}$ into horizontal slices, we can easily see that we would need two sets of computations - one for the region where the left edge is $x = 1$ and the right edge is $x = 2$, and one for the region where the left edge is $f(x) = x$ and the right edge is $x = 2$. This should motivate us to try vertical slices.

**VERTICAL SLICES:** Slicing the region $\mathbf{R}$ into vertical slices means that each has a width of $\Delta x$, and so all of our work needs to be in terms of $x$. Moreover, a rotation about the vertical line $x = -1$ means we are creating shells. The radius of rotation to the $i^{\text{th}}$ slice is $x_R - x_L = x_i^* - (-1) = x_i^* + 1$. The height of the slice is $h(x_i^*) = y_T - y_B = x_i^* - 0 = x_i^*$. Therefore, the volume of the $i^{\text{th}}$ slice is

$$V_i = 2\pi r(x_i^*)h(x_i^*)\Delta x = 2\pi(x_i^* + 1)x_i^*\Delta x.$$

Thus, the volume of the solid is given by

$$\begin{aligned} V &= 2\pi \int_{x=1}^{x=2} x^2 + x\, dx \\ &= 2\pi \left[\frac{x^3}{3} + \frac{x^2}{2}\right]\Big|_1^2 \\ &= \frac{23\pi}{3} \text{ units}^3 \end{aligned}$$

**? Checkpoint 6.2.4**

Define $\mathbf{R}$ as the region bounded above by the graph of $f(x) = x^2$ and below by the $x$-axis over the interval $[0, 1]$. Find the volume of the solid of revolution formed by revolving $\mathbf{R}$ around the line $x = -2$.

**Answer**

$\frac{11\pi}{6}$ units$^3$

For our final example in this section, let's look at the volume of a solid of revolution for which the graphs of two functions bound the region of revolution.

## Example 6.2.5

Define $\mathbf{R}$ as the region bounded above by the graph of the function $f(x) = \sqrt{x}$, below by the graph of the function $g(x) = 1/x$, and on the right by $x = 4$. Find the volume of the solid of revolution generated by revolving $\mathbf{R}$ around the $y$-axis.

**Solution**

First, graph the region $\mathbf{R}$ and the associated solid of revolution, as shown in Figure 6.2.9. During this process, you will need to find the point of intersection of these two curves, which is $(1, 1)$.

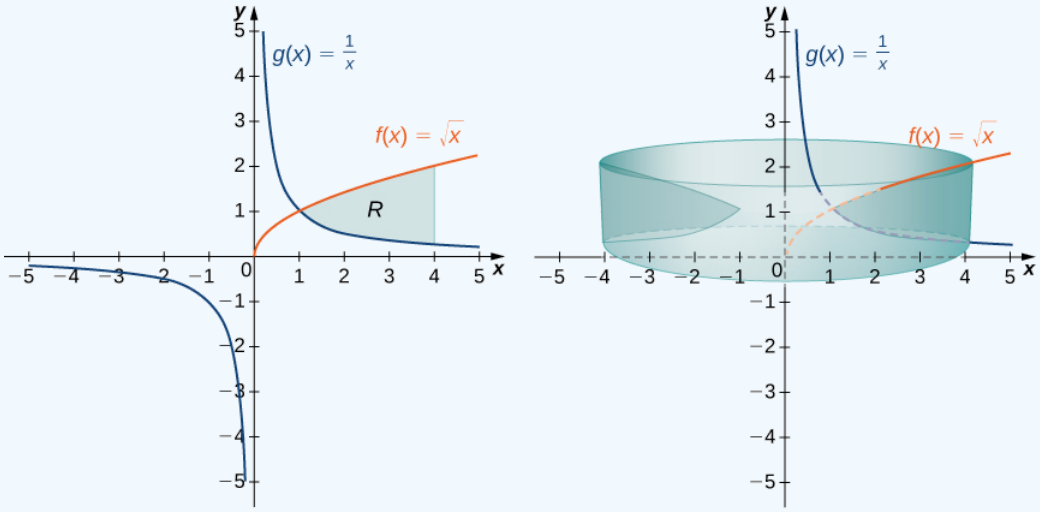

Figure 6.2.9($a$): The region $\mathbf{R}$ between the graph of $f(x)$ and the graph of $g(x)$ over the interval $[1, 4]$.
Figure 6.2.9($b$): The solid of revolution generated by revolving $\mathbf{R}$ around the $y$-axis.

**HORIZONTAL OR VERTICAL SLICES?** Since we are rotating about the $y$-axis, a quick inspection reveals that horizontal slices yield two separate regions (one below $y = 1$ and one above $y = 1$), so this is likely not the best choice.

Now that we know to slice vertically, we also know that each slice has width $\Delta x$. Again, this means all of our eventual work must be in terms of $x$. Moreover, vertical slices rotated about the $y$-axis leads to shells. Hence, we are using the Method of Cylindrical Shells. The radius of rotation for the $i^{\text{th}}$ shell is $x_R - x_L = x_i^* - 0 = x_i^*$. The height of this slice is $h(x_i^*) = y_T - y_B = \sqrt{x_i^*} - \frac{1}{x_i^*}$. Combining this information, we setup the volume of the $i^{\text{th}}$ slice to be

$$V_i = 2\pi r(x_i^*)h(x_i^*)\Delta x = 2\pi x_i^* \left(\sqrt{x_i^*} - \frac{1}{x_i^*}\right)\Delta x.$$

Then the volume of the solid is given by

$$\begin{aligned} V &= \int_{x=1}^{x=4} \left(2\pi x \left(\sqrt{x} - \frac{1}{x}\right)\right) dx \\ &= 2\pi \int_{x=1}^{x=4} (x^{3/2} - 1)\, dx \\ &= 2\pi \left[\frac{2x^{5/2}}{5} - x\right]\Big|_1^4 \\ &= \frac{94\pi}{5} \text{ units}^3. \end{aligned}$$

## Checkpoint 6.2.5

Define $\mathbf{R}$ as the region bounded above by the graph of $f(x) = x$ and below by the graph of $g(x) = x^2$ over the interval $[0, 1]$. Find the volume of the solid of revolution formed by revolving $\mathbf{R}$ around the $y$-axis.

**Answer**

$\frac{\pi}{6}$ units$^3$

https://math.libretexts.org/@go/page/175579

# 6.2E: Exercises

## Reading Questions

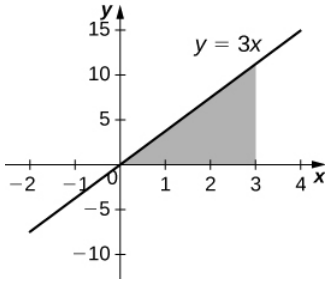
1. What is the primary difference between the Method of Cylindrical Shells and the Disk/Washer methods regarding the variable of integration?
2. When a vertical rectangle is revolved around the y-axis, what is the resulting three-dimensional shape called?
3. The volume of a single cylindrical shell can be approximated by "unrolling" it into what simple geometric shape?
4. What are the three components that are multiplied together to find the approximate volume of a single cylindrical shell?
5. When revolving a region bounded by $y = f(x)$ around the y-axis, how are the shell's radius and height typically expressed in terms of $x$ and $y$?
6. In Example 1.4.4, the region is revolved around the vertical line $x = -1$. How is the radius of rotation for a slice at position $x$ calculated?

**For exercises 1 - 6, find the volume generated when the region between the two curves is rotated around the given axis. Use both the shell method and the Washer Method. Use technology to graph the functions and draw a typical slice by hand.**

1) [Technology Required] Over the curve of $y = 3x$, $x = 0$, and $y = 3$ rotated around the $y$-axis.

2) [Technology Required] Under the curve of $y = 3x$, $x = 0$, and $x = 3$ rotated around the $y$-axis.

**Answer**

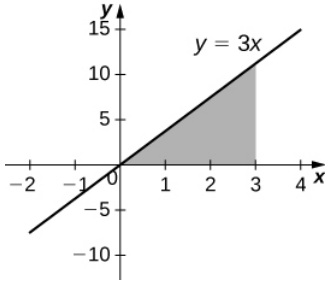


$V = 54\pi$ units$^3$

3) [Technology Required] Over the curve of $y = 3x$, $x = 0$, and $y = 3$ rotated around the $x$-axis.

4) [Technology Required] Under the curve of $y = 3x$, $x = 0$, and $x = 3$ rotated around the $x$-axis.

**Answer**



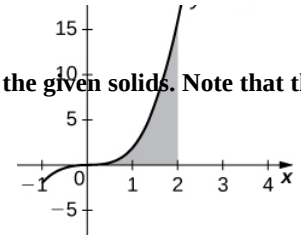
$V = 81\pi$ units$^3$

5) [Technology Required] Under the curve of $y = 2x^3$, $x = 0$, and $x = 2$ rotated around the $y$-axis.

6) [Technology Required] Under the curve of $y = 2x^3$, $x = 0$, and $x = 2$ rotated around the $x$-axis.

**Answer**

$V = \frac{512\pi}{7}$ units$^3$



**For exercises 7 - 16, use shells to find the volumes of the given solids. Note that the rotated regions lie between the curve and the $x$-axis and are rotated around the $y$-axis.**

7) $y = 1 - x^2$, $x = 0$, and $x = 1$

8) $y = 5x^3$, $x = 0$, and $x = 1$

**Answer**

$V = 2\pi$ units$^3$

9) $y = \frac{1}{x}$, $x = 1$, and $x = 100$

10) $y = \sqrt{1 - x^2}$, $x = 0$, and $x = 1$

**Answer**

$V = \frac{2\pi}{3}$ units$^3$

11) $y = \frac{1}{1 + x^2}$, $x = 0$,and $x = 3$

12) $y = \sin x^2, x = 0$, and $x = \sqrt{\pi}$

**Answer**

$V = 2\pi$ units$^3$

13) $y = \frac{1}{\sqrt{1 - x^2}}$, $x = 0$, and $x = \frac{1}{2}$

14) $y = \sqrt{x}$, $x = 0$, and $x = 1$

**Answer**

$V = \frac{4\pi}{5}$ units$^3$

15) $y = (1 + x^2)^3$, $x = 0$, and $x = 1$

16) $y = 5x^3 - 2x^4$, $x = 0$, and $x = 2$

**Answer**

$V = \frac{64\pi}{3}$ units$^3$

**For exercises 17 - 26, use shells to find the volume generated by rotating the regions between the given curve and $y = 0$ around the $x$-axis.**

17) $y = \sqrt{1 - x^2}$, $x = 0$, and $x = 1$

18) $y = x^2$, $x = 0$, and $x = 2$

**Answer**

$V = \frac{32\pi}{5}$ units$^3$

19) $y = e^x$, $x = 0$, and $x = 1$

20) $y = \ln(x)$, $x = 1$, and $x = e$

**Answer**

$V = \pi(e - 2)$ units$^3$

21) $x = \frac{1}{1 + y^2}$, $y = 1$, and $y = 4$

https://math.libretexts.org/@go/page/175580

22) $x = \dfrac{1+y^2}{y}$, $y = 0$, and $y = 2$

**Answer**

$V = \frac{28\pi}{3}$ units$^3$

23) $x = \cos y$, $y = 0$, and $y = \pi$

24) $x = y^3 - 4y^2$, $x = -1$, and $x = 2$

**Answer**

$V = \frac{84\pi}{5}$ units$^3$

25) $x = ye^y$, $x = -1$, and $x = 2$

26) $x = e^y \cos y$, $x = 0$, and $x = \pi$

**Answer**

$V = e^\pi \pi^2$ units$^3$

**For exercises 27 - 36, find the volume generated when the region between the curves is rotated around the given axis.**

27) $y = 3 - x$, $y = 0$, $x = 0$, and $x = 2$ rotated around the $y$-axis.

28) $y = x^3$, $y = 0$, $x = 0$, and $y = 8$ rotated around the $y$-axis.

**Answer**

$V = \frac{64\pi}{5}$ units$^3$

29) $y = x^2$, $y = x$, rotated around the $y$-axis.

30) $y = \sqrt{x}$, $x = 0$, and $x = 1$ rotated around the line $x = 2$.

**Answer**

$V = \frac{28\pi}{15}$ units$^3$

31) $y = \dfrac{1}{4-x}$, $x = 1$, and $x = 2$ rotated around the line $x = 4$.

32) $y = \sqrt{x}$ and $y = x^2$ rotated around the $y$-axis.

**Answer**

$V = \frac{3\pi}{10}$ units$^3$

33) $y = \sqrt{x}$ and $y = x^2$ rotated around the line $x = 2$.

34) $x = y^3$, $y = \dfrac{1}{x}$, $x = 1$, and $y = 2$ rotated around the $x$-axis.

**Answer**

$\frac{52\pi}{5}$ units$^3$

35) $x = y^2$ and $y = x$ rotated around the line $y = 2$.

36) [Technology Required] Left of $x = \sin(\pi y)$, right of $y = x$, around the $y$-axis.

**Answer**

$V \approx 0.9876$ units$^3$

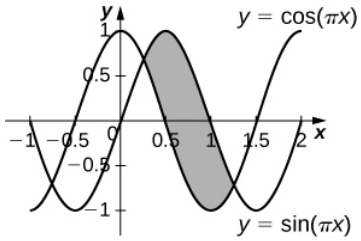
**For exercises 37 - 44, use technology to graph the region. Determine which method you think would be easiest to use to calculate the volume generated when the function is rotated around the specified axis. Then, use your chosen method to find**

**the volume.**

37) [Technology Required] $y = x^2$ and $y = 4x$ rotated around the $y$-axis.

38) [Technology Required] $y = \cos(\pi x), y = \sin(\pi x), x = \frac{1}{4}$, and $x = \frac{5}{4}$ rotated around the $y$-axis.

**Answer**

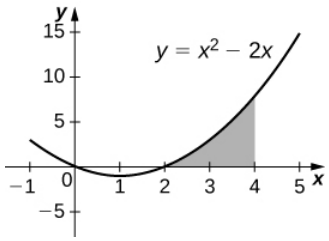


$V = 3\sqrt{2}$ units$^3$

39) [Technology Required] $y = x^2 - 2x,\ x = 2$, and $x = 4$ rotated around the $y$-axis.

40) [Technology Required] $y = x^2 - 2x,\ x = 2$, and $x = 4$ rotated around the $x$-axis.

**Answer**

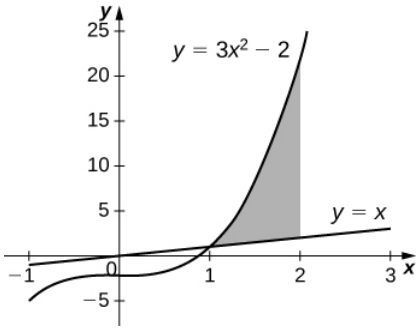


$V = \frac{496\pi}{15}$ units$^3$

41) [Technology Required] $y = 3x^3 - 2,\ y = x$, and $x = 2$ rotated around the $x$-axis.

42) [Technology Required] $y = 3x^3 - 2,\ y = x$, and $x = 2$ rotated around the $y$-axis.

**Answer**

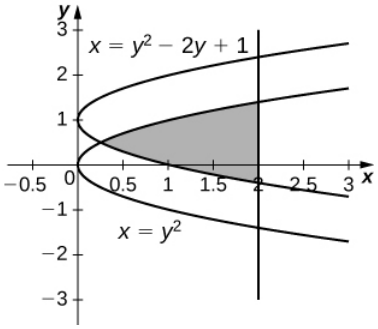


$V = \frac{398\pi}{15}$ units$^3$

43) [Technology Required] $x = \sin(\pi y^2)$ and $x = \sqrt{2}y$ rotated around the $x$-axis.

44) [Technology Required] $x = y^2,\ x = y^2 - 2y + 1$, and $x = 2$ rotated around the $y$-axis.

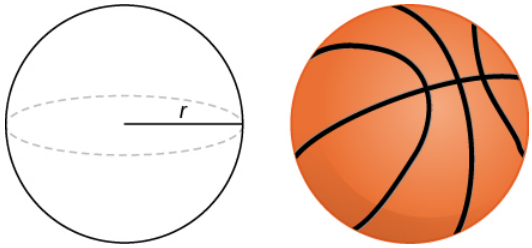
**Answer**



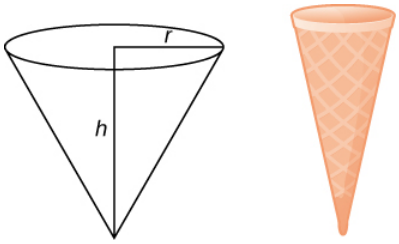
$V = 15.9074$ units$^3$

**For exercises 45 - 51, use the method of shells to approximate the volumes of some common objects, which are pictured in accompanying figures.**

45) Use the method of shells to find the volume of a sphere of radius $r$.



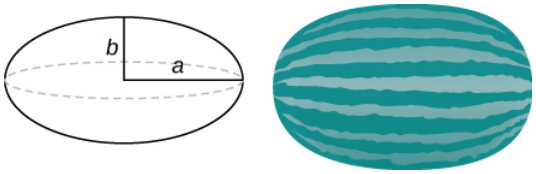
46) Use the method of shells to find the volume of a cone with radius $r$ and height $h$.



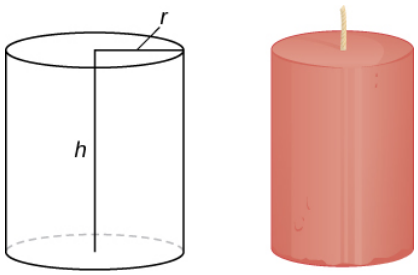
**Answer**

$V = \frac{1}{3}\pi r^2 h$ units$^3$

47) Use the method of shells to find the volume of an ellipse $(x^2/a^2) + (y^2/b^2) = 1$ rotated around the $x$-axis.



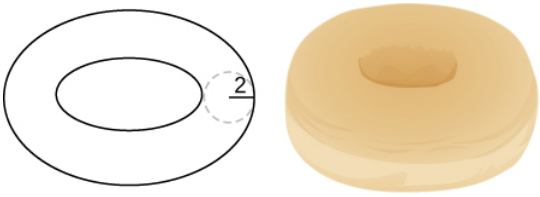
48) Use the method of shells to find the volume of a cylinder with radius $r$ and height $h$.



**Answer**

$V = \pi r^2 h$ units$^3$

49) Use the method of shells to find the volume of the donut created when the circle $x^2 + y^2 = 4$ is rotated around the line $x = 4$.



50) Consider the region enclosed by the graphs of $y = f(x)$, $y = 1 + f(x)$, $x = 0$, $y = 0$, and $x = a > 0$. What is the volume of the solid generated when this region is rotated around the $y$-axis? Assume that the function is defined over the interval $[0, a]$.

**Answer**

$V = \pi a^2$ units$^3$

51) Consider the function $y = f(x)$, which decreases from $f(0) = b$ to $f(1) = 0$. Set up the integrals for determining the volume, using both the shell method and the Disk Method, of the solid generated when this region, with $x = 0$ and $y = 0$, is rotated around the $y$-axis. Prove that both methods approximate the same volume. Which method is easier to apply? (Hint: Since $f(x)$ is one-to-one, there exists an inverse $f^{-1}(y)$.)

52) Find the volume of the shape created when rotating this curve from $x = 1$ to $x = 2$ around the $x$-axis, as pictured here.

# 6.3: Arc Length of a Curve and Surface Area

**Note to the Instructor (click to expand)**

The title of this section pretty much sums it up. If you have taught out of the Stewart text, you will know this material occurs *much* earlier in this text. This is because it flows naturally from the previous topics. Any integrals requiring special (read as, "untaught") integration techniques are avoided. If you choose to skip this and teach it with parametrics and polars (as in the Stewart text), be warned - the homework in the integration techniques chapter frequently uses this material.

---

To succeed in this section, you'll need to use some skills from previous courses. While you should already know them, this is the first time they've been required. You can review these skills in CRC's Corequisite Codex. If you have a support class, it might cover some, **but not all**, of these topics.

**Prerequisite Skills and Support Topics (click to expand)**

The following is a list of prerequisite skills (all of which can be reviewed in CRC's Corequisite Codex) needed for this section **that have not already been mentioned in any previous section**. If you are enrolled in a course with a Support section, some (but definitely not all) of these topics might be covered or reviewed in the Support section of your course.

- **Simplifying Expressions**
  - Simplifying Radical Expressions: The integrands for both arc length and surface area involve a square root, $\sqrt{1+[f'(x)]^2}$. Simplifying the expression inside the radical is a critical step.
- **An Overview of Functions**
  - The Difference Quotient: The derivation of the arc length formula uses the expression $\frac{\Delta y_i}{\Delta x}$, which is the difference quotient over a small interval, and relates it to the derivative $f'(x_i^*)$ via the Mean Value Theorem.

---

The following is a list of learning objectives for this section.

**Learning Objectives (click to expand)**

- Determine the length of a curve, $y=f(x)$, between two points.
- Determine the length of a curve, $x=g(y)$, between two points.
- Find the surface area of a solid of revolution.

Hawk A.I. Section-Specific Tutor

EST. 1970 COSUMNES RIVER COLLEGE MATHEMATICS

To access the Hawk A.I. Tutor, you will need to be logged into your campus Gmail account.

In this section, we use definite integrals to find the arc length of a curve. We can think of arc length as the distance you would travel if you walked along the curve's path. Many real-world applications involve arc length. If a rocket is launched along a

parabolic path, we want to know how far the rocket travels. Or, if a curve on a map represents a road, we might want to know how far we have to drive to reach our destination.

We begin by calculating the arc length of curves defined as functions of $x$. We examine the same process for curves defined as functions of $y$.[1] The techniques we use to find arc length can be extended to find the surface area of a surface of revolution. We close the section by examining this concept.

## Arc Length of the Curve $y = f(x)$

In previous applications of integration, we required the function $f(x)$ to be integrable, or at most continuous. However, for calculating arc length, we have a more stringent requirement for $f(x)$. Here, we require $f(x)$ to be differentiable, and we require its derivative, $f'(x)$, to be continuous. Functions like this, which have continuous derivatives, are called **continuously differentiable**.[2]

Let $f(x)$ be a continuously differentiable function defined over $[a, b]$. We want to calculate the length, $L$, of the curve from the point $(a, f(a))$ to the point $(b, f(b))$. We start by using line segments to approximate the length of the curve. For $i = 0, 1, 2, \ldots, n$, let $P = \{x_i\}$ be a regular partition of the interval $[a, b]$. Then, for $i = 1, 2, \ldots, n$, construct a line segment from the point $(x_{i-1}, f(x_{i-1}))$ to the point $(x_i, f(x_i))$. Although it might seem logical to use either horizontal or vertical line segments, we want our line segments to approximate the curve as closely as possible. Figure **6.3.1** depicts this construct for $n = 5$.

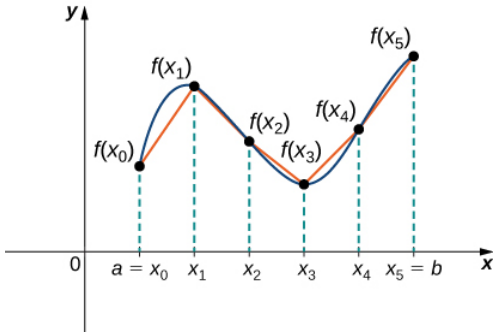

Figure **6.3.1**: We can approximate the length of a curve by adding line segments.

To help us find the length of each line segment, we look at the change in vertical distance as well as the change in horizontal distance over each interval. Because we have used a regular partition, the change in horizontal distance over each interval is given by $\Delta x$. The change in vertical distance varies from interval to interval, though, so we use

$$\Delta y_i = f(x_i) - f(x_{i-1})$$

to represent the change in vertical distance over the interval $[x_{i-1}, x_i]$, as shown in Figure **6.3.2**.[3] We will denote the length of the line segment from the point $(x_{i-1}, f(x_{i-1}))$ to the point $(x_i, f(x_i))$ as $l_i$.

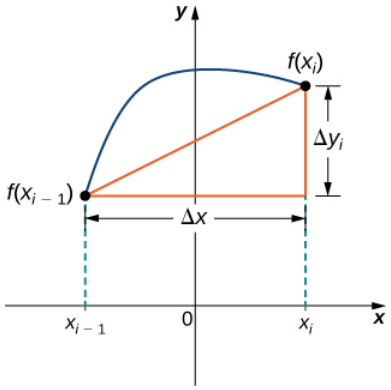

Figure **6.3.2**: A representative line segment approximates the curve over the interval $[x_{i-1}, x_i]$.

By the Pythagorean Theorem, the length of the $i^{\text{th}}$ line segment is

$$\begin{aligned} l_i &= \sqrt{(\Delta x)^2 + (\Delta y_i)^2} \\ &= \sqrt{1 + \left(\frac{\Delta y_i}{\Delta x}\right)^2}\Delta x. \end{aligned}$$

Moreover, by the Mean Value Theorem for Derivatives, there is a point $x_i^* \in [x_{i-1}, x_i]$ such that $f'(x_i^*) = \frac{\Delta y_i}{\Delta x}$. Therefore, we can rewrite the last formula as

$$l_i = \sqrt{1 + [f'(x_i^*)]^2}\Delta x.$$

Adding up the lengths of all the line segments, we get

$$L \equiv \text{Arc Length} \approx \sum_{i=1}^{n} l_i = \sum_{i=1}^{n} \sqrt{1 + [f'(x_i^*)]^2}\Delta x.$$

This is a Riemann sum. Taking the limit as $n \to \infty$, we have

$$\begin{aligned} L &= \lim_{n\to\infty} \sum_{i=1}^{n} \sqrt{1 + [f'(x_i^*)]^2}\Delta x \\ &= \int_{x=a}^{x=b} \sqrt{1 + [f'(x)]^2}\, dx. \end{aligned}$$

Before we formalize all the work up to this point into a theorem, it is useful to create an **arc length function**, $s(x)$, that allows us to find the length of the continuously differentiable curve $f$ from the constant point $(a, f(a))$ to the arbitrary point $(x, f(x))$. Using our knowledge of integral functions, we determine that

$$s(x) = \int_a^x \sqrt{1 + [f'(t)]^2}\, dt,$$

is the arc length function.[4] From the Fundamental Theorem of Calculus, Part 1 (FTC1) and our previous work with differentials,

$$ds = s'(x)dx \implies ds = \sqrt{1 + [f'(x)]^2}\, dx.$$

We will discover throughout the remainder of this course that the differential we just found, $ds$, has four equivalent forms. The choice of forms will depend on the structure of the curve with which we work; however, in all forms, the *meaning* of this differential is the same.

> *$ds$ is the infinitesimal change in arc length given an infinitesimal change in some other value.*

In our current case, $ds$ is the infinitesimal change in arc length given an infinitesimal change in $x$.

We now have enough mathematical language to streamline our discussion of arc length (and other future topics). We summarize these findings in the following theorem.

**Theorem: Arc Length of a Curve (with respect to $x$)**

Let $f(x)$ be a continuously differentiable function over the interval $[a, b]$. Then the arc length, $L$, of the portion of the graph of $f(x)$ from the point $(a, f(a))$ to the point $(b, f(b))$ is given by

$$L = \int_{x=a}^{x=b} ds, \tag{6.3.1}$$

where[5]

$$ds = \sqrt{1 + [f'(x)]^2}\, dx. \tag{6.3.2}$$

A few things need to be pointed out about this previous theorem. First, the limits of the integral in Equation 6.3.1 are in terms of $x$ - not $s$. Therefore, evaluating Equation 6.3.1 as written is "mathematically illegal." To evaluate a definite integral, the limits of integration must be in terms of the variable of integration. Luckily, substituting in Equation 6.3.2 allows us to evaluate Equation 6.3.1 "legally."

This brings us to our next point. We did all that work to get $ds$, but why not just say, "The arc length of $f$ over $[a, b]$ is

$$L = \int_a^b \sqrt{1 + [f'(x)]^2}\, dx?"$$

As was mentioned before this theorem, $ds$ will eventually have four equivalent (and often interchangeable) forms. Throughout these forms, the basic structure of the arc length integral, $L = \int ds$, will not change - we will only need to worry about changing the limits of the integral and swapping out $ds$ for an appropriate form.

Finally, we are integrating an expression involving $f'(x)$, so we need to be sure $f'(x)$ is integrable. This is why we require $f(x)$ to be continuously differentiable.

The following example shows how to apply the theorem.

### Example 6.3.1: Calculating the Arc Length of a Function of $x$

Let $f(x) = 2x^{3/2}$. Calculate the arc length of the graph of $f(x)$ over the interval $[0, 1]$.

**Solution**

To get us into a "good habit," let's start by recognizing that $f$ is a function of $x$.[6]

We have $f'(x) = 3x^{1/2}$, so $[f'(x)]^2 = 9x$. Therefore,

$$ds = \sqrt{1 + [f'(x)]^2}\, dx = \sqrt{1 + 9x}\, dx.$$

Then, the arc length is

$$\begin{aligned} L &= \int_{x=a}^{x=b} ds && \text{(arc length formula)} \\ &= \int_{x=0}^{x=1} \sqrt{1 + 9x}\, dx \\ &= \frac{1}{9}\int_{u=1}^{u=10} \sqrt{u}\, du && \text{(Let } u = 1 + 9x \implies du = 9\, dx\text{, and change the limits of integration accordingly)} \\ &= \frac{1}{9} \cdot \frac{2}{3} u^{3/2}\Big|_1^{10} \\ &= \frac{2}{27}[10\sqrt{10} - 1] \end{aligned}$$

### Checkpoint 6.3.1

Let $f(x) = (4/3)x^{3/2}$. Calculate the arc length of the graph of $f(x)$ over the interval $[0, 1]$.

**Answer**

$$\frac{1}{6}(5\sqrt{5} - 1)$$

Although it is nice to have a formula for calculating arc length, this particular theorem often generates expressions that are difficult to integrate. We will gain some ability to evaluate these integrals in the next chapter. Still, in some cases, we may have to use a computer or calculator to approximate the value of the integral.

### Example 6.3.2: Using a Computer or Calculator to Determine the Arc Length of a Function of $x$

Let $y = x^2$. Calculate the arc length of the graph of $y$ over the interval $[1, 3]$.

**Solution**

Noting that $y$ is a function of $x$, we compute $y' = 2x$, so that $(y')^2 = 4x^2$. Therefore,

$$ds = \sqrt{1 + 4x^2}\, dx.$$

Then the arc length is given by

$$L = \int_{x=a}^{x=b} ds = \int_1^3 \sqrt{1 + 4x^2}\, dx.$$

Using the Right Endpoint Method with $n = 10$,[7] we get

$$\int_1^3 \sqrt{1 + 4x^2}\, dx \approx R_{10} = \sum_{n=1}^{10} \sqrt{1 + 4\left(1 + \frac{1}{5}n\right)^2} \cdot \frac{1}{5} \approx 8.65347.$$

### Checkpoint 6.3.2

Let $y = \sin(x)$. Calculate the arc length of the graph of $y$ over the interval $[0, \pi]$. Use a computer or calculator to approximate the value of the integral.

**Answer**

Depending on how many subintervals you choose (and whether you are using the Left Endpoint or the Right Endpoint Method), the value should approach

$$\text{Arc Length} \approx 3.8202.$$

## Arc Length of the Curve $x = g(y)$

We have just seen how to approximate the length of a curve with line segments. If we want to find the arc length of the graph of a function of $y$, we can repeat the same process, except we partition the $y$-axis instead of the $x$-axis. Figure 6.3.3 shows a representative line segment.

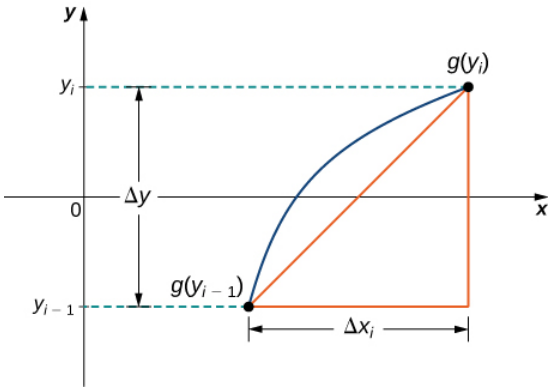

Figure 6.3.3: A representative line segment over the interval $[y_{i-1}, y_i]$.

Then the length of the line segment is

$$l_i = \sqrt{(\Delta y)^2 + (\Delta x_i)^2} = \sqrt{1 + \left(\frac{\Delta x_i}{\Delta y}\right)^2}\, \Delta y.$$

If we now follow the same development we did earlier, we get a formula for the arc length of a function $x = g(y)$.

**Theorem: Arc Length of a Curve (with respect to $y$)**

Let $g(y)$ be a continuously differentiable function over the ($y$-axis) interval $[c,d]$. Then the arc length, $L$, of the portion of the graph of $g(y)$ from the point $(c,g(c))$ to the point $(d,g(d))$ is given by

$$L=\int_{y=c}^{y=d} ds,$$

where[8]

$$ds=\sqrt{1+[g'(y)]^2}\,dy. \tag{6.3.3}$$

**Example 6.3.3: Approximating the Arc Length of a Function of $y$**

Let $x=3y^3$. Approximate the arc length of the curve over the ($y$-axis) interval $[1,2]$.

**Solution**

Note that $x$ is definitely a function of $y$. So we have $x'=9y^2$, so $(x'(y))^2=81y^4$. Therefore,

$$ds=\sqrt{1+81y^4}\,dy.$$

Thus, the arc length is

$$L=\int_{y=c}^{y=d} ds=\int_1^2 \sqrt{1+81y^4}\,dy.$$

Choosing to approximate this value using 20 slices,[9] we get

$$\begin{aligned} L &\approx L_{20} \\ &= \sum_{n=1}^{20}\sqrt{1+81\left(1+\frac{1}{20}(n-1)\right)^4}\cdot\frac{1}{20} \\ &\approx 20.3576 \end{aligned}$$

**Checkpoint 6.3.3**

Let $g(y)=\frac{1}{y}$. Calculate the arc length of the graph of $g(y)$ over the interval $[1,4]$. Use a computer or calculator to approximate the value of the integral.

**Answer**

$$\text{Arc Length}\approx 3.15018$$

## Arc Lengths - A Wealth of Choices

In the derivation of the arc length formulas, both with respect to $x$ and with respect to $y$, the base integral for arc length had the form

$$s=\int ds,$$

where $s$ was the *initial* independent variable. We chose to trade out $ds$ for an expression involving $dx$ or $dy$ depending on what we were learning at the moment; however, how would we know what form to use in a general scenario? Is the correct choice to trade out $ds$ for an expression involving $dx$? Or would it be better to trade $ds$ for its equivalent form in terms of $dy$? The good news is that

there is a way to determine which option is viable. The bad news is that sometimes *both* options are viable and you have the extra work of determining which is the best to use.

### Determining Which Form of $ds$ to Use

Simply put, the form of $ds$ available for use depends solely on whether the given curve is a function of $x$, $y$, or both over the given interval. That is if the given curve is a function of $x$ over the given interval, then

$$ds = \sqrt{1 + [f'(x)]^2}\, dx$$

is a viable form. If the given curve is a function of $y$ over the given interval, then

$$ds = \sqrt{1 + [g'(y)]^2}\, dy$$

is a viable form. If the curve is *both* a function of $x$ *and* a function of $y$ over the given interval, then you can use either form of $ds$; however, it is often the case that one such form will be easier to work with than the other.

Let's see this in an example.

**Example 6.3.4**

Find the length of the curve $y = \left(\frac{3}{2}x\right)^{2/3} + 1$ on the ($x$-axis) interval $\left[0, \frac{2}{3}(3)^{3/2}\right]$.

**Solution**

First, all arc length problems boil down to evaluating

$$L = \int ds.$$

We need to determine the proper limits of integration and which form of $ds$ to use. Since we were not explicitly told which variable to integrate with respect to, we need to do a little investigation.

**With Respect to $x$**

It's simple to see that, over the given interval of $x$-values, $y$ is a function of $x$. So we know that we can use $ds = \sqrt{1 + [y'(x)]^2}\, dx$. Let's set up the corresponding arc length integral to see how it looks.

$$y' = \frac{2}{3}\left(\frac{3}{2}x\right)^{-1/3} \cdot \frac{3}{2} = \left(\frac{3}{2}x\right)^{-1/3} \implies (y')^2 = \left(\frac{3}{2}x\right)^{-2/3}.$$

Therefore, the arc length could be found by evaluating

$$L = \int_{x=0}^{x=\frac{2}{3}(3)^{3/2}} \sqrt{1 + \left(\frac{3}{2}x\right)^{-2/3}}\, dx.$$

While not impossible to evaluate, the complex structure of this integrand should give you pause - especially when you know there *might* be a way to approach this problem. Let's pause on this approach and see if the curve is a function of $y$ over the given interval. If it's not, then we will come back to this and see if we can evaluate this integral analytically.[10]

**With Respect to $y$**

Solving the given equation for $x$, we arrive at $\left[\frac{2}{3}(y-1)\right]^{3/2} = x$. This already looks uglier than the original equation, but do not let that stop you - Integral Calculus is full of pleasant surprises. It should be somewhat obvious that $x$ is a function of $y$ wherever the function is defined (when $y \geq 1$), so we should now investigate the interval of $y$-values corresponding to the original interval. When $x = 0$, $y = 1$, and when $x = \frac{2}{3}(3)^{3/2}$, $y = \left(\frac{3}{2} \cdot \frac{2}{3}(3)^{3/2}\right)^{2/3} + 1 = 3 + 1 = 4$.

Finding the derivatives for the corresponding arc length integral, we get

$$x' = \frac{3}{2}\left[\frac{2}{3}(y-1)\right]^{1/2} \cdot \frac{2}{3} = \left[\frac{2}{3}(y-1)\right]^{1/2} \implies (x')^2 = \frac{2}{3}(y-1).$$

Hence, the arc length function is

$$\begin{aligned} L &= \int_{y=1}^{y=4} \sqrt{1+\frac{2}{3}(y-1)}\,dy \\ &= \int_{y=1}^{y=4} \sqrt{\frac{2}{3}y+\frac{1}{3}}\,dy \\ &= \frac{3}{2}\int_{u=1}^{u=3} \sqrt{u}\,du \qquad \left(\text{Let } u=\tfrac{2}{3}y+\tfrac{1}{3} \implies du=\tfrac{2}{3}\,dy\text{, and change the limits of integration correspondingly}\right) \\ &= \frac{3}{2}\cdot\frac{2}{3}u^{3/2}\Big|_{u=1}^{u=3} \\ &= 3^{3/2}-1 \end{aligned}$$

Example 6.3.4 illustrates the need to investigate whether a given curve is a function of *both* $x$ and $y$ over a given interval. As we found, the difference in computational expense can be vastly different between approaches. I leave it to the reader to verify that the first integral (with respect to $x$) results in the same value as the second.[11]

## Applications

One physical application of hyperbolic functions involves hanging cables. Suppose a cable of uniform density is suspended between two supports without any load other than its weight. In that case, the cable forms a **catenary** curve. High-voltage power lines, chains hanging between two posts, and spider web strands all form catenaries. The following figure shows chains hanging from a row of posts.

Figure 6.3.4: Chains between these posts take the shape of a catenary. (credit: modification of work by OKFoundryCompany, Flickr)

Hyperbolic functions can be used to model catenaries. Specifically, functions of the form $y = a\cdot\cosh\left(\frac{x}{a}\right)$ are catenaries. Figure 6.3.5 shows the graph of $y = 2\cosh\left(\frac{x}{2}\right)$.

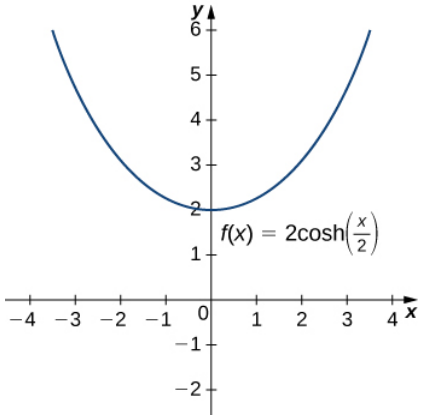

Figure 6.3.5: A hyperbolic cosine function forms the shape of a catenary.

### Example 6.3.5: Using a Catenary to Find the Length of a Cable

Assume a hanging cable has the shape $10\cosh\left(\frac{x}{10}\right)$ for $-15 \le x \le 15$, where $x$ is measured in feet. Determine the length of the cable (in feet).

**Solution**

We have $f(x) = 10\cosh\left(\frac{x}{10}\right)$, so $f'(x) = \sinh\left(\frac{x}{10}\right)$. Then the arc length is

$$\int_a^b \sqrt{1+[f'(x)]^2}\,dx = \int_{-15}^{15} \sqrt{1+\sinh^2\left(\frac{x}{10}\right)}\,dx.$$

Now recall that

$$1+\sinh^2(x) = \cosh^2(x),$$

so we have

$$\begin{aligned}
\text{Arc Length} &= \int_{-15}^{15} \sqrt{1+\sinh^2\left(\frac{x}{10}\right)}\,dx \\
&= \int_{-15}^{15} \cosh\left(\frac{x}{10}\right)\,dx \\
&= 10\sinh\left(\frac{x}{10}\right)\Big|_{-15}^{15} \\
&= 10\left[\sinh\left(\frac{3}{2}\right) - \sinh\left(-\frac{3}{2}\right)\right] \\
&= 20\sinh\left(\frac{3}{2}\right) \\
&\approx 42.586 \text{ ft.}
\end{aligned}$$

### Checkpoint 6.3.5

Assume a hanging cable has the shape $15\cosh\left(\frac{x}{15}\right)$ for $-20 \le x \le 20$. Determine the length of the cable (in feet).

**Answer**

52.95 ft

## Area of a Surface of Revolution

The concepts we used to find the arc length of a curve can be extended to find the surface area of a surface of revolution. **Surface area** is the total area of the outer layer of an object. For objects such as cubes or bricks, the object's surface area is the sum of the areas of all of its faces. For curved surfaces, the situation is more complex. Let $f(x)$ be a nonnegative continuously differentiable function over the interval $[a, b]$. We wish to find the surface area of the surface of revolution created by revolving the graph of $y = f(x)$ around the $x$-axis as shown in the following figure.

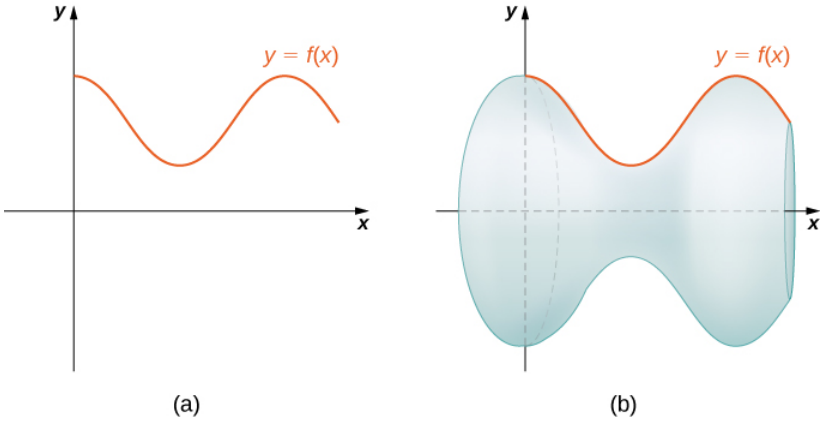

Figure **6.3.6***a*: A curve representing the function $f(x)$.

Figure **6.3.6***b*: The surface of revolution formed by revolving the graph of $f(x)$ around the $x$-axis.

As we have done many times before, we are going to partition the interval $[a, b]$ and approximate the surface area by calculating the surface area of simpler shapes. As we did earlier in this section, we start by using line segments to approximate the curve. For $i = 0, 1, 2, \ldots, n$, let $P = \{x_i\}$ be a regular partition of $[a, b]$. Then, for $i = 1, 2, \ldots, n$, construct a line segment from the point $(x_{i-1}, f(x_{i-1}))$ to the point $(x_i, f(x_i))$. Now, revolve these line segments around the $x$-axis to generate an approximation of the surface of revolution as shown in the following figure.

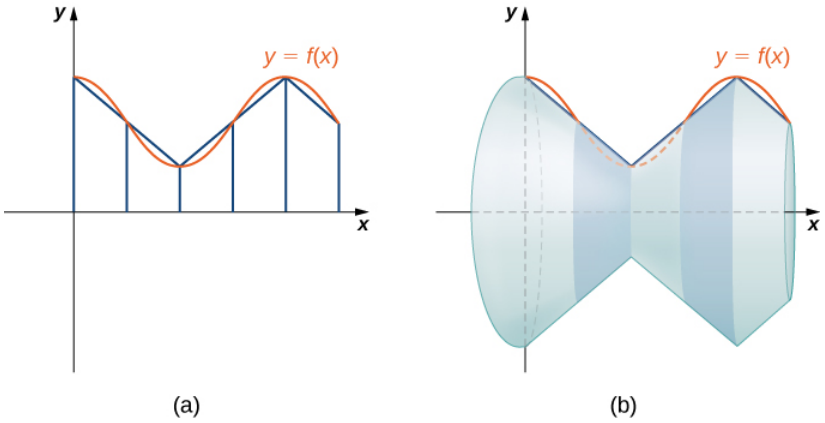

Figure **6.3.7***a*: Approximating $f(x)$ with line segments.

Figure **6.3.7***b*: The surface of revolution formed by revolving the line segments around the $x$-axis.

Notice that when each line segment is revolved around the axis, it produces a band. These bands are pieces of cones.[12] A piece of a cone like this is called a **frustum** of a cone.

### Deriving the Surface Area of a Frustum

In order to derive a formula for the surface area of the *entire* rotational volume, we must first focus our efforts on deriving a formula for the surface area of *one* of the bands of the overall rotated volume. To do so, we take a few steps back to Geometry.

To find the surface area of the band, we need to find the frustum's lateral surface area, $S$.[13] Let $r_1$ and $r_2$ be the radii of the wide end and the narrow end of the frustum, respectively, and let $l$ be the slant height of the frustum as shown in the Figure **6.3.8**.

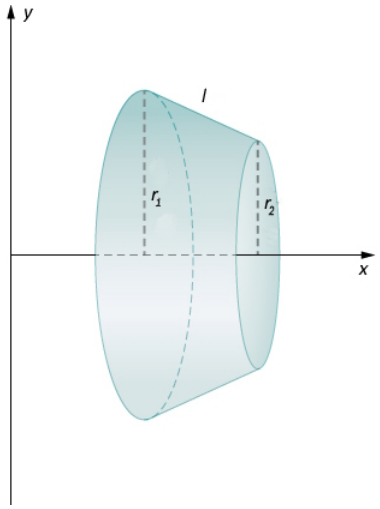

Figure 6.3.8: A frustum of a cone can approximate a small part of the surface area.

From Geometry, we know the lateral surface area of a *cone* is given by

$$\text{Lateral Surface Area} = \pi rs,$$

where $r$ is the radius of the base of the cone and $s$ is the slant height (Figure 6.3.9).

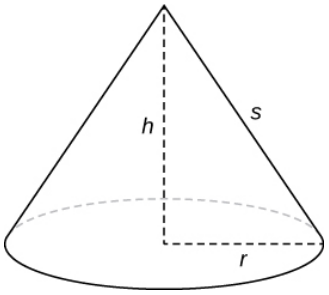

Figure 6.3.9: The lateral surface area of the cone is given by $\pi rs$.

Since a frustum can be thought of as a piece of a cone, the lateral surface area of the frustum is given by the lateral surface area of the whole cone less the lateral surface area of the smaller cone (the pointy tip) that was cut off (Figure 6.3.10).

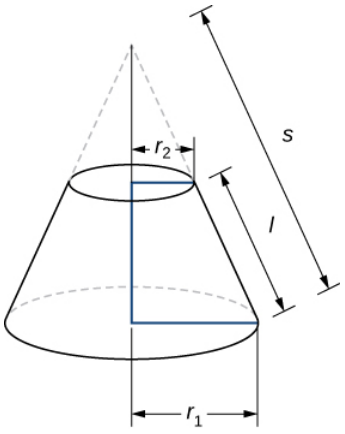

Figure 6.3.10: Calculating the lateral surface area of a frustum of a cone.

The cross-sections of the small cone and the large cone are similar triangles, so we see that

$$\frac{r_2}{r_1} = \frac{s-l}{s}, \tag{6.3.4}$$

which can also be written as

$$\frac{r_2 s}{r_1} = s - l. \tag{6.3.5}$$

Solving Equation 6.3.5 for $s$, we get

$$\begin{aligned} \frac{r_2 s}{r_1} &= s - l \\ \Longrightarrow \quad r_2 s &= r_1(s-l) \\ \Longrightarrow \quad r_2 s &= r_1 s - r_1 l \\ \Longrightarrow \quad r_1 l &= r_1 s - r_2 s \\ \Longrightarrow \quad r_1 l &= (r_1 - r_2)s \\ \Longrightarrow \quad \frac{r_1 l}{r_1 - r_2} &= s \end{aligned}$$

We will use this last result,

$$s = \frac{r_1 l}{r_1 - r_2}, \tag{6.3.6}$$

to help compute the surface area of the frustum.

If $S$ is the surface area of the frustum, then

$$\begin{aligned} S &= \text{(Lateral surface area of large cone)} \\ &\quad - \text{(Lateral surface area of small cone)} \\ &= \pi r_1 s - \pi r_2 (s-l) \\ &= \pi r_1 s - \pi r_2 \left(\frac{r_2 s}{r_1}\right) && \text{(from Equation 6.3.5)} \\ &= \pi s \left(r_1 - \frac{r_2^2}{r_1}\right) \\ &= \pi \left(\frac{r_1 l}{r_1 - r_2}\right)\left(\frac{r_1^2 - r_2^2}{r_1}\right) && \text{(from Equation 6.3.6)} \\ &= \pi \left(\frac{\cancel{r_1} l}{\cancel{(r_1 - r_2)}}\right)\left(\frac{\cancel{(r_1 - r_2)}\,(r_1 + r_2)}{\cancel{r_1}}\right) \\ &= \pi (r_1 + r_2) l. \end{aligned}$$

Multiplying the numerator and denominator of this last result by 2, we get

$$S = 2\pi \left(\frac{r_1 + r_2}{2}\right) l = 2\pi \bar{r} l, \tag{6.3.7}$$

where $\bar{r} = \frac{r_1 + r_2}{2}$ is the average value of the radii of the band.

### Deriving and Computing the Surface Area of a Rotational Volume

We now turn our attention back to the fact that we are rotating a function about an axis. To calculate the surface area of each of the bands formed by revolving the line segments around the $x$-axis, we consider the $i^{\text{th}}$ subinterval and exchange $l_i$ for $l$. Moreover, without loss of generality, we can assume $r_1$ in our previous discussion is $f(x_{i-1})$, and $r_2$ is $f(x_i)$.[14] The $i^{\text{th}}$ band is shown in Figure 6.3.11.

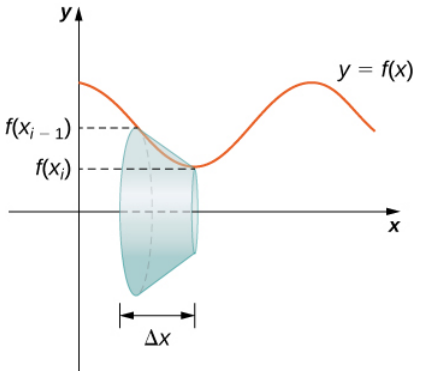

Figure 6.3.11: A representative band used for determining surface area.

The surface area, $S_i$, of this $i^{\text{th}}$ band is therefore

$$\begin{aligned} S_i &= 2\pi \bar{r} l_i \\ &= 2\pi \left( \frac{f(x_{i-1}) + f(x_i)}{2} \right) \sqrt{1 + (f'(x_i^*))^2} \Delta x \end{aligned}$$

Furthermore, since $f(x)$ is continuous, by the Intermediate Value Theorem, there is a point $x_i^{**} \in [x_{i-1}, x_i]$ such that $f(x_i^{**}) = \frac{f(x_{i-1}) + f(x_i)}{2}$, so we get

$$S_i = 2\pi f(x_i^{**}) \sqrt{1 + (f'(x_i^*))^2} \Delta x.$$

Then the approximate surface area of the whole surface of revolution is given by

$$S \equiv \text{Surface Area} \approx \sum_{i=1}^{n} 2\pi f(x_i^{**}) \sqrt{1 + (f'(x_i^*))^2} \Delta x.$$

This almost looks like a Riemann sum, except we have functions evaluated at two different points, $x_i^*$ and $x_i^{**}$, over the interval $[x_{i-1}, x_i]$. Although we do not examine the details here, it turns out that because $f(x)$ is continuously differentiable, if we let $n \to \infty$, the limit works the same as a Riemann sum even with the two different evaluation points. This makes sense intuitively. Both $x_i^*$ and $x_i^{**}$ are in the interval $[x_{i-1}, x_i]$, so it makes sense that as $n \to \infty$, both $x_i^*$ and $x_i^{**}$ approach $x$.[15]

Taking the limit as $n \to \infty$, we get

$$\begin{aligned} S \equiv \text{Surface Area} &= \lim_{n \to \infty} \sum_{i=1}^{n} 2\pi f(x_i^{**}) \sqrt{1 + (f'(x_i^*))^2} \Delta x \\ &= \int_{x=a}^{x=b} 2\pi f(x) \sqrt{1 + (f'(x))^2)}\, dx \end{aligned}$$

As with arc length, we can conduct a similar development for functions of $y$ to get a formula for the surface area of surfaces of revolution about the $y$-axis. These findings are summarized in the following theorem.

### Theorem: Surface Area of a Surface of Revolution

The surface area of the surface of revolution formed by revolving the graph of a nonnegative, continuously differentiable function about an axis is

$$S = \int_a^b 2\pi r ds,$$

where $r$ is the radius of rotation and

$$ds = \sqrt{1 + (f'(x))^2} dx$$

or

$$ds = \sqrt{1 + (g'(y))^2}\,dy.$$

Recall, the differential $ds$ represents an infinitesimal change in arc length. Which form you choose for $ds$ will, again, depend on whether the given curve is a function of $x$ or $y$ (or both). The radius of rotation function, $r$, is a function that gives the distance between the axis of rotation and the curve.

A great interpretation of the surface area integral

$$\int 2\pi r\,ds$$

is that the surface area of the $i^{\text{th}}$ band is the product of its circumference and its width. The circumference of the band is $2\pi r_i$ and its width is $\Delta s$.

### Example 6.3.6: Calculating the Surface Area of a Surface of Revolution 1.

Let $f(x) = \sqrt{x}$ over the interval $[1, 4]$. Find the surface area of the surface generated by revolving the graph of $f(x)$ around the $x$-axis.

**Solution**

As always, begin by sketching the function, the volume, and a representative slice (not shown). The graph of $f(x)$ and the surface of rotation are shown in Figure 6.3.12.

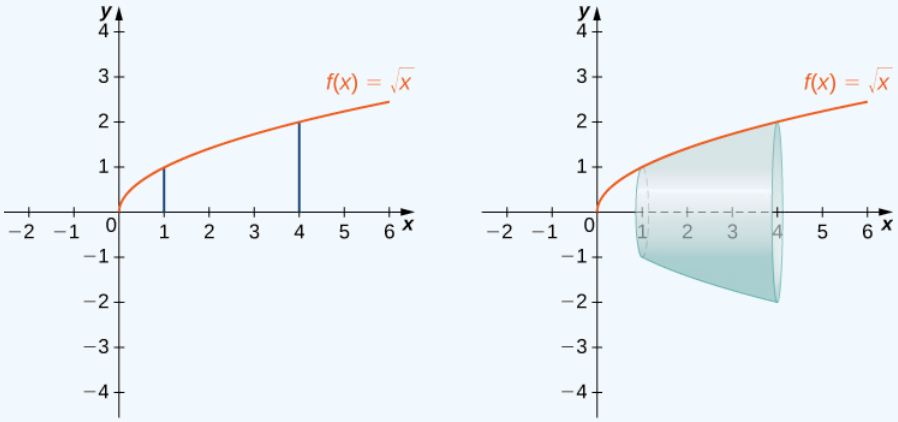

Figure 6.3.12*a*: The graph of $f(x)$.
Figure 6.3.12*b*: The surface of revolution.

To showcase how flexible we can be, we are going to perform several different setups for this problem (we will only compute the value of one of them, as they all result in the same value).

**With Respect to $x$**

This is the approach most students would take because we know $y = \sqrt{x}$ is a function of $x$ on the given interval. Therefore, it makes sense to build an integral with respect to $x$.

All surface area integrals have the common form

$$S = \int 2\pi r\,ds.$$

Since we are rotating the curve about the $x$-axis, the radius of rotation is $y_T - y_B = \sqrt{x} - 0 = \sqrt{x}$. Furthermore, replacing $ds$ with a function of $x$, we get

$$\begin{aligned} ds &= \sqrt{1+(y')^2}\,dx \\ &= \sqrt{1+\left(\frac{1}{2\sqrt{x}}\right)^2}\,dx \\ &= \sqrt{1+\tfrac{1}{4x}}\,dx \end{aligned}$$

Therefore,

$$\begin{aligned} S &= \int_{x=a}^{x=b} 2\pi r\,ds \\ &= \int_{x=1}^{x=4} 2\pi\sqrt{x}\sqrt{1+\frac{1}{4x}}\,dx \\ &= 2\pi\int_{x=1}^{x=4} \sqrt{x}\sqrt{\frac{4x+1}{4x}}\,dx \\ &= 2\pi\int_{x=1}^{x=4} \frac{1}{2}\sqrt{4x+1}\,dx \\ &= \pi\int_{x=1}^{x=4} \sqrt{4x+1}\,dx \\ &= \frac{\pi}{4}\int_{u=5}^{u=17} \sqrt{u}\,du \qquad \text{(Let } u=4x+1 \implies du=4\,dx\text{, and change the limits of integration accordingly)} \\ &= \frac{\pi}{4}\cdot\frac{2}{3}u^{3/2}\Big|_{u=5}^{u=17} \\ &= \frac{\pi}{6}\left(17^{3/2}-5^{3/2}\right) \end{aligned}$$

**With Respect to $y$**

This is *not* the approach most students would take, but I want to make certain that you understand all of your options. We were given $y=\sqrt{x}$ on the $x$-interval $[1,4]$. On this interval, the curve is one-to-one. That is, it passes both the Vertical Line Test and the Horizontal Line Test. Hence, we could represent the curve as a function of $y$ on this interval. Specifically, $y^2=x$ on the $y$-interval $[1,2]$.

All surface area integrals have the common form

$$S=\int 2\pi r\,ds.$$

Since we are rotating the curve about the $x$-axis, the radius of rotation is $y_T-y_B=y-0=y$. Moreover, since we are choosing to integrate with respect to $y$,

$$ds=\sqrt{1+(x')^2}\,dy=\sqrt{1+(2y)^2}\,dy=\sqrt{1+4y^2}\,dy.$$

Putting this altogether, we get

$$
\begin{aligned}
S &= \int_{y=1}^{y=2} 2\pi r\, ds \\
&= \int_{y=1}^{y=2} 2\pi y\sqrt{1+4y^2}\, dy \\
&= 2\pi \int_{y=1}^{y=2} y\sqrt{1+4y^2}\, dy \\
&= \frac{\pi}{4}\int_{u=5}^{y=17} \sqrt{u}\, du \qquad \text{(Let } u = 1+4y^2 \implies du = 8y\, dy\text{, and change the limits of integration accordingly)} \\
&= \frac{\pi}{4}\cdot\frac{2}{3}u^{3/2}\Big|_{u=5}^{u=17} \\
&= \frac{\pi}{6}\left(17^{3/2} - 5^{3/2}\right)
\end{aligned}
$$

Example **6.3.6** is another great illustration that knowing we have a choice can simplify our computations. While not the intuitive approach, integrating with respect to $y$ led to a simpler integral.

**? Checkpoint 6.3.6**

Let $f(x) = \sqrt{1-x}$ over the interval $[0, 1/2]$. Find the surface area of the surface generated by revolving the graph of $f(x)$ around the $x$-axis.

**Answer**

$$\frac{\pi}{6}(5\sqrt{5} - 3\sqrt{3})$$

**✓ Example 6.3.7: Calculating the Surface Area of a Surface of Revolution 2**

Let $y = \sqrt[3]{3x}$. Consider the portion of the curve where $0 \le y \le 2$.

a. Find the surface area of the surface generated by revolving the graph of $f(x)$ around the $y$-axis.
b. Setup, but do not evaluate, and integral for the surface area of the surface generated by revolving the graph of $f(x)$ about the line $x = 4$.

**Solution**

a. A quick sketch of the curve, the solid, and a slice (not shown) is the starting point.

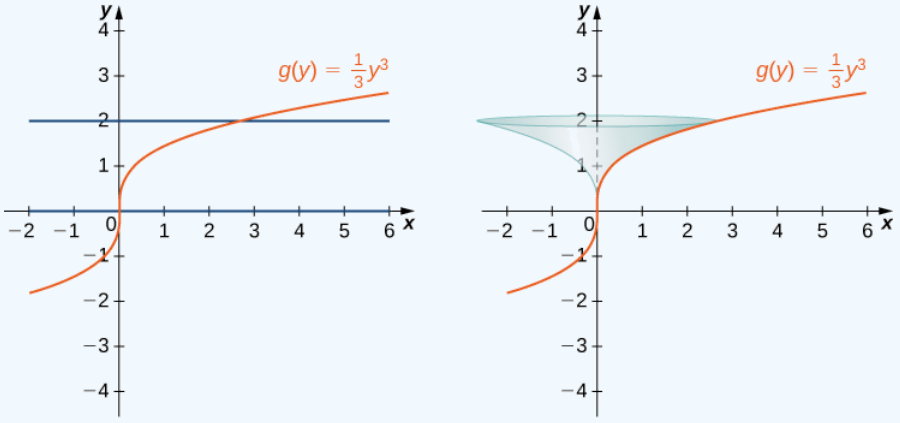

Figure 6.3.13a: The graph of $g(y)$.
Figure 6.3.13b: The surface of revolution.

We know that all surface area integrals share the form

$$S = \int 2\pi r\, ds.$$

If we decided to integrate with respect to $x$, then the entire integrand must be written in terms of $x$. The radius of rotation is $x_R - x_L = x - 0 = x$ and our choice for $ds$ would be

$$\begin{aligned} ds &= \sqrt{1+(y')^2}\,dx \\ &= \sqrt{1+\left(\frac{1}{3}(3x)^{-2/3}\cdot 3\right)^2}\,dx \\ &= \sqrt{1+\left((3x)^{-2/3}\right)^2}\,dx \\ &= \sqrt{1+(3x)^{-4/3}}\,dx \end{aligned}$$

and so the surface area of this solid of revolution would be computed using

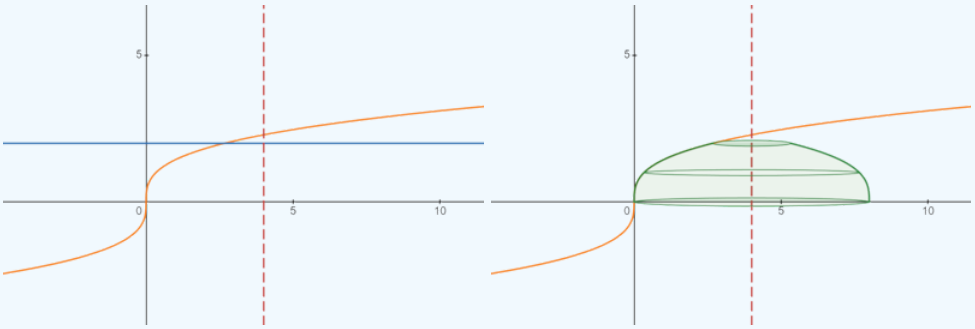
$$\begin{aligned} S &= \int_{x=0}^{x=8/3} 2\pi r\, ds \\ &= 2\pi \int_{x=0}^{x=8/3} x\sqrt{1+(3x)^{-4/3}}\,dx \end{aligned}$$

While we could evaluate this integral, it might be best to check if an integral in terms of $y$ is cleaner.

Solving for $x$, we have $x = \frac{1}{3}y^3$, so $x' = y^2$ and $(x')^2 = y^4$. Moreover, the radius of rotation is $x_R - x_L = \frac{1}{3}y^3 - 0 = \frac{1}{3}y^3$. Hence,

$$\begin{aligned} S &= \int_{y=0}^{y=2} 2\pi r\, ds \\ &= 2\pi \int_{y=0}^{y=2} \frac{1}{3}y^3\sqrt{1+y^4}\, dy \\ &= \frac{\pi}{6}\int_{u=1}^{u=17} \sqrt{u}\, du \qquad \text{(Let } u = 1+y^4 \implies du = 4y^3\, dy\text{, and change the limits of integration accordingly)} \\ &= \frac{\pi}{9}\cdot u^{3/2}\Big|_{u=1}^{u=17} \\ &= \frac{\pi}{9}\left(17^{3/2}-1\right) \end{aligned}$$

A sketch of the curve and solid is shown below.



b. Building the integral with respect to $y$ (I will leave building the integral with respect to $x$ for the interested reader), we get

$$\begin{aligned} S &= \int_{y=0}^{y=2} 2\pi r\, ds \\ &= 2\pi \int_{y=0}^{y=2} (x_R - x_L)\, ds \\ &= 2\pi \int_{y=0}^{y=2} \left(4-\frac{1}{3}y^3\right)\sqrt{1+y^4}\, dy \end{aligned}$$

Notice that the radius of rotation is the distance from the axis of rotation, $x = 4$, to the curve, $x = \frac{1}{3}y^3$. If you draw a radius line from the function to the axis of rotation, the *right* edge, $x_R$, is at $x = 4$, and the left edge, $x_L$, is at the curve, $x = \frac{1}{3}y^3$. This is why the value of $r$ is $4-\frac{1}{3}y^3$.

Also, note that $ds$ didn't change. When rotating about a line that is *not* an axis, the only factor that changes in the formula for the surface area integral is $r$ (because all you are doing is changing the radius of rotation).

## ? Checkpoint 6.3.7

Let $g(y) = \sqrt{9-y^2}$ over the interval $y \in [0,2]$. Find the surface area of the surface generated by revolving the graph of $g(y)$ around the $y$-axis.

**Answer**

$12\pi$

## Footnotes

[1] The process is identical, with the roles of $x$ and $y$ reversed.

[2] This property comes up again in later chapters.

[3] Note that some (or all) $\Delta y_i$ may be negative.

[4] To be clear, we defined the arc length of a given function over a *constant* interval using the dependent variable $L$, but we defined the arc length *function* over a *varying* interval using the dependent variable $s$.

[5] There is often a confusion as to why we use $s$ for the arc length function and $L$ for the arc length of a curve. Why not just use $s$ in both cases? In fact, wouldn't it make more sense to use $s$ for the arc length of a curve given that we used $s$ in Trigonometry for the arc length of the circle subtended by an angle $\theta$? The answer is more complex than most students care to hear, but since you are curious enough to investigate...

Recall that we arrived at the differential, $ds$, by allowing $s(x) = \int_a^x \sqrt{1+[f'(t)]^2}\,dt$. This was all to streamline the eventual arc length formula into the simple statement in Equation 6.3.1. Had we *also* used the dependent variable $s$ for this computed arc length, we would have arrived at

$$s = \int_{x=a}^{x=b} ds.$$

This would be completely nonsensical as we would be stating that the definite integral, *which is a constant*, is equal to $s$; however, if $s$ is constant, then its differential, $ds$, would be 0, and so $s \equiv 0$ always.

[6] I get it that this is obvious, but there is an actual reason for recognizing that this is a function of $x$. We will see why in a little bit.

[7] The choice of using the Right Endpoint Method as opposed to the Left Endpoint Method was completely arbitrary here, as was the decision to use $n = 10$ subintervals. In Differential Calculus, we were explicitly told what method to use and how many subintervals to consider, however, now that we are beyond that course, there will be times when *we* have to play the scientific investigator and make the decision of method and number of subintervals for ourselves.

[8] As was promised, here is another, equivalent form for $ds$.

[9] Another arbitrary choice.

[10] "Analytically" means "by hand."

[11] I promise, you *can* actually finish that first integral. It just takes some work, but it's worth the practice.

[12] Think of an ice cream cone with the pointy end cut off.

[13] The area of just the slanted outside surface of the frustum, not including the areas of the top or bottom faces.

[14] The phrase, "without loss of generality," is used quite extensively in mathematics. It means that, had the alternative situation occurred (in this case, had $r_1$ in our previous discussion been $f(x_i)$ and $r_2$ been $f(x_{i-1})$), the results (with the appropriate adjustments) would be the same.

[15] Those of you who are interested in the details should consult an advanced calculus text.

# 6.3E: Exercises

## Reading Questions

1. What does it mean for a function to be "continuously differentiable," and why is this a requirement for calculating arc length?
2. The formula for arc length is derived by approximating the curve with a series of straight line segments. What theorem is used to find the length of each of these small segments?
3. What is the formula for the arc length differential, $ds$, for a curve defined by $y = f(x)$?
4. What is a catenary, and what type of function is used to model it?
5. What is the general integral formula for the surface area of a surface of revolution, using the terms "radius of rotation" ($r$) and "arc length differential" ($ds$)?
6. When a line segment is revolved around an axis, it creates a band. What is the geometric name for this shape?
7. In the surface area integral, $S = \int 2\pi r ds$, how is the radius of rotation, $r$, defined?

**For exercises 1 - 3, find the length of the functions over the given interval.**

1) $y = 5x$ from $x = 0$ to $x = 2$

**Answer**

$s = 2\sqrt{26}$ units

2) $y = -\frac{1}{2}x + 25$ from $x = 1$ to $x = 4$

3) $x = 4y$ from $y = -1$ to $y = 1$

**Answer**

$s = 2\sqrt{17}$ units

4) Pick an arbitrary linear function $x = g(y)$ over any interval of your choice $(y_1, y_2)$. Determine the length of the function and then prove the length is correct by using geometry.

5) Find the surface area of the volume generated when the curve $y = \sqrt{x}$ revolves around the $x$-axis from $(1, 1)$ to $(4, 2)$, as seen here.

**Answer**

$A = \frac{\pi}{6}(17\sqrt{17} - 5\sqrt{5})$ units$^2$

6) Find the surface area of the volume generated when the curve $y = x^2$ revolves around the $y$-axis from $(1, 1)$ to $(3, 9)$.

**For exercises 7 - 16, find the lengths of the functions of $x$ over the given interval. If you cannot evaluate the integral exactly, use technology to approximate it.**

7) $y = x^{3/2}$ from $(0, 0)$ to $(1, 1)$

**Answer**

$s = \frac{13\sqrt{13} - 8}{27}$ units

8) $y = x^{2/3}$ from $(1, 1)$ to $(8, 4)$

9) $y = \frac{1}{3}(x^2 + 2)^{3/2}$ from $x = 0$ to $x = 1$

**Answer**

$s = \frac{4}{3}$ units

10) $y = \frac{1}{3}(x^2 - 2)^{3/2}$ from $x = 2$ to $x = 4$

11) [Technology Required] $y = e^x$ on $x = 0$ to $x = 1$

**Answer**

$s \approx 2.0035$ units

12) $y = \dfrac{x^3}{3} + \dfrac{1}{4x}$ from $x = 1$ to $x = 3$

13) $y = \dfrac{x^4}{4} + \dfrac{1}{8x^2}$ from $x = 1$ to $x = 2$

**Answer**

$s = \frac{123}{32}$ units

14) $y = \dfrac{2x^{3/2}}{3} - \dfrac{x^{1/2}}{2}$ from $x = 1$ to $x = 4$

15) $y = \frac{1}{27}(9x^2 + 6)^{3/2}$ from $x = 0$ to $x = 2$

**Answer**

$s = 10$ units

16) [Technology Required] $y = \sin x$ on $x = 0$ to $x = \pi$

**For exercises 17 - 26, find the lengths of the functions of $y$ over the given interval. If you cannot evaluate the integral exactly, use technology to approximate it.**

17) $y = \dfrac{5 - 3x}{4}$ from $y = 0$ to $y = 4$

**Answer**

$s = \frac{20}{3}$ units

18) $x = \frac{1}{2}(e^y + e^{-y})$ from $y = -1$ to $y = 1$

19) $x = 5y^{3/2}$ from $y = 0$ to $y = 1$

**Answer**

$s = \frac{1}{675}(229\sqrt{229} - 8)$ units

20) [Technology Required] $x = y^2$ from $y = 0$ to $y = 1$

21) $x = \sqrt{y}$ from $y = 0$ to $y = 1$

**Answer**

$s = \frac{1}{8}(4\sqrt{5} + \ln(9 + 4\sqrt{5}))$ units

22) $x = \frac{2}{3}(y^2 + 1)^{3/2}$ from $y = 1$ to $y = 3$

23) [Technology Required] $x = \tan y$ from $y = 0$ to $y = \frac{3}{4}$

**Answer**

$s \approx 1.201$ units

24) [Technology Required] $x = \cos^2 y$ from $y = -\frac{\pi}{2}$ to $y = \frac{\pi}{2}$

25) [Technology Required] $x = 4^y$ from $y = 0$ to $y = 2$

**Answer**

$s \approx 15.2341$ units

26) [Technology Required] $x = \ln(y)$ on $y = \dfrac{1}{e}$ to $y = e$

**For exercises 27 - 34, find the surface area of the volume generated when the following curves revolve around the $x$-axis. If you cannot evaluate the integral exactly, use your calculator to approximate it.**

27) $y = \sqrt{x}$ from $x = 2$ to $x = 6$

**Answer**

$A = \frac{49\pi}{3}$ units$^2$

28) $y = x^3$ from $x = 0$ to $x = 1$

29) $y = 7x$ from $x = -1$ to $x = 1$

**Answer**

$A = 70\pi\sqrt{2}$ units$^2$

30) [Technology Required] $y = \frac{1}{x^2}$ from $x = 1$ to $x = 3$

31) $y = \sqrt{4 - x^2}$ from $x = 0$ to $x = 2$

**Answer**

$A = 8\pi$ units$^2$

32) $y = \sqrt{4 - x^2}$ from $x = -1$ to $x = 1$

33) $y = 5x$ from $x = 1$ to $x = 5$

**Answer**

$A = 120\pi\sqrt{26}$ units$^2$

34) [Technology Required] $y = \tan x$ from $x = -\frac{\pi}{4}$ to $x = \frac{\pi}{4}$

**For exercises 35 - 42, find the surface area of the volume generated when the following curves revolve around the $y$-axis. If you cannot evaluate the integral exactly, use your calculator to approximate it.**

35) $y = x^2$ from $x = 0$ to $x = 2$

**Answer**

$A = \frac{\pi}{6}(17\sqrt{17} - 1)$ units$^2$

36) $y = \frac{1}{2}x^2 + \frac{1}{2}$ from $x = 0$ to $x = 1$

37) $y = x + 1$ from $x = 0$ to $x = 3$

**Answer**

$A = 9\sqrt{2}\pi$ units$^2$

38) [Technology Required] $y = \frac{1}{x}$ from $x = \frac{1}{2}$ to $x = 1$

39) $y = \sqrt[3]{x}$ from $x = 1$ to $x = 27$

**Answer**

$A = \frac{10\sqrt{10}\pi}{27}(73\sqrt{73} - 1)$ units$^2$

40) [Technology Required] $y = 3x^4$ from $x = 0$ to $x = 1$

41) [Technology Required] $y = \frac{1}{\sqrt{x}}$ from $x = 1$ to $x = 3$

**Answer**

$A \approx 25.645$ units$^2$

42) [Technology Required] $y = \cos x$ from $x = 0$ to $x = \frac{\pi}{2}$

43) The base of a lamp is constructed by revolving a quarter circle $y = \sqrt{2x - x^2}$ around the $y$-axis from $x = 1$ to $x = 2$, as seen here. Create an integral for the surface area of this curve and compute it.

**Answer**

$A = 2\pi$ units$^2$

44) A light bulb is a sphere with radius $1/2$ in. with the bottom sliced off to fit exactly onto a cylinder of radius $1/4$ in. and length $1/3$ in., as seen here. The sphere is cut off at the bottom to fit exactly onto the cylinder, so the radius of the cut is $1/4$ in. Find the surface area (not including the top or bottom of the cylinder).

45) [Technology Required] A lampshade is constructed by rotating $y = 1/x$ around the $x$-axis from $y = 1$ to $y = 2$, as seen here. Determine how much material you would need to construct this lampshade—that is, the surface area—accurate to four decimal places.

**Answer**

$10.5017$ units$^2$

46) [Technology Required] An anchor drags behind a boat according to the function $y = 24e^{-x/2} - 24$, where $y$ represents the depth beneath the boat and $x$ is the horizontal distance of the anchor from the back of the boat. If the anchor is $23$ ft below the boat, how much rope do you have to pull to reach the anchor? Round your answer to three decimal places.

47) [Technology Required] You are building a bridge that will span $10$ ft. You intend to add decorative rope in the shape of $y = 5|\sin((x\pi)/5)|$, where $x$ is the distance in feet from one end of the bridge. Find out how much rope you need to buy, rounded to the nearest foot.

**Answer**

$23$ ft

**For exercise 48, find the exact arc length for the following problems over the given interval.**

48) $y = \ln(\sin x)$ from $x = \frac{\pi}{4}$ to $x = \frac{3\pi}{4}$. (Hint: Recall trigonometric identities.)

49) Draw graphs of $y = x^2, y = x^6$, and $y = x^{10}$. For $y = x^n$, as $n$ increases, formulate a prediction on the arc length from $(0, 0)$ to $(1, 1)$. Now, compute the lengths of these three functions and determine whether your prediction is correct.

**Answer**

$2$

50) Compare the lengths of the parabola $x = y^2$ and the line $x = by$ from $(0, 0)$ to $(b^2, b)$ as $b$ increases. What do you notice?

51) Solve for the length of $x = y^2$ from $(0, 0)$ to $(1, 1)$. Show that $x = \dfrac{y^2}{2}$ from $(0, 0)$ to $(2, 2)$ is twice as long. Graph both functions and explain why this is so.

**Answer**

Answers may vary

52) [Technology Required] Which is longer between $(1, 1)$ and $(2, \frac{1}{2})$: the hyperbola $y = \dfrac{1}{x}$ or the graph of $x + 2y = 3$?

53) Explain why the surface area is infinite when $y = 1/x$ is rotated around the $x$-axis for $1 \leq x < \infty$, but the volume is finite.

**Answer**

For more information, look up Gabriel's Horn.

**In exercises 54 - 57, solve each problem.**

54) [Technology Required] A chain hangs from two posts $2$m apart to form a catenary described by the equation $y = 2\cosh(x/2) - 1$. Find the slope of the catenary at the left fence post.

**Answer**

$-0.521095$

55) A telephone line is a catenary described by $y = a\cosh(x/a)$. Find the ratio of the area under the catenary to its arc length. Does this confirm your answer for the previous question?

56) [Technology Required] A chain hangs from two posts four meters apart to form a catenary described by the equation $y = 4\cosh(x/4) - 3$. Find the total length of the catenary (arc length).

57) [Technology Required] A high-voltage power line is a catenary described by $y = 10\cosh(x/10)$. Find the ratio of the area under the catenary to its arc length. What do you notice?

**Answer**

$10$

58) [Technology Required] Find the arc length of $y = 1/x$ from $x = 1$ to $x = 4$.

59) [Technology Required] Find the surface area of the shape created when rotating the curve in the previous exercise from $x = 1$ to $x = 2$ around the $x$-axis.

60) [Technology Required] Find the arc length of $\ln x$ from $x = 1$ to $x = 2$.

# 6.4: Work

**Note to the Instructor (click to expand)**

This section covers the physics of mechanical work, including spring-mass problems (as an introduction to force), and the work to lift fluid and non-fluid objects.

---

To succeed in this section, you'll need to use some skills from previous courses. While you should already know them, this is the first time they've been required. You can review these skills in CRC's Corequisite Codex. If you have a support class, it might cover some, **but not all**, of these topics.

**Prerequisite Skills and Support Topics (click to expand)**

The following is a list of prerequisite skills (all of which can be reviewed in CRC's Corequisite Codex) needed for this section **that have not already been mentioned in any previous section**. If you are enrolled in a course with a Support section, some (but definitely not all) of these topics might be covered or reviewed in the Support section of your course.

- **Sets and Numbers**
  - Scientific Notation: Some homework problems, particularly those involving gravitational force, use scientific notation for physical constants (e.g., Homework Problem #18).
- **Linear Functions**
  - Linear Models: Hooke's Law, which states that the force required to stretch a spring is proportional to the distance stretched ($F = kx$), is a fundamental linear model used in this section.
- **Trigonometry**
  - Trigonometric Functions - Right Triangle Definition: This is needed to resolve a force vector into its components. In Example 1.6.1, the horizontal component of a force applied at an angle is found using cosine.

---

The following is a list of learning objectives for this section.

**Learning Objectives (click to expand)**

- Calculate the work done by a variable force acting along a line.
- Calculate the work done in lifting objects.
- Calculate the work done in pumping a liquid from one height to another.

COSUMNES RIVER COLLEGE MATHEMATICS

To access the Hawk A.I. Tutor, you will need to be logged into your campus Gmail account.

---

In this section, we turn our attention to work. The concept of work is the backbone of many Physics problems, and we will investigate the energy expenditure in several increasingly complex situations.

## Work Done by a Constant Force

You have likely read about **Newton's Second Law of Motion**, which states that **force** (which is often intuitively defined as a push or a pull on an object) is the product of an object's mass and its acceleration. That is,

$$F = ma.$$

For our current conversation, we will only consider the acceleration due to gravity, traditionally denoted $g$. Therefore, we replace $a$ with $g$ to get.[1]

$$F = mg. \tag{6.4.1}$$

When a force moves an object, we say the force does **work** on the object. In other words, work can be thought of as the amount of energy it takes to move an object through a distance. According to Physics, work can be expressed as the product of force and distance. That is,

$$W = Fd. \tag{6.4.2}$$

You would not be wrong to state that we could combine Equations 6.4.1 and 6.4.2 to arrive at

$$W = mgd; \tag{6.4.3}$$

however, the choice to do our mathematics with Equation 6.4.2 or Equation 6.4.3 will depend on which measurement system we are given.

### The Metric and U.S. Customary Systems

There are two measurement systems we deal with in science - the **English system** (also known as the **U.S. Customary System**) and the **metric system** (also known as the **International System of Units**, or the **S.I. System**). We work with both systems in this course. For simplicity, the following table gives the unit names in each system (the base unit for time in both systems is the second).

| | **Distance** $d$ | **Mass** $m$ | **Gravitational Constant (at sea level)** $g$ | **Force** $F = mg$ | **Work** $W = Fd$ |
|---|---|---|---|---|---|
| **English System** | foot (ft) | slug | $\approx 32.2 \left(\frac{\text{ft}}{\text{s}^2}\right)$ | pound $\left(\frac{\text{slug}\cdot\text{ft}}{\text{s}^2}\right)$ | foot-pound $(\text{ft}\cdot\text{lbs})$ |
| **Metric System** | meter (m) | kilogram (kg) | $\approx 9.8 \left(\frac{\text{m}}{\text{s}^2}\right)$ | newton $\left(\frac{\text{kg m}}{\text{s}^2} \equiv \text{N}\right)$ | joule $\left(\frac{\text{kg m}}{\text{s}^2}\cdot\text{m} = \text{N m}\right)$ |

In the English system, the unit of force is the pound and the unit of distance is the foot. Therefore, according to Equation 6.4.2, work is given in **foot-pounds**. It is incredibly rare in the English system to state the mass of an object - instead, the *force* the Earth is exerting on that object (which we call pounds) is typically given. Therefore, when asked to compute the work done in a scenario involving the English system, you will use Equation 6.4.2.

In the metric system, kilograms and meters are used. The unit of force is called the **newton**.[2] Hence, according Equation 6.4.2, work is given in **newton-meters**. Unlike the English system, the metric system has a special unit name for work - the **joule**. Therefore, you can use the terminology "joule" and "newton-meter" interchangeably. Another difference between the English and metric systems is that, in the metric system, you will often be given the object's mass. Therefore, when computing work in scenarios involving the metric system, you will use Equation 6.4.3.

### ✔ Example 6.4.1: The Work Required to Push a Lawn Mower

Suppose you are pushing a lawn mower along flat, even ground. The handle makes an angle of $60°$ with the ground and you are pushing with a constant force of 40 lbs over a distance of 80 feet. Compute the amount of work done on the lawn mower over this distance.

**Solution**

Only the horizontal component of the force adds work to the mower in this situation (the vertical component is wasted by pushing the mower into the ground), so we first need to compute the horizontal force we are applying to the mower. Suppose the force of 40 lbs is along the handle. In that case, the horizontal component of the force is computed using some spectacular Right Triangle Trigonometry:

$$F_h = F\cos(60^\circ) = (40 \text{ lbs})(0.5) = 20 \text{ lbs}.$$

Hence, according to Equation 6.4.2, the work done on the mower over an 80-foot stretch of ground is

$$W = F_h \cdot d = (20 \text{ lbs}) \cdot (80 \text{ feet}) = 160 \text{ ft-lbs}.$$

Notice in Example **6.4.1** that I said "the work done on *the mower*," not "the work *we* did." When moving the mower, we are imparting energy to the mower; however, the energy we are imparting to the mower might not be (and, in this case, is not) the same as the energy we are expending in the process of moving the mower. Part of the energy we are using is pushing downward (into the ground) as we move the mower. This energy is not imparted to the mower and is completely wasted in the entire process. The only way to counteract this waste is to either push the mower from closer to ground level or build a mower tall enough that we are pushing from chest level. The issue with the former is that we would have to crawl or lean over the entire time, and the issue with the latter is that we would have to push with more force because the mower would be larger.

Before diving into an example, we need to discuss the concept of density briefly. The **volumetric density** (referred to as **density**) of a three-dimensional object is its mass per unit volume. In some disciplines, this is also known as the object's **specific mass**. If we let $\rho$, $m$, and $V$ be the density, mass, and volume, respectively, then

$$\rho = \frac{m}{V} \implies m = \rho V. \tag{6.4.4}$$

**Caution: Tricky Wording**

What most people refer to as "density" in the U.S. Customary System is the **weight density** (also referred to as the **specific weight**) of the object. That is, since density is mass per unit volume, the units for density in the U.S. Customary System are technically slugs per cubic foot; however, you would search far and wide before you found anyone stating that the density of water is approximately $1.9 \text{ slugs/ft}^3$. Most people, even in scientific circles, cite the density of water (at $32^\circ F$ as approximately $62.4 \text{ lbs/ft}^3$.

This "loose" definition of density is scientifically inaccurate as the pound is a force and, therefore, the quantity being used is *force* per unit volume - not *mass* per unit volume. To avoid confusion, I use "weight density" when referring to force per unit volume. The Greek letter $\gamma$ (lowercase "gamma") is traditionally used when referring to the weight density of an object, so I will use that convention in this text as well.

In light of the Cautionary statement above, it's best to (re)summarize our current knowledge in a table.

| | **Distance** $d$ | **Mass** $m$ | **Gravitational Constant (at sea level)** $g$ | **Force** $F = mg$ | **Density** $\rho = \frac{m}{d^3}$ | **Weight Density** $\gamma = \rho g = \frac{F}{d^3}$ |
|---|---|---|---|---|---|---|
| **English System** | foot (ft) | slug | $\approx 32.2 \left(\frac{\text{ft}}{\text{s}^2}\right)$ | pound $\left(\frac{\text{slug-ft}}{\text{s}^2}\right)$ | $\left(\frac{\text{slugs}}{\text{ft}^3}\right)$ | $\left(\frac{\text{lbs}}{\text{ft}^3}\right)$ |
| **Metric System** | meter (m) | kilogram (kg) | $\approx 9.8 \left(\frac{\text{m}}{\text{s}^2}\right)$ | newton $\left(\frac{\text{kg m}}{\text{s}^2} \equiv \text{N}\right)$ | $\left(\frac{\text{kg}}{\text{m}^3}\right)$ | $\left(\frac{\text{N}}{m^3}\right)$ |

The equations in 6.4.4 will become incredibly important as we move forward. It's best to get used to them now.

### Example 6.4.2: The Work Required to Lift a Bucket (Part 1)

A 5-liter bucket is filled with water. By itself, the bucket has a mass of 2 kg.[3] How much work is done in lifting the bucket from the bottom of a 60-meter-deep well? (Water has a density of $\rho_{\text{w}} = 1000\,\text{kg/m}^3$, where $1\,\text{L} = 0.001\,\text{m}^3$).

**Solution**

The total mass of the bucket, including water, is

$$\begin{aligned} m &= m_{\text{b}} + m_{\text{w}} \\ &= m_{\text{b}} + \rho_{\text{w}} \cdot V_{\text{w}} \\ &= 2\,\text{kg} + 1\frac{\text{kg}}{\cancel{\text{L}}} \cdot 5\,\cancel{\text{L}} \\ &= 7\,\text{kg} \end{aligned}$$

Hence, according to Equation 6.4.3, the work done in lifting the bucket is

$$\begin{aligned} W &= m \cdot g \cdot d \\ &\approx (7\,\text{kg})\left(9.8\,\frac{\text{m}}{\text{s}^2}\right)(60\,\text{m}) \\ &= 4116\,\frac{\text{kg m}}{\text{s}^2} \cdot \text{m} \\ &= 4116\,\text{N-m} \\ &= 4116\,\text{J} \end{aligned}$$

The end of Example 6.4.2 showcases a couple important "unit concepts." First, the newton is often denoted $N$, and the joule is often denoted $J$. Second, force in the metric system (which is measured in newtons) is $\frac{\text{kg m}}{\text{s}^2}$.

## Work Done by a Variable Force

When we have a constant force, things are pretty easy. It is rare, however, for a force to be constant. For example, the work done to compress (or elongate) a spring varies depending on how far the spring has already been compressed (or stretched). We look at springs in more detail later in this section.

Suppose we have a variable force, $F(x)$, that moves an object in a positive direction along the $x$-axis from point $a$ to point $b$. To calculate the work done, we partition the interval $[a, b]$ and estimate the work done over each subinterval. So, for $i = 0, 1, 2, \ldots, n$, let $P = \{x_i\}$ be a regular partition of the interval $[a, b]$, and for $i = 1, 2, \ldots, n$, choose an arbitrary point $x_i^* \in [x_{i-1}, x_i]$. To calculate the work done to move an object from point $x_{i-1}$ to point $x_i$, we assume the force is roughly constant over this short interval, and use $F(x_i^*)$ to approximate the force used to move the object through this interval. The work done over the interval $[x_{i-1}, x_i]$, then, is given by

$$W_i \approx F(x_i^*)(x_i - x_{i-1}) = F(x_i^*)\Delta x.$$

Therefore, the work done over the interval $[a, b]$ is approximately

$$W \approx \sum_{i=1}^{n} W_i \approx \sum_{i=1}^{n} F(x_i^*)\Delta x.$$

Taking the limit of this expression as $n \to \infty$ gives us the exact value for work:

$$W = \lim_{n\to\infty}\sum_{i=1}^{n} F(x_i^*)\Delta x$$

$$= \int_a^b F(x)dx.$$

Thus, we can define work as follows.

**Definition: Work**

If a variable force $F(x)$ moves an object in a positive direction along the $x$-axis from point $a$ to point $b$, then the **work** done on the object is

$$W = \int_a^b F(x)\,dx. \tag{6.4.5}$$

Note that if $F$ is constant, the integral evaluates to $F\cdot(b-a) = Fd$, which is Equation 6.4.2.

**Example 6.4.3**

When a particle is located a distance $x$ meters from the origin, a force of $\cos\left(\frac{\pi x}{3}\right)$ newtons acts on it. Compute the amount of work done on the particle in moving it between the following $x$-values.

a. From $x = 1$ to $x = 2$.
b. From $x = 1$ to $x = 1.5$.
c. From $x = 1.5$ to $x = 2$.

**Solution**

a. From Equation 6.4.5, we get

$$W = \int_1^2 \cos\left(\frac{\pi x}{3}\right)dx$$

$$= \frac{3}{\pi}\sin\left(\frac{\pi x}{3}\right)\Big|_{x=1}^{x=2}$$

$$= \frac{3}{\pi}\left(\sin\left(\frac{2\pi}{3}\right) - \sin\left(\frac{\pi}{3}\right)\right)$$

$$= \frac{3}{\pi}\left(\frac{\sqrt{3}}{2} - \frac{\sqrt{3}}{2}\right)$$

$$= 0$$

Therefore, no work is done on the particle in moving it from $x = 1$ to $x = 2$. If this seems strange, the next two parts *might* clarify what happened.

b. Repeating the setup from part a, we get

$$\begin{aligned} W &= \int_1^{3/2} \cos\left(\frac{\pi x}{3}\right) dx \\ &= \frac{3}{\pi}\sin\left(\frac{\pi x}{3}\right)\Big|_{x=1}^{x=3/2} \\ &= \frac{3}{\pi}\left(\sin\left(\frac{\pi}{2}\right) - \sin\left(\frac{\pi}{3}\right)\right) \\ &= \frac{3}{\pi}\left(1 - \frac{\sqrt{3}}{2}\right) \\ &\approx 0.1279 \end{aligned}$$

Thus, work of approximately $0.1279$ joules have been imparted to the particle over the interval $[1, 1.5]$.

c. For our final calculation, we get

$$\begin{aligned} W &= \int_{3/2}^{2} \cos\left(\frac{\pi x}{3}\right) dx \\ &= \frac{3}{\pi}\sin\left(\frac{\pi x}{3}\right)\Big|_{x=3/2}^{x=2} \\ &= \frac{3}{\pi}\left(\sin\left(\frac{2\pi}{3}\right) - \sin\left(\frac{\pi}{2}\right)\right) \\ &= \frac{3}{\pi}\left(\frac{\sqrt{3}}{2} - 1\right) \\ &\approx -0.1279 \end{aligned}$$

In this case, work of approximately $-0.1279$ joules have been extracted from the particle over the interval $[1.5, 2]$. The work done during the first 0.5 meters of movement is undone in the second 0.5 meter. This explains why the total amount of work done over the interval $[1, 2]$ is zero.[4]

## Spring-Mass Problems and Hooke's Law

Now let's look at the specific example of the work done to compress or elongate a spring. Consider a block attached to a horizontal spring.[5] The block moves back and forth as the spring stretches and compresses. This type of problem is called a **spring-mass system**, and it is a common topic in Differential Equations. Although, in the real world, we would have to account for the friction between the block and the surface on which it is resting, we ignore this here and assume the block is resting on a frictionless surface. When the spring is at its natural length (at rest), the system is said to be at **equilibrium**. In this state, the spring is neither elongated nor compressed, and in this **equilibrium position** the block does not move until some force is introduced. We orient the system such that $x = 0$ corresponds to the equilibrium position (Figure $6.4.1$).

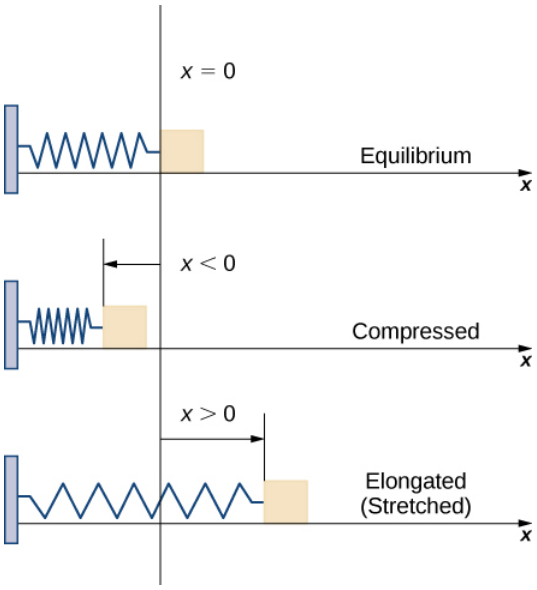

Figure 6.4.1: A block attached to a horizontal spring at equilibrium, compressed, and elongated.

According to Hooke's law, the force required to compress or stretch a spring from an equilibrium position is given by

$$F(x) = kx, \tag{6.4.6}$$

where $k > 0$ depends on the physical characteristics of the spring and, as such, is called the **spring constant**. We can use this information to calculate the work done to compress or elongate a spring, as shown in the following example.

### Example 6.4.4: The Work Required to Stretch or Compress a Spring

Suppose it takes a force of $10$ N (in the *negative* direction) to compress a spring $0.2$ m from the equilibrium position. How much work is done to *stretch* the spring $0.5$ m from the equilibrium position?

**Solution**

First, we find the spring constant, $k$.

When $x = -0.2$, we know $F(x) = -10$, so

$$\begin{aligned} F(x) &= kx \\ \Rightarrow \quad -10 &= k(-0.2) \\ \Rightarrow \quad k &= 50 \end{aligned}$$

and $F(x) = 50x$. Then, to calculate work, we integrate the force function, obtaining

$$\begin{aligned} W &= \int_a^b F(x)\,dx \\ &= \int_0^{0.5} 50x\,dx \\ &= 25x^2\Big|_0^{0.5} \\ &= 6.25. \end{aligned}$$

The work done to stretch the spring $0.5$ m from equilibrium is $6.25$ J.

**? Checkpoint 6.4.4**

Suppose it takes a force of 8 lb to stretch a spring 6 in. from the equilibrium position. How much work is done to stretch the spring 1 ft from the equilibrium position?

**Answer**

8 ft-lb

## Lifting Distributed Masses

In Example 6.4.2, we lifted a simple object - a bucket filled with water. We can consider this bucket as a point mass. A **point mass** appropriately represents any object whenever its size, shape, and structure are irrelevant in a given context. That is, the shape and size of the bucket never entered our conversation when talking about lifting it - the mathematics doesn't change if we draw the bucket as a car, a dog, or a point. In fact, in the context of work, buckets, cars, dogs, books, baseballs, and dumbbells are all examples of point masses. There is no difference in the work done lifting them if we compress them to a single point with the same mass.

A **distributed mass**, on the other hand, refers to a system where the mass is spread out or distributed over a certain region or volume, instead of being concentrated at a single point. It is often used to describe objects or systems that have a continuous mass distribution. For our purposes, we will consider an object to be a distributed mass if we cannot consider it a point mass. Therefore, chains, cables, and ropes are all common examples of distributed masses in this text.

Computing the work to lift an object that can be considered a point mass is simple - replace the object with a point having the same mass and compute the work necessary to lift it using Equations 6.4.2, 6.4.3, or 6.4.5.

Computing the work to lift an object that cannot be considered a point mass (and is, therefore, a distributed mass) requires a little more thinking. For example, if we had a cable of length $l$ hanging over a cliff of height $h$ that we needed to pull to the top, we would consider that cable to be a distributed mass. As we pull the cable, the weight we are lifting (the force) becomes less and less because there is less cable to lift. How do we account for this phenomenon mathematically?

As with most of our processes in mathematics, we start by drawing a picture to help us conceptualize what is going on.

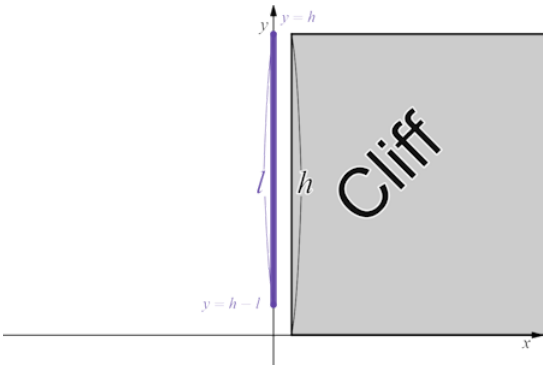

Figure 6.4.2: A cable hanging from the edge of a cliff.

I like to place the bottom of the cable on the $x$-axis, but if you prefer (or your instructor prefers) to place the $x$-axis at the top of the cliff, the only difference will be minor perspective changes.

Lifting the entire cable to the top of the cliff is the same as lifting small segments (slices) of the cable to the top, one by one. That is, we will partition the $y$-interval, $[h-l, h]$ into $n$ equally-spaced subintervals. We need to compute the work required to lift the $i^{\text{th}}$ slice to the top of the cliff. From Equation 6.4.2, we know that

$$W_i = F_i d_i,$$

where $F_i$ is the weight of the $i^{\text{th}}$ slice and $d_i$ is the distance the $i^{\text{th}}$ slice needs to move to get to the top of the cliff. If we let $y_i^* \in [y_{i-1}, y_i]$, then the distance from the $i^{\text{th}}$ slice to the top of the cliff is approximately $d_i^* = h - y_i^*$ (see Figure 6.4.3 below).

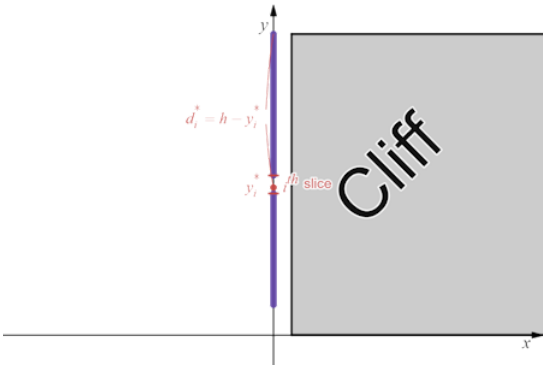

Figure **6.4.3**: Lifting the $i^{\text{th}}$ slice a distance $d_i^*$.

That is,

$$W_i \approx F_i d_i^* = F_i (h - y_i^*) .$$

Moreover, if $F$ represents the force (weight) of the entire cable we need to lift, we can compute the unit force of the cable, $\frac{F}{l}$, and multiply that result by the width of the $i^{\text{th}}$ slice, $\Delta y$, to arrive at

$$F_i = \frac{F}{l} \cdot \Delta y.$$

A little unit analysis shows that our argument is solid: since the unit length is in pounds per foot and $\Delta y$ is in feet, the result is in pounds - a force!

In the end, the work to lift the $i^{\text{th}}$ slice is

$$W_i \approx F_i d_i^* = F_i (h - y_i^*) = \frac{F}{l} \Delta y (h - y_i^*) .$$

As we have done many times up to this point, we would sum all of these little pieces of work, which creates a Riemann sum, take the limit as $n \to \infty$, and arrive at an integral; however, rather than providing a closed-form integral, it's best to derive a proper integral for each situation - this is because these types of problems can vary wildly, and knowing the derivation will provide you with a *much* better understanding of the physics in the background.

### Example **6.4.5**: The Work Required to Lift a Bucket (Part 2)

A chain is attached to a 5-liter bucket which is filled with molten gold. The bucket has a mass of 80 kg (it has to be made of strong stuff to hold molten metals). The chain has a mass of 3.1 kg per meter. How much work is done in lifting the bucket from the bottom of a 60-meter-deep well? (Molten gold has a density of $\rho_g = 17,310\,\text{kg/m}^3$, and $1,000\,\text{L} = 1\,\text{m}^3$).

**Solution**

It is wise to treat this problem as lifting two separate masses - the point mass (the bucket of molten gold) and the distributed mass (the chain).

**Work to Lift the Point Mass**

The work to lift the bucket is

$$\begin{aligned} W_{\mathrm{b}} &= F_{\mathrm{b}} d_{\mathrm{b}} \\ &= \left(m_{\mathrm{b}} + m_{\mathrm{g}}\right) g d_{\mathrm{b}} \\ &\approx \left(80\,\mathrm{kg} + \rho_{\mathrm{g}} V_{\mathrm{g}}\right)\left(9.8\,\mathrm{m/s^2}\right)\left(60\,\mathrm{m}\right) \\ &\approx \left(80\,\mathrm{kg} + 17,310\,\tfrac{\mathrm{kg}}{\mathrm{m^3}} \cdot 5\,\mathrm{L}\right)\left(9.8\,\tfrac{\mathrm{m}}{\mathrm{s^2}}\right)\left(60\,\mathrm{m}\right) \\ &= \left(80\,\mathrm{kg} + 17,310\,\tfrac{\mathrm{kg}}{\cancel{\mathrm{m^3}}} \cdot 5\,\tfrac{1}{1000}\,\cancel{\mathrm{m^3}}\right)\left(9.8\,\tfrac{\mathrm{m}}{\mathrm{s^2}}\right)\left(60\,\mathrm{m}\right) \\ &= \left(80\,\mathrm{kg} + 86.55\,\mathrm{kg}\right)\left(9.8\,\tfrac{\mathrm{m}}{\mathrm{s^2}}\right)\left(60\,\mathrm{m}\right) \\ &= \left(166.55\right)\left(9.8\right)\left(60\right)\tfrac{\mathrm{kg\,m}}{\mathrm{s^2}} \cdot \mathrm{m} \\ &\approx 97,931\,\mathrm{J} \end{aligned}$$

**Work to Lift the Distributed Mass**

The work to lift the $i^{\text{th}}$ slice of the chain is

$$W_i = F_i d_i = m_i g d_i \approx \left(9.8\frac{\mathrm{m}}{\mathrm{s^2}}\right) m_i d_i.$$

Assuming the bottom of the well is the $x$-axis and $y_i^* \in [y_{i-1}, y_i]$, then $d_i \approx d_i^* = 60\,\mathrm{m} - y_i^*\,\mathrm{m} = (60 - y_i^*)\,\mathrm{m}$. Therefore,

$$W_i \approx \left(9.8\frac{\mathrm{m}}{\mathrm{s^2}}\right) m_i \left(60 - y_i^*\right)\,\mathrm{m}.$$

To compute the mass of the $i^{\text{th}}$ slice, we need the mass per unit length of the chain and then we need to multiply that by the width of the $i^{\text{th}}$ slice. Luckily, we were told the mass per unit length of the chain was $3.1$ kg per meter. Thus, $m_i = \left(3.1\,\tfrac{\mathrm{kg}}{\cancel{\mathrm{m}}}\right)\Delta y\,\cancel{\mathrm{m}} = 3.1\Delta y\,\mathrm{kg}$. Therefore,

$$W_i \approx \left(9.8\frac{\mathrm{m}}{\mathrm{s^2}}\right)\left(3.1\Delta y\,\mathrm{kg}\right)\left(60 - y_i^*\right)\,\mathrm{m} = (9.8)(3.1)(60 - y_i^*)\Delta y\,\mathrm{J}.$$

Forming a Riemann sum, taking the limit, and transposing it into an integral, we get the work to lift the chain (by itself) to be

$$\begin{aligned} W_{\mathrm{c}} &= \int_{y=0}^{y=60} (9.8)(3.1)(60 - y)\,dy \\ &= 30.38\left(60y - \tfrac{y^2}{2}\right)\Big|_0^{60} \\ &= 54,684\,\mathrm{J} \end{aligned}$$

**Total Work**

We now need to add these two computations.

$$W = W_{\mathrm{b}} + W_{\mathrm{c}} \approx 152,615\,\mathrm{J}.$$

The limits of the integral in Example $6.4.5$ can be read as, "We are moving slices starting at the height of $y = 0$ and ending at the height of $y = 60$." It is important to understand this. If the well were 60 meters deep, but we were only lifting the chain 10 meters, then we would consider the length of the chain from $y = 0$ to $y = 50$ as a point mass being lifted only 10 meters. We would then lift the upper 10 meters using the integral

$$\int_{y=50}^{y=60} (9.8)(3.1)(60-y)\,dy,$$

because it is only that section that loses mass as we lift the chain.

## Lifting Point Masses that Gain or Lose Mass

Suppose an object is a point mass that starts with a mass of $m_{\text{initial}}$ and ends with a mass $m_{\text{final}}$, where $m_{\text{initial}} \neq m_{\text{final}}$ and where the gain or loss of mass is linear (i.e., the mass gains or loses the same amount of mass per unit length). For purposes of this discussion, we will assume that the object has lost mass. Still, you only need to adjust a single part of your thought process to accommodate an object gaining mass.

To see how we approach this type of problem, it's best to consider an example.

### Example 6.4.6: The Work Required to Lift a Bucket (Part 3)

A chain is attached to a 5-liter *leaky* bucket which is filled with molten gold. The leak is such that the molten gold drains from the bucket at a constant rate, and by the time the bucket reaches the top of the well, the bucket is 80% empty. The bucket has a mass of 80 kg. The chain has a mass of 3.1 kg per meter. How much work is done in lifting the bucket from the bottom of a 60-meter-deep well? (Molten gold has a density of $\rho_g = 17,310\ \text{kg/m}^3$, and $1,000\,\text{L} = 1\,\text{m}^3$).

**Solution**

Again, we treat this as two separate problems - the leaky point mass (the leaky bucket of molten gold) and the distributed mass (the chain).

**Work to Lift the Leaky Point Mass**

From our previous work, we know that the bucket and the molten gold have a combined mass of $166.55$ kg; however, we are now told that the bucket loses 80% of mass due to molten gold by the time it reaches the top of the well. Since it drained at a constant rate, we can safely say that the bucket loses $0.80\left(\frac{1731}{20}\right) = 69.24$ kg of mass over the 60-meter lift. That is, it loses $1.154$ kg per meter.

Consider partitioning the interval $[0, 60]$ into $n$ equally-spaced subintervals. The distance to move the mass from $y_{i-1}$ to $y_i$ is $\Delta y$. Therefore, the work needed to lift this mass in this small interval is

$$W_i = F_i d_i = m_i g d_i = m_i \left(9.8\,\frac{\text{m}}{\text{s}^2}\right)\Delta y.$$

If $y_i^* \in [y_{i-1}, y_i]$, then we can consider the mass of the object in the small interval $[y_{i-1}, y_i]$ to approximately be

$$m_i^* \approx m_{\text{initial}} - m_{\text{lost}} = 166.55\,\text{kg} - 1.154\,\frac{\text{kg}}{\cancel{\text{m}}}\,y_i^*\,\cancel{\text{m}} = (166.55 - 1.154y_i^*)\,\text{kg}.$$

Thus, the work to lift the leaky bucket is

$$\begin{aligned} W_{\text{b}} &= \int_{y=0}^{y=60} (166.55 - 1.154y)(9.8)\,dy \\ &= 9.8\left(166.55y - 0.577y^2\right)\Big|_{y=0}^{y=60} \\ &= 77,574.84\,\text{J} \end{aligned}$$

**Work to Lift the Distributed Mass**

Nothing changes about this part, so we can use the 54,684 J computed previously.

**Total Work**

The total work done is

$$W = W_b + W_c = 132,258.84\,\text{J}.$$

A quick logic check helps here. Notice this is *less* work than before. That should make sense as we are lifting a bucket with a hole!

## Lifting Fluids

Consider the work done to pump water (or some other liquid) out of a tank. Pumping problems are more complicated than spring problems because many of the calculations depend on the shape and size of the tank. In addition, instead of being concerned about the work done to move a single mass, we are looking at the work done to move a volume of water. It takes more work to move the water from the bottom of the tank (which has to be moved farther) than moving the water from the top of the tank.

We examine the process in the context of a cylindrical tank, then look at a couple of examples using tanks of different shapes.

Assume a cylindrical tank of radius $4$ m and height $10$ m is filled to a depth of $8$ m. How much work does it take to pump all the water over the top edge of the tank?

The first thing we need to do is define a frame of reference. We let $x$ represent the vertical distance below the top of the tank. That is, we orient the $x$-axis vertically, with the origin at the top of the tank and the downward direction being positive (Figure 6.4.4).[6]

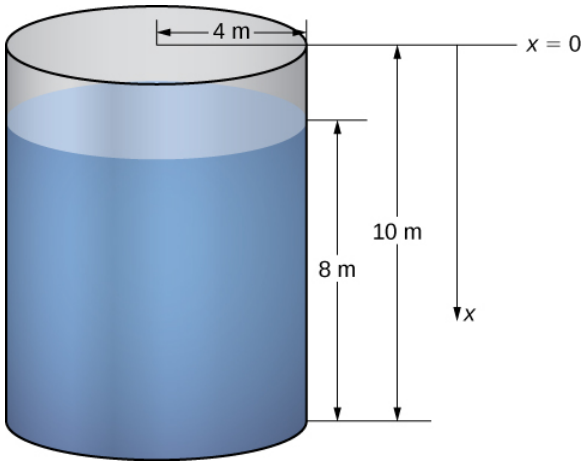

Figure 6.4.4: How much work is needed to empty a tank partially filled with water?

Using this coordinate system, the water extends from $x = 2$ to $x = 10$.[7] Therefore, we partition the interval $[2, 10]$ and look at the work required to lift each individual "layer" of water. So, for $i = 0, 1, 2, \ldots, n$, let $P = x_i$ be a regular partition of the interval $[2, 10]$, and for $i = 1, 2, \ldots, n$, choose an arbitrary point $x_i^* \in [x_{i-1}, x_i]$. Figure 6.4.5 shows a representative layer.[8]

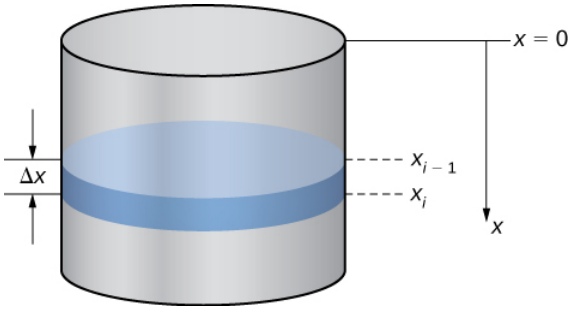

Figure 6.4.5: A representative layer of water.

In pumping problems, the force required to lift the water to the top of the tank is the force required to overcome gravity, so it is equal to the weight of the water. In the metric system, the density of water is $\rho_w = 1000\,\text{kg/m}^3$, which means the *weight density* is

$$\gamma_w = \rho_w g \approx 1000\,\frac{\text{kg}}{\text{m}^3} \cdot 9.8\,\frac{\text{m}}{\text{s}^2} = 9800\,\frac{\text{kg m/s}^2}{\text{m}^3} = 9800\,\frac{\text{N}}{\text{m}^3}. \tag{6.4.7}$$

In the U.S. Customary System, the *weight density* of water is $\gamma_w \approx 62.4\,\text{lb/ft}^3$.

Calculating the volume of each layer gives us the weight. In this case, we have

$$V = \pi(4)^2 \Delta x = 16\pi\Delta x.$$

The force needed to lift each layer is

$$F = 9800 \cdot 16\pi\Delta x = 156,800\pi\Delta x.$$

Note that this step becomes a little more difficult if we have a noncylindrical tank (that will be our next example).

We also need to know the distance the water must be lifted. Based on our choice of coordinate systems, we can use $x_i^*$ as an approximation of the distance the layer must be lifted.[9] Then the work to lift the $i^{\text{th}}$ layer of water $W_i$ is approximately[10]

$$W_i \approx 156,800\pi x_i^* \Delta x.$$

Adding the work for each layer, we see the approximate work to empty the tank is given by

$$\begin{aligned} W &\approx \sum_{i=1}^{n} W_i \\ &\approx \sum_{i=1}^{n} 156,800\pi x_i^* \Delta x. \end{aligned}$$

This is a Riemann sum, so taking the limit as $n \to \infty$, we get

$$\begin{aligned} W &= \lim_{n\to\infty} \sum_{i=1}^{n} 156,800\pi x_i^* \Delta x \\ &= 156,800\pi \int_2^{10} x\, dx \\ &= 156,800\pi \left(\frac{x^2}{2}\right)\Big|_2^{10} \\ &= 7,526,400\pi \\ &\approx 23,644,883. \end{aligned}$$

The work required to empty the tank is approximately 23,650,000 J.[11]

For pumping problems, the calculations vary depending on the shape of the tank or container. The following problem-solving strategy lays out a step-by-step process for solving pumping problems.

### Problem-Solving Strategy: Solving Pumping Problems

1. Sketch a picture of the tank and select an appropriate frame of reference.
2. Calculate the volume of a representative layer of water.
3. Multiply the volume by the weight-density of water to get the force.
4. Calculate the distance the layer of water must be lifted.
5. Multiply the force and distance to estimate the work needed to lift the layer of water.
6. Sum the work required to lift all the layers. This expression is an estimate of the work needed to pump out the desired amount of water, and it is in the form of a Riemann sum.
7. Take the limit as $n \to \infty$ and evaluate the resulting integral to get the exact work required to pump out the desired amount of water.

We now apply this problem-solving strategy in an example with a noncylindrical tank.

## Example 6.4.7: A Pumping Problem with a Noncylindrical Tank

Assume a tank in the shape of an inverted cone, with height $12$ ft and base radius $4$ ft. The tank is full to start with, and water is pumped over the upper edge of the tank until the height of the water remaining in the tank is $4$ ft. How much work is required to pump out that amount of water?

**Solution**

The tank is depicted in Figure 6.4.6. As we did in the example with the cylindrical tank, we orient the $x$-axis vertically, with the origin at the top of the tank and the downward direction being positive.

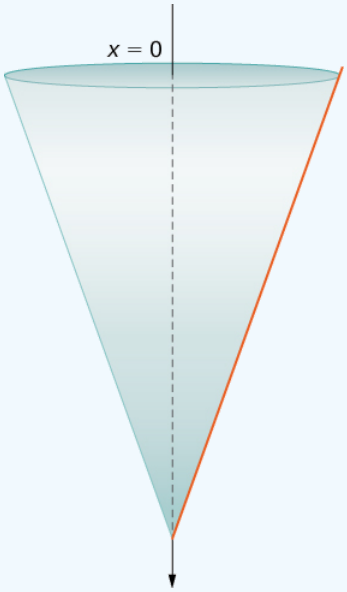

Figure 6.4.6: A water tank shaped like an inverted cone.

The tank starts out full and ends with $4$ ft of water left, so, based on our chosen frame of reference, we need to partition the interval $[0, 8]$. Then, for $i = 0, 1, 2, \ldots, n$, let $P = x_i$ be a regular partition of the interval $[0, 8]$, and for $i = 1, 2, \ldots, n$, choose an arbitrary point $x_i^* \in [x_{i-1}, x_i]$. We can approximate the volume of a layer by using a disk, then use similar triangles to find the radius of the disk (Figure 6.4.7).

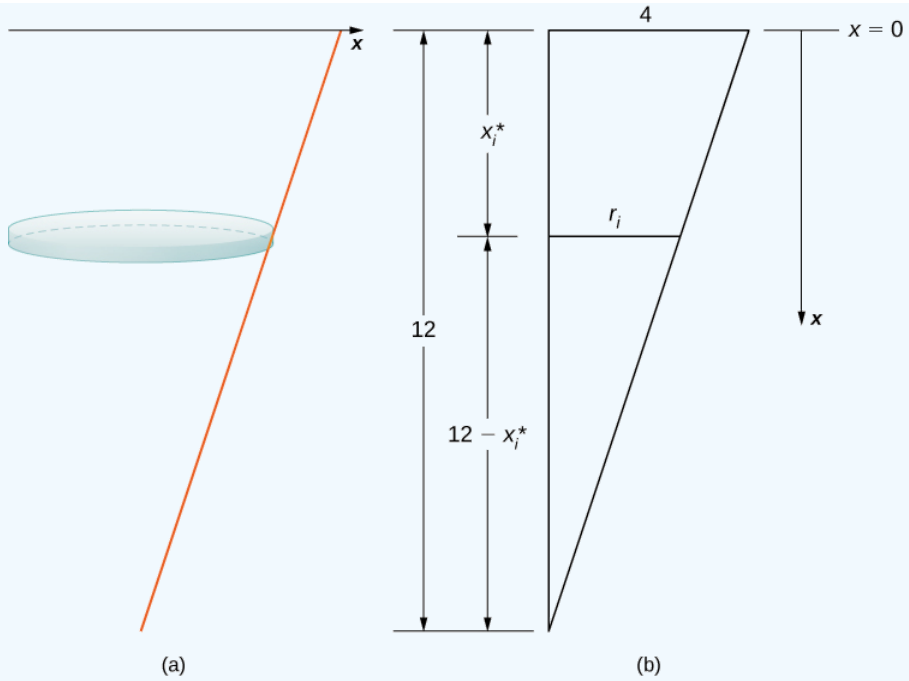

Figure **6.4.7**: Using similar triangles to express the radius of a disk of water.

From properties of similar triangles, we have

$$\begin{aligned} \frac{r_i}{12 - x_i^*} &= \frac{4}{12} = \frac{1}{3} \\ \Longrightarrow \quad 3r_i &= 12 - x_i^* \\ \Longrightarrow \quad r_i &= \frac{12 - x_i^*}{3} \\ \Longrightarrow \quad r_i &= 4 - \frac{x_i^*}{3}. \end{aligned}$$

Then the volume of the disk is

$$V_i = \pi \left(4 - \frac{x_i^*}{3}\right)^2 \Delta x.$$

The *weight density* of water is $62.4\ \text{lb/ft}^3$, so the force needed to lift each layer is approximately

$$F_i \approx 62.4\pi \left(4 - \frac{x_i^*}{3}\right)^2 \Delta x$$

Based on the diagram, the distance the water must be lifted is approximately $x_i^*$ feet, so the approximate work needed to lift the layer is

$$W_i \approx 62.4\pi x_i^* \left(4 - \frac{x_i^*}{3}\right)^2 \Delta x.$$

Summing the work required to lift all the layers, we get an approximate value of the total work:

$$W = \sum_{i=1}^{n} W_i \approx \sum_{i=1}^{n} 62.4\pi x_i^* \left(4 - \frac{x_i^*}{3}\right)^2 \Delta x.$$

Taking the limit as $n \to \infty$, we obtain

$$\begin{aligned} W &= \lim_{n\to\infty}\sum_{i=1}^{n} 62.4\pi x_i^*(4-\frac{x_i^*}{3})^2\Delta x \\ &= \int_0^8 62.4\pi x\left(4-\frac{x}{3}\right)^2 dx \\ &= 62.4\pi\int_0^8 x\left(16-\frac{8x}{3}+\frac{x^2}{9}\right) dx \\ &= 62.4\pi\int_0^8 \left(16x-\frac{8x^2}{3}+\frac{x^3}{9}\right) dx \\ &= 62.4\pi\left[8x^2-\frac{8x^3}{9}+\frac{x^4}{36}\right]\Big|_0^8 \\ &= 10,649.6\pi \\ &\approx 33,456.7. \end{aligned}$$

It takes approximately $33,450$ ft-lb of work to empty the tank to the desired level.[12]

**? Checkpoint 6.4.7**

A tank is shaped like an inverted cone, with height $10$ ft and a base radius of 6 ft. The tank is filled to a depth of 8 ft to start with, and water is pumped over the upper edge of the tank until 3 ft of water remains in the tank. How much work is required to pump out that amount of water?

**Answer**

Approximately $43,255.2$ ft-lb

## Footnotes

[1] In more complex systems, you could have several factors contributing different accelerations. For example, in a car, you experience acceleration due to gravity (otherwise, your car would begin to rise in the air) and acceleration due to the movement of the car.

[2] For a great diversion into why some argue the unit of force in the metric system is the Newton, and not the newton, I encourage the reader to take a look at this excerpt by the Australian physicist, Don Koks.

[3] We do not say, "The bucket has a *weight* of 2 kg," because kilograms is a measure of mass - weight is a measure of force. Mass is unchangeable (unless something gets added to or removed from the object); however, weight *can* change depending on the mass of the planet and your position on that planet. That is, according to Equation 6.4.1, the 2-kg bucket has a *weight* of

$$F = mg \approx (2\,\text{kg})\left(9.8\,\frac{\text{kg m}}{\text{s}^2}\right) \approx 19.6\,\text{N}$$

at sea level on the Earth. However, on the surface of Jupiter, the bucket will still have a mass of 2 kg, but its weight would be

$$F = mg \approx (2\,\text{kg})\left(24.5\,\frac{\text{kg m}}{\text{s}^2}\right) = 49\,\text{N}.$$

[4] As confounding as this might seem, from a physics perspective it is correct. The "tripping" point for most students is a perspective issue. For example, if a book is lifted straight up 3 feet and then lowered the same 3 feet, it makes sense to all of us that *we* expended energy in the lifting and lowering process; however, we need to change our perspective when it comes to work problems and physics. Instead of asking how much work (energy) have *we* have spent, we need to focus on how much work (energy) the

object (the book) has gained or lost over that process. This concept is related to the conservation of energy. When you lift the object, you provide potential energy to it, which is converted from the energy you expend. When you lower the object back down, the potential energy is converted back into the same amount of energy you initially provided. No additional work is done on the object in the overall process.

[5] The choice of having the spring oriented horizontally is not essential. We could have written this entire derivation assuming the spring was attached to the ceiling and oriented vertically. In that case, the block would have been connected to the bottom of the spring. It is important to clarify that, in the vertical orientation, the equilibrium position is the point where the **restorative force** of the spring is counteracted by the weight of the mass. That is, the equilibrium position would be where the spring stretches to once the mass is attached.

[6] Your instructor might take a different approach for the frame of reference for fluid-work problems. For example, it is perfectly acceptable to place the *bottom* of the tank on the $x$-axis (centered at the origin) and still consider the upward direction as the positive $y$-axis - this is how I normally teach it.

[7] Or, from $y = 0$ to $y = 8$, if your instructor is using the standard coordinate system.

[8] Again, if your instructor is using the standard coordinate system, then the intervals are $[0, 8]$.

[9] If using the standard coordinate system, the layer we are considering is at a "height" (from the bottom of the tank) of $y_i^*$ m. To move this layer to the top of the tank, we must move it $(10 - y_i^*)$ m.

[10] Again, if using the standard coordinate system, the work to lift this $i^{\text{th}}$ layer is $W_i = F_i \times d_i \approx 156,800\pi \times (10 - y_i^*)$.

[11] You would have reached this same value using the standard coordinate system and computing

$$W = \int_{y=0}^{y=8} 156,800\pi(10 - y)\, dy.$$

Conceptually, you would read this as, "I am lifting plates of fluid, starting at a height of 0 meters (the bottom), and the final plate is at a height of 8 meters. Each plate weighs $156,800$ newtons and is being lifted $10$ minus its height in meters."

[12] Done using the standard coordinate system, we would place the *bottom* of the tank on the $x$-axis, centered at the origin. We would need to lift the slices of water starting with the slice at $y = 4$ feet and ending with the slice at $y = 12$ feet (leaving the bottom 4 feet). The volume of the $i^{\text{th}}$ slice is

$$V_i = \text{surface area} \times \Delta y = \pi r_i^2 \Delta y.$$

Visually, we can see that $r_i = x_i^*$, but we need a relationship between $x_i^*$ and $y_i^*$ to continue. Luckily, we can find the equation of the edge of the tank. It's a line going through the origin having slope $\frac{12}{4} = 3$. Hence, $y_i^* = 3x_i^*$. That is, $x_i^* = \frac{y_i^*}{3}$. Therefore,

$$V_i = \pi \left(\frac{y_i^*}{3}\right)^2 \Delta y = \frac{\pi}{9}(y_i^*)^2 \Delta y.$$

Hence, the force needed to lift this layer is

$$F_i \approx 62.4 \cdot \frac{\pi}{9}(y_i^*)^2 \Delta y.$$

We need to lift this layer $(12 - y_i^*)$ feet, so the work done moving this specific layer is

$$W_i \approx 62.4 \cdot \frac{\pi}{9}(y_i^*)^2 (12 - y_i^*) \Delta y.$$

Thus,

$$W = 62.4 \cdot \frac{\pi}{9} \int_{y=4}^{y=12} y^2(12 - y)\, dy$$

This will become approximately 33,456.7 ft-lb.

# 6.4E: Exercises

## Reading Questions

1. What is the formula for the work done by a constant force $F$ over a distance $d$?
2. How is work calculated when the force, $F(x)$, is not constant over the interval from $x = a$ to $x = b$?
3. What is Hooke's Law, and what does the spring constant $k$ represent?
4. What is the key difference between a "point mass" and a "distributed mass" in the context of work problems?
5. When setting up an integral to find the work required to pump a liquid out of a tank, what three quantities must be determined for a representative "slice" of the liquid?
6. Why is the force required to wind up a hanging cable considered a variable force?
7. What is the difference between mass density and weight density, and which one is used to calculate the force on a slice of water in a pumping problem?

### Basic Work Problems

**For exercises 1 - 6, find the work done.**

1) Find the work done when a constant force $F = 12$ lb moves a chair from $x = 0.9$ to $x = 1.1$ ft.

2) How much work is done when a person lifts a $50$ lb box of comics onto a truck that is $3$ ft off the ground?

**Answer**

$W = 150$ ft-lb

3) What is the work done lifting a $20$ kg child from the floor to a height of $2$ m? (Note that $1$ kg equates to $9.8$ N)

4) Find the work done when you push a box along the floor $2$ m, when you apply a constant force of $F = 100$ N.

**Answer**

$W = 200$ J

5) Compute the work done for a force $F = \dfrac{12}{x^2}$ N from $x = 1$ to $x = 2$ m.

6) What is the work done moving a particle from $x = 0$ to $x = 1$ m if the force acting on it is $F = 3x^2$ N?

**Answer**

$W = 1$ J

### Spring Work Problems

7) A $12$-in. spring is stretched to $15$ in. by a force of $75$ lb. What is the spring constant?

8) A spring has a natural length of $10$ cm. It takes $2$ J to stretch the spring to $15$ cm. How much work would it take to stretch the spring from $15$ cm to $20$ cm?

**Answer**

$W = 6$ J

9) A $1$-m spring requires $10$ J to stretch the spring to $1.1$ m. How much work would it take to stretch the spring from $1$ m to $1.2$ m?

10) A spring requires $5$ J to stretch the spring from $8$ cm to $12$ cm, and an additional $4$ J to stretch the spring from $12$ cm to $14$ cm. What is the natural length of the spring?

**Answer**

The natural length is $5$ cm.

11) A shock absorber is compressed 1 in. by a weight of 1 ton. What is the spring constant?

12) A force of $F = (20x - x^3)$ N stretches a nonlinear spring by $x$ meters. What work is required to stretch the spring from $x = 0$ to $x = 2$ m?

**Answer**

$W = 36$ J

### Cable and Chain Work Problems

13) Find the work done by winding up a hanging cable of length $100$ ft and *weight density* $5$ lb/ft.

14) For the cable in the preceding exercise, how much work is done to lift the cable $50$ ft?

**Answer**

$W = 18,750$ ft-lb

15) For the cable in the preceding exercise, how much additional work is done by hanging a $200$ lb weight at the end of the cable?

### Pyramid & Satellite/Rocket Work Problems

16) [Technology Required] A pyramid of height $500$ ft has a square base $800$ ft by $800$ ft. Find the area $A$ at height $h$. If the rock used to build the pyramid weighs approximately $w = 100\ \text{lb/ft}^3$, how much work did it take to lift all the rock?

**Answer**

$W = \frac{32}{3} \times 10^9$ ft-lb

17) [Technology Required] For the pyramid in the preceding exercise, assume there were $1000$ workers each working $10$ hours a day, $5$ days a week, $50$ weeks a year. If each of the workers, on average, lifted ten 100-lb rocks $2$ ft/hr, how long did it take to build the pyramid?

18) [Technology Required] The force of gravity on a mass $m$ is $F = -((GMm)/x^2)$ newtons. For a rocket of mass $m = 1000$ kg, compute the work to lift the rocket from $x = 6400$ to $x = 6500$ km. (Note: $G = 6 \times 10^{-17}\ \text{N m}^2/\text{kg}^2$ and $M = 6 \times 10^{24}$ kg.)

**Answer**

$W = 8.65 \times 10^5$ J

19) [Technology Required] For the rocket in the preceding exercise, find the work to lift the rocket from $x = 6400$ to $x = \infty$.

### Pumping Work Problems

20) [Technology Required] Find the work required to pump all the water out of a cylinder that has a circular base of radius $5$ft and height $200$ ft. Use the fact that the *weight density* of water is $62$ lb/ft$^3$.

21) [Technology Required] Find the work required to pump all the water out of the cylinder in the preceding exercise if the cylinder is only half full.

**Answer**

$W = 23.25\pi$ million ft-lb

22) [Technology Required] How much work is required to pump out a swimming pool if the area of the base is $800\ \text{ft}^2$, the water is $4$ ft deep, and the top is $1$ ft above the water level? Assume that the *weight density* of water is $62$ lb/ft$^3$.

23) A cylinder of depth $H$ and cross-sectional area $A$ stands full of water at density $\rho$. Compute the work to pump all the water to the top.

**Answer**

$W = \frac{A\rho H^2}{2}$

24) For the cylinder in the preceding exercise, compute the work to pump all the water to the top if the cylinder is only half full.

25) A cone-shaped tank has a cross-sectional area that increases with its depth: $A = \frac{\pi r^2 h^2}{H^3}$. Show that the work to empty it is half the work for a cylinder with the same height and base.

**Answer**

Answers may vary.

# 6.5: Hydrostatic Force and Pressure

**Note to the Instructor (click to expand)**

This topic flows naturally from Work. It's a short section, but can be entertaining and strangely useful.

---

To succeed in this section, you'll need to use some skills from previous courses. While you should already know them, this is the first time they've been required. You can review these skills in CRC's Corequisite Codex. If you have a support class, it might cover some, **but not all**, of these topics.

**Prerequisite Skills and Support Topics (click to expand)**

- **Linear Functions**
  - Equations of Lines: In problems involving non-rectangular submerged surfaces, such as the trapezoidal dam in Example 1.7.2, it is necessary to find a linear function for the width of the plate, $w(x)$. This often involves finding the equation of the line that forms the slanted edge of the object.

---

The following is a list of learning objectives for this section.

**Learning Objectives (click to expand)**

- Find the hydrostatic force against a submerged vertical plate.

## Hydrostatic Force and Pressure

Let's look at the force and pressure exerted on an object submerged in a liquid. **Pressure**, $P$, is force per unit area. That is,

$$P = \frac{F}{A}. \tag{6.5.1}$$

Therefore, in the English system, we have pounds per square foot (or, perhaps more commonly, pounds per square inch, denoted psi). In the metric system, we have newtons per square meter, also called **pascals**.

We begin with the simple case of a plate of area $A$ submerged horizontally in water at a depth $s$ (Figure 6.5.1). The force exerted on the plate is simply the weight of the water above it, which gives

$$F = \rho A s, \tag{6.5.2}$$

where $\rho$ is the volumetric density of water. To find the **hydrostatic pressure** - that is, the pressure exerted by water on a submerged object - we substitute $F$ from Equation 6.5.2 into Equation 6.5.1 so that

$$P = \frac{F}{A} = \frac{\rho A s}{A} = \rho s.$$

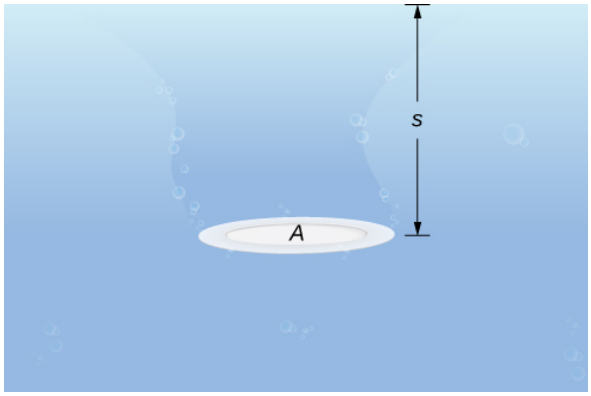

Figure 6.5.1: A plate submerged horizontally in water.

By Pascal's principle, the pressure at a given depth is the same in all directions, so it does not matter if the plate is submerged horizontally or vertically. So, as long as we know the depth, we know the pressure. We can apply Pascal's principle to find the force exerted on surfaces, such as dams, that are oriented vertically. We *cannot*, however, apply the Equation 6.5.2 directly, because the depth varies from point to point on a vertically-oriented surface. So, as we have done many times before, we form a partition, a Riemann sum, and, ultimately, a definite integral to calculate the force.

Suppose a thin plate is submerged in water. We choose our frame of reference such that the $x$-axis is oriented vertically, with the downward direction being positive, and point $x = 0$ corresponding to a logical reference point.[1] Let $s(x)$ denote the depth at point $x$. Note we often let $x = 0$ correspond to the surface of the water. In this case, depth at any point is given by $s(x) = x$. However, in some cases we may want to select a different reference point for $x = 0$, so we proceed with the development in the more general case. Finally, let $w(x)$ denote the width of the plate at the point $x$.

Assume the top edge of the plate is at point $x = a$ and the bottom edge of the plate is at point $x = b$. Then, for $i = 0, 1, 2, \ldots, n$, let $P = \{x_i\}$ be a regular partition of the interval $[a, b]$, and for $i = 1, 2, \ldots, n$, choose an arbitrary point $x_i^* \in [x_{i-1}, x_i]$. The partition divides the plate into several thin, rectangular strips (Figure 6.5.2).

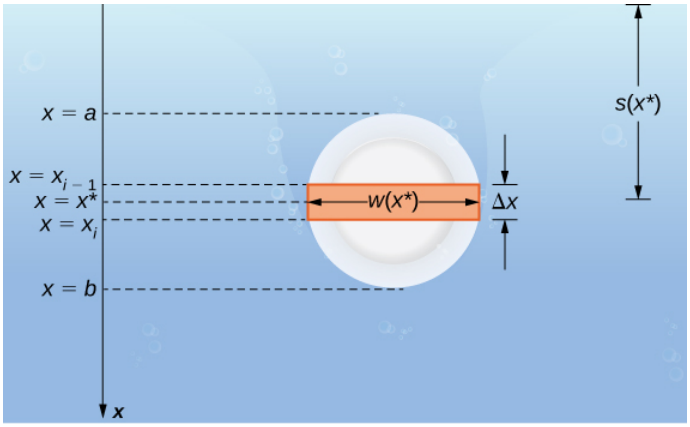

Figure 6.5.2: A thin plate submerged vertically in water.

Let's now estimate the force on a representative strip. If the strip is thin enough, we can treat it as if it is at a constant depth, $s(x_i^*)$. We then have

$$F_i = \rho A s = \rho[w(x_i^*)\Delta x]s(x_i^*).$$

Adding the forces, we get an estimate for the force on the plate:

$$F \approx \sum_{i=1}^{n} F_i = \sum_{i=1}^{n} \rho[w(x_i^*)\Delta x]s(x_i^*).$$

This is a Riemann sum, so taking the limit gives us the exact force. We obtain

$$F = \lim_{n\to\infty} \sum_{i=1}^{n} \rho[w(x_i^*)\Delta x]s(x_i^*) = \int_a^b \rho w(x)s(x)\,dx. \tag{6.5.3}$$

Evaluating this integral gives us the force on the plate. We summarize this in the following problem-solving strategy.

### Problem-Solving Strategy: Finding Hydrostatic Force

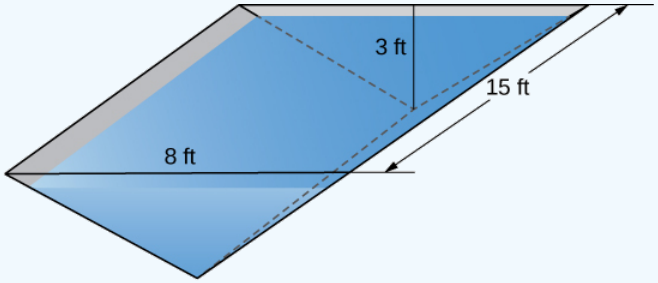
1. Sketch a picture and select an appropriate frame of reference. (Note that if we select a frame of reference other than the one used earlier, we may have to adjust Equation 6.5.3 accordingly.)
2. Determine the depth and width functions, $s(x)$ and $w(x)$.
3. Determine the *weight density* of whatever liquid with which you are working. The *weight density* of water is $62.4\,\text{lb/ft}^3$, or $9800\,\text{N/m}^3$.
4. Use the equation to calculate the total force.

### Example 6.5.1: Finding Hydrostatic Force

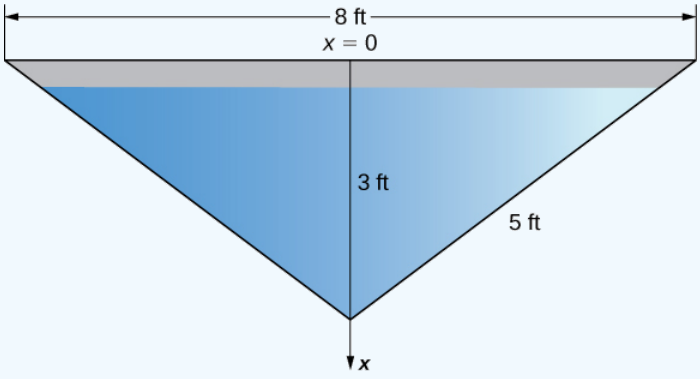
A water trough 15 ft long has ends shaped like inverted isosceles triangles, with a base of 8 ft and a height of 3 ft. Find the force on one end of the trough if the trough is full of water.

**Solution**

Figure 6.5.3 shows the trough and a more detailed view of one end.



(a)



(b)

Figure 6.5.3*a*: A water trough with a triangular cross-section.
Figure 6.5.3*b*: Dimensions of one end of the water trough.

Select a frame of reference with the $x$-axis oriented vertically and the downward direction being positive. Select the top of the trough as the point corresponding to $x = 0$. The depth function, then, is $s(x) = x$. Using similar triangles, we see that $w(x) = 8 - \frac{8}{3}x$. Now, the *weight density* of water is approximately $62.4\,\text{lb/ft}^3$, so applying Equation 6.5.3, we obtain

$$
\begin{aligned}
F &= \int_a^b \rho w(x) s(x)\, dx \\
&= \int_0^3 62.4 \left(8 - \frac{8}{3}x\right) x\, dx \\
&= 62.4 \int_0^3 \left(8x - \frac{8}{3}x^2\right) dx \\
&= 62.4 \left[4x^2 - \frac{8}{9}x^3\right] \Big|_0^3 \\
&\approx 748.8.
\end{aligned}
$$

The water exerts a force of approximately 748.8 lb on the end of the trough.

**Checkpoint 6.5.1**

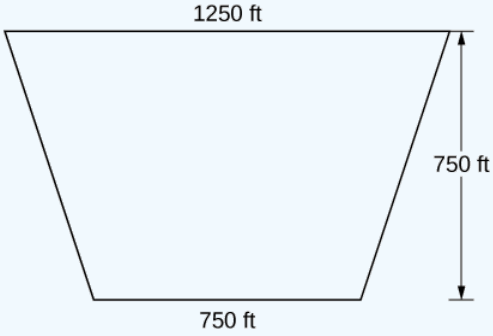
A water trough 12 m long has ends shaped like inverted isosceles triangles, with a base of 6 m and height of 4 m. Find the force on one end of the trough if the trough is full of water.

**Solution**

$156,800$ N

**Example 6.5.2: Finding Hydrostatic Force**

We now turn our attention to the Hoover Dam. The actual dam is arched rather than flat, but we are going to make some simplifying assumptions to help us with the calculations. Assume the face of the Hoover Dam is shaped like an isosceles trapezoid with a lower base of 750 ft, upper base of 1250 ft, and a height of 750 ft (see the following figure).



When the reservoir is full, Lake Mead's maximum depth is about 530 ft, and the lake's surface is about 10 ft below the top of the dam (see the following figure).

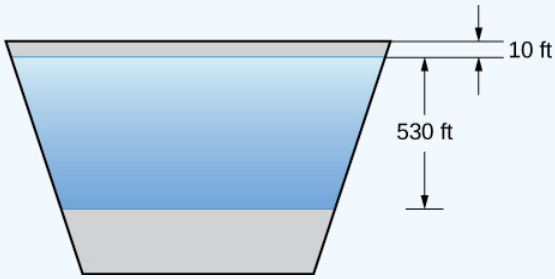


Figure 6.5.4: A simplified model of the Hoover Dam with assumed dimensions.

a. Find the force on the face of the dam when the reservoir is full.
b. The southwest United States has been experiencing a drought, and the surface of Lake Mead is about 125 ft below where it would be if the reservoir were full. What is the force on the face of the dam under these circumstances?

**Solution**

a. We begin by establishing a frame of reference. As usual, we choose to orient the $x$-axis vertically, with the downward direction being positive. This time, however, we will let $x = 0$ represent the top of the dam, rather than the water's surface. When the reservoir is full, the surface of the water is $10$ ft below the top of the dam, so $s(x) = x - 10$ (see the following figure).

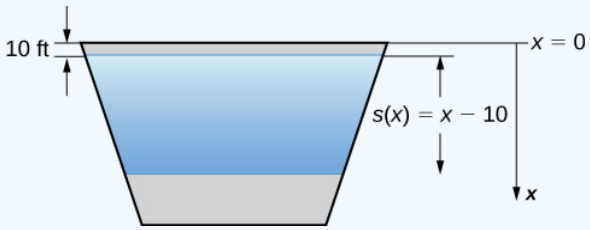

Figure 6.5.5: We first choose a frame of reference.

To find the width function, we again turn to similar triangles, as shown in the figure below.

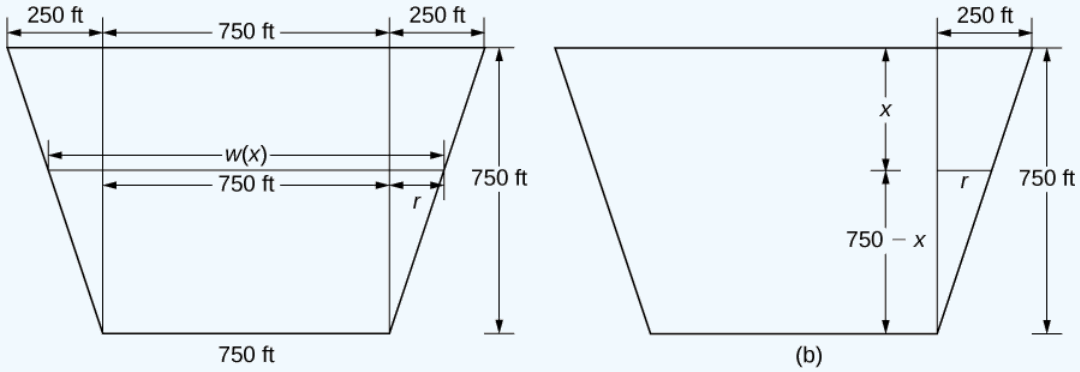

Figure 6.5.6: We use similar triangles to determine a function for the width of the dam. (a) Assumed dimensions of the dam; (b) highlighting the similar triangles.

The figure shows that $w(x) = 750 + 2r$. Using properties of similar triangles, we get $r = 250 - \frac{1}{3}x$. Thus,

$$w(x) = 1250 - \frac{2}{3}x$$

Using a *weight density* of $62.4\,\text{lb/ft}^3$ and applying Equation 6.5.3, we get

$$\begin{aligned} F &= \int_a^b \rho\, w(x) s(x)\, dx \\ &= \int_{10}^{540} 62.4 \left(1250 - \frac{2}{3}x\right)(x-10)\, dx \\ &= 62.4 \int_{10}^{540} -\frac{2}{3}(x^2 - 1885x + 18750)\, dx \\ &= -62.4 \left(\frac{2}{3}\right)\left(\frac{x^3}{3} - \frac{1885x^2}{2} + 18750x\right)\Big|_{10}^{540} \\ &\approx 8,832,245,000 \text{ lb} \\ &= 4,416,122.5 \text{ tons.} \end{aligned}$$

Note the change from pounds to tons ($2000$lb = $1$ ton).

b. This changes our depth function, $s(x)$, and our limits of integration. We have $s(x) = x - 135$. The lower limit of integration is 135. The upper limit remains $540$. Evaluating the integral, we get

$$\begin{aligned} F &= \int_a^b \rho\, w(x) s(x)\, dx \\ &= \int_{135}^{540} 62.4 \left(1250 - \frac{2}{3}x\right)(x-135)\, dx \\ &= -62.4(\frac{2}{3}) \int_{135}^{540} (x-1875)(x-135)\, dx \\ &= -62.4 \left(\frac{2}{3}\right) \int_{135}^{540} (x^2 - 2010x + 253125)\, dx \\ &= -62.4 \left(\frac{2}{3}\right)\left(\frac{x^3}{3} - 1005x^2 + 253125x\right)\Big|_{135}^{540} \\ &\approx 5,015,230,000 \text{ lb} \\ &= 2,507,615 \text{ tons.} \end{aligned}$$

**? Checkpoint 6.5.2**

When the reservoir is at its average level, the surface of the water is about 50 ft below where it would be if the reservoir were full. What is the force on the face of the dam under these circumstances?

**Solution**

Approximately 7,164,520,000 lb or 3,582,260 tons

## Footnotes

[1] As before, you could treat this entire subsection using the standard coordinate system. The reader is trusted to be able to derive the relevant mechanics.

# 6.5E: Exercises

## Reading Questions

1. What is the definition of pressure, and what are its common units in the English and metric systems?
2. What is the formula for the force exerted on a plate of area $A$ submerged horizontally at a depth $s$?
3. According to Pascal's principle, if you know the pressure at a specific depth, do you need to worry about the orientation (horizontal or vertical) of a surface at that depth to determine the pressure on it?
4. In the integral for hydrostatic force, $F = \int_a^b \rho w(x) s(x) dx$, what do the functions $w(x)$ and $s(x)$ represent?
5. What is the approximate weight density of water in lb/ft$^3$?
6. When setting up a hydrostatic force problem, why is it important to first sketch a picture and establish a frame of reference?

### Hydrostatic Force and Pressure

1) [Technology Required] A rectangular dam is $40$ ft high and $60$ ft wide. Compute the total force $F$ on the dam when

a. the surface of the water is at the top of the dam and

b. the surface of the water is halfway down the dam.

**Answer**

a. $3,000,000$ lb,
b. $749,000$ lb

# 6.6: Moments and Centers of Mass

**Note to the Instructor (click to expand)**

This is the typical moments and centers of mass topic. There is nothing out of the ordinary here from other texts with the exception of its placement. Since it is an application of intergration, I have moved it from its traditional place (later in the course) to the first chapter. Exercises from this material will occur throughout many sections from this point forward.

---

To succeed in this section, you'll need to use some skills from previous courses. While you should already know them, this is the first time they've been required. You can review these skills in CRC's Corequisite Codex. If you have a support class, it might cover some, **but not all**, of these topics.

**Prerequisite Skills and Support Topics (click to expand)**

- **Graphing Functions**
  - Symmetry: The Symmetry Principle is a key tool in this section. Recognizing if a region is symmetric about the x-axis, y-axis, or origin can significantly simplify the process of finding the centroid.

---

The following is a list of learning objectives for this section.

**Learning Objectives (click to expand)**

- Determine the mass of a one-dimensional object from its linear density function.
- Determine the mass of a two-dimensional circular object from its radial density function.
- Find the center of mass of objects distributed along a line.
- Locate the center of mass of a thin plate.
- Use symmetry to help locate the centroid of a thin plate.
- Apply the theorem of Pappus for volume.

In this section, we consider centers of mass (also called centroids, under certain conditions) and moments. The basic idea of the center of mass is a balancing point. Many of us have seen performers spin plates on the ends of sticks. The performers try to keep several spinning without allowing them to drop. If we look at a single plate (without spinning it), there is a sweet spot where it balances perfectly on the stick. If we put the stick anywhere other than that sweet spot, the plate does not balance and falls to the ground. (That is why performers spin the plates; the spin helps keep the plates from falling even if the stick is not exactly in the right place.) Mathematically, that sweet spot is called the center of mass of the plate.

This section examines these concepts in a one-dimensional context. Then, we expand our development to consider centers of mass of two-dimensional regions and symmetry. Last, we use centroids to find the volume of certain solids by applying the Theorem of Pappus.

## Mass and Linear Density

We can use integration to develop a formula for calculating mass based on a **linear density** function. First, we consider a thin rod or wire. Orient the rod so it aligns with the $x$-axis, with the left end of the rod at $x = a$ and the right end of the rod at $x = b$ (Figure

6.6.1). Note that although we depict the rod with some thickness in the figures, for mathematical purposes, we assume the rod is thin enough to be treated as a one-dimensional object.

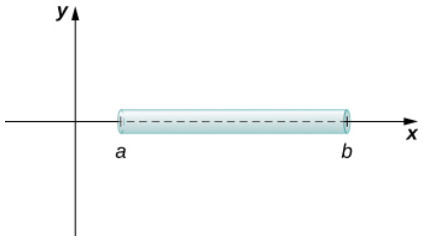

Figure 6.6.1: We can calculate the mass of a thin rod oriented along the $x$-axis by integrating its linear density function.

If the rod has constant linear density $\rho$, given in terms of mass per unit length (i.e., $\rho = m/l$), then the mass of the rod is just the product of the linear density and the length of the rod. That is,

$$m = \rho(b-a).$$

If the linear density of the rod is not constant, however, the problem becomes a little more challenging. When the linear density of the rod varies from point to point, we use a **linear density function**, $\rho(x)$, to denote the density of the rod at any point, $x$. Let $\rho(x)$ be an integrable linear density function. Now, for $i = 0, 1, 2, \ldots, n$ let $P = \{x_i\}$ be a regular partition of the interval $[a, b]$, and for $i = 1, 2, \ldots, n$ choose an arbitrary point $x_i^* \in [x_{i-1}, x_i]$. Figure 6.6.2 shows a representative segment of the rod.

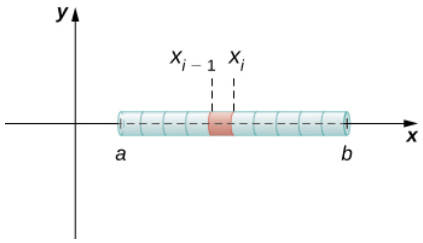

Figure 6.6.2: A representative segment of the rod.

The mass, $m_i$, of the segment of the rod from $x_{i-1}$ to $x_i$ is approximated by

$$\begin{aligned} m_i &\approx \rho(x_i^*)(x_i - x_{i-1}) \\ &= \rho(x_i^*)\Delta x. \end{aligned}$$

Adding the masses of all the segments gives us an approximation for the mass of the entire rod:

$$\begin{aligned} m &= \sum_{i=1}^{n} m_i \\ &\approx \sum_{i=1}^{n} \rho(x_i^*)\Delta x. \end{aligned}$$

This is a Riemann sum. Taking the limit as $n \to \infty$, we get an expression for the exact mass of the rod:

$$\begin{aligned} m &= \lim_{n\to\infty} \sum_{i=1}^{n} \rho(x_i^*)\Delta x \\ &= \int_a^b \rho(x)\,dx. \end{aligned}$$

We state this result in the following theorem.

### Theorem: Mass–Linear Density and Weight-Linear Weight Density Formulas of a One-Dimensional Object

Given a thin rod oriented along the $x$-axis over the interval $[a, b]$, let $\rho(x)$ denote a linear density function giving the density of the rod at a point $x$ in the interval. Then the mass of the rod is given by

$$m = \int_a^b \rho(x)\,dx. \tag{6.6.1}$$

If given the linear *weight* density function, $\gamma(x)$, then the *weight* of the rod is given by

$$F = \int_a^b \gamma(x)\,dx. \tag{6.6.2}$$

Before we move on, we must understand how the units work with Equations 6.6.1 and 6.6.2.

In Equation 6.6.1, we are given the linear density function $\rho(x)$. The unit types for this density function are

$$\frac{\text{mass}}{\text{length}},$$

where the mass unit could be in kilograms, grams, slugs, or any other unit of mass we are interested in, and the length unit is in meters, centimeters, feet, inches, or whatever unit of length in which we are interested. The unit type for $dx$ is length (which we would make sure matches the units of the length in the density function). Hence, the unit type for the integral is

$$\frac{\text{mass}}{\cancel{\text{length}}^{1}} \cdot \cancel{\text{length}}^{1} = \text{mass},$$

which is exactly what we are trying to compute.

Likewise, in Equation 6.6.2, we are given the linear *weight* density function $\gamma(x)$. The unit types for this *weight* density function are

$$\frac{\text{force}}{\text{length}},$$

where the force unit could be either in pounds or newtons (and only those two choices), and the length unit is in meters, centimeters, feet, inches, or whatever unit of length in which we are interested. The unit type for $dx$ is length (which we would make sure matches the units of the length in the *weight* density function). Hence, the unit type for the integral is

$$\frac{\text{force}}{\cancel{\text{length}}^{1}} \cdot \cancel{\text{length}}^{1} = \text{force},$$

which is, again, exactly what we are trying to compute.

The previous discussion using unit analysis will be especially helpful in physics and engineering (and, luckily, the homework). We apply this theorem in the next example.

### Example 6.6.1: Calculating Mass from Linear Density

Consider a thin rod oriented on the $x$-axis over the interval $[\frac{\pi}{2}, \pi]$. If the linear density of the rod is given by $\rho(x) = \sin x$, what is the mass of the rod?

**Solution**

Applying Equation 6.6.1 directly, we have

$$\begin{aligned} m &= \int_a^b \rho(x)\,dx \\ &= \int_{\pi/2}^{\pi} \sin x\,dx \\ &= -\cos x\Big|_{\pi/2}^{\pi} \\ &= 1. \end{aligned}$$

**? Checkpoint 6.6.1**

Consider a thin rod oriented on the $x$-axis over the interval $[1,3]$. If the linear density of the rod is given by $\rho(x) = 2x^2 + 3$, what is the mass of the rod?

**Answer**

$70/3$

## Mass and Radial Density

We now extend this concept to find the mass of a two-dimensional disk of radius $r$. As with the rod we looked at in the one-dimensional case, here we assume the disk is thin enough that, for mathematical purposes, we can treat it as a two-dimensional object. We assume the density is given in terms of mass per unit area (i.e., $\rho = m/A$), which is why this is often called the **area density**. For this discussion, we will further assume the area density varies only along the disk's radius. In this situation, we could call the area density by a different name - the **radial density**. This is because it is a function of how far away a point is from the disk's center.

We orient the disk in the $xy$-plane, with the center at the origin. Then, the density of the disk can be treated as a function of $x$, denoted $\rho(x)$. We assume $\rho(x)$ is integrable. Because density is a function of $x$, we partition the interval from $[0,r]$ along the $x$-axis. For $i = 0, 1, 2, \ldots, n$, let $P = \{x_i\}$ be a regular partition of the interval $[0,r]$, and for $i = 1, 2, \ldots, n$, choose an arbitrary point $x_i^* \in [x_{i-1}, x_i]$. Use the partition to break the disk into thin (two-dimensional) washers. A disk and a representative washer are depicted in the following figure.

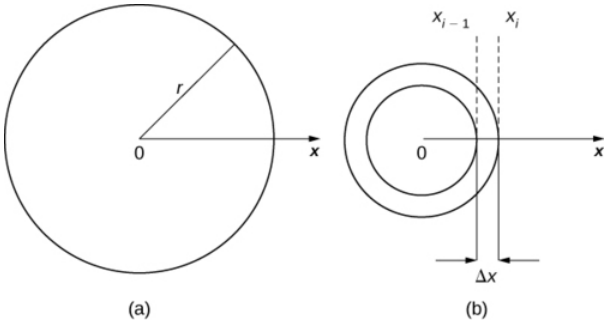

Figure **6.6.3***a*: A thin disk in the $xy$-plane.
Figure **6.6.3***b*: A representative washer.

We now approximate the density and area of the washer to calculate an approximate mass, $m_i$. Note that the area of the washer is given by

$$\begin{aligned} A_i &= \pi(x_i)^2 - \pi(x_{i-1})^2 \\ &= \pi[x_i^2 - x_{i-1}^2] \\ &= \pi(x_i + x_{i-1})(x_i - x_{i-1}) \\ &= \pi(x_i + x_{i-1})\Delta x. \end{aligned}$$

https://math.libretexts.org/@go/page/175587

You may recall that we had an expression similar to this when we were computing volumes by the Method of Cylindrical Shells. As we did there, we use $x_i^* \approx (x_i + x_{i-1})/2$ to approximate the average radius of the washer. We obtain

$$A_i = \pi(x_i + x_{i-1})\Delta x \approx 2\pi x_i^* \Delta x.$$

Using $\rho(x_i^*)$ to approximate the (radial) density of the washer, we approximate the mass of the washer by

$$m_i \approx 2\pi x_i^* \rho(x_i^*)\Delta x.$$

Adding up the masses of the washers, we see the mass $m$ of the entire disk is approximated by

$$m = \sum_{i=1}^{n} m_i \approx \sum_{i=1}^{n} 2\pi x_i^* \rho(x_i^*)\Delta x.$$

We again recognize this as a Riemann sum and take the limit as $n \to \infty$. This gives us

$$\begin{aligned} m &= \lim_{n\to\infty} \sum_{i=1}^{n} 2\pi x_i^* \rho(x_i^*)\Delta x \\ &= \int_0^r 2\pi x \rho(x)\, dx. \end{aligned}$$

We summarize these findings in the following theorem.

**Theorem: Mass–Radial Density and Weight-Radial Weight Density Formulas of a Circular Object**

Let $\rho(x)$ be an integrable function representing the radial density of a disk of radius $r$. Then the disk's mass is given by

$$m = \int_0^r 2\pi x \rho(x)\, dx. \tag{6.6.3}$$

If given the radial *weight* density function, $\gamma(x)$, the *weight* of the disk is given by

$$F = \int_0^r 2\pi x \gamma(x)\, dx. \tag{6.6.4}$$

As we did with linear density, a unit analysis discussion for radial density is helpful.

In Equation 6.6.3, we are given the radial density function $\rho(x)$. The unit types for this radial density function are

$$\frac{\text{mass}}{\text{length}^2},$$

where, just like before, the mass unit could be in kilograms, grams, slugs, or any other unit of mass we are interested in, and the length unit is in meters, centimeters, feet, inches, or whatever unit of length in which we are interested. The unit type for $dx$ is length, and the unit type for $x$ is also length. Hence, the unit type for the integral is

$$\text{length} \cdot \frac{\text{mass}}{\text{length}^2} \cdot \text{length} = \frac{\text{mass}}{\cancel{\text{length}^2}^{\,1}} \cdot \cancel{\text{length}^2}^{\,1} = \text{mass},$$

which is exactly what we are trying to compute.

Likewise, in Equation 6.6.4, we are given the radial *weight* density function $\gamma(x)$. The unit types for this radial *weight* density function are

$$\frac{\text{force}}{\text{length}^2},$$

where, yet again, the force unit could be either in pounds or newtons. The length unit is in meters, centimeters, feet, inches, or whatever unit of length we are interested in. The unit type for $dx$ is length, and the unit type for $x$ is also length. Hence, the unit type for the integral is

$$\text{length} \cdot \frac{\text{force}}{\text{length}^2} \cdot \text{length} = \frac{\text{force}}{\cancel{\text{length}^2}^{\,1}} \cdot \cancel{\text{length}^2}^{\,1} = \text{force},$$

which is, again, exactly what we are trying to compute.

**Example 6.6.2: Calculating Mass from Radial Density**

Let $\rho(x) = \sqrt{x}$ represent the radial density of a disk. Calculate the mass of a disk of radius 4.

**Solution**

Applying Equation 6.6.3, we find

$$\begin{aligned} m &= \int_0^r 2\pi x \rho(x)\, dx \\ &= \int_0^4 2\pi x \sqrt{x}\, dx \\ &= 2\pi \int_0^4 x^{3/2}\, dx \\ &= \frac{4\pi}{5} x^{5/2} \Big|_0^4 \\ &= \frac{128\pi}{5}. \end{aligned}$$

**Checkpoint 6.6.2**

Let $\rho(x) = 3x + 2$ represent the radial density of a disk. Calculate the mass of a disk of radius 2.

**Answer**

$24\pi$

## Center of Mass and Moments

We now step away from standard shapes like rods and circles and instead try to focus on irregular-shaped regions. Specifically, we want to discuss a given two-dimensional object's center of mass (the balancing point). To do so, however, we first need a bit of theory.

Let's begin by looking at the center of mass in a one-dimensional context. Consider a long, thin wire or rod of negligible mass resting on a **fulcrum**, as shown in Figure 6.6.4*a*. Now suppose we place objects having masses $m_1$ and $m_2$ at distances $d_1$ and $d_2$ from the fulcrum, respectively, as shown in Figure 6.6.4*b*.

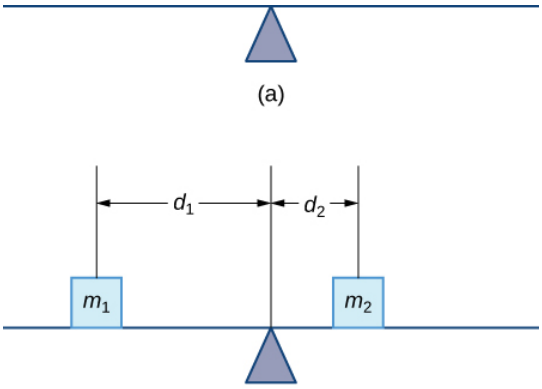

Figure 6.6.4*a*: A thin rod rests on a fulcrum.
Figure 6.6.4*b*: Masses are placed on the rod.

The most common real-life example of a system like this is a playground seesaw, or teeter-totter, with children of different weights sitting at different distances from the center. On a seesaw, if one child sits at each end, the heavier child sinks, and the lighter child is lifted into the air. Suppose the heavier child slides in toward the center, though the seesaw balances. Applying this concept to the masses on the rod, we note that the masses balance each other if and only if

$$m_1 d_1 = m_2 d_2.$$

In the seesaw example, we balanced the system by moving the masses (children) with respect to the fulcrum. However, we are interested in systems where the masses cannot move. Instead, we balance the system by moving the fulcrum. Suppose we have two **point masses**,[1] $m_1$ and $m_2$, located on a number line at points $x_1$ and $x_2$, respectively (Figure 6.6.5). The center of mass, $\bar{x}$, is where the fulcrum should be placed to balance the system.

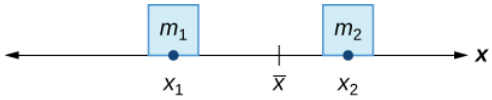

Figure 6.6.5: The center of mass $\bar{x}$ is the balance point of the system.

Thus, we have

$$\begin{aligned} & m_1|x_1 - \bar{x}| &&= m_2|x_2 - \bar{x}| \\ \Longrightarrow \quad & m_1(\bar{x} - x_1) &&= m_2(x_2 - \bar{x}) \\ \Longrightarrow \quad & m_1\bar{x} - m_1x_1 &&= m_2x_2 - m_2\bar{x} \\ \Longrightarrow \quad & \bar{x}(m_1 + m_2) &&= m_1x_1 + m_2x_2 \end{aligned}$$

or

$$\bar{x} = \frac{m_1x_1 + m_2x_2}{m_1 + m_2} \tag{6.6.5}$$

The expression in the numerator of Equation 6.6.5, $m_1x_1 + m_2x_2$, is called the **first moment of the system** with respect to the origin. If the context is clear, we often drop the word first and refer to this expression as the **moment of the system**. The expression in the denominator, $m_1 + m_2$, is the system's total mass. Thus, the **center of mass of the system** is the point at which the system's total mass could be concentrated without changing the moment.

This idea is more expansive than two point masses. In general, if $n$ masses, $m_1, m_2, \ldots, m_n$, are placed on a number line at points $x_1, x_2, \ldots, x_n$, respectively, then the center of mass of the system is given by

$$\bar{x} = \frac{\sum_{i=1}^{n} m_i x_i}{\sum_{i=1}^{n} m_i}.$$

### Theorem: Center of Mass of Objects on a Line

Let $m_1, m_2, \ldots, m_n$ be point masses placed on a number line at points $x_1, x_2, \ldots, x_n$, respectively, and let $m = \sum_{i=1}^{n} m_i$ denote the total mass of the system. Then, the moment of the system with respect to the origin is given by

$$M = \sum_{i=1}^{n} m_i x_i \tag{6.6.6}$$

and the center of mass of the system is given by

$$\bar{x} = \frac{M}{m}. \tag{6.6.7}$$

We apply this theorem in the following example.

### Example 6.6.3: Finding the Center of Mass of Objects along a Line

Suppose four point masses are placed on a number line as follows:

- $m_1 = 30\,\text{kg}$, placed at $x_1 = -2\,\text{m}$
- $m_2 = 5\,\text{kg}$, placed at $x_2 = 3\,\text{m}$
- $m_3 = 10\,\text{kg}$, placed at $x_3 = 6\,\text{m}$
- $m_4 = 15\,\text{kg}$, placed at $x_4 = -3\,\text{m}$.

Find the moment of the system with respect to the origin and find the center of mass of the system.

**Solution**

First, we need to calculate the moment of the system (Equation 6.6.6):

$$\begin{aligned} M &= \sum_{i=1}^{4} m_i x_i \\ &= -60 + 15 + 60 - 45 \\ &= -30. \end{aligned}$$

Now, to find the center of mass, we need the total mass of the system:

$$\begin{aligned} m &= \sum_{i=1}^{4} m_i \\ &= 30 + 5 + 10 + 15 \\ &= 60\,\text{kg} \end{aligned}$$

Then we have (from Equation 6.6.7)

$$\bar{x} = \frac{M}{m} = -\frac{30}{60} = -\frac{1}{2}.$$

The center of mass is located 1/2 m to the left of the origin.

### Checkpoint 6.6.3

Suppose four point masses are placed on a number line as follows:

- $m_1 = 12\,\text{kg}$ placed at $x_1 = -4\,\text{m}$
- $m_2 = 12\,\text{kg}$ placed at $x_2 = 4\,\text{m}$

- $m_3 = 30\,\text{kg}$ placed at $x_3 = 2\,\text{m}$
- $m_4 = 6\,\text{kg}$, placed at $x_4 = -6\,\text{m}$.

Find the moment of the system with respect to the origin and find the center of mass of the system.

**Answer**

$M = 24, \bar{x} = \frac{2}{5}\,\text{m}$

We can generalize this concept to find the center of mass of a system of point masses in a plane.

Let $m_1$ be a point mass located at point $(x_1, y_1)$ in the plane. Then the **moment $M_x$ of the mass with respect to the $x$-axis** is given by $M_x = m_1 y_1$. Similarly, the **moment $M_y$ with respect to the $y$-axis** is given by $M_y = m_1 x_1$.

Notice that the $x$-coordinate of the point is used to calculate the moment with respect to the $y$-axis, and vice versa. The reason is that the $x$-coordinate gives the distance from the point mass to the $y$-axis, and the $y$-coordinate gives the distance to the $x$-axis (see Figure 6.6.6).

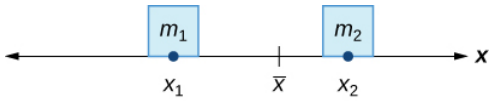

Figure 6.6.6: Point mass $m_1$ is located at point $(x_1, y_1)$ in the plane.

If we have several point masses in the $xy$-plane, we can use the moments with respect to the $x$- and $y$-axes to calculate the $x$- and $y$-coordinates of the center of mass of the system.

### Theorem: Center of Mass of Objects in a Plane

Let $m_1, m_2, \ldots, m_n$ be point masses located in the $xy$-plane at points $(x_1, y_1), (x_2, y_2), \ldots, (x_n, y_n)$, respectively, and let $m = \sum_{i=1}^{n} m_i$ denote the total mass of the system. Then the moments $M_x$ and $M_y$ of the system with respect to the $x$- and $y$-axes, respectively, are given by

$$M_x = \sum_{i=1}^{n} m_i y_i \tag{6.6.8}$$

and

$$M_y = \sum_{i=1}^{n} m_i x_i. \tag{6.6.9}$$

Also, the coordinates of the center of mass $(\bar{x}, \bar{y})$ of the system are

$$\bar{x} = \frac{M_y}{m} \tag{6.6.10}$$

and

$$\bar{y} = \frac{M_x}{m}. \tag{6.6.11}$$

The next example demonstrates how the center of mass formulas (Equations 6.6.8 - 6.6.11) may be applied.

### Example 6.6.4: Finding the Center of Mass of Objects in a Plane

Suppose three point masses are placed in the $xy$-plane as follows (assume coordinates are given in meters):

- $m_1 = 2\,\text{kg}$ placed at $(-1, 3)$,
- $m_2 = 6\,\text{kg}$ placed at $(1, 1)$,
- $m_3 = 4\,\text{kg}$ placed at $(2, -2)$.

Find the center of mass of the system.

**Solution**

First we calculate the total mass of the system:

$$m = \sum_{i=1}^{3} m_i = 2 + 6 + 4 = 12\,\text{kg}.$$

Next we find the moments with respect to the $x$- and $y$-axes:

$$M_y = \sum_{i=1}^{3} m_i x_i = -2 + 6 + 8 = 12,$$

$$M_x = \sum_{i=1}^{3} m_i y_i = 6 + 6 - 8 = 4.$$

Then we have

$$\bar{x} = \frac{M_y}{m} = \frac{12}{12} = 1$$

and

$$\bar{y} = \frac{M_x}{m} = \frac{4}{12} = \frac{1}{3}.$$

The center of mass of the system is $\left(1, \frac{1}{3}\right)$, in meters.

**? Checkpoint 6.6.4**

Suppose three point masses are placed on a number line as follows (assume coordinates are given in meters):

- $m_1 = 5\,\text{kg}$ placed at $(-2, -3)$,
- $m_2 = 3\,\text{kg}$ placed at $(2, 3)$,
- $m_3 = 2\,\text{kg}$ placed at $(-3, -2)$.

Find the center of mass of the system.

**Answer**

$(-1, -1)$ m

## Center of Mass of Thin Plates

So far, we have looked at systems of point masses on a line and in a plane. Now, instead of having the mass of a system concentrated at discrete points, we want to look at systems in which the system's mass is distributed continuously across a thin sheet of material. For our purposes, we assume the sheet is thin enough that it can be treated as if it is two-dimensional. Such a sheet is called a **lamina**. Next, we develop techniques to find the center of mass of a lamina. In this section, we also assume the area density of the lamina is constant.

Laminas are often represented by a two-dimensional region in a plane. The geometric center of such a region is called its **centroid**. Since we have assumed the area density of the lamina is constant, the center of mass of the lamina depends only on the shape of the corresponding region in the plane; it does *not* depend on the area density. In this case, the center of mass of the lamina corresponds to the centroid of the delineated region in the plane. As with systems of point masses, we need to find the total mass of the lamina, as well as the moments of the lamina with respect to the $x$- and $y$-axes.

We first consider a lamina in a rectangle shape. Recall that the center of mass of a lamina is the point where the lamina balances. For a rectangle, that point is the rectangle's horizontal and vertical center. Based on this understanding, it is clear that the center of

mass of a rectangular lamina is the point where the diagonals intersect, resulting from the **symmetry principle**, and it is stated here without proof.

**Theorem: Symmetry Principle**

If a region $\mathbf{R}$ is symmetric about a line $l$, then the centroid of $\mathbf{R}$ lies on $l$.

Let's turn to more general laminas. Suppose we have a lamina bounded above by the graph of a continuous function $f(x)$, below by the $x$-axis, and on the left and right by the lines $x = a$ and $x = b$, respectively, as shown in Figure 6.6.7.

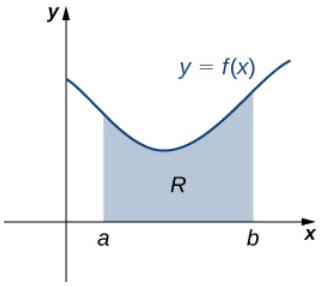

Figure 6.6.7: A region in the plane representing a lamina.

As with systems of point masses, to find the center of mass of the lamina, we need to find the total mass of the lamina, as well as the moments of the lamina with respect to the $x$- and $y$-axes. As we have often done, we approximate these quantities by partitioning the interval $[a, b]$ and constructing rectangles.

For $i = 0, 1, 2, \ldots, n$, let $P = \{x_i\}$ be a regular partition of $[a, b]$. Recall that we can choose any point within the interval $[x_{i-1}, x_i]$ as our $x_i^*$. In this case, we want $x_i^*$ to be the $x$-coordinate of the centroid of our rectangles. Thus, for $i = 1, 2, \ldots, n$, we select $x_i^* \in [x_{i-1}, x_i]$ such that $x_i^*$ is the midpoint of the interval. That is, $x_i^* = \frac{x_{i-1}+x_i}{2}$. Now, for $i = 1, 2, \ldots, n$, construct a rectangle of height $y_T - y_B = f(x_i^*) - 0 = f(x_i^*)$ on $[x_{i-1}, x_i]$. The center of mass of this rectangle is $\left(x_i^*, \frac{f(x_i^*)}{2}\right)$, as shown in the following figure.

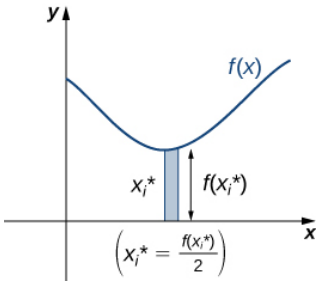

Figure 6.6.8: A representative rectangle of the lamina.

Next, we need to find the total mass of the rectangle. Let $\rho$ represent the area density of the lamina (note that $\rho$ is a constant). Therefore, $\rho$ is expressed in mass per unit area. Thus, to find the total mass of the rectangle, we multiply the area of the rectangle by $\rho$. Then, the mass of the rectangle is given by $\rho f(x_i^*)\Delta x$.

To get the approximate mass of the lamina, we add the masses of all the rectangles to get

$$m \approx \sum_{i=1}^{n} \rho f(x_i^*)\Delta x. \tag{6.6.12}$$

Equation 6.6.12 is a Riemann sum. Taking the limit as $n \to \infty$ gives the exact mass of the lamina:

$$\begin{aligned} m &= \lim_{n\to\infty} \sum_{i=1}^{n} \rho f(x_i^*)\Delta x \\ &= \rho \int_a^b f(x)\, dx. \end{aligned}$$

Next, we calculate the moment of the lamina with respect to the $x$-axis. Returning to the representative rectangle, recall its center of mass is $\left(x_i^*, \frac{f(x_i^*)}{2}\right)$. Recall also that treating the rectangle as if it is a point mass located at the center of mass does not change the moment. Thus, the moment of the rectangle with respect to the $x$-axis is given by the mass of the rectangle, $\rho f(x_i^*)\Delta x$, multiplied by the distance from the center of mass to the $x$-axis: $\frac{f(x_i^*)}{2}$. Therefore, the moment with respect to the $x$-axis of the rectangle is $\rho\left(\frac{[f(x_i^*)]^2}{2}\right)\Delta x$. Adding the moments of the rectangles and taking the limit of the resulting Riemann sum, we see that the moment of the lamina with respect to the $x$-axis is

$$\begin{aligned} M_x &= \lim_{n\to\infty}\sum_{i=1}^{n}\rho\frac{[f(x_i^*)]^2}{2}\Delta x \\ &= \rho\int_a^b \frac{[f(x)]^2}{2}\,dx. \end{aligned}$$

We derive the moment with respect to the $y$-axis similarly, noting that the distance from the center of mass of the rectangle to the $y$-axis is $x_i^*$. Then the moment of the lamina with respect to the $y$-axis is given by

$$\begin{aligned} M_y &= \lim_{n\to\infty}\sum_{i=1}^{n}\rho x_i^* f(x_i^*)\Delta x \\ &= \rho\int_a^b xf(x)\,dx. \end{aligned}$$

We find the coordinates of the center of mass by dividing the moments by the total mass to give $\bar{x} = \frac{M_y}{m}$ and $\bar{y} = \frac{M_x}{m}$. If we look closely at the expressions for $M_x, M_y$, and $m$, we notice that the constant $\rho$ cancels out when $\bar{x}$ and $\bar{y}$ are calculated.

We summarize these findings in the following theorem.

**Theorem: Center of Mass of a Thin Plate in the $xy$-Plane**

Let $\mathbf{R}$ denote a region bounded above by the graph of a continuous function $f(x)$, below by the $x$-axis, and on the left and right by the lines $x = a$ and $x = b$, respectively. Let $\rho$ denote the area density of the associated lamina. Then we can make the following statements:

i. The mass of the lamina is

$$m = \rho\int_a^b f(x)\,dx. \tag{6.6.13}$$

ii. The moments $M_x$ and $M_y$ of the lamina with respect to the $x$- and $y$-axes, respectively, are

$$M_x = \rho\int_a^b \frac{[f(x)]^2}{2}dx \tag{6.6.14}$$

and

$$M_y = \rho\int_a^b xf(x)dx. \tag{6.6.15}$$

iii. The coordinates of the center of mass $(\bar{x}, \bar{y})$ are

$$\bar{x} = \frac{M_y}{m} \tag{6.6.16}$$

and

$$\bar{y} = \frac{M_x}{m}. \tag{6.6.17}$$

In the next example, we use this theorem to find the center of mass of a lamina.

## Example 6.6.5: Finding the Center of Mass of a Lamina

Let $\mathbf{R}$ be the region bounded above by the graph of the function $f(x) = \sqrt{x}$ and below by the $x$-axis over the interval $[0, 4]$. Find the centroid of the region.

**Solution**

The region is depicted in the following figure.

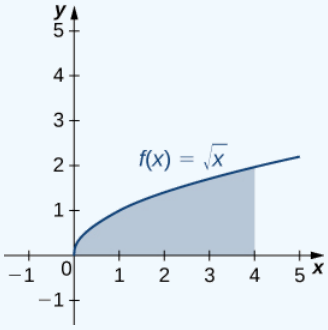

Figure 6.6.9: Finding the center of mass of a lamina.

Since we are only asked for the region's centroid rather than the mass or moments of the associated lamina, we know the area density constant $\rho$ cancels out of the calculations eventually. Therefore, for the sake of convenience, let's assume $\rho = 1$.

First, we need to calculate the total mass (Equation 6.6.13):

$$\begin{aligned} m &= \rho \int_a^b f(x)\,dx \\ &= \int_0^4 \sqrt{x}\,dx \\ &= \frac{2}{3}x^{3/2}\Big|_0^4 \\ &= \frac{2}{3}[8-0] \\ &= \frac{16}{3}. \end{aligned}$$

Next, we compute the moments (Equation 6.6.16):

$$\begin{aligned} M_x &= \rho \int_a^b \frac{[f(x)]^2}{2}\,dx \\ &= \int_0^4 \frac{x}{2}\,dx \\ &= \frac{1}{4}x^2\Big|_0^4 \\ &= 4 \end{aligned}$$

and (Equation 6.6.15):

$$\begin{aligned} M_y &= \rho \int_a^b x f(x)\, dx \\ &= \int_0^4 x\sqrt{x}\, dx \\ &= \int_0^4 x^{3/2}\, dx \\ &= \frac{2}{5}x^{5/2}\Big|_0^4 \\ &= \frac{2}{5}[32-0] \\ &= \frac{64}{5}. \end{aligned}$$

Thus, we have (Equation 6.6.16):

$$\begin{aligned} \bar{x} &= \frac{M_y}{m} \\ &= \frac{64/5}{16/3} \\ &= \frac{64}{5}\cdot\frac{3}{16} \\ &= \frac{12}{5} \end{aligned}$$

and (Equation 6.6.17):

$$\begin{aligned} \bar{y} &= \frac{M_x}{m} \\ &= \frac{4}{16/3} \\ &= 4\cdot\frac{3}{16} \\ &= \frac{3}{4}. \end{aligned}$$

The centroid of the region is $\left(\frac{12}{5}, \frac{3}{4}\right)$.

**? Checkpoint 6.6.5**

Let $\mathbf{R}$ be the region bounded above by the graph of the function $f(x) = x^2$ and below by the $x$-axis over the interval $[0, 2]$. Find the centroid of the region.

**Answer**

The centroid of the region is $\left(\frac{3}{2}, \frac{6}{5}\right)$.

We can also adapt this approach to find centroids of more complex regions. Suppose our region is bounded above by the graph of a continuous function $f(x)$, as before, but now, instead of having the lower bound for the region be the $x$-axis, suppose the region is bounded below by the graph of a second continuous function, $g(x)$, as shown in Figure **6.6.10**.

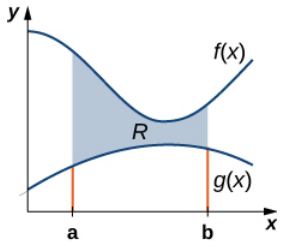

Figure 6.6.10: A region between two functions.

Again, we partition the interval $[a, b]$ and construct rectangles. A representative rectangle is shown in Figure 6.6.11.

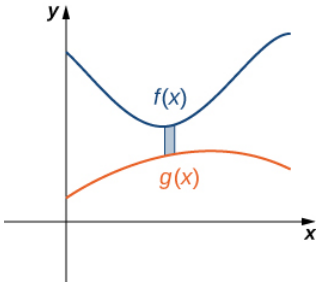

Figure 6.6.11: A representative rectangle of the region between two functions.

Note that the centroid of this rectangle is $\left(x_i^*, \frac{f(x_i^*)+g(x_i^*)}{2}\right)$. We won't go through all the details of the Riemann sum development, but let's look at some of the key steps. In the development of the formulas for the mass of the lamina and the moment with respect to the $y$-axis, the height of each rectangle is given by $y_T - y_B = f(x_i^*) - g(x_i^*)$, which leads to the expression $f(x) - g(x)$ in the integrands.

In the development of the formula for the moment with respect to the $x$-axis, the moment of each rectangle is found by multiplying the area density of the rectangle, $\rho[f(x_i^*) - g(x_i^*)]\Delta x$, by the distance of the centroid from the $x$-axis, $\frac{f(x_i^*)+g(x_i^*)}{2}$, which gives $\rho\frac{1}{2}\left[f(x_i^*)\right]^2 - [g(x_i^*)]^2] \, \Delta x$. Summarizing these findings, we arrive at the following theorem.

### Theorem: Center of Mass of a Lamina Bounded by Two Functions

Let $\mathbf{R}$ denote a region bounded above by the graph of a continuous function $f(x)$, below by the graph of the continuous function $g(x)$, and on the left and right by the lines $x = a$ and $x = b$, respectively. Let $\rho$ denote the area density of the associated lamina. Then we can make the following statements:

i. The mass of the lamina is

$$m = \rho \int_a^b [f(x) - g(x)] \, dx.$$

ii. The moments $M_x$ and $M_y$ of the lamina with respect to the $x$- and $y$-axes, respectively, are

$$M_x = \rho \int_a^b \frac{1}{2} \left( [f(x)]^2 - [g(x)]^2 \right) \, dx$$

and

$$M_y = \rho \int_a^b x[f(x) - g(x)] \, dx.$$

iii. The coordinates of the center of mass $(\bar{x}, \bar{y})$ are

$$\bar{x} = \frac{M_y}{m}$$

and

$$\bar{y} = \frac{M_x}{m}.$$

We illustrate this theorem in the following example.

**Example 6.6.6: Finding the Centroid of a Region Bounded by Two Functions**

Let $\mathbf{R}$ be the region bounded above by the graph of the function $f(x) = 1 - x^2$ and below by the graph of the function $g(x) = x - 1$. Find the centroid of the region.

**Solution**

The region is depicted in the following figure.

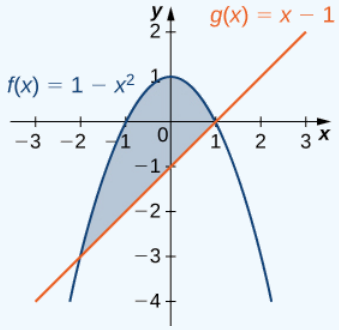

Figure 6.6.12: Finding the centroid of a region between two curves.

The graphs of the functions intersect at $(-2, -3)$ and $(1, 0)$, so we integrate from $-2$ to 1. Once again, for the sake of convenience, assume $\rho = 1$.

First, we need to calculate the total mass:

$$\begin{aligned} m &= \rho \int_a^b [f(x) - g(x)]\, dx \\ &= \int_{-2}^{1} [1 - x^2 - (x - 1)]\, dx \\ &= \int_{-2}^{1} (2 - x^2 - x)\, dx \\ &= \left[2x - \frac{1}{3}x^3 - \frac{1}{2}x^2\right]\Big|_{-2}^{1} \\ &= \left[2 - \frac{1}{3} - \frac{1}{2}\right] - \left[-4 + \frac{8}{3} - 2\right] \\ &= \frac{9}{2}. \end{aligned}$$

Next, we compute the moments:

$$\begin{aligned} M_x &= \rho \int_a^b \frac{1}{2}\left([f(x)]^2 - [g(x)]^2\right)\,dx \\ &= \frac{1}{2}\int_{-2}^{1}((1-x^2)^2 - (x-1)^2)\,dx \\ &= \frac{1}{2}\int_{-2}^{1}(x^4 - 3x^2 + 2x)\,dx \\ &= \frac{1}{2}\left[\frac{x^5}{5} - x^3 + x^2\right]\Big|_{-2}^{1} \\ &= -\frac{27}{10} \end{aligned}$$

and

$$\begin{aligned} M_y &= \rho \int_a^b x[f(x) - g(x)]\,dx \\ &= \int_{-2}^{1} x[(1-x^2) - (x-1)]\,dx \\ &= \int_{-2}^{1} x[2 - x^2 - x]\,dx \\ &= \int_{-2}^{1}(2x - x^4 - x^2)\,dx \\ &= \left[x^2 - \frac{x^5}{5} - \frac{x^3}{3}\right]\Big|_{-2}^{1} \\ &= -\frac{9}{4}. \end{aligned}$$

Therefore, we have

$$\begin{aligned} \bar{x} &= \frac{M_y}{m} \\ &= -\frac{9}{4}\cdot\frac{2}{9} \\ &= -\frac{1}{2} \end{aligned}$$

and

$$\begin{aligned} \bar{y} &= \frac{M_x}{m} \\ &= -\frac{27}{10}\cdot\frac{2}{9} \\ &= -\frac{3}{5}. \end{aligned}$$

The centroid of the region is $\left(-\frac{1}{2}, -\frac{3}{5}\right)$.

**Checkpoint 6.6.6**

Let $\mathbf{R}$ be the region bounded above by the graph of the function $f(x) = 6 - x^2$ and below by the graph of the function $g(x) = 3 - 2x$. Find the centroid of the region.

**Answer**

The centroid of the region is $\left(1, \frac{13}{5}\right)$.

## The Symmetry Principle

We stated the symmetry principle earlier when we were looking at the centroid of a rectangle. The symmetry principle can greatly help when finding centroids of symmetric regions. Consider the following example.

**Example 6.6.7: Finding the Centroid of a Symmetric Region**

Let $\mathbf{R}$ be the region bounded above by the graph of the function $f(x) = 4 - x^2$ and below by the $x$-axis. Find the centroid of the region.

**Solution**

The region is depicted in the following figure

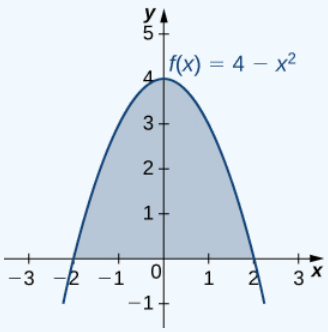

Figure 6.6.13: We can use the symmetry principle to help find the centroid of a symmetric region.

The region is symmetric with respect to the $y$-axis. Therefore, the $x$-coordinate of the centroid is zero. We need only calculate $\bar{y}$. Once again, for the sake of convenience, assume $\rho = 1$.

First, we calculate the total mass:

$$\begin{aligned} m &= \rho \int_a^b f(x)\,dx \\ &= \int_{-2}^{2} (4 - x^2)\,dx \\ &= \left[4x - \frac{x^3}{3}\right]\Big|_{-2}^{2} \\ &= \frac{32}{3}. \end{aligned}$$

Next, we calculate the moments. We only need $M_x$:

$$\begin{aligned} M_x &= \rho \int_a^b \frac{[f(x)]^2}{2}\, dx \\ &= \frac{1}{2}\int_{-2}^{2} \left[4 - x^2\right]^2 dx \\ &= \frac{1}{2}\int_{-2}^{2} (16 - 8x^2 + x^4)\, dx \\ &= \frac{1}{2}\left[\frac{x^5}{5} - \frac{8x^3}{3} + 16x\right]\Big|_{-2}^{2} \\ &= \frac{256}{15} \end{aligned}$$

Then we have

$$\bar{y} = \frac{M_x}{m} = \frac{256}{15} \cdot \frac{3}{32} = \frac{8}{5}.$$

The centroid of the region is $\left(0, \frac{8}{5}\right)$.

**? Checkpoint 6.6.7**

Let $\mathbf{R}$ be the region bounded above by the graph of the function $f(x) = 1 - x^2$ and below by $x$-axis. Find the centroid of the region.

**Answer**

The centroid of the region is $\left(0, \frac{2}{5}\right)$.

**The Grand Canyon Skywalk**

The Grand Canyon Skywalk opened on March 28, 2007. This engineering marvel is a horseshoe-shaped observation platform suspended 4000 ft above the Colorado River on the Grand Canyon's West Rim. Its crystal-clear glass floor allows stunning views of the canyon below (see the following figure).

Figure **6.6.14**: The Grand Canyon Skywalk offers magnificent canyon views. (credit: 10da_ralta, Wikimedia Commons)

The Skywalk is a cantilever design, meaning that the observation platform extends over the canyon's rim with no visible means of support below it. Despite the lack of visible support posts or struts, cantilever structures are engineered to be very stable, and the Skywalk is no exception. The observation platform is attached firmly to support posts that extend 46 ft down into bedrock. The structure was built to withstand 100-mph winds and an 8.0-magnitude earthquake within 50 mi and is capable of supporting more than 70,000,000 lb.

One factor affecting the Skywalk's stability is the structure's center of gravity. We will calculate the center of gravity of the Skywalk and examine how the center of gravity changes when tourists walk out onto the observation platform.

The observation platform is U-shaped. The legs of the U are 10 ft wide and begin on land, under the visitors' center, 48 ft from the canyon's edge. The platform extends 70 ft over the edge of the canyon.

To calculate the center of mass of the structure, we treat it as a lamina and use a two-dimensional region in the $xy$-plane to represent the platform. We begin by dividing the area into three subregions so we can consider each subregion separately. The first region, denoted $\mathbf{R}_1$, consists of the curved part of the U. We model $\mathbf{R}_1$ as a semicircular annulus, with an inner radius of 25 ft and outer radius 35 ft, centered at the origin (Figure **6.6.12**).

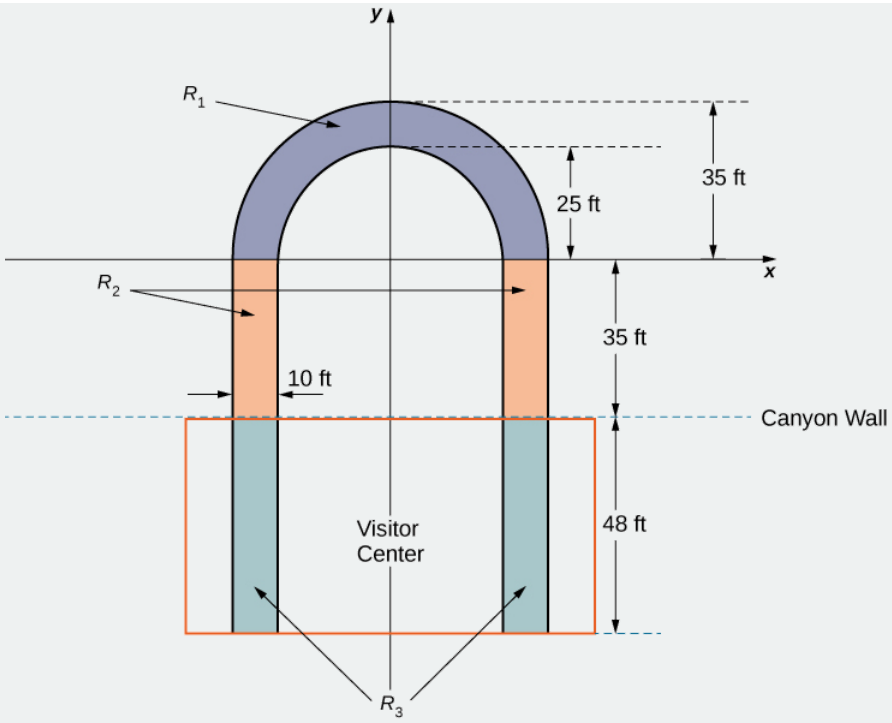

Figure **6.6.12**: We model the Skywalk with three sub-regions.

The legs of the platform, extending 35 ft between $\mathbf{R_1}$ and the canyon wall, comprise the second sub-region, $\mathbf{R_2}$. Last, the ends of the legs, which extend 48 ft under the visitor center, comprise the third sub-region, $\mathbf{R_3}$. Assume the area density of the lamina is constant and assume the total weight of the platform is 1,200,000 lb (not including the weight of the visitor center; we will consider that later). Use $g = 32\ \text{ft/sec}^2$.

1. Compute the area of each of the three sub-regions. Note that the areas of regions $\mathbf{R_2}$ and $\mathbf{R_3}$ should include the areas of the legs only, not the open space between them. Round answers to the nearest square foot.
2. Determine the mass associated with each of the three sub-regions.
3. Calculate the center of mass of each of the three sub-regions.
4. Now, treat each of the three sub-regions as a point mass located at the center of mass of the corresponding sub-region. Using this representation, calculate the center of mass of the entire platform.
5. Assume the visitor center weighs 2,200,000 lb, with a center of mass corresponding to the center of mass of $\mathbf{R_3}$. Treating the visitor center as a point mass, recalculate the system's center of mass. How does the center of mass change?
6. Although the Skywalk was built to limit the number of people on the observation platform to 120, the platform can support up to 800 people weighing 200 lb each. If all 800 people were allowed on the platform, and all of them went to the farthest end of the platform, how would the system's center of gravity be affected? (Include the visitor center in the calculations and represent the people by a point mass located at the farthest edge of the platform, 70 ft from the canyon wall.)

## Theorem of Pappus

This section ends with a discussion of the **Theorem of Pappus for volume**, which allows us to find the volume of particular kinds of solids by using the centroid.[2]

### Theorem of Pappus for Volume

Let $\mathbf{R}$ be a region in the plane and let $l$ be a line in the plane that does not intersect $\mathbf{R}$. Then the volume of the solid of revolution formed by revolving $\mathbf{R}$ around $l$ is equal to the area of $\mathbf{R}$ multiplied by the distance, $d$, traveled by the centroid of $\mathbf{R}$.

**Proof**

We can prove the case when the region is bounded above by the graph of a function $f(x)$ and below by the graph of a function $g(x)$ over an interval $[a, b]$, and for which the axis of revolution is the $y$-axis. In this case, the area of the region is $A = \int_a^b [f(x) - g(x)]\,dx$. Since the axis of rotation is the $y$-axis, the distance traveled by the centroid of the region depends only on the $x$-coordinate of the centroid, $\bar{x}$, which is

$$x = \frac{M_y}{m},$$

where

$$m = \rho \int_a^b [f(x) - g(x)]\,dx$$

and

$$M_y = \rho \int_a^b x[f(x) - g(x)]\,dx.$$

Then,

$$d = 2\pi \frac{\rho \int_a^b x[f(x) - g(x)]\,dx}{\rho \int_a^b [f(x) - g(x)]\,dx}$$

and thus

$$d \cdot A = 2\pi \int_a^b x[f(x) - g(x)]\,dx.$$

However, using the Method of Cylindrical Shells, we have

$$V = 2\pi \int_a^b x[f(x) - g(x)]\,dx.$$

So,

$$V = d \cdot A$$

and the proof is complete.

### Example 6.6.8: Using the Theorem of Pappus for Volume

Let $\mathbf{R}$ be a circle of radius 2 centered at $(4, 0)$. Use the Theorem of Pappus for Volume to find the volume of the torus generated by revolving $\mathbf{R}$ around the $y$-axis.

**Solution**

The region and torus are depicted in the following figure.

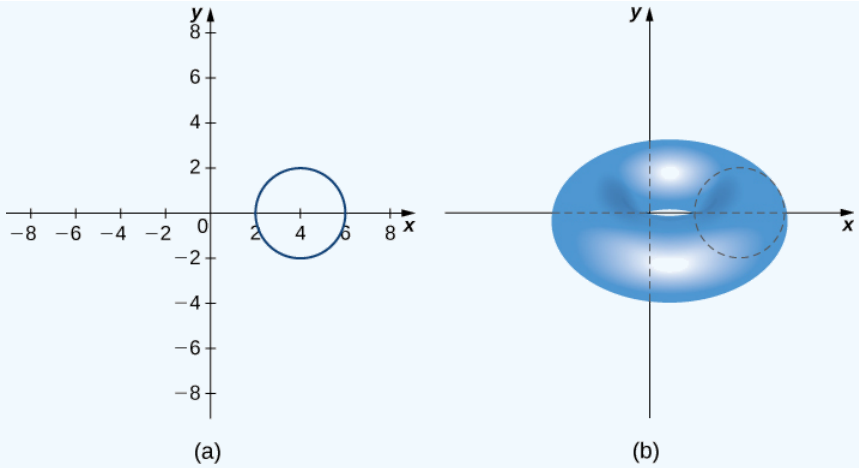

Figure 6.6.15: Determining a torus's volume using the Pappus theorem. (a) A circular region $\mathbf{R}$ in the plane; (b) the torus generated by revolving $\mathbf{R}$ about the $y$-axis.

The region $\mathbf{R}$ is a circle of radius 2, so the area of $\mathbf{R}$ is $A = 4\pi \text{ units}^2$. By the symmetry principle, the centroid of $\mathbf{R}$ is the circle's center. The centroid travels around the $y$-axis in a circular path of radius 4, so the centroid travels $d = 8\pi$ units. Then, the volume of the torus is $A \cdot d = 32\pi^2 \text{ units}^3$.

**? Checkpoint 6.6.8**

Let $\mathbf{R}$ be a circle of radius 1 centered at $(3, 0)$. Use the Theorem of Pappus for Volume to find the volume of the torus generated by revolving $\mathbf{R}$ around the $y$-axis.

**Answer**

$6\pi^2 \text{ units}^3$.

## Footnotes

[1] A point mass refers to an idealized object that is considered to have mass but negligible size and shape.

[2] There is also a **Theorem of Pappus for Surface Area**, but it is much less useful than the theorem for volume.

# 6.6E: Exercises

## Reading Questions

1. What is the physical interpretation of the center of mass?
2. What is the difference between a center of mass and a centroid, and under what condition are they the same?
3. For a system of point masses in a plane, why does the calculation for the moment about the x-axis ($M_x$) use the y-coordinates of the masses?
4. What is the formula for the mass of a thin rod on the interval $[a, b]$ with a linear density function $\rho(x)$?
5. How can the Symmetry Principle be used to simplify the process of finding the centroid of a region?
6. For a lamina bounded by $y = f(x)$ and the x-axis, what are the integral expressions for the moments $M_x$ and $M_y$?
7. State the Theorem of Pappus for Volume. What three quantities does it relate?

**In exercises 1 - 4, find the weight of the one-dimensional object.**

1) A wire that is $2$ ft long (starting at $x = 0$) and has a *weight density* function of $\gamma(x) = x^2 + 2x$ lb/ft

2) A car antenna that is $3$ ft long (starting at $x = 0$) and has a *weight density* function of $\gamma(x) = 3x + 2$ lb/ft

**Answer**

$\frac{39}{2}$ lbs.

3) A metal rod that is $8$ in. long (starting at $x = 0$) and has a *weight density* function of $\gamma(x) = e^{1/2x}$ lb/in.

4) A pencil that is $4$ in. long (starting at $x = 2$) and has a *weight density* function of $\gamma(x) = \dfrac{5}{x}$ oz/in.

**Answer**

$\ln(243)$ oz.

5) Using the Left Endpoint Method with $n = 6$, approximate the weight of a one-dimensional ruler that is $12$ in. long (starting at $x = 5$) and has a *weight density* function of $\gamma(x) = \ln(x) + (1/2)x^2$ oz/in.

**In exercises 6 - 7, find the weight of the two-dimensional object that is centered at the origin.**

6) An oversized hockey puck of radius $2$ in. with radial *weight* density function $\gamma(x) = x^3 - 2x + 5$ $\text{lb/in}^2$.

**Answer**

$\frac{332\pi}{15}$ lbs.

7) A disk of radius $5$ cm with radial *weight* density function $\gamma(x) = \sqrt{3x}$ $\text{g/cm}^2$

**Answer**

$20\pi\sqrt{15}$ g.

8) Using the Right Endpoint Method with $n = 6$, approximate the weight of a two-dimensional frisbee (centered at the origin) of radius $6$ in. with radial *weight* density function $\gamma(x) = e^{-x}$ $\text{oz/in}^2$.

**In exercises 9 - 14, calculate the center of mass for the collection of masses given.**

9) $m_1 = 2$ at $x_1 = 1$ and $m_2 = 4$ at $x_2 = 2$

10) $m_1 = 1$ at $x_1 = -1$ and $m_2 = 3$ at $x_2 = 2$

**Answer**

$x = \frac{5}{4}$

11) $m = 3$ at $x = 0, 1, 2, 6$

12) Unit masses at $(x, y) = (1, 0), (0, 1), (1, 1)$

**Answer**

$\left(\frac{2}{3}, \frac{2}{3}\right)$

13) $m_1 = 1$ at $(1, 0)$ and $m_2 = 4$ at $(0, 1)$

14) $m_1 = 1$ at $(1, 0)$ and $m_2 = 3$ at $(2, 2)$

**Answer**

$\left(\frac{7}{4}, \frac{3}{2}\right)$

**In exercises 15 - 24, compute the center of mass $\bar{x}$.**

15) $\rho = 1$ for $x \in (-1, 3)$

16) $\rho = x^2$ for $x \in (0, L)$

**Answer**

$\frac{3L}{4}$

17) $\rho = 1$ for $x \in (0, 1)$ and $\rho = 2$ for $x \in (1, 2)$

18) $\rho = \sin x$ for $x \in (0, \pi)$

**Answer**

$\frac{\pi}{2}$

19) $\rho = \cos x$ for $x \in \left(0, \frac{\pi}{2}\right)$

20) $\rho = e^x$ for $x \in (0, 2)$

**Answer**

$\frac{e^2 + 1}{e^2 - 1}$

21) $\rho = x^3 + xe^{-x}$ for $x \in (0, 1)$

22) $\rho = x \sin x$ for $x \in (0, \pi)$

**Answer**

$\frac{\pi^2 - 4}{\pi}$

23) $\rho = \sqrt{x}$ for $x \in (1, 4)$

24) $\rho = \ln x$ for $x \in (1, e)$

**Answer**

$\frac{1}{4}(1 + e^2)$

**In exercises 25 - 27, compute the center of mass $(\bar{x}, \bar{y})$. Use symmetry to help locate the center of mass whenever possible.**

25) $\rho = 7$ in the square $0 \le x \le 1,\ 0 \le y \le 1$

26) $\rho = 3$ in the triangle with vertices $(0, 0)$, $(a, 0)$, and $(0, b)$

**Answer**

$\left(\frac{a}{3}, \frac{b}{3}\right)$

27) $\rho = 2$ for the region bounded by $y = \cos(x)$, $y = -\cos(x)$, $x = -\frac{\pi}{2}$, and $x = \frac{\pi}{2}$

**In exercises 28 - 34, use a calculator to draw the region, then compute the center of mass $(\bar{x}, \bar{y})$. Use symmetry to help locate the center of mass whenever possible.**

28) [Technology Required] The region bounded by $y = \cos(2x)$, $x = -\frac{\pi}{4}$, and $x = \frac{\pi}{4}$

**Answer**

$\left(0, \frac{\pi}{8}\right)$

29) [Technology Required] The region between $y = 2x^2$, $y = 0$, $x = 0$, and $x = 1$

30) [Technology Required] The region between $y = \frac{5}{4}x^2$ and $y = 5$

**Answer**

$(0, 3)$

31) [Technology Required] Region between $y = \sqrt{x}$, $y = \ln x$, $x = 1$, and $x = 4$

32) [Technology Required] The region bounded by $y = 0$ and $\frac{x^2}{4} + \frac{y^2}{9} = 1$

**Answer**

$\left(0, \frac{4}{\pi}\right)$

33) [Technology Required] The region bounded by $y = 0$, $x = 0$, and $\frac{x^2}{4} + \frac{y^2}{9} = 1$

34) [Technology Required] The region bounded by $y = x^2$ and $y = x^4$ in the first quadrant

**Answer**

$\left(\frac{5}{8}, \frac{1}{3}\right)$

**In exercises 35 - 39, use the Theorem of Pappus to determine the volume of the shape.**

35) Rotating $y = mx$ around the $x$-axis between $x = 0$ and $x = 1$

36) Rotating $y = mx$ around the $y$-axis between $x = 0$ and $x = 1$

**Answer**

$V = \frac{m\pi}{3}$ units$^3$

37) A general cone created by rotating a triangle with vertices $(0, 0)$, $(a, 0)$, and $(0, b)$ around the $y$-axis. Does your answer agree with the volume of a cone?

38) A general cylinder created by rotating a rectangle with vertices $(0, 0)$, $(a, 0)$, $(0, b)$, and $(a, b)$ around the $y$-axis. Does your answer agree with the volume of a cylinder?

**Answer**

$V = \pi a^2 b$ units$^3$

39) A sphere created by rotating a semicircle with radius $a$ around the $y$-axis. Does your answer agree with the volume of a sphere?

**In exercises 40 - 44, use a calculator to draw the region enclosed by the curve. Find the area $M$ and the centroid $(\bar{x}, \bar{y})$ for the given shapes. Use symmetry to help locate the center of mass whenever possible.**

40) [Technology Required] Quarter-circle: $y = \sqrt{1 - x^2}$, $y = 0$, and $x = 0$

**Answer**

$\left(\frac{4}{3\pi}, \frac{4}{3\pi}\right)$

41) [Technology Required] Triangle: $y = x$, $y = 2 - x$, and $y = 0$

42) [Technology Required] Lens: $y = x^2$ and $y = x$

**Answer**

$\left(\frac{1}{2}, \frac{2}{5}\right)$

43) [Technology Required] Ring: $y^2 + x^2 = 1$ and $y^2 + x^2 = 4$

44) [Technology Required] Half-ring: $y^2 + x^2 = 1$, $y^2 + x^2 = 4$, and $y = 0$

**Answer**

$\left(0, \frac{28}{9\pi}\right)$

45) Find the generalized center of mass in the sliver between $y = x^a$ and $y = x^b$ with $a > b$. Then, use the Pappus theorem to find the volume of the solid generated when revolving around the $y$-axis.

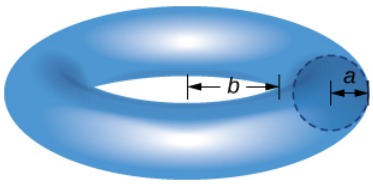
46) Find the generalized center of mass between $y = a^2 - x^2$, $x = 0$, and $y = 0$. Then, use the Pappus theorem to find the volume of the solid generated when revolving around the $y$-axis.

**Answer**

Center of mass: $\left(\frac{a}{6}, \frac{4a^2}{5}\right)$,
Volume: $\frac{2\pi a^4}{9}$ units$^3$

47) Find the generalized center of mass between $y = b\sin(ax)$, $x = 0$, and $x = \frac{\pi}{a}$. Then, use the Theorem of Pappus to find the volume of the solid generated when revolving around the $y$-axis.

48) Use the Theorem of Pappus to find the volume of a torus (pictured here). Assume that a disk of radius $a$ is positioned with the left end of the circle at $x = b$, $b > 0$, and is rotated around the $y$-axis.



**Answer**

Volume: $V = 2\pi^2 a^2(b + a)$

49) Find the center of mass $(\bar{x}, \bar{y})$ for a thin wire along the semicircle $y = \sqrt{1 - x^2}$ with unit mass. (Hint: Use the Theorem of Pappus.)

# 6.7: The Mean Value Theorem for Integrals

**Note to the Instructor (click to expand)**

This is an *incredibly* short section - perhaps a half lecture.

---

To succeed in this section, you'll need to use some skills from previous courses. While you should already know them, this is the first time they've been required. You can review these skills in CRC's Corequisite Codex. If you have a support class, it might cover some, **but not all**, of these topics.

**Prerequisite Skills and Support Topics (click to expand)**

- **Solving Equations**
  - Solving Trigonometric Equations Using Identities: Homework problem #9 requires solving a trigonometric equation to find the times when the number of daylight hours equals the average value.

---

The following is a list of learning objectives for this section.

**Learning Objectives (click to expand)**

- Describe the meaning of the Mean Value Theorem for Integrals.

Hawk A.I. Section-Specific Tutor

To access the Hawk A.I. Tutor, you will need to be logged into your campus Gmail account.

This short section is dedicated to an examination of another essential theorem, the Mean Value Theorem for Integrals.

## The Mean Value Theorem for Integrals

Recall, for a discrete list of values, $\{a_1, a_2, \ldots, a_n\}$, we compute the average using the formula

$$a_{\text{avg}} = \frac{a_1 + a_2 + \cdots + a_n}{n}.$$

We now have the "mathematical technology" to create the analog for a continuous function, $f(x)$, over a closed interval $[a, b]$.

We can *approximate* the average value of $f$ as follows

$$f_{\text{avg}} \approx \frac{\sum_{i=1}^{n} f(x_i)}{n},$$

where $x_i$ is defined using our traditional definitions from Riemann sums. However, we now perform a little manipulation to force the numerator to become a Riemann sum.

$$f_{\text{avg}} \approx \frac{\Delta x \sum_{i=1}^{n} f(x_i)}{n\Delta x} = \frac{\sum_{i=1}^{n} f(x_i)\Delta x}{n\Delta x} = \frac{\sum_{i=1}^{n} f(x_i)\Delta x}{b-a},$$

where we used the fact that $\Delta x = \frac{b-a}{n}$ in our last step.

Taking the limit as $n \to \infty$, we obtain the exact value of the average for $f$ over the closed interval $[a, b]$, simply called the **average value** of $f$,

$$f_{\text{avg}} = \frac{1}{b-a}\int_a^b f(x)dx.$$

This definition leads us to a new theorem to add to our "toolkit." The **Mean Value Theorem for Integrals** states that a continuous function on a closed interval takes on its average value at the same point in that interval. The theorem guarantees that if $f(x)$ is continuous, a point $c$ exists in an interval $[a, b]$ such that the value of the function at $c$ is equal to the average value of $f(x)$ over $[a, b]$.

We state this theorem mathematically with the help of the formula for the average value of a function that we presented in Calculus I.

### Theorem: The Mean Value Theorem for Integrals

If $f(x)$ is continuous over an interval $[a, b]$, then there is at least one point $c \in [a, b]$ such that

$$f(c) = \frac{1}{b-a} \int_a^b f(x)\, dx.$$

This formula can also be stated as

$$\int_a^b f(x)\, dx = f(c)(b-a).$$

**Proof**

Since $f(x)$ is continuous on $[a, b]$, by the Extreme Value Theorem, it assumes minimum and maximum values - $m$ and $M$, respectively - on $[a, b]$. Then, for all $x$ in $[a, b]$, we have $m \leq f(x) \leq M$. Therefore, by the Comparison Theorem, we have

$$m(b-a) \leq \int_a^b f(x)\, dx \leq M(b-a).$$

Dividing by $b-a$ gives us

$$m \leq \frac{1}{b-a} \int_a^b f(x)\, dx \leq M.$$

Since $\frac{1}{b-a} \int_a^b f(x)\, dx$ is a number between $m$ and $M$, and since $f(x)$ is continuous and assumes the values $m$ and $M$ over $[a, b]$, by the Intermediate Value Theorem, there is a number $c$ over $[a, b]$ such that

$$f(c) = \frac{1}{b-a} \int_a^b f(x)\, dx,$$

and the proof is complete.

### Example 6.7.1: Finding the Average Value of a Function

Find the average value of the function $f(x) = 8 - 2x$ over the interval $[0, 4]$ and find $c$ such that $f(c)$ equals the average value of the function over $[0, 4]$.

**Solution**

The formula states the mean value of $f(x)$ is given by

$$\frac{1}{4-0} \int_0^4 (8 - 2x)\, dx.$$

We can see in Figure 6.7.1 that the function represents a straight line and forms a right triangle bounded by the $x$- and $y$-axes. The area of the triangle is $A = \frac{1}{2}(base)(height)$. We have

$$A = \frac{1}{2}(4)(8) = 16.$$

The average value is found by multiplying the area by $1/(4-0)$. Thus, the average value of the function is

$$\frac{1}{4}(16) = 4$$

Set the average value equal to $f(c)$ and solve for $c$.

$$\begin{aligned} 8-2c &= 4 \\ c &= 2 \end{aligned}$$

At $c=2, f(2)=4$.

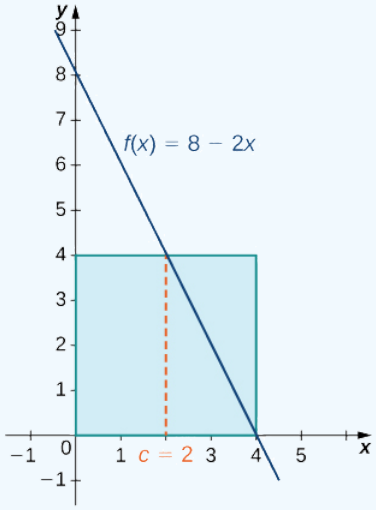

Figure 6.7.1: By the Mean Value Theorem, the continuous function $f(x)$ takes on its average value at $c$ at least once over a closed interval.

## Checkpoint 6.7.1

Find the average value of the function $f(x)=\frac{x}{2}$ over the interval $[0,6]$ and find c such that $f(c)$ equals the average value of the function over $[0,6]$.

**Answer**

The average value is $1.5$ and $c=3$.

## Example 6.7.2: Finding the Point Where a Function Takes on Its Average Value

Given $\int_0^3 x^2\,dx=9$, find $c$ such that $f(c)$ equals the average value of $f(x)=x^2$ over $[0,3]$.

**Solution**

We are looking for the value of $c$ such that

$$f(c)=\frac{1}{3-0}\int_0^3 x^2\,dx=\frac{1}{3}(9)=3.$$

Replacing $f(c)$ with $c^2$, we have

$$\begin{aligned} c^2 &= 3 \\ c &= \pm\sqrt{3}. \end{aligned}$$

Since $-\sqrt{3}$ is outside the interval, take only the positive value. Thus, $c=\sqrt{3}$ (Figure 6.7.2).

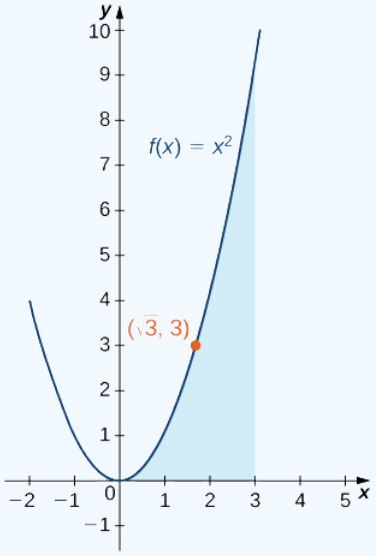

Figure 6.7.2: Over the interval $[0, 3]$, the function $f(x) = x^2$ takes on its average value at $c = \sqrt{3}$.

**? Checkpoint 6.7.2**

Given $\int_0^3 (2x^2 - 1)\,dx = 15$, find $c$ such that $f(c)$ equals the average value of $f(x) = 2x^2 - 1$ over $[0, 3]$.

**Answer**

$c = \sqrt{3}$

https://math.libretexts.org/@go/page/175589

# 6.7E: EXERCISES

## READING QUESTIONS

1. What is the formula for the average value of a continuous function $f(x)$ over an interval $[a, b]$?
2. What does the Mean Value Theorem for Integrals guarantee about a continuous function on a closed interval?
3. What are the two equivalent ways to write the conclusion of the Mean Value Theorem for Integrals?
4. In Example 1.9.2, why is the value $c = -\sqrt{3}$ discarded as a valid solution?
5. How is the average value of a continuous function derived from the concept of averaging a discrete list of numbers?

1) Consider two athletes running at variable speeds $v_1(t)$ and $v_2(t)$. The runners start and finish a race at exactly the same time. Explain why the two runners must be going the same speed at some point.

2) Two mountain climbers start their climb at base camp, taking two different routes, one steeper than the other, and arrive at the peak at exactly the same time. Is it necessarily true that, at some point, both climbers increased in altitude at the same rate?

**Answer**

Yes. It is implied by the Mean Value Theorem for Integrals.

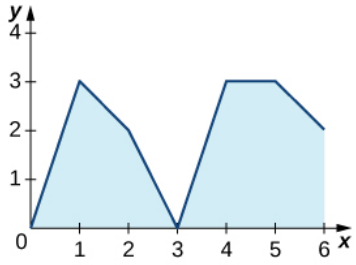
3) To get on a certain toll road a driver has to take a card that lists the mile entrance point. The card also has a timestamp. When going to pay the toll at the exit, the driver is surprised to receive a speeding ticket along with the toll. Explain how this can happen.

4) Set $F(x) = \int_1^x (1 - t)\, dt$. Find $F'(2)$ and the average value of $F'$ over $[1, 2]$.

**Answer**

$F'(2) = -1$; average value of $F'$ over $[1, 2]$ is $-1/2$.

5) The graph of $y = \int_0^x f(t)\, dt$, where $f$ is a piecewise constant function, is shown here.

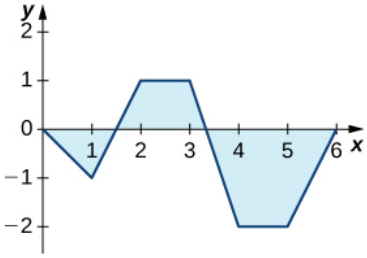


a. Over which intervals is $f$ positive? Over which intervals is it negative? Over which intervals, if any, is it equal to zero?

b. What are the maximum and minimum values of $f$?

c. What is the average value of $f$?

6) The graph of $y = \int_0^x f(t)\, dt$, where $f$ is a piecewise constant function, is shown here.



a. Over which intervals is $f$ positive? Over which intervals is it negative? Over which intervals, if any, is it equal to zero?

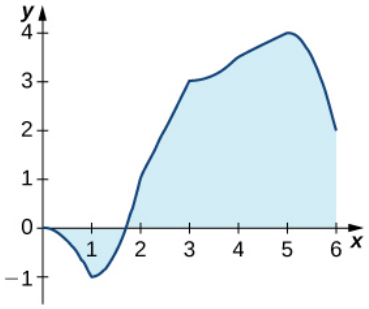
b. What are the maximum and minimum values of $f$?

c. What is the average value of $f$?

**Answer**

a. $f$ is positive over $[1,2]$ and $[5,6]$, negative over $[0,1]$ and $[3,4]$, and zero over $[2,3]$ and $[4,5]$.
b. The maximum value is $2$ and the minimum is $-3$.
c. The average value is $0$.

7) The graph of $y = \int_0^x \ell(t)\,dt$, where $\ell$ is a piecewise linear function, is shown here.

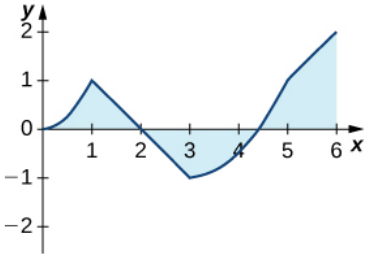


a. Over which intervals is $\ell$ positive? Over which intervals is it negative? Over which, if any, is it zero?

b. Over which intervals is $\ell$ increasing? Over which is it decreasing? Over which, if any, is it constant?

c. What is the average value of $\ell$?

8) The graph of $y = \int_0^x \ell(t)\,dt$, where $\ell$ is a piecewise linear function, is shown here.



a. Over which intervals is $\ell$ positive? Over which intervals is it negative? Over which, if any, is it zero?

b. Over which intervals is $\ell$ increasing? Over which is it decreasing? Over which intervals, if any, is it constant?

c. What is the average value of $\ell$?

**Answer**

a. $\ell$ is positive over $[0,1]$ and $[3,6]$, and negative over $[1,3]$.
b. It is increasing over $[0,1]$ and $[3,5]$, and it is constant over $[1,3]$ and $[5,6]$.
c. Its average value is $\frac{1}{3}$.

9) Suppose that the number of hours of daylight on a given day in Seattle is modeled by the function $-3.75\cos(\frac{\pi t}{6}) + 12.25$, with $t$ given in months and $t = 0$ corresponding to the winter solstice.

a. What is the average number of daylight hours in a year?

b. At which times $t_1$ and $t_2$, where $0 \le t_1 < t_2 < 12$, do the number of daylight hours equal the average number?

c. Write an integral that expresses the total number of daylight hours in Seattle between $t_1$ and $t_2$

d. Compute the mean hours of daylight in Seattle between $t_1$ and $t_2$, where $0 \le t_1 < t_2 < 12$, and then between $t_2$ and $t_1$, and show that the average of the two is equal to the average day length.

10) Suppose the rate of gasoline consumption in the United States can be modeled by a sinusoidal function of the form $(11.21 - \cos(\frac{\pi t}{6})) \times 10^9$ gal/mo.

a. What is the average monthly consumption, and for which values of $t$ is the rate at time $t$ equal to the average rate?

b. What is the number of gallons of gasoline consumed in the United States in a year?

c. Write an integral that expresses the average monthly U.S. gas consumption during the part of the year between the beginning of April $(t = 3)$ and the end of September $(t = 9)$.

**Answer**

a. The average is $11.21 \times 10^9$ since $\cos(\frac{\pi t}{6})$ has period 12 and integral 0 over any period. Consumption is equal to the average when $\cos(\frac{\pi t}{6}) = 0$, when $t = 3$, and when $t = 9$.

b. Total consumption is the average rate times duration: $11.21 \times 12 \times 10^9 = 1.35 \times 10^{11}$

c. $10^9(11.21 - \frac{1}{6}\int_3^9 \cos(\frac{\pi t}{6})\,dt) = 10^9(11.21 + 2\pi) = 11.84x10^9$

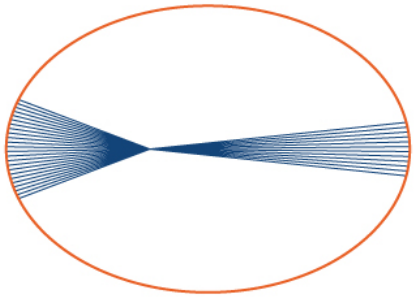
11) Explain why, if $f$ is continuous over $[a, b]$, there is at least one point $c \in [a, b]$ such that $f(c) = \frac{1}{b-a}\int_a^b f(t)\,dt$.

12) Explain why, if $f$ is continuous over $[a, b]$ and is not equal to a constant, there is at least one point $M \in [a, b]$ such that $f(M) = \frac{1}{b-a}\int_a^b f(t)\,dt$ and at least one point $m \in [a, b]$ such that $f(m) < \frac{1}{b-a}\int_a^b f(t)\,dt$.

**Answer**

If $f$ is not constant, then its average is strictly smaller than the maximum and larger than the minimum, which are attained over $[a, b]$ by the Extreme Value Theorem.

13) Kepler's first law states that the planets move in elliptical orbits with the Sun at one focus. The closest point of a planetary orbit to the Sun is called the **perihelion** (for Earth, it currently occurs around January 3) and the farthest point is called the **aphelion** (for Earth, it currently occurs around July 4). Kepler's second law states that planets sweep out equal areas of their elliptical orbits in equal times. Thus, the two arcs indicated in the following figure are swept out in equal times. At what time of year is Earth moving fastest in its orbit? When is it moving slowest? Kepler's first law states that the planets move in elliptical orbits with the Sun at one focus. The closest point of a planetary orbit to the Sun is called the perihelion (for Earth, it currently occurs around January 3) and the farthest point is called the aphelion (for Earth, it currently occurs around July 4). Kepler's second law states that planets sweep out equal areas of their elliptical orbits in equal times. Thus, the two arcs indicated in the following figure are swept out in equal times. At what time of year is Earth moving fastest in its orbit? When is it moving slowest?



14) A point on an ellipse with major axis length $2a$ and minor axis length $2b$ has the coordinates $(a\cos\theta, b\sin\theta), \quad 0 \le \theta \le 2\pi$.

a. Show that the distance from this point to the focus at $(-c, 0)$ is $d(\theta) = a + c\cos\theta$, where $c = \sqrt{a^2 - b^2}$.

Use these coordinates to show that the average distance $\bar{d}$ from a point on the ellipse to the focus at $(-c, 0)$, with respect to angle $\theta$, is $a$.

**Answer**

a. $d^2\theta = (a\cos\theta + c)^2 + b^2\sin^2\theta = a^2 + c^2\cos^2\theta + 2ac\cos\theta = (a + c\cos\theta)^2$;

b. $\bar{d} = \frac{1}{2\pi}\int_0^{2\pi}(a + 2c\cos\theta)\,d\theta = a$

15) As implied earlier, according to Kepler's laws, Earth's orbit is an ellipse with the Sun at one focus. The perihelion for Earth's orbit around the Sun is 147,098,290 km and the aphelion is 152,098,232 km.

a. By placing the major axis along the $x$-axis, find the average distance from Earth to the Sun.

b. The classic definition of an astronomical unit (AU) is the distance from Earth to the Sun, and its value was computed as the average of the perihelion and aphelion distances. Is this definition justified?

16) The force of gravitational attraction between the Sun and a planet is $F(\theta) = \frac{GmM}{r^2(\theta)}$, where $m$ is the mass of the planet, $M$ is the mass of the Sun, $G$ is a universal constant, and $r(\theta)$ is the distance between the Sun and the planet when the planet is at an angle $\theta$ with the major axis of its orbit. Assuming that $M$, $m$, and the ellipse parameters $a$ and $b$ (half-lengths of the major and minor axes) are given, set up—but do not evaluate—an integral that expresses in terms of $G$, $m$, $M$, $a$, $b$ the average gravitational force between the Sun and the planet.

**Answer**

Mean gravitational force $= \dfrac{GmM}{2}\displaystyle\int_0^{2\pi} \dfrac{1}{(a+2\sqrt{a^2-b^2}\cos\theta)^2}\,d\theta.$

The displacement from rest of a mass attached to a spring satisfies the simple harmonic motion equation $x(t) = A\cos(\omega t - \phi)$, where $\phi$ is a phase constant, $\omega$ is the angular frequency, and $A$ is the amplitude. Find the average velocity, the average speed (magnitude of velocity), the average displacement, and the average distance from rest (magnitude of displacement) of the mass.

# 6.8: CHAPTER 1 REVIEW EXERCISES

***True or False?* Justify your answer with a proof or a counterexample.**

1) The amount of work to pump the water out of a half-full cylinder is half the amount of work to pump the water out of the full cylinder.

**Answer**

False

2) If the force is constant, the amount of work to move an object from $x = a$ to $x = b$ is $F(b - a)$.

3) The disk method can be used in any situation in which the washer method is successful at finding the volume of a solid of revolution.

**Answer**

False

4) If the half-life of $seaborgium - 266$ is $360$ ms, then $k = \dfrac{\ln 2}{360}$.

**For exercises 5 - 8, use the requested method to determine the volume of the solid.**

5) The volume that has a base of the ellipse $\dfrac{x^2}{4} + \dfrac{y^2}{9} = 1$ and cross-sections of an equilateral triangle perpendicular to the $y$-axis. Use the method of slicing.

**Answer**

$V = 32\sqrt{3}\,\text{units}^3$

6) $y = x^2 - x$, from $x = 1$ to $x = 4$, rotated around the $y$-axis using the washer method

7) $x = y^2$ and $x = 3y$ rotated around the $y$-axis using the washer method

**Answer**

$V = \frac{162\pi}{5}\,\text{units}^3$

8) $x = 2y^2 - y^3,\ x = 0$,and $y = 0$ rotated around the $x$-axis using cylindrical shells

**For exercises 9 - 14, find**

**a. the area of the region,**

**b.the volume of the solid when rotated around the $x$-axis, and**

**c. the volume of the solid when rotated around the $y$-axis. Use whichever method seems most appropriate to you.**

9) $y = x^3, x = 0, y = 0$, and $x = 2$

**Answer**

a. $A = 4$ units$^2$
b. $V = \frac{128\pi}{7}$ units$^3$
c. $V = \frac{64\pi}{5}$ units$^3$

10) $y = x^2 - x$ and $x = 0$

11) [T] $y = \ln(x) + 2$ and $y = x$

**Answer**

a. $A \approx 1.949$ units$^2$
b. $V \approx 21.952$ units$^3$
c. $V = \approx 17.099$ units$^3$

12) $y = x^2$ and $y = \sqrt{x}$

13) $y = 5 + x, y = x^2, x = 0$, and $x = 1$

**Answer**

a. $A = \frac{31}{6}$ units$^2$
b. $V = \frac{452\pi}{15}$ units$^3$
c. $V = \frac{31\pi}{6}$ units$^3$

14) Below $x^2 + y^2 = 1$ and above $y = 1 - x$

15) Find the mass of $\rho = e^{-x}$ on a disk centered at the origin with radius $4$.

**Answer**

$m \approx 245.282$

16) Find the center of mass for $\rho = \tan^2 x$ on $x \in (-\frac{\pi}{4}, \frac{\pi}{4})$.

17) Find the mass and the center of mass of $\rho = 1$ on the region bounded by $y = x^5$ and $y = \sqrt{x}$.

**Answer**

Mass: $\frac{1}{2}$,
Center of mass: $(\frac{18}{35}, \frac{9}{11})$

**For exercises 18 - 19, find the requested arc lengths.**

18) The length of $x$ for $y = \cosh(x)$ from $x = 0$ to $x = 2$.

19) The length of $y$ for $x = 3 - \sqrt{y}$ from $y = 0$ to $y = 4$

**Answer**

$s = [\sqrt{17} + \frac{1}{8}\ln(33 + 8\sqrt{17})]$ units

**For exercises 20 - 21, find the surface area and volume when the given curves are revolved around the specified axis.**

20) The shape created by revolving the region between $y = 4 + x$, $y = 3 - x$, $x = 0$, and $x = 2$ rotated around the $y$-axis.

21) The loudspeaker created by revolving $y = \dfrac{1}{x}$ from $x = 1$ to $x = 4$ around the $x$-axis.

**Answer**

Volume: $V = \frac{3\pi}{4}$ units$^3$
Surface area: $A = \pi\left(\sqrt{2} - \sinh^{-1}(1) + \sinh^{-1}(16) - \frac{\sqrt{257}}{16}\right)$ units$^2$

**For exercise 22, consider the Karun-3 dam in Iran. Its shape can be approximated as an isosceles triangle with height 205 m and width 388 m. Assume the current depth of the water is 180 m. The density of water is 1000 kg/m$^3$.**

22) Find the total force on the wall of the dam.

23) You are a crime scene investigator attempting to determine the time of death of a victim. It is noon and $45$ °F outside and the temperature of the body is $78$ °F. You know the cooling constant is $k = 0.00824$ °F/min. When did the victim die, assuming that a human's temperature is $98$ °F?

**Answer**

11:02 a.m.

**For the following exercise, consider the stock market crash in 1929 in the United States. The table lists the Dow Jones industrial average per year leading up to the crash.**

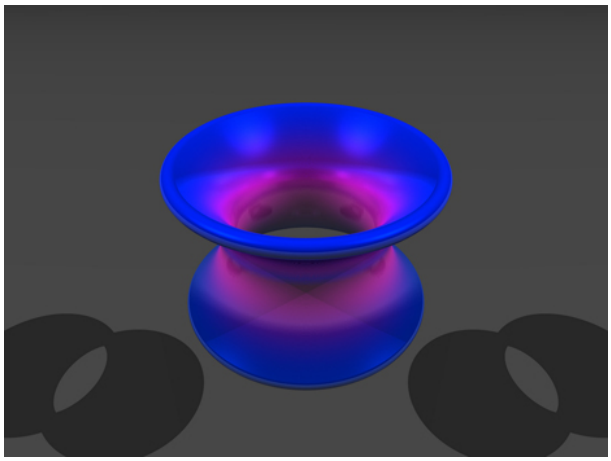
| Year after 1920 | Value ($) |
|---|---|
| 1 | 63.90 |
| 3 | 100 |
| 5 | 110 |
| 7 | 160 |
| 9 | 381.17 |

*Source*: http:/stockcharts.com/freecharts/hi...a19201940.html

24) [T] The best-fit exponential curve to these data is given by $y = 40.71 + 1.224^x$. Why do you think the gains of the market were unsustainable? Use first and second derivatives to help justify your answer. What would this model predict the Dow Jones industrial average to be in **2014** ?

**For exercises 25 - 26, consider the catenoid, the only solid of revolution that has a minimal surface, or zero mean curvature. A catenoid in nature can be found when stretching soap between two rings.**

25) Find the volume of the catenoid $y = \cosh(x)$ from $x = -1$ to $x = 1$ that is created by rotating this curve around the $x$-**axis,** as shown here.



**Answer**

$V = \pi\left(1 + \sinh(1)\cosh(1)\right)$ units$^3$

26) Find surface area of the catenoid $y = \cosh(x)$ from $x = -1$ to $x = 1$ that is created by rotating this curve around the $x$-**axis.**

# 6.9: Areas Between Curves

https://math.libretexts.org/@go/page/175573

**Note to the Instructor (click to expand)**

This section only covers areas between curves (with a clarification of the difference between a direct integration problem and being requested to find areas). Focus should be on requiring graphing skills (algebraic, trigonometric, exponential, etc.).

---

To succeed in this section, you'll need to use some skills from previous courses. While you should already know them, this is the first time they've been required. You can review these skills in CRC's Corequisite Codex. If you have a support class, it might cover some, **but not all**, of these topics.

**Prerequisite Skills and Support Topics (click to expand)**

- **Geometry**
  - The Pythagorean Theorem, Distance Formula, and Midpoint Formula: The concept of distance, particularly the distance formula, is reviewed in the section as foundational for understanding $y_T - y_B$ and $x_R - x_L$.
- **Simplifying Expressions**
  - Multiplying and Distributing Polynomial Expressions: Necessary for simplifying the integrand $f(x) - g(x)$ after substitution.
- **Solving Equations**
  - Solving Linear Equations: Essential for finding intersection points when the bounding curves are lines.
  - Solving Quadratic Equations: Required for finding intersection points when one or both bounding curves are quadratic functions (as seen in Example 2).
  - Solving Polynomial Equations: Generally needed to find points where $f(x) = g(x)$ if the functions are polynomials, which define the limits of integration.
  - Solving Radical Equations: May be needed if functions involve roots and intersections are sought, or when converting $y = f(x)$ to $x = v(y)$.
- **Graphs**
  - The Cartesian Coordinate System and the Quadrants: Fundamental for setting up and visualizing the area problem in a 2D plane.
  - Ordered Pairs and Graphing Relations by Point-Plotting: Essential for sketching the functions to correctly identify the region, the upper/lower or right/left functions, and the limits of integration.
- **An Overview of Functions**
  - The Definition of a Function: Crucial for understanding the relationships $y = f(x)$ and $x = u(y)$ that define the boundaries of the area.
  - Evaluating Functions: Necessary for finding specific points on curves, comparing function values, and for numerical approximation methods.

Hawk A.I. Section-Specific Tutor

COSUMNES RIVER COLLEGE MATHEMATICS

To access the Hawk A.I. Tutor, you will need to be logged into your campus Gmail account.

- The Domain and Range of a Function: Important for understanding the intervals over which functions are defined and where intersections might occur.

- **Graphing Functions**
  - Graphs of Functions: The ability to sketch or visualize graphs is paramount for setting up the correct integral for the area between curves.
  - Base Graphs: Recognizing the shapes of common functions (lines, parabolas, square roots, trigonometric functions) helps in quickly sketching the region.
- **Trigonometry**
  - Evaluating Trigonometric Functions at Special Angles: Required for calculations when limits of integration or intersection points involve these specific angles (e.g., $\frac{\pi}{4}$).
  - Base Graphs of the Trigonometric Functions: Important for visualizing regions bounded by trigonometric curves like sine and cosine.
  - Solving Simple Trigonometric Equations: Necessary for finding the intersection points of trigonometric functions, which determine the limits of integration.
  - Trigonometric Identities - The Pythagorean Identities: Often used in simplifying expressions or solving trigonometric equations.
  - Trigonometric Identities - Sum and Difference of Angles Identities: Useful in various trigonometric manipulations.
  - Trigonometric Identities - Double-Angle Identities: Can be needed for solving equations or simplifying integrands.
  - Trigonometric Identities - Half-Angle and Power Reduction Identities: Particularly power reduction formulas can be useful in integration, though not directly for area setup here, they are part of the expected mastery.

---

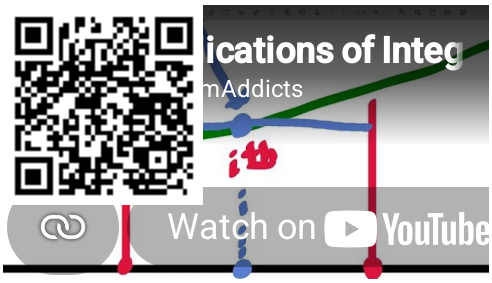
The following is a list of learning objectives for this section.

**Learning Objectives (click to expand)**

- Determine the area of a region between two curves by integrating with respect to the independent variable.
- Find the area of a compound region.
- Determine the area of a region between two curves by integrating with respect to the dependent variable.

## A Review of Necessary Prerequisite Theory

The following video is an excellent place to start before your first class meeting. It contains a review of the necessary theory from Differential Calculus (a.k.a. Calculus I) to begin your pathway to success in this course.



In Differential Calculus, we developed the definite integral concept to calculate the area between a curve and an axis on a given interval. In this section, we expand that idea to calculate the area of more complex regions. We start by finding the area between two curves that are functions of $x$, beginning with the simple case in which one function is always greater than the other. We then look at instances where the graphs of the functions cross. Lastly, we consider how to calculate the area between two curves that are functions of $y$.

## An Aside: Measuring Distances

Before we dive into Integral Calculus (a.k.a., Calculus II), let's take a moment to discuss something simple and familiar - distance.[1] Specifically, we need to recall the Distance Formula. The distance between any two points, $P(x_1, y_1)$ and $Q(x_2, y_2)$, in the Cartesian plane is

$$d(P,Q) = \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2}. \tag{6.9.1}$$

If the two points share the same $x$-coordinate (i.e., they lie on the same vertical line), then Equation 6.9.1 becomes

$$d(P,Q) = \sqrt{(y_1 - y_2)^2} = |y_1 - y_2| = \begin{cases} y_1 - y_2 & \text{if} \quad y_1 \geq y_2 \\ y_2 - y_1 & \text{if} \quad y_1 < y_2 \end{cases}.$$

This can be read as follows:

> *The distance between any two points on a vertical line is* $y_T - y_B$, *where* $y_T = y_{\text{Top}} = \max\{y_1, y_2\}$ *and* $y_B = y_{\text{Bottom}} = \min\{y_1, y_2\}$.

This interpretation will be *critical* as we move forward.

If we, instead, assume that the points $P$ and $Q$ lie on the same horizontal line (thereby having the same $y$-coordinates), then Equation 6.9.1 becomes

$$d(P,Q) = \sqrt{(x_1 - x_2)^2} = |x_1 - x_2| = \begin{cases} x_1 - x_2 & \text{if} \quad x_1 \geq x_2 \\ x_2 - x_1 & \text{if} \quad x_1 < x_2 \end{cases}.$$

This can be read as follows:

> *The distance between any two points on a horizontal line is* $x_R - x_L$, *where* $x_R = x_{\text{Right}} = \max\{x_1, x_2\}$ *and* $x_L = x_{\text{Left}} = \min\{x_1, x_2\}$.

The two statements, that the distance between two points on a vertical line is $y_{\text{Top}} - y_{\text{Bottom}}$ and the distance between two points on the horizontal line is $x_{\text{Right}} - x_{\text{Left}}$, are going to be used repeatedly in this course. For example, we will often need to determine the distance between a function, say $f(x)$, and a horizontal line, say $y = L$. If we know that $L \geq f(x)$ on the interval $[a, b]$, then the vertical distance between $y = L$ and the function $f(x)$ is always going to be $y_{\text{Top}} - y_{\text{Bottom}} = L - f(x)$, for all $x \in [a, b]$. Likewise, if we know the function $g(y)$ is always to the left of $h(y)$ for $y \in [c, d]$, then the *horizontal* distance between these two functions for any value of $y$ in $[c, d]$ is $x_{\text{Right}} - x_{\text{Left}} = h(y) - g(y)$.

While the previous paragraph is (hopefully) simple to understand, the results are immensely helpful for us. It's now time to return to Calculus!

## Area of a Region between Two Curves

Let $f(x)$ and $g(x)$ be continuous functions over an interval $[a, b]$ such that $f(x) \geq g(x)$ on $[a, b]$. We want to find the area between the graphs of the functions, as shown in Figure 6.9.1.

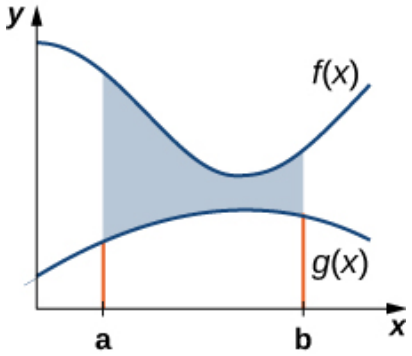


Figure 6.9.1: The area between the graphs of two functions, $f(x)$ and $g(x)$, on the interval $[a, b]$

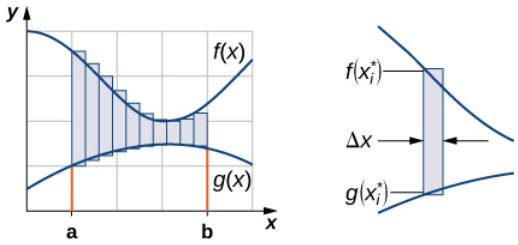
As we did before, we will partition the interval on the $x$-axis and approximate the area between the graphs of the functions with rectangles. So, for $i = 0, 1, 2, \ldots, n$, let $P = \{x_i\}$ be a regular partition of $[a, b]$. Then, for $i = 1, 2, \ldots, n$, choose a point $x_i^* \in [x_{i-1}, x_i]$, and on each interval $[x_{i-1}, x_i]$ construct a rectangle that extends vertically from $g(x_i^*)$ to $f(x_i^*)$. Figure 6.9.2(a) shows the rectangles when $x_i^*$ is selected to be the left endpoint of the interval and $n = 10$. Figure 6.9.2(b) shows a representative rectangle in detail.



(a) (b)

Figure 6.9.2: (a) We can approximate the area between the graphs of two functions, $f(x)$ and $g(x)$, with rectangles. (b) The area of a typical rectangle goes from one curve to the other.

The height of each individual rectangle is $y_{T_i} - y_{B_i} = f(x_i^*) - g(x_i^*)$ and the width of each rectangle is $\Delta x$. Adding the areas of all the rectangles, we see that the area between the curves is approximated by

$$A \approx \sum_{i=1}^{n} [y_{T_i} - y_{B_i}] \Delta x = \sum_{i=1}^{n} [f(x_i^*) - g(x_i^*)] \Delta x.$$

This is a Riemann sum, so we take the limit as $n \to \infty$ and we get

$$A = \lim_{n \to \infty} \sum_{i=1}^{n} [f(x_i^*) - g(x_i^*)] \Delta x = \int_a^b [f(x) - g(x)] dx.$$

These findings are summarized in the following theorem.

### Theorem: Area between Two Curves

Let $f(x)$ and $g(x)$ be continuous functions such that $f(x) \geq g(x)$ over an interval $[a, b]$. Let $\mathbf{R}$ denote the region bounded above by the graph of $f(x)$, below by the graph of $g(x)$, and on the left and right by the lines $x = a$ and $x = b$, respectively. Then, the area of $\mathbf{R}$ is given by

$$A = \int_a^b [f(x) - g(x)] dx.$$

We apply this theorem in the following example.

**Example 6.9.1**

If $\mathbf{R}$ is the region bounded above by the graph of the function $f(x) = x + 4$ and below by the graph of the function $g(x) = 3 - \frac{x}{2}$ over the interval $[1, 4]$, find the area of region $\mathbf{R}$.

**Solution**

Graphing the requested region, depicted in the following figure, will be a requirement.

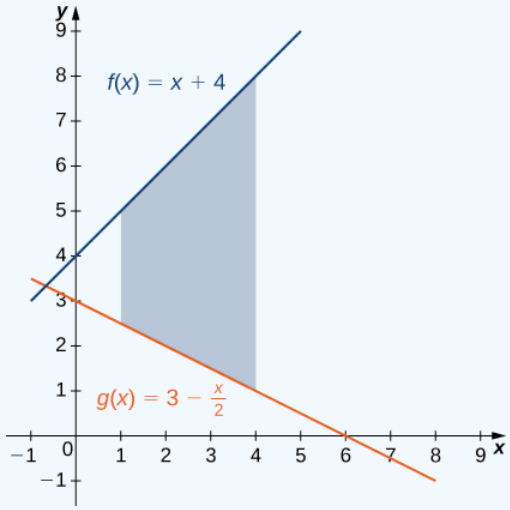


Figure 6.9.3: A region between two curves is shown where one curve is always greater than the other.

We can see that the values of $y_T$ are always "played by" $f(x)$ and the values of $y_B$ are always "played by" $g(x)$. Therefore, we have

$$\begin{aligned} A &= \int_a^b [y_T - y_B]\, dx \\ &= \int_a^b [f(x) - g(x)]\, dx \\ &= \int_1^4 \left[(x+4) - \left(3 - \frac{x}{2}\right)\right] dx \\ &= \int_1^4 \left[\frac{3x}{2} + 1\right] dx \\ &= \left[\frac{3x^2}{4} + x\right]\Big|_1^4 \\ &= \left(16 - \frac{7}{4}\right) \\ &= \frac{57}{4}. \end{aligned}$$

The area of the region is $\frac{57}{4}$ $\text{units}^2$.

**? Checkpoint 6.9.1**

If $\mathbf{R}$ is the region bounded by the graphs of the functions $f(x) = \frac{x}{2} + 5$ and $g(x) = x + \frac{1}{2}$ over the interval $[1, 5]$, find the area of region $\mathbf{R}$.

**Answer**

$12 \text{ units}^2$

In Example 6.9.1, we defined the interval of interest as part of the problem statement. Quite often, though, we want to define our interval of interest based on where the graphs of the two functions intersect. This is illustrated in the following example.

**✔ Example 6.9.2**

If $\mathbf{R}$ is the region bounded above by the graph of the function $f(x) = 9 - (\frac{x}{2})^2$ and below by the graph of the function $g(x) = 6 - x$, find the area of region $\mathbf{R}$.

**Solution**

The region is depicted in the following figure, and we can see that $y_T = f(x)$ and $y_B = g(x)$ over the entire region.

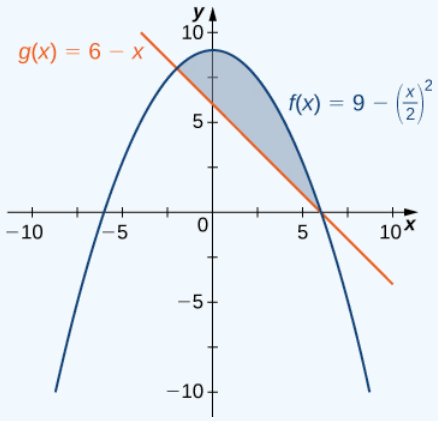

Figure 6.9.4: This graph shows the region below the graph of $f(x)$ and above the graph of $g(x)$.

We first need to compute where the graphs of the functions intersect. Setting $f(x) = g(x)$, we get

$$\begin{aligned} f(x) &= g(x) \\ \Rightarrow \quad 9 - \left(\frac{x}{2}\right)^2 &= 6 - x \\ \Rightarrow \quad 9 - \frac{x^2}{4} &= 6 - x \\ \Rightarrow \quad 36 - x^2 &= 24 - 4x \\ \Rightarrow \quad x^2 - 4x - 12 &= 0 \\ \Rightarrow \quad (x-6)(x+2) &= 0. \end{aligned}$$

The graphs of the functions intersect when $x = 6$ or $x = -2$, so we want to integrate from $-2$ to $6$. Therefore,

$$\begin{aligned} A &= \int_a^b [y_T - y_B]\,dx \\ &= \int_a^b [f(x) - g(x)]\,dx \\ &= \int_{-2}^6 \left[9 - \left(\frac{x}{2}\right)^2 - (6 - x)\right]\,dx \\ &= \int_{-2}^6 \left[3 - \frac{x^2}{4} + x\right]\,dx \\ &= \left[3x - \frac{x^3}{12} + \frac{x^2}{2}\right]\Big|_{-2}^6 \\ &= \frac{64}{3}. \end{aligned}$$

The area of the region is $\frac{64}{3}$ $\text{units}^2$.

**? Checkpoint 6.9.2**

If $\mathbf{R}$ is the region bounded above by the graph of the function $f(x) = x$ and below by the graph of the function $g(x) = x^4$, find the area of region $\mathbf{R}$.

**Answer**

$\frac{3}{10}$ $\text{units}^2$

## Areas of Compound Regions

What if we want to examine regions bounded by graphs of functions that cross one another? In that case, we modify the process we just developed by using the absolute value function.

**Theorem: Finding the Area of a Region between Curves That Cross**

Let $f(x)$ and $g(x)$ be continuous functions over an interval $[a, b]$. Let $\mathbf{R}$ denote the region between the graphs of $f(x)$ and $g(x)$, and be bounded on the left and right by the lines $x = a$ and $x = b$, respectively. Then, the area of $\mathbf{R}$ is given by

$$A = \int_a^b |f(x) - g(x)|dx.$$

In practice, applying this theorem requires us to break up the interval $[a, b]$ and evaluate several integrals, depending on which function values are greater over a given part of the interval. We study this process in the following example.

**✓ Example 6.9.3**

If $\mathbf{R}$ is the region between the graphs of the functions $f(x) = \sin(x)$ and $g(x) = \cos(x)$ over the interval $[0, \pi]$, find the area of region $\mathbf{R}$.

**Solution**

The region is depicted in the following figure.

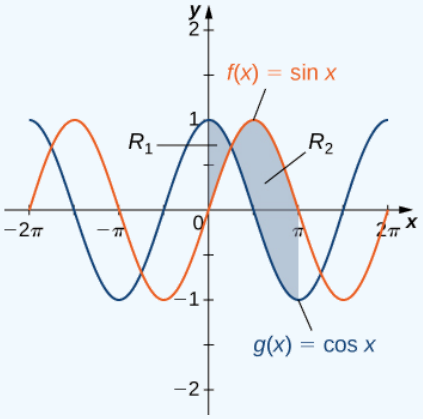

Figure 6.9.5: The region between two curves can be broken into two sub-regions.

The graphs of the functions intersect at $x = \frac{\pi}{4}$. Since the roles of $y_T$ and $y_B$ switch between regions $\mathbf{R}_1$ and $\mathbf{R}_2$, our notation for $y_{\text{top}}$ and $y_{\text{bottom}}$ needs to gain a little more complexity.

For $x \in [0, \frac{\pi}{4}]$,

$$|f(x) - g(x)| = y_{T_1} - y_{B_1} = \cos(x) - \sin(x).$$

On the other hand, for $x \in [\frac{\pi}{4}, \pi]$,

$$|f(x) - g(x)| = y_{T_2} - y_{B_2} = \sin(x) - \cos(x).$$

Then

$$\begin{aligned} A &= \int_a^b |f(x) - g(x)|dx \\ &= \int_0^{\pi} |\sin(x) - \cos(x)|dx \\ &= \int_0^{\pi/4} (y_{T_1} - y_{B_1})dx + \int_{\pi/4}^{\pi} (y_{T_2} - y_{B_2})dx \\ &= \int_0^{\pi/4} (\cos(x) - \sin(x))dx + \int_{\pi/4}^{\pi} (\sin(x) - \cos(x))dx \\ &= [\sin(x) + \cos(x)]\Big|_0^{\pi/4} + [-\cos(x) - \sin(x)]\Big|_{\pi/4}^{\pi} \\ &= (\sqrt{2} - 1) + (1 + \sqrt{2}) \\ &= 2\sqrt{2}. \end{aligned}$$

The area of the region is $2\sqrt{2}$ units$^2$.

**Caution: Mastery of Trigonometry is required in this course**

Your success in Calculus II will rely heavily on your mastery of concepts from Trigonometry. You will frequently need to recall, without any prompting, the following identities and theorems:

- Pythagorean Identities,
- Sum and Difference Formulas (for sine and cosine),

- Double-Angle Identities (for sine and cosine),
- Half-Angle Formulas (for sine and cosine) - these are also known as the Power Reduction Formulas, and
- the Even/Odd Identities.

Moreover, it is assumed you can perform each of the following skills without using technology for help:

- evaluate all trigonometric functions at special angles, or at angles having special angles as reference angles, as well as at axial angles,
- accurately graph transformations of trigonometric functions,
- solve trigonometric equations,
- evaluate inverse trigonometric functions,
- understand the domain and range restrictions of all base trigonometric functions, and
- understand the domain and range restrictions of all base inverse trigonometric functions.

If you need a quick review of your Trigonometry, please see Section 1.6 of the Differential Calculus textbook. If you need a deeper review, an entire course in Trigonometry (i.e., Math 373 at CRC) is a great choice.

**? Checkpoint 6.9.3**

If $\mathbf{R}$ is the region between the graphs of the functions $f(x) = \sin(x)$ and $g(x) = \cos(x)$ over the interval $[\frac{\pi}{2}, 2\pi]$, find the area of region $\mathbf{R}$.

**Answer**

$2 + 2\sqrt{2}$ units$^2$

**✓ Example 6.9.4**

Consider the region depicted in Figure 6.9.6. Find the area of $\mathbf{R}$.

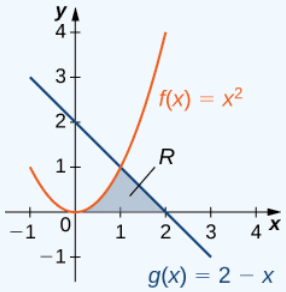

Figure 6.9.6: Two integrals are required to calculate the area of this region.

**Solution**

As with Example 6.9.3, we need to divide the interval into two pieces. The graphs of the functions intersect at $x = 1$ (set $f(x) = g(x)$ and solve for $x$), so we evaluate two separate integrals: one over the interval $[0, 1]$ and one over the interval $[1, 2]$.

Over the interval $[0, 1]$, the region is bounded above by $y_{T_1} = f(x) = x^2$ and below by $y_{B_1} = 0$, which is the $x$-axis, so we have

$$A_1 = \int_0^1 (y_{T_1} - y_{B_1})\,dx = \int_0^1 (x^2 - 0)dx = \int_0^1 x^2 dx = \frac{x^3}{3}\Big|_0^1 = \frac{1}{3}.$$

Over the interval $[1, 2]$, the region is bounded above by $y_{T_2} = g(x) = 2 - x$ and below by $y_{B_2} = 0$, which again is the $x$-axis, so we have

$$A_2 = \int_1^2 (y_{T_2} - y_{B_2})\,dx = \int_1^2 (2 - x - 0)dx = \int_1^2 (2 - x)dx = \left[2x - \frac{x^2}{2}\right]\Big|_1^2 = \frac{1}{2}.$$

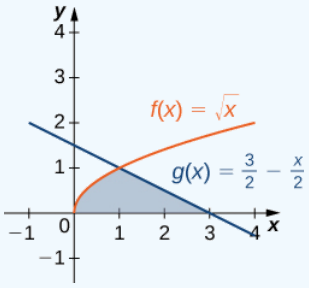
Adding these areas together, we obtain

$$A = A_1 + A_2 = \frac{1}{3} + \frac{1}{2} = \frac{5}{6}.$$

The area of the region is $\frac{5}{6}$ units$^2$.

**? Checkpoint 6.9.4**

Consider the region depicted in the following figure. Find the area of $\mathbf{R}$.



**Answer**

$\frac{5}{3}$ units$^2$

## Regions Defined with Respect to $y$

In Example 6.9.4, we had to evaluate two separate integrals to calculate the area of the region. However, there is another approach that requires only one integral. What if we treat the curves as functions of $y$ instead of as functions of $x$? Review Figure 6.9.6. Note that the left graph, shown in red, is represented by the function $y = f(x) = x^2$. We could just as easily solve this for $x$ and represent the curve by the function of $y$, $x = v(y) = \sqrt{y}$.[2] Similarly, the right graph is represented by the function $y = g(x) = 2 - x$, but could just as easily be represented by the function $x = u(y) = 2 - y$. When the graphs are represented as functions of $y$, we see the region is bounded on the left by the graph of one function and on the right by the graph of the other function. Therefore, if we integrate with respect to $y$, we only need to evaluate one integral. Let's develop a formula for this type of integration.

Let $u(y)$ and $v(y)$ be continuous functions over an interval $[c, d]$ such that $u(y) \geq v(y)$ for all $y \in [c, d]$. We want to find the area between the graphs of the functions, as shown in Figure 6.9.7.

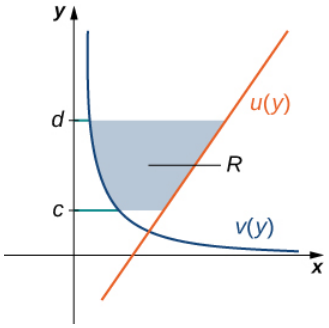


Figure 6.9.7: We can find the area between the graphs of two functions, $u(y)$ and $v(y)$.

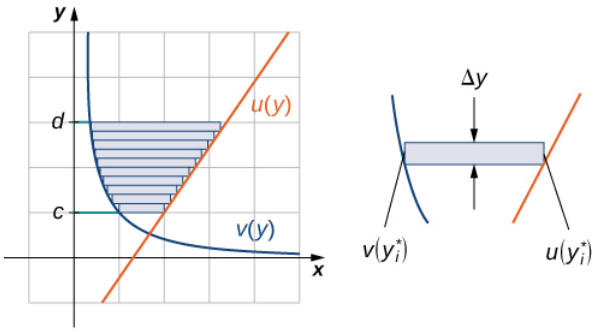
This time, we are going to partition the interval on the $y$-axis and use horizontal rectangles to approximate the area between the functions. So, for $i = 0, 1, 2, \ldots, n$, let $Q = \{y_i\}$ be a regular partition of $[c, d]$. Then, for $i = 1, 2, \ldots, n$, choose a point $y_i^* \in [y_{i-1}, y_i]$, then over each interval $[y_{i-1}, y_i]$ construct a rectangle that extends horizontally from $v(y_i^*)$ to $u(y_i^*)$. Figure 6.9.8(a) shows the rectangles when $y_i^*$ is selected to be the lower endpoint of the interval and $n = 10$. Figure 6.9.8(b) shows a representative rectangle in detail.



(a) (b)

Figure 6.9.8: (a) Approximating the area between the graphs of two functions, $u(y)$ and $v(y)$, with rectangles. (b) The area of a typical rectangle.

The height of each individual rectangle is $\Delta y$ and the width of each rectangle is $x_{R_i} - x_{L_i} = u(y_i^*) - v(y_i^*)$. Therefore, the area between the curves is approximately

$$A \approx \sum_{i=1}^{n} [x_{R_i} - x_{L_i}]\Delta y = \sum_{i=1}^{n} [u(y_i^*) - v(y_i^*)]\Delta y.$$

This is a Riemann sum, so we take the limit as $n \to \infty$, obtaining

$$\begin{aligned} A &= \lim_{n\to\infty} \sum_{i=1}^{n} [x_{R_i} - x_{L_i}]\Delta y \\ &= \lim_{n\to\infty} \sum_{i=1}^{n} [u(y_i^*) - v(y_i^*)]\Delta y \\ &= \int_c^d [u(y) - v(y)]dy. \end{aligned}$$

These findings are summarized in the following theorem.

**Theorem: Finding the Area between Two Curves, Integrating along the $y$-axis**

Let $u(y)$ and $v(y)$ be continuous functions such that $u(y) \geq v(y)$ for all $y \in [c, d]$. Let $\mathbf{R}$ denote the region bounded on the right by the graph of $u(y)$, on the left by the graph of $v(y)$, and above and below by the lines $y = d$ and $y = c$, respectively. Then, the area of $\mathbf{R}$ is given by

$$A = \int_c^d [u(y) - v(y)]dy.$$

**Example 6.9.5**

Let's revisit Example 6.9.4; only this time, let's integrate with respect to $y$. Let $\mathbf{R}$ be the region depicted in Figure 6.9.9. Find the area of $\mathbf{R}$ by integrating with respect to $y$.

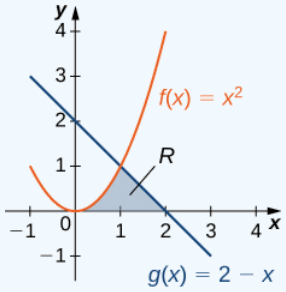


Figure 6.9.9: The area of region $\mathbf{R}$ can be calculated using one integral only when the curves are treated as functions of $y$.

**Solution**

We must first express the graphs as functions of $y$. As we saw at the beginning of this section, the curve on the left can be represented by the function $x_L = v(y) = \sqrt{y}$, and the curve on the right can be represented by the function $x_R = u(y) = 2 - y$.

Now, we have to determine the limits of integration. The region is bounded below by the $x$-axis, so the lower limit of integration is $y = 0$. The upper limit of integration is determined by the point where the two graphs intersect, which is the point $(1, 1)$, so the upper limit of integration is $y = 1$. Thus, we have $[c, d] = [0, 1]$.

Calculating the area of the region, we get

$$\begin{aligned} A &= \int_c^d [x_R - x_L]dy \\ &= \int_c^d [u(y) - v(y)]dy \\ &= \int_0^1 [(2 - y) - \sqrt{y}]dy \\ &= \left[2y - \frac{y^2}{2} - \frac{2}{3}y^{3/2}\right]\Big|_0^1 \\ &= \frac{5}{6}. \end{aligned}$$

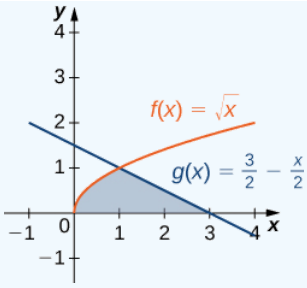
The area of the region is $\frac{5}{6}$ $\text{units}^2$.

**Caution: Understand the meaning of $|f(x) - g(x)|$**

While the notations, $y_T$, $y_B$, $x_R$, and $x_L$ are incredibly helpful in properly setting up integrals to determine areas between curves (and, later, for rotational volumes), you are not excused from understanding the true definition of $|f(x) - g(x)|$.

**Checkpoint 6.9.5**

Let's revisit Checkpoint 6.9.4; only this time, let's integrate with respect to $y$. Let $\mathbf{R}$ be the region depicted in the following figure. Find the area of $\mathbf{R}$ by integrating with respect to $y$.



**Answer**

$\frac{5}{3}$ $\text{units}^2$

## Approximating Areas Between Curves

We can combine concepts from Calculus I with our new knowledge to approximate the area between two curves.

**Example 6.9.6**

Approximate the area between $f(x) = \cosh(x)$ and $g(x) = -\frac{x}{2x^2+1}$ on the interval $[-2, 2]$ using vertical slices and right endpoints with $n = 8$.

**Solution**

First, it is actually possible for us to compute the exact area between these two curves. Consider the Figure 6.9.10 below.

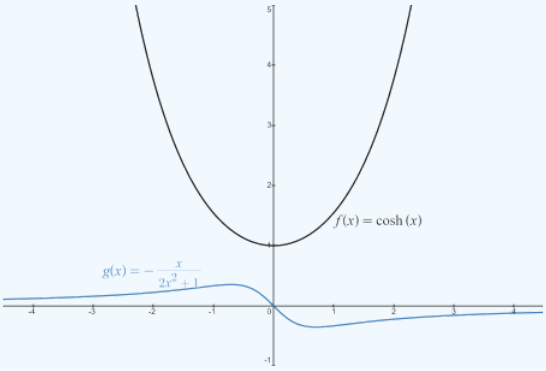


Figure 6.9.10

We can easily see that the area can be computed using the definite integral

$$
\begin{aligned}
A &= \int_{-2}^{2} (y_T - y_B)\,dx \\
&= \int_{-2}^{2} (f(x) - g(x))\,dx \\
&= \int_{-2}^{2} \left(\cosh(x) + \frac{x}{2x^2+1}\right) dx \\
&= \int_{-2}^{2} \cosh(x)dx + \int_{-2}^{2} \frac{x}{2x^2+1}dx \\
&= \int_{-2}^{2} \cosh(x)dx + 0 \qquad \left(\frac{x}{2x^2+1} \text{ is an odd function being integrated over a symmetric interval.}\right) \\
&= 2\int_{0}^{2} \cosh(x)dx \qquad (\cosh(x) \text{ is an even function being integrated over a symmetric interval.}) \\
&= 2\sinh(x)\Big|_0^2 \\
&= 2\sinh(2) - 2\sinh(0) \\
&= 2\sinh(2) - 0 \\
&= 2\sinh(2)
\end{aligned}
$$

However, we are being asked to *approximate* the value of this area, so let's practice our skills from Calculus I.

We are given $n = 8$, which implies $\Delta x = \frac{b-a}{n} = \frac{2-(-2)}{8} = \frac{1}{2}$ and $x_i = a + i\Delta x = -2 + \frac{1}{2}i$. Therefore,

$$
\begin{aligned}
A &\approx R_8 \\
&= \sum_{i=1}^{8} (y_{T_i} - y_{B_i})\,\Delta x \\
&= \sum_{i=1}^{8} (f(x_i) - g(x_i))\,\Delta x \\
&= \sum_{i=1}^{8} \left(f\left(-2+\frac{1}{2}i\right) - g\left(-2+\frac{1}{2}i\right)\right)\frac{1}{2} \\
&= \frac{1}{2}\sum_{i=1}^{8} \left(\cosh\left(-2+\frac{1}{2}i\right) + \frac{-2+\frac{1}{2}i}{2\left(-2+\frac{1}{2}i\right)^2+1}\right) \\
&= \frac{1}{2}\left\{\left[\cosh\left(-\frac{3}{2}\right) + \frac{-\frac{3}{2}}{2\left(-\frac{3}{2}\right)^2+1}\right] + \left[\cosh(-1) + \frac{-1}{2(-1)^2+1}\right] + \cdots + \left[\cosh(2) + \frac{2}{2(2)^2+1}\right]\right\} \\
&\approx 7.5153
\end{aligned}
$$

**Advice: Review hyperbolic functions**

The hyperbolic functions you learned from Calculus I will creep up at random points throughout Integral Calculus and Differential Equations. If your Calculus I instructor did not cover them, then you can always review the necessary concepts in Section 1.7 of the Differential Calculus textbook.

## Footnotes

[1] We will use the language and notation of this mini-review of distances throughout the remainder of Calculus II.

[2] Note that $x = -\sqrt{y}$ is also a valid representation of the function $y = f(x) = x^2$ as a function of $y$. However, based on the graph, it is clear we are interested in the positive square root.

# 6.9E: EXERCISES

## READING QUESTIONS

1. What is the general formula for finding the area of a region R bounded above by $y = f(x)$, below by $y = g(x)$, and between $x = a$ and $x = b$, assuming $f(x) \geq g(x)$ on $[a, b]$?

   **Answer:** $A = \int_a^b [f(x) - g(x)]dx$.

2. How does the formula change if the curves $f(x)$ and $g(x)$ intersect one or more times between $x = a$ and $x = b$?

   **Answer:** The area is given by $A = \int_a^b |f(x) - g(x)|dx$. In practice, this means you must find the points of intersection, split the interval $[a, b]$ into subintervals based on these intersections, and then integrate the difference of $(y_{Top} - y_{Bottom})$ over each subinterval, ensuring the integrand is always positive, then sum the results.

3. Under what circumstances might you choose to integrate with respect to $y$ instead of $x$ to find the area between two curves?

   **Answer:** You might choose to integrate with respect to $y$ if the curves are more easily expressed as functions of $y$ (i.e., $x = u(y)$ and $x = v(y)$), or if integrating with respect to $x$ would require splitting the region into multiple parts while integrating with respect to $y$ would only require a single integral. This often happens when the region is bounded more simply by a "right" curve and a "left" curve over an interval of $y$-values.

4. What do the expressions $y_{Top} - y_{Bottom}$ and $x_{Right} - x_{Left}$ represent geometrically when setting up integrals for area?

   **Answer:** $y_{Top} - y_{Bottom}$ represents the height of a typical vertical rectangular strip used to approximate the area when integrating with respect to $x$. $x_{Right} - x_{Left}$ represents the width of a typical horizontal rectangular strip used to approximate the area when integrating with respect to $y$.

5. If a region R is bounded on the right by $x = u(y)$, on the left by $x = v(y)$, and between $y = c$ and $y = d$, with $u(y) \geq v(y)$ on $[c, d]$, what is the integral for its area?

   **Answer:** $A = \int_c^d [u(y) - v(y)]dy$.

6. What is the typical first algebraic step if you are asked to find the area of a region bounded by two curves, say $y = f(x)$ and $y = g(x)$, but the interval of integration is not given?

   **Answer:** The typical first step is to find the points of intersection of the two curves by setting $f(x) = g(x)$ and solving for $x$. These x-values will typically define the limits of integration $a$ and $b$.

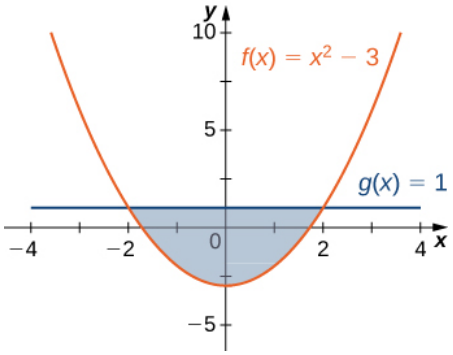
7. The section mentions a "caution" regarding trigonometry. What are students expected to be proficient in regarding trigonometry for success in Calculus II?

   **Answer:** Students are expected to have mastered various trigonometric identities (Pythagorean, Sum/Difference, Double-Angle, Half-Angle/Power Reduction, Even/Odd), be able to evaluate trig functions at special/axial angles, graph transformations of trig functions, solve trig equations, evaluate inverse trig functions, and understand their domain/range restrictions, all without relying on technology.

## HOMEWORK

**For exercises 1 - 2, determine the area of the region between the two curves in the given figure by integrating over the $x$-axis.**

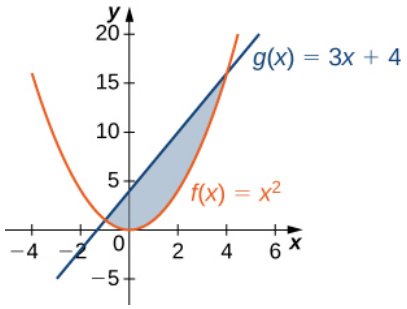
1) $y = x^2 - 3$ and $y = 1$



**Answer**

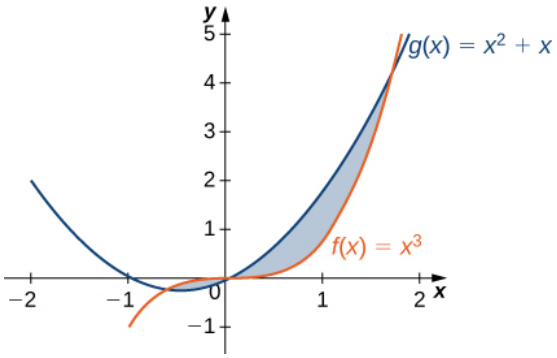
$\frac{32}{3}$ units$^2$

2) $y = x^2$ and $y = 3x + 4$



**For exercises 3 - 4, split the region between the two curves into two smaller regions, then determine the area by integrating over the $x$-axis. Note that you will have two integrals to solve.**

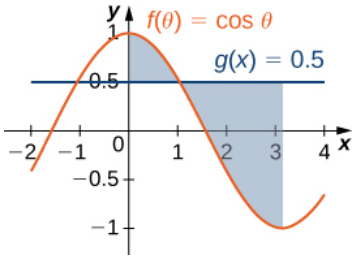
3) $y = x^3$ and $y = x^2 + x$



**Answer**

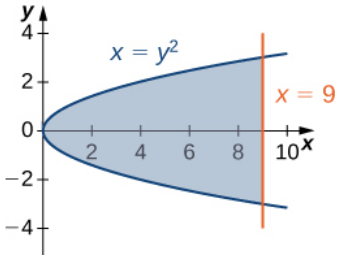
$\frac{13}{12}$ **units**$^2$

4) $y = \cos\theta$ and $y = 0.5$, for $0 \le \theta \le \pi$



**For exercises 5-6, determine the area of the region between the two curves by integrating over the $y$-axis.**

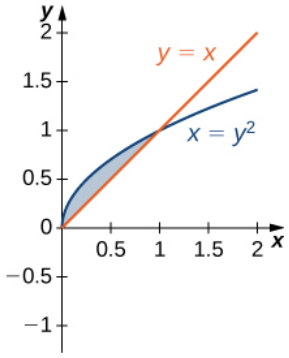
5) $x = y^2$ and $x = 9$



**Answer**

**36 units**$^2$

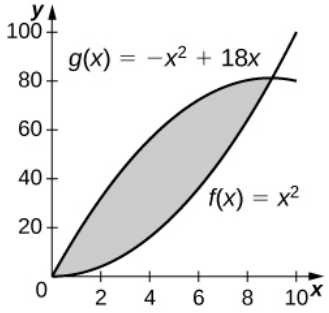
6) $y = x$ and $x = y^2$



**For exercises 7 - 13, graph the equations and shade the area of the region between the curves. Determine its area by integrating over the $x$-axis.**

7) $y = x^2$ and $y = -x^2 + 18x$

**Answer**

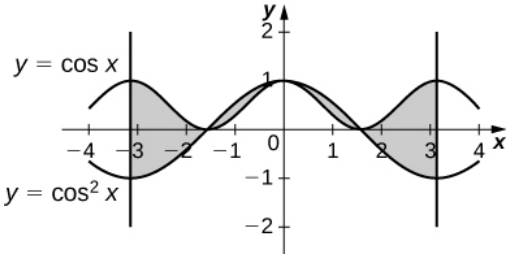


243 square units

8) $y = \frac{1}{x}$, $y = \frac{1}{x^2}$, and $x = 3$

9) $y = \cos x$ and $y = \cos^2 x$ on $x \in [-\pi, \pi]$

**Answer**

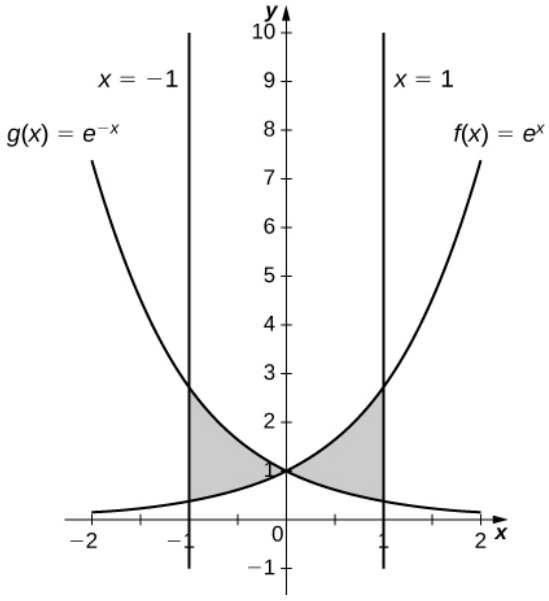


4 square units

10) $y = e^x$, $y = e^{2x-1}$, and $x = 0$

11) $y = e^x$, $y = e^{-x}$, $x = -1$ and $x = 1$

**Answer**

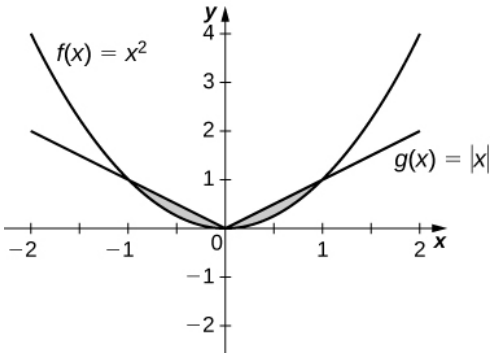


$\frac{2(e-1)^2}{e}$ units$^2$

12) $y = e$, $y = e^x$, and $y = e^{-x}$

13) $y = |x|$ and $y = x^2$

**Answer**



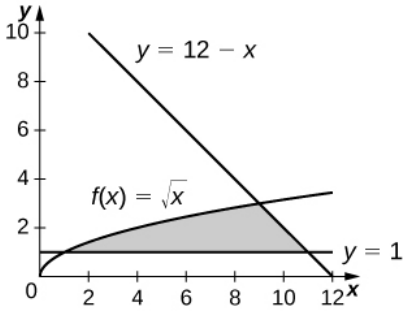
$\frac{1}{3}$ units$^2$

**For exercises 14 - 19, graph the equations and shade the area of the region between the curves. If necessary, break the region into sub-regions to determine its entire area.**

14) $y = \sin(\pi x)$, $y = 2x$, and $x > 0$

15) $y = 12 - x$, $y = \sqrt{x}$, and $y = 1$

**Answer**

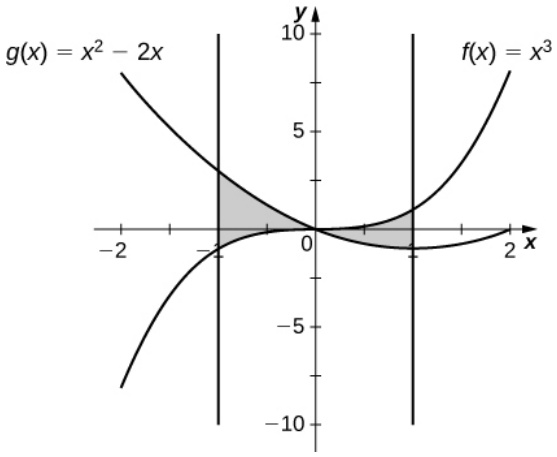


$\frac{34}{3}$ units$^2$

16) $y = \sin x$ and $y = \cos x$ over $x \in [-\pi, \pi]$

17) $y = x^3$ and $y = x^2 - 2x$ over $x \in [-1, 1]$

**Answer**

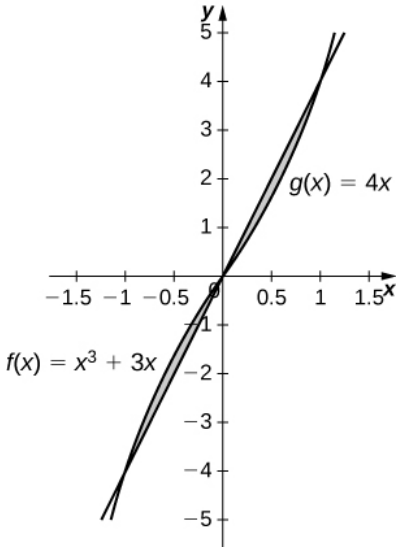


$\frac{5}{2}$ units$^2$

18) $y = x^2 + 9$ and $y = 10 + 2x$ over $x \in [-1, 3]$

19) $y = x^3 + 3x$ and $y = 4x$

**Answer**



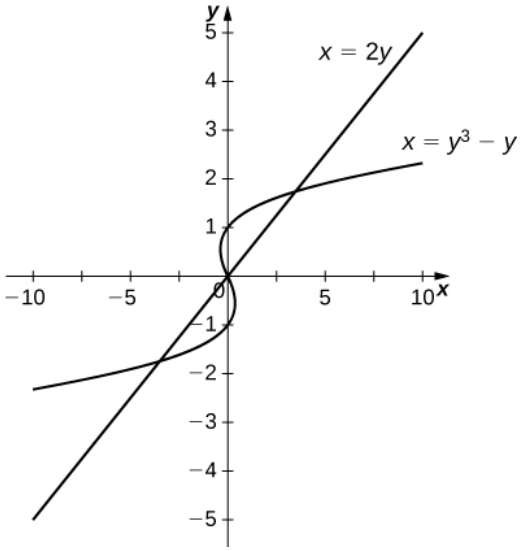
$\frac{1}{2}$ units$^2$

**For exercises 20 -25, graph the equations and shade the area of the region between the curves. Determine its area by integrating over the $y$-axis.**

20) $x = y^3$ and $x = 3y - 2$

21) $x = y$ and $x = y^3 - y$

**Answer**

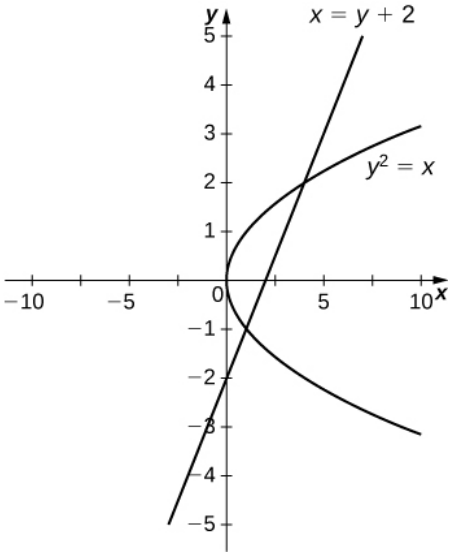


$\frac{9}{2}$ units$^2$

22) $x = -3 + y^2$ and $x = y - y^2$

23) $y^2 = x$ and $x = y + 2$

**Answer**

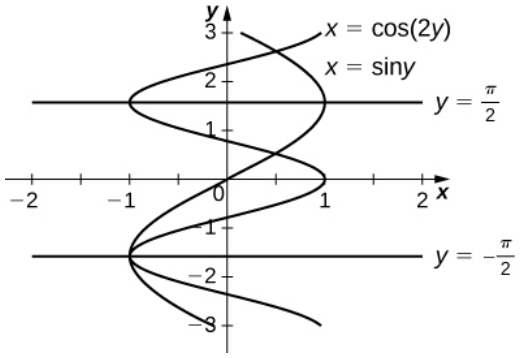


$\frac{9}{2}$ units$^2$

24) $x = |y|$ and $2x = -y^2 + 2$

25) $x = \sin y, \quad x = \cos(2y), \quad y = \pi/2$, and $y = -\pi/2$

**Answer**



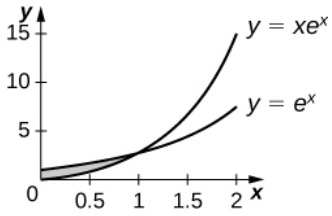
$\frac{3\sqrt{3}}{2}$ units$^2$

**For exercises 26 - 37, graph the equations and shade the area of the region between the curves. Determine its area by integrating over the $x$-axis or $y$-axis, whichever seems more convenient.**

26) $x = y^4$ and $x = y^5$

27) $y = xe^x$, $y = e^x$, $x = 0$, and $x = 1$.

**Answer**

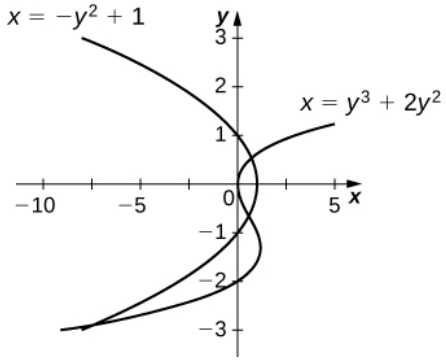


$e^{-2}$ units$^2$

28) $y = x^6$ and $y = x^4$

29) $x = y^3 + 2y^2 + 1$ and $x = -y^2 + 1$

**Answer**

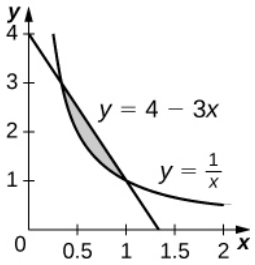


$\frac{27}{4}$ units$^2$

30) $y = |x|$ and $y = x^2 - 1$

31) $y = 4 - 3x$ and $y = \frac{1}{x}$

**Answer**

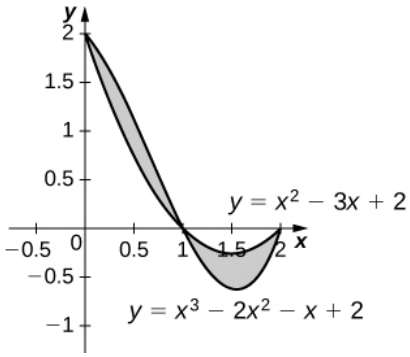


$\left(\frac{4}{3} - \ln(3)\right)$ units$^2$

32) $y = \sin x, \quad x = -\pi/6, \quad x = \pi/6,$ and $y = \cos^3 x$

33) $y = x^2 - 3x + 2$ and $y = x^3 - 2x^2 - x + 2$

**Answer**

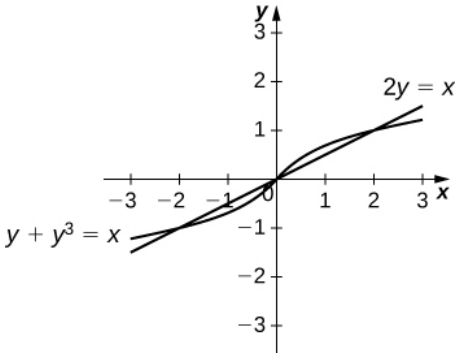


$\frac{1}{2}$ square units

34) $y = 2\cos^3(3x), \quad y = -1, \quad x = \frac{\pi}{4},$ and $x = -\frac{\pi}{4}$

35) $y + y^3 = x$ and $2y = x$

**Answer**



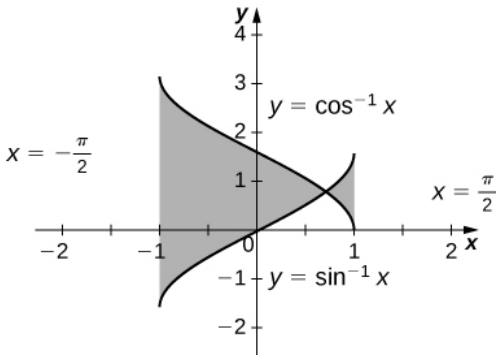
$\frac{1}{2}$ square units

36) $y = \sqrt{1 - x^2}$ and $y = x^2 - 1$

37) $y = \cos^{-1} x, \quad y = \sin^{-1} x, \quad x = -1,$ and $x = 1$

**Answer**

https://math.libretexts.org/@go/page/175574



$-2(\sqrt{2}-\pi)$ square units

**For exercises 38 - 47, find the exact area of the region bounded by the given equations if possible. If you are unable to determine the intersection points analytically, use a calculator to approximate the intersection points with three decimal places and determine the approximate area of the region.**

38) [Technology Required] $x = e^y$ and $y = x - 2$

39) [Technology Required] $y = x^2$ and $y = \sqrt{1-x^2}$

**Answer**

$1.067$ square units

40) [Technology Required] $y = 3x^2 + 8x + 9$ and $3y = x + 24$

41) [Technology Required] $x = \sqrt{4-y^2}$ and $y^2 = 1 + x^2$

**Answer**

$0.852$ square units

42) [Technology Required] $x^2 = y^3$ and $x = 3y$

43) [Technology Required] $y = \sin^3 x + 2, \quad y = \tan x, \quad x = -1.5,$ and $x = 1.5$

**Answer**

$7.523$ square units

44) [Technology Required] $y = \sqrt{1-x^2}$ and $y^2 = x^2$

45) [Technology Required] $y = \sqrt{1-x^2}$ and $y = x^2 + 2x + 1$

**Answer**

$\frac{3\pi - 4}{12}$ square units

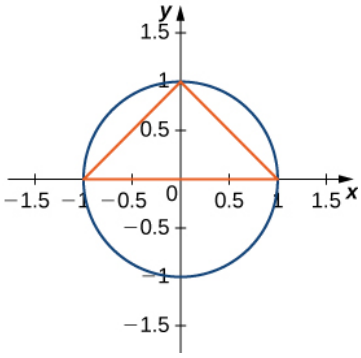
46) [Technology Required] $x = 4 - y^2$ and $x = 1 + 3y + y^2$

47) [Technology Required] $y = \cos x, \quad y = e^x, \quad x = -\pi, \quad$ and $\quad x = 0$

**Answer**

$1.429$ square units

48) The largest triangle with a base on the $x$-axis that fits inside the upper half of the unit circle $y^2 + x^2 = 1$ is given by $y = 1 + x$ and $y = 1 - x$. See the following figure. What is the area inside the semicircle but outside the triangle?



49) A factory selling cell phones has a marginal cost function $C(x) = 0.01x^2 - 3x + 229$, where $x$ represents the number of cell phones, and a marginal revenue function given by $R(x) = 429 - 2x$. Find the area between the graphs of these curves and $x = 0$. What does this area represent?

**Answer**

**$33,333.33** total profit for **200** cell phones sold

50) An amusement park has a marginal cost function $C(x) = 1000e - x + 5$, where $x$ represents the number of tickets sold, and a marginal revenue function given by $R(x) = 60 - 0.1x$. Find the total profit generated when selling **550** tickets. Use a calculator to determine intersection points, if necessary, to two decimal places.

51) The tortoise versus the hare: The speed of the hare is given by the sinusoidal function $H(t) = 1 - \cos((\pi t)/2)$ whereas the speed of the tortoise is $T(t) = (1/2)\tan^{-1}(t/4)$, where $t$ is time measured in hours and the speed is measured in miles per hour. Find the area between the curves from time $t = 0$ to the first time after one hour when the tortoise and hare are traveling at the same speed. What does it represent? Use a calculator to determine the intersection points, if necessary, accurate to three decimal places.

**Answer**

**3.263** mi represents how far ahead the hare is from the tortoise

52) The tortoise versus the hare: The speed of the hare is given by the sinusoidal function $H(t) = (1/2) - (1/2)\cos(2\pi t)$ whereas the speed of the tortoise is $T(t) = \sqrt{t}$, where $t$ is time measured in hours and speed is measured in kilometers per hour. If the race is over in 1 hour, who won the race and by how much? Use a calculator to determine the intersection points, if necessary, accurate to three decimal places.

**For exercises 53 - 55, find the area between the curves by integrating with respect to $x$ and then with respect to $y$. Is one method easier than the other? Do you obtain the same answer?**

53) $y = x^2 + 2x + 1$ and $y = -x^2 - 3x + 4$

**Answer**

$\frac{343}{24}$ square units

54) $y = x^4$ and $x = y^5$

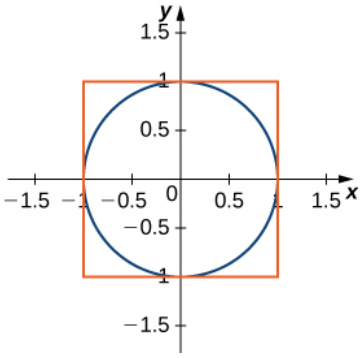
55) $x = y^2 - 2$ and $x = 2y$

**Answer**

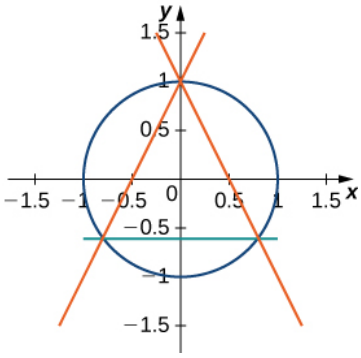
$4\sqrt{3}$ square units

**For exercises 56 - 57, solve using calculus, then check your answer with geometry.**

56) Determine the equations for the sides of the square that touches the unit circle on all four sides, as seen in the following figure. Find the area between the perimeter of this square and the unit circle. Is there another way to solve this without using calculus?



57) Find the area between the perimeter of the unit circle and the triangle created from $y = 2x + 1$, $y = 1 - 2x$ and $y = -\frac{3}{5}$, as seen in the following figure. Is there a way to solve this without using calculus?



**Answer**

$\left(\pi - \frac{32}{25}\right)$ square units

**In exercises 58 - 61, if you are unable to find intersection points analytically, use a calculator.**

58) Find the area of the region enclosed by $x = 1$ and $y = 5$ above $y = \ln x$.

**Answer**

$(e^5 - 6)$ units$^2$

59) Find the area under $y = 1/x$ and above the $x$-axis from $x = 1$ to $x = 4$.

60) Find the area of the hyperbolic quarter-circle enclosed by $x = 2$ and $y = 2$ above $y = 1/x$.

61) Find the area between $\ln x$ and the $x$-axis from $x = 1$ to $x = 2$.

**Answer**

$\ln(4) - 1)$ units$^2$

# 6.10: Determining Volumes by Slicing

**Note to the Instructor (click to expand)**

The purpose of this section is for the student to get used to Riemann Sums applied to three-dimensional objects. All volumes in this section are non-rotational.

---

To succeed in this section, you'll need to use some skills from previous courses. While you should already know them, this is the first time they've been required. You can review these skills in CRC's Corequisite Codex. If you have a support class, it might cover some, **but not all**, of these topics.

**Prerequisite Skills and Support Topics (click to expand)**

- **Geometry**
  - Similar Triangles: This concept is used to find the dimensions of a cross-section as a function of its position along the axis of integration. For example, in Example 1.2.1, similar triangles are used to relate the side length of a square cross-section to its position $x$.
  - Common Areas: The slicing method requires finding a formula for the area of a cross-section, $A(x)$. This section and its homework use areas of squares, rectangles, triangles (isosceles, right), semicircles, and circles.
- **Solving Equations**
  - Solving Literal Equations: When integrating with respect to $y$, an equation for the base region given in terms of $x$ (like $y = 4 - x^2$) must be solved for $x$ in terms of $y$.
- **Quadratic Functions**
  - Graphing Quadratic Functions Using Properties: The base region of a solid is often defined by a parabola, such as $f(x) = 4 - x^2$ in Examples 1.2.2 and 1.2.3. Visualizing this region is crucial for setting up the integral.
- **Conic Sections**
  - Ellipses: Homework problem #16 involves a solid with an elliptical base, requiring knowledge of the equation of an ellipse.

---

The following is a list of learning objectives for this section.

**Learning Objectives (click to expand)**

- Determine the volume of a solid by integrating a cross-section (the slicing method).

Hawk A.I. Section-Specific Tutor

To access the Hawk A.I. Tutor, you will need to be logged into your campus Gmail account.

In the preceding section, we used definite integrals to find the area between two curves. In this section, we use definite integrals to find volumes of three-dimensional solids. We start by developing a basic approach based on slicing.

## Volume and the Slicing Method

Just as area is the numerical measure of a two-dimensional region, volume is the numerical measure of a three-dimensional solid. Most of us have computed volumes of solids by using basic geometric formulas. The volume of a rectangular solid, for example, can be computed by multiplying length, width, and height: $V = lwh$. The following formulas for volumes have been introduced in previous courses.

- a sphere

$$V_{\text{sphere}} = \frac{4}{3}\pi r^3,$$

- a cone

$$V_{\text{cone}} = \frac{1}{3}\pi r^2 h$$

- and a pyramid

$$V_{\text{pyramid}} = \frac{1}{3}Ah$$

Although some of these formulas were derived using Geometry alone, all these formulas can be obtained using integration.

We can also calculate the volume of a cylinder. Although most of us think of a cylinder as having a circular base, such as a soup can or a metal rod, in mathematics, the word cylinder has a more general meaning. We first need to define some vocabulary to discuss cylinders in this more general context.

We define a solid's **cross-section** as the intersection of a plane with the solid. A **cylinder** is defined as any solid that can be generated by translating a plane region along a line perpendicular to the region called the **axis of the cylinder**. Thus, all cross-sections perpendicular to the axis of a cylinder are identical. The solid shown in Figure **6.10.1** is an example of a cylinder with a noncircular base. To calculate the volume of a cylinder, we multiply the area of the cross-section by the height of the cylinder: $V = A \cdot h$. In the case of a right circular cylinder (soup can), this becomes $V = \pi r^2 h$.

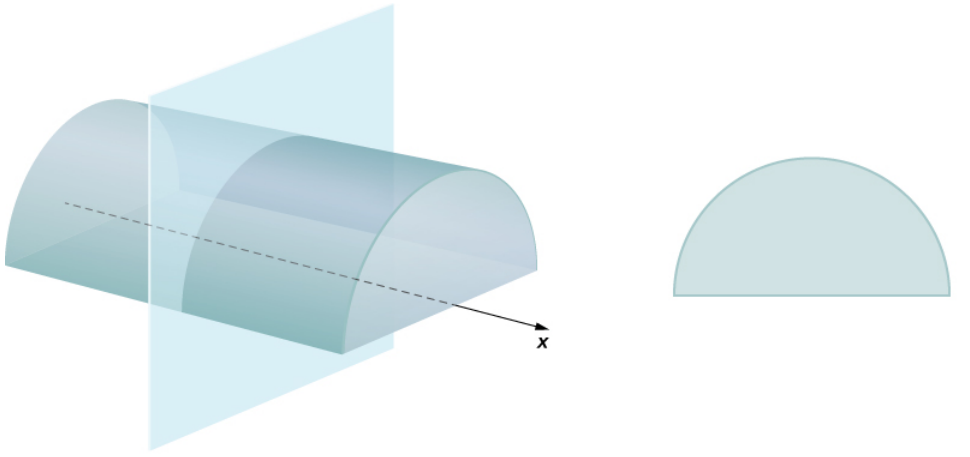

Figure **6.10.1**: Each cross-section of a particular cylinder is identical to the others.

If a solid does not have a constant cross-section (and it is not one of the other basic solids), we may not have a formula for its volume. In this case, we can use a definite integral to calculate the volume of the solid. We do this by slicing the solid into pieces, estimating the volume of each slice, and then adding those estimated volumes together. The slices should all be parallel to one another, and when we put all the slices together, we should get the whole solid. Consider, for example, the solid $S$ shown in Figure **6.10.2**, extending along the $x$-axis.

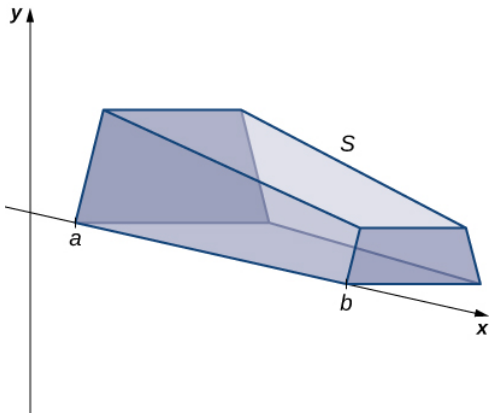

Figure 6.10.2: A solid with a varying cross-section.

We want to divide $S$ into slices perpendicular to the $x$-axis. As we see later in the chapter, there may be times when we want to slice the solid in some other direction - say, with slices perpendicular to the $y$-axis. The decision of which way to slice the solid is vital. If we make the wrong choice, the computations can get quite messy. Later in the chapter, we examine some of these situations in detail and decide which way to slice the solid. For the purposes of this section, however, we use slices perpendicular to the $x$-axis.

Because the cross-sectional area is not constant, we let $A(x)$ represent the **cross-sectional area** of the cross-section at point $x$. Now let $P = \{x_0, x_1, \ldots, x_n\}$ be a regular partition of $[a, b]$, and for $i = 1, 2, \ldots, n$, let $S_i$ represent the slice of $S$ stretching from $x_{i-1}$ to $x_i$. The following figure shows the sliced solid with $n = 3$.

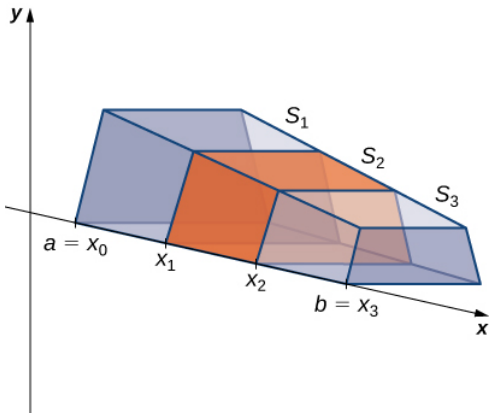

Figure 6.10.3: The solid $S$ has been divided into three slices perpendicular to the $x$-axis.

Finally, for $i = 1, 2, \ldots, n$, let $x_i^*$ be an arbitrary point in $[x_{i-1}, x_i]$. Then the volume of slice $S_i$ can be estimated by $V(S_i) \approx A(x_i^*)\,\Delta x$. Adding these approximations together, we see the volume of the entire solid $S$ can be approximated by

$$V(S) \approx \sum_{i=1}^{n} A(x_i^*)\,\Delta x.$$

By now, we can recognize this as a Riemann sum, and our next step is to take the limit as $n \to \infty$. Then we have

$$V(S) = \lim_{n\to\infty} \sum_{i=1}^{n} A(x_i^*)\,\Delta x = \int_a^b A(x)\,dx.$$

The technique we have just described is called the **slicing method**. To apply it, we use the following strategy.

**Problem-Solving Strategy: Finding Volumes by the Slicing Method**

1. Examine the solid and determine the shape of a cross-section of the solid. It is often helpful to draw a picture if one is not provided.
2. Determine a formula for the area of the cross-section.
3. Integrate the area formula over the appropriate interval to get the volume.

This section assumes the slices are perpendicular to the $x$-axis. Therefore, the area formula is in terms of $x$, and the limits of integration lie on the $x$-axis. However, the problem-solving strategy shown here is valid regardless of how we choose to slice the solid.

## Example 6.10.1

We know from Geometry that the formula for the volume of a pyramid is $V = \frac{1}{3}Ah$. If the pyramid has a square base, this becomes $V = \frac{1}{3}a^2h$, where $a$ denotes the length of one side of the base. We are going to use the slicing method to derive this formula.

**Solution**

We want to apply the slicing method to a pyramid with a square base. To set up the integral, consider the pyramid shown in Figure 6.10.4, oriented along the $x$-axis.

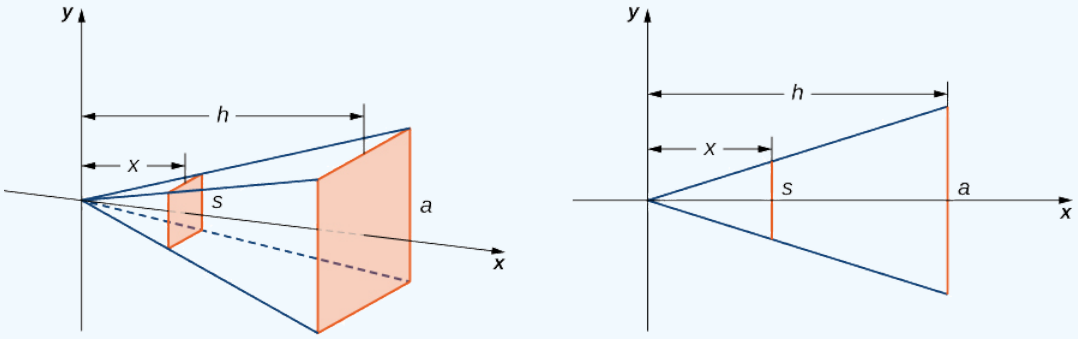

Figure 6.10.4: (a) A pyramid with a square base is oriented along the $x$-axis. (b) A two-dimensional view of the pyramid is seen from the side.

We first want to determine the shape of a cross-section of the pyramid. We know the base is a square, so the cross-sections are squares as well. Now, we want to determine a formula for the area of one of these cross-sectional squares. Looking at Figure 6.10.4(b), and using a proportion, since these are similar triangles, we have

$$\frac{s}{a} = \frac{x}{h}$$

or

$$s = \frac{ax}{h}.$$

Therefore, the area of one of the cross-sectional squares is

$$A(x) = s^2 = \left(\frac{ax}{h}\right)^2.$$

Then we find the volume of the pyramid by integrating from 0 to $h$:

$$V = \int_0^h A(x)\,dx = \int_0^h \left(\frac{ax}{h}\right)^2 dx = \frac{a^2}{h^2}\int_0^h x^2\,dx = \left[\frac{a^2}{h^2}\left(\frac{1}{3}x^3\right)\right]\Big|_0^h = \frac{1}{3}a^2h.$$

This is the formula we were looking for.

## Checkpoint 6.10.1

Use the slicing method to derive the formula

$$V = \frac{1}{3}\pi r^2 h$$

for the volume of a circular cone.

**Hint**

Use similar triangles, as in Example 6.10.1.

While Example 6.10.1 is a shape we are familiar with, it behooves us to experiment with finding the volume of a solid having a more challenging design. For this discussion, we consider solids having a **base region** defined by a given boundary. This boundary is often an area between two functions on a specified interval, however, it can be a region bounded by a non-functional curve such as a conic section. Onto this base region, we will slide in cross-sectional slices perpendicular to the base (see the Interactive Element below).

Let's take a look at two examples.

**Example 6.10.2**

Find the volume of the solid with base region bounded by $f(x) = 4 - x^2$ and the $x$-axis, where the cross-sections perpendicular to the $x$-axis are isosceles right triangles with hypotenuse in the base region.

**Solution**

We begin by drawing a top-down view of the base region, including the $i^{\text{th}}$ slice (see Figure 6.10.5 below).

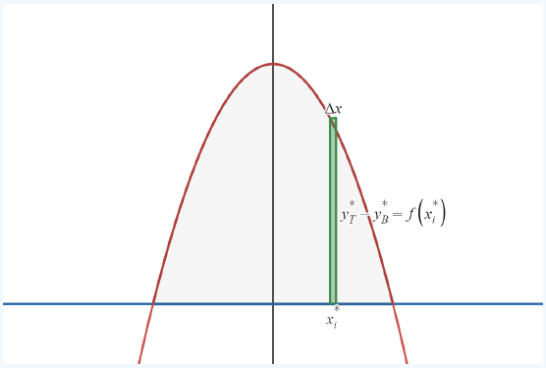

*Figure 6.10.5: A top-down view of the base region along with the $i^{\text{th}}$ slice.*

It will also be beneficial to sketch a side view of the $i^{\text{th}}$ slice (see Figure 6.10.6 below).

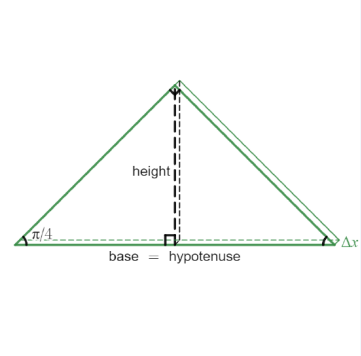

*Figure 6.10.6: A side view of the $i^{\text{th}}$ slice.*

The volume of this $i^{\text{th}}$ slice can be found using the fact that the surface area of a triangle is one-half the product of the base and the height. Hence,

$$V_i = \frac{1}{2}\,(\text{base})\,(\text{height})\,\Delta x = \frac{1}{2}\,(f(x_i^*) - 0)\,(\text{height})\,\Delta x = \frac{1}{2}\,(4 - (x_i^*)^2)\,(\text{height})\,\Delta x.$$

To determine the height of this $i^{\text{th}}$ slice, we use the fact that the base has length $4 - (x_i^*)^2$, which means half of the base has length $\frac{1}{2}\,(4 - (x_i^*)^2)$. Since the triangle is an isosceles right triangle, the height equals this half-base length. Hence,

$$V_i = \frac{1}{4}\left(4 - (x_i^*)^2\right)^2 \Delta x.$$

From Figure 6.10.5, we can see that symmetry can be used so that we only need to add up the volumes of the slices starting at $x = 0$ and ending at $x = 2$. We double this result to approximate the total area. That is,

$$V \approx 2\sum_{i=0}^{n} V_i = \frac{1}{2}\sum_{i=0}^{n}\left(4 - (x_i^*)^2\right)^2 \Delta x.$$

Taking the limit as $n \to \infty$, we get

$$\begin{aligned} V &= \frac{1}{2}\int_0^2 (4 - x^2)^2\, dx \\ &= \frac{1}{2}\int_0^2 16 - 8x^2 + x^4\, dx \\ &= \frac{1}{2}\left(16x - \frac{8}{3}x^3 + \frac{1}{5}x^5\right)\Big|_0^2 \\ &= \frac{1}{2}\left(32 - \frac{64}{3} + \frac{32}{5}\right) \\ &= \frac{128}{15} \text{ cubic units} \end{aligned}$$

## Example 6.10.3

Find the volume of the solid with base region bounded by $f(x) = 4 - x^2$ and the $x$-axis, where the cross-sections perpendicular to the **$y$-axis** are **semi-circles**.

**Solution**

Just as we did in Example 6.10.2, we begin by sketching a top-down view of the base region with the $i^{\text{th}}$ slice, and a side view of the $i^{\text{th}}$ slice (see Figure 6.10.7).

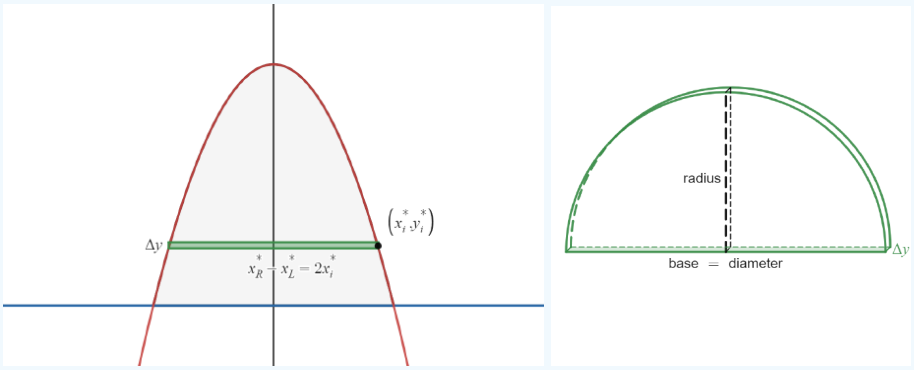

*Figure 6.10.7A: A top-down view of the base region along with the $i^{\text{th}}$ slice, and Figure 6.10.7B: A side view of the $i^{\text{th}}$ slice.*

The volume of the $i^{\text{th}}$ slice is

$$V_i = \frac{1}{2}\pi (r_i^*)^2 \Delta y = \frac{1}{2}\pi (x_i^*)^2 \Delta y.$$

Using the relation $y_i^* = 4 - (x_i^*)^2$, we get

$$V_i = \frac{1}{2}\pi (4 - y_i^*) \Delta y.$$

Therefore

$$\begin{aligned} V &= \lim_{n\to\infty} \sum_{i=0}^{n} V_i \\ &= \int_{y=0}^{y=4} \frac{1}{2}\pi (4-y)\, dy \\ &= \frac{\pi}{2}\left(4y - \frac{y^2}{2}\right)\Big|_{y=0}^{y=4} \\ &= 4\pi \text{ cubic units} \end{aligned}$$

# 6.10E: Exercises

## Reading Questions

1. What is the definition of a solid's cross-section?
2. What is the general definite integral formula for the volume of a solid using the slicing method, where $A(x)$ is the cross-sectional area at $x$?
3. List the three steps in the problem-solving strategy for finding volumes by the slicing method.
4. In Example 1.2.1, what geometric principle is used to find the side length $s$ of the square cross-section in terms of its distance $x$ from the apex of the pyramid?
5. If the cross-sections of a solid are taken perpendicular to the y-axis, what variable must the area function and the integration be in terms of?
6. According to the text, what is the mathematical definition of a cylinder? Does its base have to be a circle?

1) Derive the formula for the volume of a sphere using the slicing method.

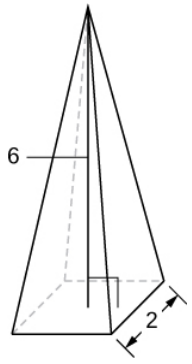
2) Use the slicing method to derive the formula for the volume of a cone.

3) Use the slicing method to derive the formula for the volume of a tetrahedron with side length $a$.

## Volumes by Slicing

**For exercises 4 - 8, draw a typical slice and find the volume using the slicing method for the given volume.**

4) A pyramid with height 6 units and square base of side 2 units, as pictured here.



**Solution:**

Here the cross-sections are squares taken perpendicular to the $y$-axis.
We use the vertical cross-section of the pyramid through its center to obtain an equation relating $x$ and $y$.
Here this would be the equation, $y = 6 - 6x$. Since we need the dimensions of the square at each $y$-level, we solve this equation for $x$ to get, $x = 1 - \frac{y}{6}$.
This is half the distance across the square cross-section at the $y$-level, so the side length of the square cross-section is, $s = 2\left(1 - \frac{y}{6}\right)$.
Thus, we have the area of a cross-section is,

$$A(y) = \left[2\left(1 - \tfrac{y}{6}\right)\right]^2 = 4\left(1 - \tfrac{y}{6}\right)^2.$$

Then, $V = \int_0^6 4\left(1 - \frac{y}{6}\right)^2 \, dy$

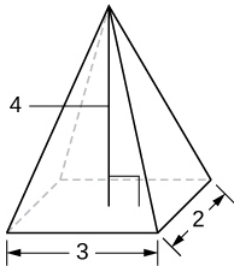
$= -24 \int_1^0 u^2 \, du, \quad \text{where } u = 1 - \frac{y}{6}, \text{ so } du = -\frac{1}{6} \, dy, \quad \Longrightarrow \quad -6 \, du = dy$

$= 24 \int_0^1 u^2 \, du = 24 \frac{u^3}{3} \Big|_0^1$

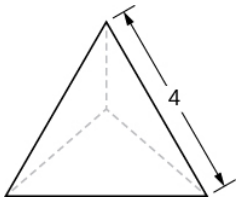
$= 8u^3 \Big|_0^1$

$= 8\left(1^3 - 0^3\right) \quad = \quad 8 \text{ units}^3$

5) A pyramid with height 4 units and a rectangular base with length 2 units and width 3 units, as pictured here.



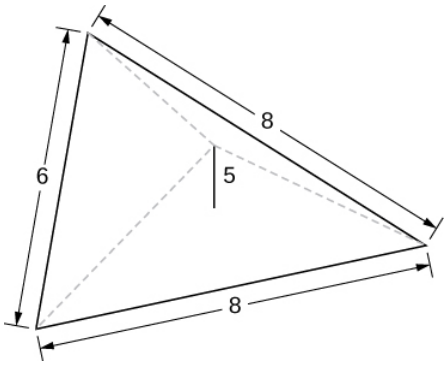
6) A tetrahedron with a base side of 4 units,as seen here.



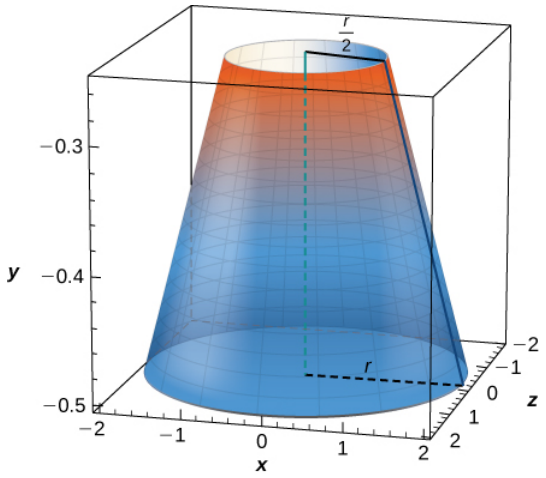
**Answer**

$V = \frac{32}{3\sqrt{2}} = \frac{16\sqrt{2}}{3}$ units$^3$

7) A pyramid with height 5 units, and an isosceles triangular base with lengths of 6 units and 8 units, as seen here.



8) A cone of radius $r$ and height $h$ has a smaller cone of radius $r/2$ and height $h/2$ removed from the top, as seen here. The resulting solid is called a frustum.



**Answer**

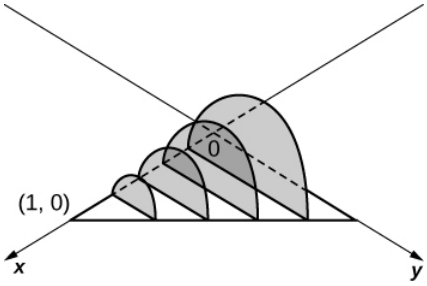
$V = \frac{7\pi}{12} hr^2$ units$^3$

**For exercises 9 - 14, draw an outline of the solid and find the volume using the slicing method.**

9) The base is a circle of radius $a$. The slices perpendicular to the base are squares.

10) The base is a triangle with vertices $(0,0), (1,0)$, and $(0,1)$. Slices perpendicular to the $xy$-plane are semicircles.

**Answer**



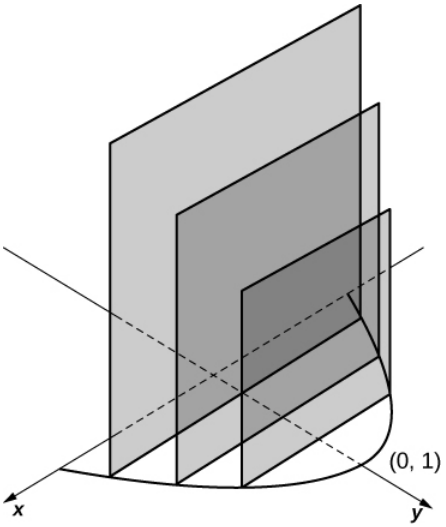
$V = \int_0^1 \frac{\pi(1-x)^2}{8}\,dx \quad = \quad \frac{\pi}{24}$ units$^3$

11) The base is the region under the parabola $y = 1 - x^2$ in the first quadrant. Slices perpendicular to the $xy$-plane are squares.

12) The base is the region under the parabola $y = 1 - x^2$ and above the $x$-**axis**. Slices perpendicular to the $y$-**axis** are squares.

**Answer**

https://math.libretexts.org/@go/page/175576

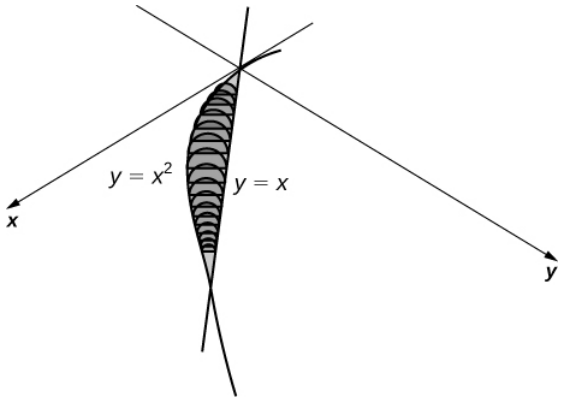


$V = \int_0^1 4(1-y)\,dy \quad = \quad 2 \text{ units}^3$

13) The base is the region enclosed by $y = x^2$ and $y = 9$. Slices perpendicular to the $x$-axis are right isosceles triangles.

14) The base is the area between $y = x$ and $y = x^2$. Slices perpendicular to the $x$-axis are semicircles.

**Answer**



$V = \int_0^1 \frac{\pi}{8}(x-x^2)^2\,dx \quad = \quad \frac{\pi}{240} \text{ units}^3$

**For exercises 15 - 16, find the volume of the solid described.**

15) The base is the region between $y = x$ and $y = x^2$. Slices perpendicular to the $x$-axis are semicircles.

16) The base is the region enclosed by the generic ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$. Slices perpendicular to the $x$-axis are semicircles.

**Answer**

$V = \frac{2ab^2\pi}{3} \text{ units}^3$

# CHAPTER OVERVIEW

## 7: Techniques of Integration

We saw in the previous chapter how important integration can be for all kinds of different topics—from calculations of volumes to flow rates, and from using a velocity function to determine a position to locating centers of mass. It is no surprise, then, that techniques for finding antiderivatives (or indefinite integrals) are important to know for everyone who uses them. We have already discussed some basic integration formulas and the method of integration by substitution. In this chapter, we study some additional techniques, including some ways of approximating definite integrals when normal techniques do not work.

# 7.1: Expanding the Substitution Method

**Note to the Instructor (click to expand)**

This section is unlike most other introductory section to integration techniques. Instead of starting with Integration by Parts, we showcase that *most* of the new integration techniques are just glorified substitution methods. Specifically, in this section we introduce radical substitution and substitutions involving powers of the trigonometric functions. We also use power reduction formulas to help us evaluate otherwise impossible integrals.

---

To succeed in this section, you'll need to use some skills from previous courses. While you should already know them, this is the first time they've been required. You can review these skills in CRC's Corequisite Codex. If you have a support class, it might cover some, **but not all**, of these topics.

**Prerequisite Skills and Support Topics (click to expand)**

- **Simplifying Expressions**
  - Laws of Exponents: This skill is essential for manipulating powers of trigonometric functions, such as rewriting $\sin^5(x)$ as $(\sin^2(x))^2\sin(x)$.
  - Dividing Polynomials - Long Division: This algebraic technique is sometimes required after a radical substitution to simplify a rational function, as shown in Example 2.1.1.
- **Polynomial Functions**
  - The Binomial Theorem: The text mentions that this theorem can be used to quickly expand expressions like $(u-1)^5$, which can arise after a substitution.
- **Trigonometry**
  - Trigonometric Identities - Sum-to-Product and Product-to-Sum Identities: The Product-to-Sum identities are used to evaluate integrals of products like $\sin(ax)\cos(bx)$, as seen in Example 2.1.8.
  - The Inverse Trigonometric Functions: The integral of $1/(a^2+x^2)$ is derived, resulting in an inverse tangent function.

---

The following is a list of learning objectives for this section.

**Learning Objectives (click to expand)**

- Solve integration problems involving radicals.
- Solve integration problems involving products and powers of $\sin x$ and $\cos x$.
- Solve integration problems involving products and powers of $\tan x$ and $\sec x$.
- Use reduction formulas to solve trigonometric integrals.

We begin our exploration of "new" integration techniques by revisiting the only technique we have so far (besides direct integration) - the Substitution Method. As we delve into the first couple sections of this chapter, we expand our use of the Substitution Method to more creative substitutions. Let's start by reviewing one of the most useful creative substitutions up to this point - a technique dubbed **radical substitution**.

## Radical Substitutions

In truth, a **radical substitution** is just a simple $u$-substitution we make when our integrand involves a radical. As an example, consider the indefinite integral

$$\int \frac{x}{\sqrt{x-3}}\,dx.$$

Most students fresh from Calculus I will perform the substitution $u = x - 3$ so that $du = dx$ and $u + 3 = x$. This gives us

$$\begin{aligned}\int \frac{x}{\sqrt{x-3}}\,dx &= \int \frac{u+3}{\sqrt{u}}\,du \\ &= \int u^{1/2} + 3u^{-1/2}\,du \\ &= \frac{2}{3}u^{3/2} + 6u^{1/2} + C \\ &= \frac{2}{3}(x-3)^{3/2} + 6(x-3)^{1/2} + C.\end{aligned}$$

However, we could have arrived at the same result using the more creative (and cleaner) substitution $u = \sqrt{x-3}$. We avoid differentiating the radical by first squaring both sides of this equation to get $u^2 = x - 3$. Employing implicit differentiation from Calculus I, we arrive at $2u\,du = dx$. Noting that we still have an $x$ in the numerator of our integrand, we solve $u^2 = x - 3$ for $x$ to get $u^2 + 3 = x$. Hence, our integral becomes

$$\begin{aligned}\int \frac{x}{\sqrt{x-3}}\,dx &= 2\int \frac{u^2+3}{u}\cdot u\,du \\ &= 2\int u^2 + 3\,du\end{aligned}$$

Using a radical substitution often leaves us with an integrand that is much nicer to work with. Continuing the process, we get

$$\begin{aligned}&= 2\left(\frac{1}{3}u^3 + 3u\right) + C \\ &= \frac{2}{3}u^3 + 6u + C \\ &= \frac{2}{3}(\sqrt{x-3})^3 + 6\sqrt{x-3} + C \\ &= \frac{2}{3}(x-3)^{3/2} + 6(x-3)^{1/2} + C.\end{aligned}$$

While this process might *look* a little longer, we benefit by not having such a complicated integrand.

Truth be told, this technique often leads to a rational function requiring a special integration technique that we will learn later in this chapter; however, we avoid such integrals for now and practice the method when the result only requires simple integration. While there is no "hard and fast" rule to how or when to apply this method, it is a good technique to try if an integrand contains an expression of the form $\sqrt[n]{g(x)}$.

### ✔ Example 7.1.1: Using a Radical Substitution

Evaluate

$$\int \frac{\sqrt{x}}{1+\sqrt[4]{x}}\,dx$$

**Solution**

I will approach this as if I were a student. I begin by thinking of all the methods we have so far to help us evaluate integrals (of which, we only have three at this moment):

- **Direct Integration:** Since the integrand is not the derivative of an established, well-known function, we cannot directly integrate.
- **Simple $u$-Substitution:** If we let $u = 1 + \sqrt[4]{x}$, then $du = \frac{1}{4}x^{-3/4}\,dx$. While this might seem messy, it is an option.
- **Radical Substitution:** If we let $u = \sqrt[4]{x}$ so that $u^4 = x$, we would get $4u^3\,du = dx$. Moreover, the $\sqrt{x}$ in the numerator of the integrand can be replaced using $u^2 = \sqrt{x}$.

Of the two viable options, the radical substitution looks the most attractive. Substituting all of the expressions into the original integral, we get

$$\begin{aligned}\int \frac{\sqrt{x}}{1+\sqrt[4]{x}}\,dx &= \int \frac{u^2}{1+u}\cdot 4u^3\,du \\ &= 4\int \frac{u^5}{1+u}\,du\end{aligned}$$

At this point, most people feel stuck. It is important to remember the Mathematical Mantra - Arithmetic before Algebra, Algebra before Trigonometry, and Trigonometry before Calculus. Calculus should be the last thing we do. Something we know from Algebra is long division!

$$\begin{aligned}\int \frac{\sqrt{x}}{1+\sqrt[4]{x}}\,dx &= 4\int \frac{u^5}{1+u}\,du \\ &= 4\int u^4 - u^3 + u^2 - u + 1 - \frac{1}{1+u}\,du \\ &= 4\left(\frac{1}{5}u^5 - \frac{1}{4}u^4 + \frac{1}{3}u^3 - \frac{1}{2}u^2 + u - \ln|1+u|\right) + C \\ &= \frac{4}{5}x^{5/4} - x + \frac{4}{3}x^{3/4} - 2x^{1/2} + 4x^{1/4} - 4\ln|1+\sqrt[4]{x}| + C\end{aligned}$$

Let's spend a moment talking about two important points concerning Example 7.1.1. First, as is often the case with integration, we had more than one option for evaluating this integral - simple $u$-substitution or a radical substitution; however, there is yet another way to evaluate this integral. If $u = \sqrt[4]{x}$ is an attractive option, then why not make it slightly "bigger" by including any neighboring constants?

Indeed, had we let

$$u = 1 + \sqrt[4]{x}, \tag{7.1.1}$$

then our work simplifies quite nicely. Before finding the differential, $du$, let's get rid of radicals by isolating $\sqrt[4]{x}$ in Equation 7.1.1 and raising both sides of to the fourth power. Therefore,

$$u - 1 = \sqrt[4]{x} \implies (u-1)^4 = x. \tag{7.1.2}$$

Then

$$4(u-1)^3\,du = dx.$$

Also, looking at the original integrand, we have $\sqrt{x}$ in the numerator, so taking the square root of both sides of the result in Equation 7.1.2, we get

$$(u-1)^2 = \sqrt{x}.$$

Therefore,

$$\begin{aligned}
\int \frac{\sqrt{x}}{1+\sqrt[4]{x}}\,dx &= \int \frac{(u-1)^2}{u}\cdot 4(u-1)^3\,du \\
&= 4\int \frac{(u-1)^5}{u}\,du \\
&= 4\int \frac{u^5-5u^4+10u^3-10u^2+5u-1}{u}\,du \\
&= 4\int u^4-5u^3+10u^2-10u+5-\frac{1}{u}\,du \\
&= 4\left(\frac{1}{5}u^5-\frac{5}{4}u^4+\frac{10}{3}u^3-5u^2+5u-\ln|u|\right)+C \\
&= \frac{4}{5}u^5-5u^4+\frac{40}{3}u^3-20u^2+20u-4\ln|u|+C \\
&= \frac{4}{5}\left(1+\sqrt[4]{x}\right)^5-5\left(1+\sqrt[4]{x}\right)^4+\frac{40}{3}\left(1+\sqrt[4]{x}\right)^3-20\left(1+\sqrt[4]{x}\right)^2+20\left(1+\sqrt[4]{x}\right) \\
&\quad -4\ln\left(1+\sqrt[4]{x}\right)+C
\end{aligned}$$

Notice that the answer in this last computation does not *look* like the answer we arrived at in Example **7.1.1**. I assure you they are equivalent, but you should check by taking their derivatives and seeing if they match.

The second point to mention has to do with our method of solution using $u=1+\sqrt[4]{x}$. The binomial expansion on the third line of the last set of computations is achieved quickly using either the Binomial Theorem (from Precalculus) or Pascal's Triangle (also from Precalculus). Knowing these concepts will be critical as we progress in this course.

There is not much else (for now) to radical substitutions - it's a great method when available. We now venture into integrands involving trigonometric functions.

## Integrands of the form $\frac{1}{a^2+x^2}$

Another integral commonly encountered throughout Calculus is of the type

$$\int \frac{1}{a^2+x^2}\,dx.$$

If this integral looks familiar, it is because you dealt with its more elementary form

$$\int \frac{1}{1+x^2}\,dx = \arctan x + C$$

in Calculus I. Let's see how to derive the antiderivative of this new form.

$$\begin{aligned}
\int \frac{1}{a^2+x^2}\,dx &= \frac{1}{a^2}\int \frac{1}{1+\left(\frac{x}{a}\right)^2}\,dx && \text{(Factoring out } a^2 \text{ from the denominator)} \\
&= \frac{a}{a^2}\int \frac{1}{1+u^2}\,du && \left(u=\tfrac{x}{a} \implies du=\tfrac{1}{a}\,dx \implies a\,du=dx\right) \\
&= \frac{1}{a}\arctan u + C \\
&= \frac{1}{a}\arctan\left(\frac{x}{a}\right)+C
\end{aligned}$$

We have proved the following theorem.

**Theorem**

$$\int \frac{1}{a^2+x^2}\,dx = \frac{1}{a}\arctan\left(\frac{x}{a}\right)+C$$

**Strive to Derive**

As with most (but not all) of Mathematics, it's best to be able to derive a theorem as easy as this one. Your memory might fail you, but your ability to logically derive a result will likely not.

**Example 7.1.2**

Evaluate

$$\int \frac{e^x}{3+e^{2x}}\,dx$$

**Solution**

Letting $u = e^x$, we find $du = e^x\,dx$. Therefore,

$$\int \frac{e^x}{3+e^{2x}}\,dx = \int \frac{1}{3+u^2}\,du = \int \frac{1}{(\sqrt{3})^2+u^2}\,du.$$

Notice that I rewrote $3$ as $(\sqrt{3})^2$. This is because, in our theorem, we are interested in $a$ - not $a^2$.
Using our newly-derived theorem, this yields

$$\int \frac{e^x}{3+e^{2x}}\,dx = \frac{1}{\sqrt{3}}\arctan\left(\frac{u}{\sqrt{3}}\right)+C = \frac{1}{\sqrt{3}}\arctan\left(\frac{e^x}{\sqrt{3}}\right)+C.$$

## Integrating Products and Powers of $\sin(x)$ and $\cos(x)$

For the remainder of this section, we look at integrating various products of trigonometric functions. As a collection, these integrals are called **trigonometric integrals**. They are an important part of the integration technique called trigonometric substitution, which is featured in Section 2.2. This technique allows us to convert algebraic expressions that we may not be able to integrate into expressions involving trigonometric functions that we might be able to integrate using the techniques described in this section. In addition, these types of integrals frequently appear when we study polar, cylindrical, and spherical coordinate systems (the first two will be studied later in this course, and the final one is left for Calculus III). Let's begin our study with products of $\sin x$ and $\cos x$.

Most authors spend an inordinate amount of time having students memorize cases; however, all of these cases can be summarized into the following statement:

**Rule of Thumb**

When dealing with integrands involving products of trigonometric functions, we strive to make a $u$-substitution to force even powers on the factor $u$ is not equal to.

This Rule of Thumb is a bit oversimplified, and there are plenty of exceptions; however, as you gain experience working with this special substitution method, you will begin to understand why this Rule of Thumb is important and when it can be used. For now, let's see it in action.

**Example 7.1.3: Integrating $\cos^j(x)\sin(x)$**

Evaluate $\int \cos^3(x)\sin(x)\,dx$.

**Solution**

Since we are at the beginning of learning new techniques, let's list out our options and discuss which ones are viable.

☒ **Direct Integration:** Since the integrand is not the derivative of an established, well-known function, we cannot directly integrate.

☑ **Simple $u$-Substitution:** We have two options:

1. If we let $u = \sin x$, then $du = \cos x\, dx$.
2. If we let $u = \cos x$, then $du = -\sin x\, dx$.

☒ **Radical Substitution:** Since the integrand does not have a radical, a radical substitution is out of the question.

Our only viable option is the simplue $u$-substitution; however, which one do we use?

**Option 1.**

If $u = \sin x$, the differential, $du$, would steal away a single power of the cosine function leaving the integrand with $\cos^2 x$. The Pythagorean Identity tells us that $\cos^2 x = 1 - \sin^2 x = 1 - u^2$. Hence

$$\begin{aligned}\int \cos^3 x \sin x\, dx &= \int (1-u^2)u\, du \\ &= \int u - u^3\, du \\ &= \frac{1}{2}u^2 - \frac{1}{4}u^4 + C \\ &= \frac{1}{2}\sin^2 x - \frac{1}{4}\sin^4 x + C\end{aligned}$$

**Option 2.**

If $u = \cos(x)$, then $du = -\sin x\, dx$. Since the integrand doesn't have a $-\sin x\, dx$ to steal, we rewrite this as $-du = \sin x\, dx$. Thus,

$$\int \cos^3(x)\sin(x)\, dx = -\int u^3\, du = -\frac{1}{4}u^4 + C = -\frac{1}{4}\cos^4(x) + C.$$

Let's dissect Example **7.1.3** to get a better intuition of what is happening.

The first question that springs to students' minds when looking at the two different substitutions we used is, "Why are the answers different?" The short answer is, they aren't! Trigonometric functions (especially powers of trigonometric functions) are incredibly malleable - they can be rewritten in terms of other trigonometric functions somewhat easily. In fact,

$$\begin{aligned}-\frac{1}{4}\cos^4 x + C &= -\frac{1}{4}\left(\cos^2 x\right)^2 + C \\ &= -\frac{1}{4}\left(1 - \sin^2 x\right)^2 + C \\ &= -\frac{1}{4}\left(1 - 2\sin^2 x + \sin^4 x\right) + C \\ &= -\frac{1}{4} + \frac{1}{2}\sin^2 x - \frac{1}{4}\sin^4 x + C\end{aligned}$$

However, $-\frac{1}{4} + C$ is just a constant, so we could easily call that $C_1$. Hence,

$$-\frac{1}{4}\cos^4 x + C = \frac{1}{2}\sin^2 x - \frac{1}{4}\sin^4 x + C_1.$$

**Note: Get Used to Equivalent Answers That Look Different**

Since the constant of integration can "absorb" constants, be prepared to see answers from other students (and in the answer keys to homework) that *look* different from your answers. Before assuming you are wrong, take a few moments to

1. algebraically manipulate your answer to see if it is equivalent to what you are comparing it to (but, possibly, off by a constant), or
2. use graphing technology to see if the graph of your answer is equivalent to what you are comparing it to (but, again, possibly off by a constant), or
3. take the derivative of your answer and the answer you are comparing with to see if their derivatives are the same as the integrand.

The second thing to notice about our solution to **7.1.2** is that in both cases, we made $u$-substitutions that forced an even power on the factor that $u$ was *not* equal to. In the first case, our substitution of $u = \sin x$ left us with $\cos^2 x$. In the second case, our substitution of $u = \cos x$ left us with $\sin^0 x$. Note that **2** and **0** are both even numbers - this aligns nicely with the Rule of Thumb!

**? Checkpoint 7.1.3**

Evaluate $\int \sin^4(x)\cos(x)\,dx$.

**Answer**

$$\int \sin^4(x)\cos(x)\,dx = \frac{1}{5}\sin^5 x + C$$

**✓ Example 7.1.4: A Preliminary Example: Integrating $\cos^j(x)\sin^k(x)$ where $k$ is Odd**

Evaluate $\int \cos^2(x)\sin^3(x)\,dx$.

**Solution**

☒ **Direct Integration**

☑ **Simple $u$-Substitution**

$$u = \cos x \implies du = -\sin x\,dx \quad \text{or} \quad u = \sin x \implies du = \cos x\,dx$$

## ☒ Radical Substitution

Again, a simple substitution is the only option; however, this time our hand is forced. If we choose $u = \sin x \implies du = \cos x\,dx$, the ultimate power left on the cosine (which is what $u$ is *not* equal to) is odd and we would not be able to rewrite $\cos x$ in terms of $u = \sin x$. Therefore, our only choice is to make the substitution $u = \cos x \implies -du = \sin x\,dx$. This would leave our integrand with $\sin^2(x) = 1 - \cos^2(x) = 1 - u^2$. Thus,

$$\begin{aligned}
\int \cos^2(x)\sin^3(x)\,dx &= \int \cos^2(x)\sin^2 x \sin(x)\,dx \\
&= \int \cos^2(x)(1-\cos^2(x))\sin(x)\,dx \\
&= -\int u^2(1-u^2)\,du \\
&= \int (u^4 - u^2)\,du \\
&= \frac{1}{5}u^5 - \frac{1}{3}u^3 + C \\
&= \frac{1}{5}\cos^5(x) - \frac{1}{3}\cos^3(x) + C.
\end{aligned}$$

**? Checkpoint 7.1.4**

Evaluate $\int \cos^3(x)\sin^2(x)\,dx$.

**Answer**

$$\int \cos^3(x)\sin^2(x)\,dx = \frac{1}{3}\sin^3(x) - \frac{1}{5}\sin^5(x) + C$$

In the next example, we see the strategy that must be applied when there are only even powers of $\sin(x)$ and $\cos(x)$. For integrals of this type, the identities

$$\sin^2(x) = \frac{1-\cos(2x)}{2} = \frac{1}{2} - \frac{1}{2}\cos(2x)$$

and

$$\cos^2(x) = \frac{1+\cos(2x)}{2} = \frac{1}{2} + \frac{1}{2}\cos(2x)$$

are invaluable. These identities are sometimes known as the **Power Reduction Identities** and they may be derived from the Double-Angle Identity $\cos(2x) = \cos^2(x) - \sin^2(x)$ and the Pythagorean Identity $\cos^2(x) + \sin^2(x) = 1$.

### ✔ Example 7.1.5: Integrating an Even Power of $\sin(x)$

Evaluate $\int \sin^2(x)\,dx$.

**Solution**

☒ **Direct Integration**

☒ **Simple $u$-Substitution**

☒ **Radical Substitution**

When you are facing an integral and none of your methods work, you should immediately think of the Mathematical Mantra. There isn't any Arithmetic or Algebra that will clean up the integrand, but we have a couple of options from Trigonometry. The first is the Pythagorean Identity, $\sin^2 x = 1 - \cos^2 x$; however, this will leave us with a similar quandary - how do we integrate the square of cosine?

Thus, we change identities to the Power Reduction Formula, $\sin^2(x) = \frac{1}{2} - \frac{1}{2}\cos(2x)$. Using this yields

$$\int \sin^2(x)\,dx = \int \left(\frac{1}{2} - \frac{1}{2}\cos(2x)\right) dx = \frac{1}{2}x - \frac{1}{4}\sin(2x) + C.$$

### ? Checkpoint 7.1.5

Evaluate $\int \cos^2(x)\,dx$.

**Answer**

$$\int \cos^2(x)\,dx = \frac{1}{2}x + \frac{1}{4}\sin(2x) + C$$

Again, the general process for integrating products of powers of $\sin(x)$ and $\cos(x)$ boils down to making a $u$-substitution (for either $\sin(x)$ or $\cos(x)$) so that the differential, $du$, "steals" the odd power off of the other trigonometric function. Using the Pythagorean Identity, you then rewrite the entire integrand in terms of $u$. You must use the Power Reduction Identities if there are no odd powers. Rather than writing out a "Problem-Solving Strategy" (which is too bulky and algorithmic), we showcase the process through examples.

### ✔ Example 7.1.6: Integrating $\cos^j(x)\sin^k(x)$ where $k$ is Odd

Evaluate $\int \cos^8(x)\sin^5(x)\,dx$.

**Solution**

☒ **Direct Integration**

☑ **Simple $u$-Substitution**

☒ **Radical Substitution**

We would prefer to have all powers even (this allows us to use identities from Trigonometry). Therefore, we let $u = \cos(x)$ so that $du = -\sin(x)\,dx$ "steals" the odd power of the sine function away. Thus,

$$\begin{aligned}
\int \cos^8(x)\sin^5(x)\,dx &= \int \cos^8(x)\sin^4(x)\sin(x)\,dx \\
&= \int \cos^8(x)(\sin^2(x))^2\sin(x)\,dx && \text{(Laws of Exponents)} \\
&= \int \cos^8(x)(1-\cos^2(x))^2\sin(x)\,dx && \text{(Pythagorean Identity)} \\
&= \int u^8(1-u^2)^2(-du) && \text{(Let } u=\cos(x) \text{ and } du=-\sin(x)\,dx\text{)} \\
&= \int (-u^8+2u^{10}-u^{12})\,du \\
&= -\frac{1}{9}u^9+\frac{2}{11}u^{11}-\frac{1}{13}u^{13}+C \\
&= -\frac{1}{9}\cos^9(x)+\frac{2}{11}\cos^{11}(x)-\frac{1}{13}\cos^{13}(x)+C && \text{(resubstitute)}
\end{aligned}$$

## ? Checkpoint 7.1.6

Evaluate $\int \cos^3(x)\,dx$.

**Answer**

$$\int \cos^3(x)\,dx = \sin(x)-\frac{1}{3}\sin^3(x)+C$$

## ✓ Example 7.1.7: Integrating $\cos^j(x)\sin^k(x)$ where $k$ and $j$ are Even

Evaluate $\int \sin^4(x)\,dx$.

**Solution**

☒ **Direct Integration**

☒ **Simple $u$-Substitution:** Since the power on both sine and cosine are even (4 and 0, respectively), any $u$-substitution will result in "stealing" a power off of sine (or cosine), resulting in an expression not having an odd power. This will leave us stuck.

☒ **Radical Substitution**

Using the Mathematical Mantra, we see we must resort to using the Power Reduction Identities.

$$\begin{aligned}
\int \sin^4(x)\,dx &= \int \left(\sin^2(x)\right)^2\,dx && \text{(Laws of Exponents)}\\
&= \int \left(\frac{1}{2}-\frac{1}{2}\cos(2x)\right)^2\,dx && \text{(Power Reduction Identities)}\\
&= \int \left(\frac{1}{4}-\frac{1}{2}\cos(2x)+\frac{1}{4}\cos^2(2x)\right)\,dx && \text{(distributing)}\\
&= \int \left(\frac{1}{4}-\frac{1}{2}\cos(2x)+\frac{1}{4}\left(\frac{1}{2}+\frac{1}{2}\cos(4x)\right)\right)\,dx && \text{(Power Reduction Identities)}\\
&= \int \left(\frac{3}{8}-\frac{1}{2}\cos(2x)+\frac{1}{8}\cos(4x)\right)\,dx\\
&= \frac{3}{8}x-\frac{1}{4}\sin(2x)+\frac{1}{32}\sin(4x)+C
\end{aligned}$$

**? Checkpoint 7.1.7**

Evaluate $\int \cos^2(3x)\,dx$.

**Answer**

$$\int \cos^2(3x)\,dx = \frac{1}{2}x+\frac{1}{12}\sin(6x)+C$$

In some areas of physics, such as quantum mechanics, signal processing, and the computation of Fourier series, it is often necessary to integrate products that include $\sin(ax), \sin(bx), \cos(ax)$, and $\cos(bx)$. These integrals are evaluated by applying the **Product-to-Sum Identities** from Trigonometry. These identities are listed below because no student should be made to memorize them.

**Theorem: Product-to-Sum Identities**

$$\begin{aligned}
\sin(ax)\sin(bx) &= \frac{1}{2}\cos((a-b)x)-\frac{1}{2}\cos((a+b)x)\\
\sin(ax)\cos(bx) &= \frac{1}{2}\sin((a-b)x)+\frac{1}{2}\sin((a+b)x)\\
\cos(ax)\cos(bx) &= \frac{1}{2}\cos((a-b)x)+\frac{1}{2}\cos((a+b)x)
\end{aligned}$$

**✓ Example 7.1.8: Evaluating $\int \sin(ax)\cos(bx)\,dx$**

Evaluate $\int \sin(5x)\cos(3x)\,dx$.

**Solution**

☒ **Direct Integration**

☒ **Simple $u$-Substitution**

☒ **Radical Substitution**

Again, using the Mathematical Mantra, we begin by applying the identity $\sin(5x)\cos(3x) = \frac{1}{2}\sin(2x)+\frac{1}{2}\sin(8x)$. Thus,

$$\int \sin(5x)\cos(3x)\,dx = \int \frac{1}{2}\sin(2x)+\frac{1}{2}\sin(8x)\,dx = -\frac{1}{4}\cos(2x)-\frac{1}{16}\cos(8x)+C.$$

**Checkpoint 7.1.8**

Evaluate $\int \cos(6x)\cos(5x)\,dx$.

**Answer**

$$\int \cos(6x)\cos(5x)\,dx = \frac{1}{2}\sin x + \frac{1}{22}\sin(11x) + C$$

## Integrating Products and Powers of $\tan(x)$ and $\sec(x)$

Before discussing the integration of products and powers of $\tan(x)$ and $\sec(x)$, we need to introduce the antiderivative of the secant.

**Theorem: $\int \sec(x)\,dx$ and $\int \csc(x)\,dx$**

$$\int \sec(x)\,dx = \ln|\sec(x)+\tan(x)| + C$$

and

$$\int \csc(x)\,dx = -\ln|\csc(x)+\cot(x)| + C$$

**Proof**

$$\begin{aligned}
\int \sec(x)\,dx &= \int \frac{\sec(x)(\sec(x)+\tan(x))}{\sec(x)+\tan(x)}\,dx && \text{(multiplying numerator and denominator by } \sec(x)+\tan(x)\text{)}\\
&= \int \frac{\sec^2(x)+\sec(x)\tan(x)}{\sec(x)+\tan(x)}\,dx\\
&= \int \frac{1}{u}\,du && (u = \sec(x)+\tan(x) \implies du = (\sec(x)\tan(x)+\sec^2(x))\,dx)\\
&= \ln|u| + C\\
&= \ln|\sec(x)+\tan(x)| + C && \text{(resubstitute)}
\end{aligned}$$

The proof for the integral of the cosecant is generally left as a homework exercise.

For completeness, let's list the integrals involving $\tan(x)$ and $\sec(x)$ we have learned so far:

$$\begin{aligned}
\int \sec^2(x)\,dx &= \tan(x) + C\\
\int \sec(x)\tan(x)\,dx &= \sec(x) + C\\
\int \tan(x)\,dx &= \ln|\sec(x)| + C\\
\int \sec(x)\,dx &= \ln|\sec(x)+\tan(x)| + C
\end{aligned}$$

For *most* integrals of products and powers of $\tan(x)$ and $\sec(x)$, we rewrite the expression we wish to integrate as the sum or difference of integrals of the form $\int \tan^j(x)\sec^2(x)\,dx$ or $\int \sec^j(x)\tan(x)\,dx$. In the former case, we can see that allowing $u = \tan(x)$ would cause $du$ to "steal" the $\sec^2(x)\,dx$. In the latter case, allowing $u = \sec(x)$ causes $du$ to "steal" a single power of $\sec(x)$ along with the $\tan(x)\,dx$. In both cases, the integral simplifies nicely.

Let's see this in action.

### Example 7.1.9: Evaluating $\int \sec^j(x)\tan(x)\,dx$

Evaluate $\int \sec^5(x)\tan(x)\,dx$.

**Solution**

☒ **Direct Integration**

☑ **Simple $u$-Substitution:** Choosing to let $u=\tan(x)$ would result in $du=\sec^2(x)\,dx$. This would "steal" two powers off the secant function and result in an odd power remaining on secant. This is *not* desirable; however, if we let $u=\sec(x)$ so that $du=\sec(x)\tan(x)\,dx$, the differential would "steal" a single power from the tangent, leaving an even power on the tangent (a power of 0), which is what we want.

☒ **Radical Substitution**

$$\begin{aligned}\int \sec^5(x)\tan(x)\,dx &= \int \sec^4(x)\sec(x)\tan(x)\,dx \\ &= \int u^4\,du && (u=\sec(x),\text{ then } du=\sec(x)\tan(x)\,dx) \\ &= \frac{1}{5}u^5+C \\ &= \frac{1}{5}\sec^5(x)+C && (\text{resubstitute})\end{aligned}$$

### Checkpoint 7.1.9

Evaluate $\int \tan^5(x)\sec^2(x)\,dx$.

**Answer**

$$\int \tan^5(x)\sec^2(x)\,dx=\frac{1}{6}\tan^6(x)+C$$

When working with products and powers of the sine and cosine, the Rule of Thumb was to make a $u$-substitution so that the "non-$u$" function ended with an even power. We then use the Pythagorean Identity to rewrite the integrand entirely in terms of $u$. The only exception to this strategy was if *both* sine and cosine have even powers. In that case, we start by using the Power Reduction Identities. When dealing with products and powers of the secant and the tangent, things are not so clean. As such, writing out a "Problem-Solving Strategy" is helpful, but still not as good as experience.

### Problem-Solving Strategy: Integrating $\int \tan^k(x)\sec^j(x)\,dx$

To integrate $\int \tan^k(x)\sec^j(x)\,dx$, use the following strategies:

1. If $j$ is even and $j\geq 2$, rewrite $\sec^j(x)=\sec^{j-2}(x)\sec^2(x)$ and use $\sec^2(x)=\tan^2(x)+1$ to rewrite $\sec^{j-2}(x)$ in terms of $\tan(x)$. Let $u=\tan(x)$ and $du=\sec^2(x)\,dx$.
2. If $k$ is odd and $j\geq 1$, rewrite $\tan^k(x)\sec^j(x)=\tan^{k-1}(x)\sec^{j-1}(x)\sec(x)\tan(x)$ and use $\tan^2(x)=\sec^2(x)-1$ to rewrite $\tan^{k-1}(x)$ in terms of $\sec(x)$. Let $u=\sec(x)$ and $du=\sec(x)\tan(x)\,dx$. (Note: If $j$ is even and $k$ is odd, then either strategy 1 or strategy 2 may be used.)
3. If $k$ is odd where $k\geq 3$ and $j=0$, rewrite $\tan^k(x)=\tan^{k-2}(x)\tan^2(x)=\tan^{k-2}(x)(\sec^2(x)-1)=\tan^{k-2}(x)\sec^2(x)-\tan^{k-2}(x)$. It may be necessary to repeat this process on the $\tan^{k-2}(x)$ term.
4. The case where $k$ is even and $j$ is odd requires a method we will introduce later in this chapter. For now, we focus only on integrands of the form 1, 2, or 3.

**Caution: Strive to Understand - Not to Memorize**

The preceding "Problem-Solving Strategy" is complex, but there is no way around it. Integration techniques are mostly heuristic methods. As such, it's best to learn them by working through many problems - experience is a *much* better teacher than memorizing the preceding strategy.

### Example 7.1.10: Integrating $\tan^k(x)\sec^j(x)$ when $j$ is Even

Evaluate $\int \tan^6(x)\sec^4(x)\,dx$.

**Solution**

☒ **Direct Integration**

☑ **Simple $u$-Substitution:** Both powers on tangent and secant are already even, so whatever $u$-substitution (if any) that we perform, we would like to keep those even powers there (this allows us to use our trigonometric identities, if needed). To keep the powers even after a $u$-substitution, we set $u = \tan(x)$ so that $du = \sec^2(x)\,dx$. This differential "steals" two powers off the secant function (keeping the power even in the end).

☒ **Radical Substitution**

$$\begin{aligned}
\int \tan^6(x)\sec^4(x)\,dx &= \int \tan^6(x)(\tan^2(x)+1)\sec^2(x)\,dx && \text{(Pythagorean Identity)}\\
&= \int u^6(u^2+1)\,du && (u=\tan(x) \text{ and } du=\sec^2(x)dx)\\
&= \int (u^8+u^6)\,du\\
&= \frac{1}{9}u^9+\frac{1}{7}u^7+C\\
&= \frac{1}{9}\tan^9(x)+\frac{1}{7}\tan^7(x)+C && \text{(resubstitute)}
\end{aligned}$$

### Example 7.1.11: Integrating $\tan^k(x)\sec^j(x)$ when $k$ is Odd

Evaluate $\int \tan^5(x)\sec^3(x)\,dx$.

**Solution**

☒ **Direct Integration**

☑ **Simple $u$-Substitution:** If we let $u = \sec(x)$, then $du = \sec(x)\tan(x)\,dx$ will "steal" enough power so that the tangent (the non-$u$ function) is left with an even power.

☒ **Radical Substitution**

$$\begin{aligned}
\int \tan^5(x)\sec^3(x)\,dx &= \int \tan^4(x)\sec^2(x)\sec(x)\tan(x)\,dx \\
&= \int (\tan^2(x))^2\sec^2(x)\sec(x)\tan(x)\,dx && \text{(Laws of Exponents)} \\
&= \int (\sec^2(x)-1)^2\sec^2(x)\sec(x)\tan(x)\,dx && \text{(Pythagorean Identity)} \\
&= \int (u^2-1)^2u^2\,du && (u=\sec(x) \text{ and } du=\sec(x)\tan(x)\,dx) \\
&= \int (u^6-2u^4+u^2)\,du \\
&= \frac{1}{7}u^7-\frac{2}{5}u^5+\frac{1}{3}u^3+C \\
&= \frac{1}{7}\sec^7(x)-\frac{2}{5}\sec^5(x)+\frac{1}{3}\sec^3(x)+C && \text{(resubstitute)}
\end{aligned}$$

### Example 7.1.12: Integrating $\tan^k(x)$ where $k$ is Odd and $k \geq 3$

Evaluate $\int \tan^3(x)\,dx$.

**Solution**

☒ **Direct Integration**

☒ **Simple $u$-Substitution:** We could probably stare at this for a while and think, "What kind of substitution would lead to an even power on that tangent?" The answer is, in the form this integral is written, no substitution will help!

☒ **Radical Substitution**

Since there is no "obvious" integration technique, we go back to the Mathematical Mantra to get creative. If we recognize that

$$\tan^3(x) = \tan(x)\tan^2(x) = \tan(x)\left(\sec^2(x)-1\right) = \tan(x)\sec^2(x)-\tan(x),$$

we can make some progress.

$$\begin{aligned}
\int \tan^3(x)\,dx &= \int (\tan(x)\sec^2(x)-\tan(x))\,dx \\
&= \int \tan(x)\sec^2(x)\,dx - \int \tan(x)\,dx \\
&= \frac{1}{2}\tan^2(x) - \ln|\sec(x)| + C.
\end{aligned}$$

For the first integral, we used the substitution $u=\tan(x)$. For the second integral, we used the formula.

### Checkpoint 7.1.12

Evaluate $\int \tan^3(x)\sec^7(x)\,dx$.

**Answer**

$$\int \tan^3(x)\sec^7(x)\,dx = \frac{1}{9}\sec^9(x)-\frac{1}{7}\sec^7(x)+C$$

# 7.1E: Exercises

## Reading Questions

1. When an integrand contains a radical, such as $\sqrt[n]{g(x)}$, what is a "radical substitution" you could try?
2. What is the general antiderivative of the function $f(x) = \frac{1}{a^2+x^2}$?
3. When integrating $\int \sin^m(x)\cos^n(x)dx$, what is the general strategy if the power of sine ($m$) is odd?
4. What trigonometric identities are required to integrate $\int \sin^m(x)\cos^n(x)dx$ when both $m$ and $n$ are even?
5. When integrating $\int \tan^k(x)\sec^j(x)dx$, if the power of secant ($j$) is even, what is the recommended choice for $u$ and $du$?
6. When integrating $\int \tan^k(x)\sec^j(x)dx$, if the power of tangent ($k$) is odd and there is at least one secant factor, what is the recommended choice for $u$ and $du$?
7. What type of trigonometric identities are used to evaluate integrals like $\int \sin(5x)\cos(3x)dx$?

**Fill in the blank to make a true statement.**

1) $\sin^2 x + _____ = 1$

**Answer**

$\cos^2 x$

2) $\sec^2 x - 1 = _____$

**Answer**

$\tan^2 x$

**Use an identity to reduce the power of the trigonometric function to a trigonometric function raised to the first power.**

3) $\sin^2 x = _____$

**Answer**

$\frac{1-\cos(2x)}{2}$

4) $\cos^2 x = _____$

**Answer**

$\frac{1+\cos(2x)}{2}$

**Evaluate each of the following integrals by $u$-substitution.**

5) $\int \sin^3 x \cos x \, dx$

**Answer**

$\int \sin^3 x \cos x \, dx = \frac{\sin^4 x}{4} + C$

6) $\int \sqrt{\cos x} \sin x \, dx$

7) $\int \tan^5(2x)\sec^2(2x)\, dx$

**Answer**

$\int \tan^5(2x)\sec^2(2x)\, dx = \frac{1}{12}\tan^6(2x) + C$

8) $\int \sin^7(2x)\cos(2x)\, dx$

9) $\int \tan(\frac{x}{2})\sec^2(\frac{x}{2})\,dx$

**Answer**

$$\int \tan(\frac{x}{2})\sec^2(\frac{x}{2})\,dx \quad = \quad \tan^2(\frac{x}{2}) + C$$

10) $\int \tan^2 x \sec^2 x\,dx$

**Compute the following integrals using the guidelines for integrating powers of trigonometric functions. Use a CAS to check the solutions. (*Note*: Some of the problems may be done using techniques of integration learned previously.)**

11) $\int \sin^3 x\,dx$

**Answer**

$$\int \sin^3 x\,dx \quad = \quad -\frac{3\cos x}{4} + \tfrac{1}{12}\cos(3x) + C = -\cos x + \frac{\cos^3 x}{3} + C$$

12) $\int \cos^3 x\,dx$

13) $\int \sin x \cos x\,dx$

**Answer**

$$\int \sin x \cos x\,dx \quad = \quad -\tfrac{1}{2}\cos^2 x + C$$

14) $\int \cos^5 x\,dx$

15) $\int \sin^5 x \cos^2 x\,dx$

**Answer**

$$\int \sin^5 x \cos^2 x\,dx \quad = \quad -\frac{5\cos x}{64} - \tfrac{1}{192}\cos(3x) + \tfrac{3}{320}\cos(5x) - \tfrac{1}{448}\cos(7x) + C$$

16) $\int \sin^3 x \cos^3 x\,dx$

17) $\int \sqrt{\sin x}\cos x\,dx$

**Answer**

$$\int \sqrt{\sin x}\cos x\,dx \quad = \quad \tfrac{2}{3}(\sin x)^{3/2} + C$$

18) $\int \sqrt{\sin x}\cos^3 x\,dx$

19) $\int \sec x \tan x\,dx$

**Answer**

$$\int \sec x \tan x\,dx \quad = \quad \sec x + C$$

20) $\int \tan(5x)\,dx$

21) $\int \tan x \sec^3 x\,dx$

22) $\int \sec^4 x\,dx$

**Answer**

$$\int \sec^4 x\,dx \quad = \quad \frac{2\tan x}{3} + \tfrac{1}{3}\sec^2 x \tan x = \tan x + \frac{\tan^3 x}{3} + C$$

23) $\int \cot x\,dx$

24) $\int \csc x\,dx$

**Answer**

$$\int \csc x\,dx \quad = \quad -\ln|\cot x + \csc x| + C$$

25) $\int \frac{\tan^3 x}{\sqrt{\sec x}}\,dx$

**For exercises 26 - 27, find a general formula for the integrals.**

26) $\int \sin^2 ax \cos ax\,dx$

**Answer**

$$\int \sin^2 ax \cos ax\,dx \quad = \quad \frac{\sin^3(ax)}{3a} + C$$

27) $\int \sin ax \cos ax\,dx.$

**Use the Double-Angle Identities to evaluate the integrals in exercises 28 - 33.**

28) $\int_0^{\pi} \sin^2 x\,dx$

**Answer**

$$\int_0^{\pi} \sin^2 x\,dx \quad = \quad \frac{\pi}{2}$$

29) $\int_0^{\pi} \sin^4 x\,dx$

30) $\int \cos^2 3x\,dx$

**Answer**

$$\int \cos^2 3x\,dx \quad = \quad \frac{x}{2} + \tfrac{1}{12}\sin(6x) + C$$

31) $\int \sin^2 x \cos^2 x\,dx$

32) $\int \sin^2 x\,dx + \int \cos^2 x\,dx$

**Answer**

$$\int \sin^2 x\,dx + \int \cos^2 x\,dx \quad = \quad x + C$$

33) $\int \sin^2 x \cos^2(2x)\,dx$

**For exercises 34 - 42, evaluate the definite integrals. Express answers in exact form whenever possible.**

34) $\int_0^{2\pi} \cos x \sin 2x\,dx$

**Answer**

$$\int_0^{2\pi} \cos x \sin 2x\,dx \quad = \quad 0$$

35) $\int_0^{\pi} \sin 3x \sin 5x \, dx$

36) $\int_0^{\pi} \cos(99x) \sin(101x) \, dx$

**Answer**

$$\int_0^{\pi} \cos(99x) \sin(101x) \, dx = 0$$

37) $\int_{-\pi}^{\pi} \cos^2(3x) \, dx$

38) $\int_0^{2\pi} \sin x \sin(2x) \sin(3x) \, dx$

**Answer**

$$\int_0^{2\pi} \sin x \sin(2x) \sin(3x) \, dx = 0$$

39) $\int_0^{4\pi} \cos(x/2) \sin(x/2) \, dx$

40) $\int_{\pi/6}^{\pi/3} \frac{\cos^3 x}{\sqrt{\sin x}} \, dx$ (Round this answer to three decimal places.)

**Answer**

$$\int_{\pi/6}^{\pi/3} \frac{\cos^3 x}{\sqrt{\sin x}} \, dx \approx 0.239$$

41) $\int_{-\pi/3}^{\pi/3} \sqrt{\sec^2 x - 1} \, dx$

42) $\int_0^{\pi/2} \sqrt{1 - \cos(2x)} \, dx$

**Answer**

$$\int_0^{\pi/2} \sqrt{1 - \cos(2x)} \, dx = \sqrt{2}$$

43) Find the area of the region bounded by the graphs of the equations $y = \sin x$, $y = \sin^3 x$, $x = 0$, and $x = \frac{\pi}{2}$.

44) Find the area of the region bounded by the graphs of the equations $y = \cos^2 x$, $y = \sin^2 x$, $x = -\frac{\pi}{4}$, and $x = \frac{\pi}{4}$.

**Answer**

$A = 1 \text{ unit}^2$

45) A particle moves in a straight line with the velocity function $v(t) = \sin(\omega t) \cos^2(\omega t)$. Find its position function $x = f(t)$ if $f(0) = 0$.

46) Find the average value of the function $f(x) = \sin^2 x \cos^3 x$ over the interval $[-\pi, \pi]$.

**Answer**

0

**For exercises 47 - 48, solve the differential equations.**

47) $\frac{dy}{dx} = \sin^2 x$. The curve passes through point $(0, 0)$.

48) $\frac{dy}{d\theta} = \sin^4(\pi\theta)$

**Answer**

$$f(x) = \frac{3\theta}{8} - \frac{1}{4\pi}\sin(2\pi\theta) + \frac{1}{32\pi}\sin(4\pi\theta) + C$$

49) Find the length of the curve $y = \ln(\csc x)$, for $\frac{\pi}{4} \le x \le \frac{\pi}{2}$.

50) Find the length of the curve $y = \ln(\sin x)$, for $\frac{\pi}{3} \le x \le \frac{\pi}{2}$.

**Answer**

$s = \ln(\sqrt{3})$

51) Find the volume generated by revolving the curve $y = \cos(3x)$ about the $x$-axis, for $0 \le x \le \frac{\pi}{36}$.

**For exercises 52 - 53, use this information: The inner product of two functions $f$ and $g$ over $[a, b]$ is defined by $f(x) \cdot g(x) = \langle f, g \rangle = \int_a^b f \cdot g \, dx$. Two distinct functions $f$ and $g$ are said to be orthogonal if $\langle f, g \rangle = 0$.**

52) Show that $\sin(2x)$, $\cos(3x)$ are orthogonal over the interval $[-\pi, \pi]$.

**Answer**

$$\int_{-\pi}^{\pi} \sin(2x)\cos(3x)\,dx = 0$$

53) Evaluate $\int_{-\pi}^{\pi} \sin(mx)\cos(nx)\,dx$.

54) Integrate $y' = \sqrt{\tan x}\sec^4 x$.

**Answer**

$$y = \int \sqrt{\tan x}\sec^4 x\,dx \quad = \quad \tfrac{2}{3}(\tan x)^{3/2} + \tfrac{2}{7}(\tan x)^{7/2} + C = \tfrac{2}{21}(\tan x)^{3/2}\left[7 + 3\tan^2 x\right] + C$$

# 7.2: Expanding the Substitution Method - Trigonometric Substitution

**Note to the Instructor (click to expand)**

This section is a continuation of expanding the Substitution Method by introducing trig subs. We painstakingly avoid the integral of $\sec^3(\theta)$ (despite it normally appearing in this material) because we need Integration by Parts to deal with that. We hold off on that gem for a future section.

---

To succeed in this section, you'll need to use some skills from previous courses. While you should already know them, this is the first time they've been required. You can review these skills in CRC's Corequisite Codex. If you have a support class, it might cover some, **but not all**, of these topics.

**Prerequisite Skills and Support Topics (click to expand)**

- **Quadratic Functions**
  - Vertex Form and Completing the Square: This algebraic technique is required to transform an integral with a general quadratic expression into a form containing a sum or difference of squares, making it suitable for trigonometric substitution. This is demonstrated in Example 2.2.8.

---

The following is a list of learning objectives for this section.

**Learning Objectives (click to expand)**

- Solve integration problems involving the square root of a sum or difference of two squares.

Hawk A.I. Section-Specific Tutor

EST. 1970 COSUMNES RIVER COLLEGE MATHEMATICS

To access the Hawk A.I. Tutor, you will need to be logged into your campus Gmail account.

In this section, we explore integrals containing expressions of the form $\sqrt{a^2-x^2}$, $\sqrt{a^2+x^2}$, and $\sqrt{x^2-a^2}$, where the values of $a$ are positive. We have already encountered and evaluated integrals containing some expressions of this type, but many remain inaccessible. The **trigonometric substitution** technique is convenient when evaluating these integrals. This technique, which is a specific use of the Substitution Method, rewrites these integrals as trigonometric integrals.

Before diving into the instruction, it's best to recall the following identities from Trigonometry (all based on the Pythagorean Identity):

- $\cos^2\theta = 1-\sin^2\theta$,
- $\sec^2\theta = 1+\tan^2\theta$, and
- $\tan^2\theta = \sec^2\theta - 1$.

Note that the *forms* of these expressions match the radicands in

- $\sqrt{a^2-x^2}$ (where $x = a\sin\theta$),
- $\sqrt{a^2+x^2}$ (where $x = a\tan\theta$), and
- $\sqrt{x^2-a^2}$ (where $x = a\sec\theta$).

This observation will be compelling. It would be best to convince yourself that these forms are incredibly similar.

The final bit of "recall" we will need before developing the method of trigonometric substitution are the ranges of the inverse trigonometric functions. Specifically, we will need to remember, from Section 1.6 in the Differential Calculus textbook, the following range restrictions:

$$\sin^{-1}(y)=\theta \quad \text{if and only if} \quad \sin(\theta)=y \quad \text{where} \quad \theta\in\left[-\frac{\pi}{2},\frac{\pi}{2}\right]$$

$$\tan^{-1}(y)=\theta \quad \text{if and only if} \quad \tan(\theta)=y \quad \text{where} \quad \theta\in\left(-\frac{\pi}{2},\frac{\pi}{2}\right)$$

$$\sec^{-1}(y)=\theta \quad \text{if and only if} \quad \sec(\theta)=y \quad \text{where} \quad \theta\in\left[0,\frac{\pi}{2}\right)\cup\left[\pi,\frac{3\pi}{2}\right).$$

You should already be comfortable with the restrictions on $\theta$ for both the arcsine and arctangent from your Trigonometry or Precalculus course; however, the following snippet from Section 1.6 in the Differential Calculus textbook should begin to justify our choice of range for the arcsecant.

> All the inverse trigonometric functions return angles in quadrant I (where all trigonometric functions are positive) and one other quadrant where the corresponding trigonometric function is negative. The returned quadrants where the corresponding trigonometric functions are negative are fairly standard and agreed upon (quadrant IV for arctangent and arcsine, and quadrant II for arccosine and arccotangent); **however**, the quadrants chosen for the ranges of the arcsecant and arccosecant are *not* universally agreed upon.
>
> In this text, we choose arcsecant and arccosecant to return angles in quadrants I and **III** for a special reason - it makes our work in calculus slightly easier. I mention this because you might have seen a slightly different choice for the ranges of these functions in another textbook. The difference is insignificant other than the ease our choice makes for our work in calculus.

## Integrals Involving $\sqrt{a^2-x^2}$

Before developing a general strategy for integrals containing $\sqrt{a^2-x^2}$, consider the integral $\int \sqrt{9-x^2}\,dx$. This integral cannot be evaluated using any of the techniques we have discussed so far. However, if we make the substitution $x = 3\sin\theta$, we have $dx = 3\cos\theta\,d\theta$. After substituting into the integral, we have

$$\int \sqrt{9-x^2}\,dx = \int \sqrt{9-(3\sin\theta)^2}\cdot 3\cos\theta\,d\theta.$$

After simplifying, we have

$$\int \sqrt{9-x^2}\,dx = \int 9\sqrt{1-\sin^2\theta}\cdot\cos\theta\,d\theta.$$

Letting $1-\sin^2\theta = \cos^2\theta$, we now have

$$\int \sqrt{9-x^2}\,dx = \int 9\sqrt{\cos^2\theta}\cos\theta\,d\theta.$$

Assuming that $\cos\theta \geq 0$,[1] we have

$$\int \sqrt{9-x^2}\,dx = \int 9\cos^2\theta\,d\theta.$$

At this point, we can evaluate the integral using the techniques developed for integrating powers and products of trigonometric functions. Before completing this example, let's examine the general theory behind this idea.

To evaluate integrals involving $\sqrt{a^2-x^2}$, we make the substitution $x = a\sin\theta$ and $dx = a\cos\theta\,d\theta$. To see that this makes sense, consider the following argument: The domain of $\sqrt{a^2-x^2}$ is $[-a,a]$. Thus,

$$-a \leq x \leq a. \tag{7.2.1}$$

Consequently,

$$-1 \leq \frac{x}{a} \leq 1.$$

Since the range of $\sin\theta$ over $[-\frac{\pi}{2},\frac{\pi}{2}]$ is $[-1,1]$, there is a unique angle $\theta$ satisfying $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$ so that $\sin\theta = \frac{x}{a}$, or equivalently, so that $x = a\sin\theta$. If we substitute $x = a\sin\theta$ into $\sqrt{a^2-x^2}$, we get

$$\begin{aligned}
\sqrt{a^2-x^2} &= \sqrt{a^2-(a\sin\theta)^2} && \left(x = a\sin\theta \text{ where } -\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}\right)\\
&= \sqrt{a^2-a^2\sin^2\theta}\\
&= \sqrt{a^2(1-\sin^2\theta)} && \text{(factoring)}\\
&= \sqrt{a^2\cos^2\theta} && \text{(Pythagorean Identity)}\\
&= |a\cos\theta| && \left(\sqrt{a^2\cos^2\theta} = |a\cos\theta|\right)
\end{aligned}$$

Since $\cos\theta \geq 0$ on $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$ and $a > 0$, $|a\cos\theta| = a\cos\theta$.

Therefore, by making the substitution $x = a\sin\theta$, we can convert an integral involving a radical into an integral involving trigonometric functions, where we have the added benefit of not worrying about absolute values. From this point, we need to evaluate the integral. Once this is done, however, we must convert the solution to an expression involving $x$. To do this, we begin by drawing a reference triangle for $\theta$ (see Figure 7.2.1).

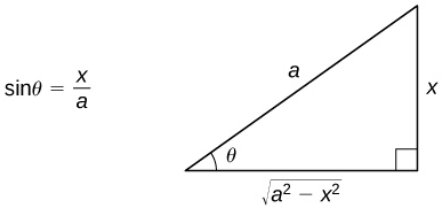

Figure 7.2.1: A reference triangle can help express the trigonometric functions evaluated at $\theta$ in terms of $x$.

Since $-\frac{\pi}{2} \le \theta \le \frac{\pi}{2}$, this reference triangle can only be drawn in quadrants I or IV. In either case,

$$\begin{aligned}\sin\theta &= \frac{x}{a}\\ \cos\theta &= \frac{\sqrt{a^2-x^2}}{a}\\ \tan\theta &= \frac{x}{\sqrt{a^2-x^2}}.\end{aligned}$$

Hence, no matter what trigonometric function is in the result of our evaluated integral, we can rewrite it as a function of $x$. Should $\theta$ appear by itself, we use $\theta = \sin^{-1}\left(\frac{x}{a}\right)$.[2]

The essential part of this discussion is summarized in the following problem-solving strategy.

**Problem-Solving Strategy: Integrating Expressions Involving $\sqrt{a^2-x^2}$**

1. It is an excellent idea to make sure the integral cannot be evaluated easily in another way. For example, although this method can be applied to integrals of the form
$$\int \frac{1}{\sqrt{a^2-x^2}}\,dx, \quad \int \frac{x}{\sqrt{a^2-x^2}}\,dx, \quad \text{and} \quad \int x\sqrt{a^2-x^2}\,dx,$$
they can each be integrated directly either by formula or by a simple $u$-substitution.
2. Make the substitution $x = a\sin\theta$ and $dx = a\cos\theta\,d\theta$. Note: This substitution yields $\sqrt{a^2-x^2} = a\cos\theta$.
3. Simplify the expression.
4. Evaluate the integral using techniques from the Section 2.1.
5. Use a reference triangle to rewrite the result in terms of $x$. You may also need to use some trigonometric identities and the relationship $\theta = \sin^{-1}\left(\frac{x}{a}\right)$.

The following example demonstrates the application of this problem-solving strategy.

**Example 7.2.1: Integrating an Expression Involving $\sqrt{a^2-x^2}$**

Evaluate

$$\int \sqrt{9-x^2}\,dx.$$

**Solution**

☒ **Direct Integration**

☒ **Simple $u$-Substitution:** Letting $u = 9-x^2$ results in $du = -2x\,dx$. I leave it to the reader to verify that this results in an uglier (and more difficult) integrand.

☒ **Radical Substitution:** Letting $u = \sqrt{9-x^2}$ means $u^2 = 9-x^2$. Therefore, $2u\,du = -2x\,dx \implies u\,du = -x\,dx$. Again, I leave it to the reader to verify that this results in an uglier (and more difficult) integrand.

☑ **Trigonometric Substitution:** We can try the trigonometric substitution $x = 3\sin\theta$ so that $dx = 3\cos\theta\, d\theta$. Since $\sin\theta = \frac{x}{3}$, we can construct the reference triangle shown in Figure **7.2.2**.

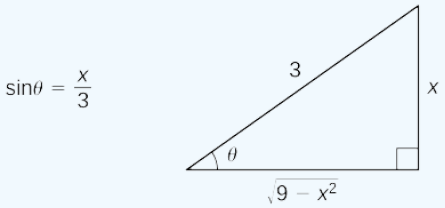

Figure **7.2.2**

Thus,

$$\begin{aligned}
\int \sqrt{9-x^2}\,dx &= \int \sqrt{9-(3\sin\theta)^2}\cdot 3\cos\theta\,d\theta && (x = 3\sin\theta \implies dx = 3\cos\theta\,d\theta)\\
&= \int \sqrt{9(1-\sin^2\theta)}\cdot 3\cos\theta\,d\theta\\
&= \int \sqrt{9\cos^2\theta}\cdot 3\cos\theta\,d\theta && \text{(Pythagorean Identity)}\\
&= \int 3|\cos\theta|3\cos\theta\,d\theta && \left(\sqrt{\blacksquare^2} = |\blacksquare|\right)\\
&= \int 9\cos^2\theta\,d\theta && \left(-\frac{\pi}{2} \le \theta \le \frac{\pi}{2} \implies \cos\theta \ge 0 \implies |\cos\theta| = \cos\theta\right)\\
&= \int 9\left(\frac{1}{2}+\frac{1}{2}\cos(2\theta)\right)d\theta && \text{(Power Reduction Identity)}\\
&= \frac{9}{2}\theta + \frac{9}{4}\sin(2\theta) + C\\
&= \frac{9}{2}\theta + \frac{9}{4}(2\sin\theta\cos\theta) + C && \text{(Double-Angle Identity)}\\
&= \frac{9}{2}\sin^{-1}\left(\frac{x}{3}\right) + \frac{9}{2}\cdot\frac{x}{3}\cdot\frac{\sqrt{9-x^2}}{3} + C && \left(\text{resubstitute } \sin^{-1}\left(\frac{x}{3}\right) = \theta \text{ and use the reference triangle}\right)\\
&= \frac{9}{2}\sin^{-1}\left(\frac{x}{3}\right) + \frac{x\sqrt{9-x^2}}{2} + C
\end{aligned}$$

Example **7.2.1** showcases something that I tell my students repeatedly - mastery of Trigonometry is a requirement for your success in Calculus. If you need to brush up on lost Trigonometry skills, please see Section 1.6 of the Differential Calculus textbook for a single-section review of all basic material required from Trigonometry for survival in Calculus. More topics are required from your Trigonometry and Precalculus course than are shown in that section; however, those missing topics (e.g., polar coordinates and parametric equations) will be reviewed later.

✔ Example **7.2.2**: Integrating an Expression Involving $\sqrt{a^2-x^2}$

Evaluate

$$\int \frac{\sqrt{4-\frac{25}{9}x^2}}{x}\,dx.$$

**Solution**

☒ **Direct Integration**

☒ **Simple $u$-Substitution:** Letting $u = 4 - \frac{25}{9}x^2$ results in $du = -\frac{50}{9}x\,dx$. I leave it to the reader to verify that this results in $-\frac{1}{2}\int \frac{\sqrt{u}}{4-u}\,du$, which is no better than where we started.

☒ **Radical Substitution:** For the same reasons that the simple $u$-substitution didn't work, a radical substitution is not viable either.

☑ **Trigonometric Substitution:** We want $\frac{25}{9}x^2 = 4\sin^2\theta$, so we make the substitution $\frac{5}{3}x = 2\sin\theta$, which leads to $\frac{5}{3}\,dx = 2\cos\theta\,d\theta$. Solving this for $dx$, we get $dx = \frac{6}{5}\cos\theta\,d\theta$. We also need to rewrite the denominator in the integrand in terms of $\theta$. Collecting

everything in a nice group, we have the following:

- $\frac{25}{9}x^2 = 4\sin^2\theta$
- $x = \frac{6}{5}\sin\theta$
- $dx = \frac{6}{5}\cos\theta\, d\theta$

As in Example 7.2.1, we draw a reference triangle to help our conversions, and we get

$$\begin{aligned}
\int \frac{\sqrt{4-\frac{25}{9}x^2}}{x}\,dx &= \int \frac{\sqrt{4-4\sin^2\theta}}{\frac{6}{5}\sin\theta}\cdot\frac{6}{5}\cos\theta\,d\theta \\
&= \int \frac{2\sqrt{\cos^2\theta}\cdot\cos\theta}{\sin\theta}\,d\theta && \text{(Pythagorean Identity)} \\
&= \int \frac{2|\cos\theta|\cdot\cos\theta}{\sin\theta}\,d\theta && \left(\sqrt{\blacksquare^2} = |\blacksquare|\right) \\
&= \int \frac{2\cos^2\theta}{\sin\theta}\,d\theta \\
&= \int \frac{2(1-\sin^2\theta)}{\sin\theta}\,d\theta && \text{(Pythagorean Identity)} \\
&= \int (2\csc\theta - 2\sin\theta)\,d\theta \\
&= 2\ln|\csc\theta-\cot\theta| + 2\cos\theta + C \\
&= 2\ln\left|\frac{6}{5x} - \frac{3\sqrt{4-\frac{25}{9}x^2}}{5x}\right| + \sqrt{4-\frac{25}{9}x^2} + C && \text{(using the reference triangle)} \\
&= 2\ln\left|\frac{6-\sqrt{36-25x^2}}{5x}\right| + \frac{1}{3}\sqrt{36-25x^2} + C
\end{aligned}$$

In the next example, we see that we sometimes have a choice of methods.

### Example 7.2.3: Integrating an Expression Involving $\sqrt{a^2-x^2}$ Two Ways

Evaluate $\int x^3\sqrt{1-x^2}dx$ two ways: first by using the substitution $u = 1-x^2$ and then by using a trigonometric substitution.

**Solution**

#### Method 1

Let $u = 1-x^2$. Hence, $x^2 = 1-u$. Thus, $du = -2x\,dx$. In this case, the integral becomes

$$\begin{aligned}
\int x^3\sqrt{1-x^2}\,dx &= -\frac{1}{2}\int x^2\sqrt{1-x^2}(-2x\,dx) \\
&= -\frac{1}{2}\int (1-u)\sqrt{u}\,du \\
&= -\frac{1}{2}\int (u^{1/2}-u^{3/2})\,du \\
&= -\frac{1}{2}\left(\frac{2}{3}u^{3/2} - \frac{2}{5}u^{5/2}\right) + C \\
&= -\frac{1}{3}(1-x^2)^{3/2} + \frac{1}{5}(1-x^2)^{5/2} + C
\end{aligned}$$

#### Method 2

Let $x = \sin\theta$. In this case, $dx = \cos\theta\,d\theta$. Using this substitution, we have

$$\begin{aligned}
\int x^3\sqrt{1-x^2}\,dx &= \int \sin^3\theta\cos^2\theta\,d\theta \\
&= \int (1-\cos^2\theta)\cos^2\theta\sin\theta\,d\theta \\
&= \int (u^4-u^2)\,du && (u=\cos\theta \implies du=-\sin\theta\,d\theta) \\
&= \frac{1}{5}u^5-\frac{1}{3}u^3+C \\
&= \frac{1}{5}\cos^5\theta-\frac{1}{3}\cos^3\theta+C \\
&= \frac{1}{5}(1-x^2)^{5/2}-\frac{1}{3}(1-x^2)^{3/2}+C && \text{(using the reference triangle)}
\end{aligned}$$

**? Checkpoint 7.2.3**

Rewrite the integral $\int \frac{x^3}{\sqrt{25-x^2}}\,dx$ using the appropriate trigonometric substitution (do not evaluate the integral).

**Answer**

$$\int 125\sin^3\theta\,d\theta$$

## Integrating Expressions Involving $\sqrt{a^2+x^2}$

For integrals containing $\sqrt{a^2+x^2}$, let's first consider the domain of this expression. Since $\sqrt{a^2+x^2}$ is defined for all real values of $x$, we restrict our choice to those trigonometric functions that have a range of all real numbers. Thus, we are restricted to selecting either $x=a\tan\theta$ or $x=a\cot\theta$. Either of these substitutions would work, but the standard substitution is $x=a\tan\theta$ or, equivalently, $\tan\theta=\frac{x}{a}$. With this substitution, we make the assumption that $-\frac{\pi}{2}<\theta<\frac{\pi}{2}$, so that we also have $\theta=\tan^{-1}\left(\frac{x}{a}\right)$. As before, let's derive the concept.

Since the range of $\tan\theta$ over $\left(-\frac{\pi}{2},\frac{\pi}{2}\right)$ is $(-\infty,\infty)$, there is a unique angle $\theta$ satisfying $-\frac{\pi}{2}<\theta<\frac{\pi}{2}$ so that $\tan\theta=\frac{x}{a}$, or equivalently, so that $x=a\tan\theta$. If we substitute $x=a\tan\theta$ into $\sqrt{a^2+x^2}$, we get

$$\begin{aligned}
\sqrt{a^2+x^2} &= \sqrt{a^2+(a\tan\theta)^2} && \left(x=a\tan\theta \text{ where } -\frac{\pi}{2}<\theta<\frac{\pi}{2}\right) \\
&= \sqrt{a^2+a^2\tan^2\theta} \\
&= \sqrt{a^2(1+\tan^2\theta)} && \text{(factoring out } a^2\text{)} \\
&= \sqrt{a^2\sec^2\theta} && \text{(Pythagorean Identity)} \\
&= |a\sec\theta| && \left(\sqrt{\blacksquare^2}=|\blacksquare|\right)
\end{aligned}$$

Since $\sec\theta\geq 0$ on $-\frac{\pi}{2}<\theta<\frac{\pi}{2}$ and $a>0$, $|a\sec\theta|=a\sec\theta$.

We again arrive at the beautiful result that making the substitution $x=a\tan\theta$ allows us to convert an integral involving a radical into an integral involving trigonometric functions, where we have the added benefit of not worrying about absolute values. To convert our solution back to an expression involving $x$, we draw a reference triangle for $\theta$ (see Figure 7.2.3).

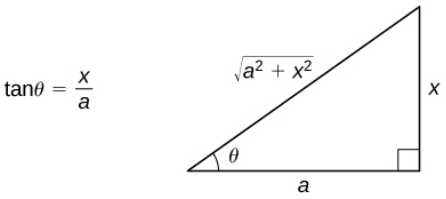

Figure 7.2.3: A reference triangle can be constructed to express the trigonometric functions evaluated at $\theta$ in terms of $x$.

Since $-\frac{\pi}{2}<\theta<\frac{\pi}{2}$, this reference triangle can only be drawn in quadrants I or IV. In either case,

$$\sin\theta = \frac{x}{\sqrt{a^2+x^2}}$$
$$\cos\theta = \frac{a}{\sqrt{a^2+x^2}}$$
$$\tan\theta = \frac{x}{a}.$$

Hence, no matter what trigonometric function is in the result of our evaluated integral, we can rewrite it as a function of $x$. Should $\theta$ appear by itself, we use $\theta = \tan^{-1}\left(\frac{x}{a}\right)$. The procedure for using this substitution is outlined in the following problem-solving strategy.

### Problem-Solving Strategy: Integrating Expressions Involving $\sqrt{a^2+x^2}$

1. Check whether the integral can be evaluated easily using another method. In some cases, it is more convenient to use an alternative method.[3]
2. Substitute $x = a\tan\theta$ and $dx = a\sec^2\theta\, d\theta$. This substitution yields
$$\sqrt{a^2+x^2} = \sqrt{a^2+(a\tan\theta)^2} = \sqrt{a^2(1+\tan^2\theta)} = \sqrt{a^2sec^2\theta} = |a\sec\theta| = a\sec\theta.$$
Since $-\frac{\pi}{2} < \theta < \frac{\pi}{2}$ and $\sec\theta > 0$ over this interval, $|a\sec\theta| = a\sec\theta$.
3. Simplify the expression.
4. Evaluate the integral using techniques from the section on trigonometric integrals.
5. Use the reference triangle from Figure 7.2.3 to rewrite the result in terms of $x$. You may also need to use some trigonometric identities and the relationship $\theta = \tan^{-1}\left(\frac{x}{a}\right)$.[4,5]

### Example 7.2.4: Integrating an Expression Involving $\sqrt{a^2+x^2}$

Evaluate $\int \frac{dx}{\sqrt{1+x^2}}$ and check the solution by differentiating.

**Solution**

☒ **Direct Integration***

☒ **Simple $u$-Substitution:** Letting $u = 1+x^2$ results in $du = 2x\,dx$. I leave it to the reader to verify that this results in an uglier (and more difficult) integrand.

☒ **Radical Substitution:** At this this point, you might have guessed that if the simple substitution doesn't work out nicely, nor will the related radical substitution.

☑ **Trigonometric Substitution:** Begin with the substitution $x = \tan\theta$ and $dx = \sec^2\theta\, d\theta$. Since $\tan\theta = x$, draw the reference triangle in Figure 7.2.4.

$\tan\theta = x = \frac{x}{1}$

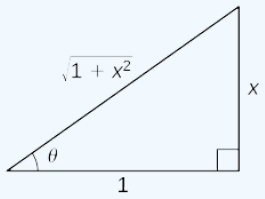

Figure 7.2.4

Thus,

$$\int \frac{dx}{\sqrt{1+x^2}} = \int \frac{\sec^2\theta}{\sec\theta}\,d\theta \qquad \left(x = \tan\theta \implies dx = \sec^2\theta\, d\theta \implies \sqrt{1+x^2} = \sec\theta\right)$$
$$= \int \sec\theta\, d\theta$$
$$= \ln|\sec\theta + \tan\theta| + C$$
$$= \ln|\sqrt{1+x^2} + x| + C \quad \text{(using the reference triangle)}$$

To check the solution, differentiate:

$$\frac{d}{dx}\left(\ln|\sqrt{1+x^2}+x|\right)=\frac{1}{\sqrt{1+x^2}+x}\cdot\left(\frac{x}{\sqrt{1+x^2}}+1\right)=\frac{1}{\sqrt{1+x^2}+x}\cdot\frac{x+\sqrt{1+x^2}}{\sqrt{1+x^2}}=\frac{1}{\sqrt{1+x^2}}.$$

Since $\sqrt{1+x^2}+x>0$ for all values of $x$, we could rewrite $\ln|\sqrt{1+x^2}+x|+C=\ln(\sqrt{1+x^2}+x)+C$, if desired.

* In Differential Calculus, you learned about the hyperbolic functions, their inverses, and the derivatives of both the base hyperbolic functions and their inverses. At the time, it was very likely that you were *not required* to memorize the derivatives of the inverse hyperbolic functions; however, if you happened to have stored those derivatives in your brain, then Example **7.2.4** could be much easier. Let's take a look at what I mean.

### ✔ Example 7.2.5: Evaluating $\int \frac{dx}{\sqrt{1+x^2}}$ Using a Different Substitution

Use the substitution $x=\sinh t$ to evaluate $\displaystyle\int\frac{dx}{\sqrt{1+x^2}}$.

**Solution**

Because $\sinh t$ has a range of all real numbers, and $1+\sinh^2 t=\cosh^2 t$, we may use the substitution $x=\sinh t$ to evaluate this integral. In this case, $dx=\cosh t\,dt$, Consequently,

$$\begin{aligned}
\int\frac{dx}{\sqrt{1+x^2}} &= \int\frac{\cosh t}{\sqrt{1+\sinh^2 t}}\,dt && (x=\sinh t \implies dx=\cosh t\,dt)\\
&= \int\frac{\cosh t}{\sqrt{\cosh^2 t}}\,dt && (1+\sinh^2 t=\cosh^2 t)\\
&= \int\frac{\cosh t}{|\cosh t|}\,dt\\
&= \int\frac{\cosh t}{\cosh t}\,dt && (\cosh t>0 \text{ for all } t \implies |\cosh t|=\cosh t)\\
&= \int dt\\
&= t+C\\
&= \sinh^{-1}x+C
\end{aligned}$$

Example **7.2.5** deserves a couple comments. First, I did not use $\theta$ as the argument for **sinh** and **cosh** because we traditionally reserve $\theta$ for angles. The argument of the hyperbolic functions are *not* angles, so it's a bit safer to use a variable that does not invoke thoughts of angles. If you were unaware of this fact, please see Section 1.7 of the Differential Calculus textbook for a discussion that the arguments of the hyperbolic functions are neither angles nor arc lengths.

The second comment is a continuation of my comments before Example **7.2.5**. Had we recalled that

$$\frac{d}{dt}\sinh^{-1}t=\frac{1}{\sqrt{1+t^2}},$$

we would have easily finished Example **7.2.5** in a single step; *however*, the answers to Examples **7.2.4** and **7.2.5** don't appear to match. To rectify this, we would need to recall that

$$\sinh^{-1}x=\ln(x+\sqrt{x^2+1}).$$

### ? Checkpoint 7.2.5

Rewrite $\displaystyle\int x^3\sqrt{x^2+4}\,dx$ by using a substitution involving $\tan\theta$.

**Answer**

$$\int 32\tan^3\theta\sec^3\theta\,d\theta$$

## Integrating Expressions Involving $\sqrt{x^2-a^2}$

The domain of the expression $\sqrt{x^2-a^2}$ is $(-\infty,-a]\cup[a,\infty)$. Thus, either $x\le -a$ or $x\ge a$. Hence, $\frac{x}{a}\le -1$ or $\frac{x}{a}\ge 1$. Since these intervals correspond to the range of $\sec\theta$ on the set $[0,\frac{\pi}{2})\cup[\pi,\frac{3\pi}{2})$, it makes sense to use the substitution $\sec\theta=\frac{x}{a}$ or, equivalently, $x=a\sec\theta$, where $0\le\theta<\frac{\pi}{2}$ or $\pi\le\theta<\frac{3\pi}{2}$. The corresponding substitution for $dx$ is $dx=a\sec\theta\tan\theta\,d\theta$. Again, we derive the process below.[6]

Since the range of $\sec\theta$ over $[0,\frac{\pi}{2})\cup[\pi,\frac{3\pi}{2})$ is $(-\infty,-1]\cup[1,\infty)$, there is a unique angle $\theta$ satisfying $0\le\theta<\frac{\pi}{2}$ or $\pi\le\theta<\frac{3\pi}{2}$ so that $\sec\theta=\frac{x}{a}$, or equivalently, so that $x=a\sec\theta$. If we substitute $x=a\sec\theta$ into $\sqrt{x^2-a^2}$, we get

$$\begin{aligned}
\sqrt{x^2-a^2} &= \sqrt{(a\sec\theta)^2-a^2} && \left(x=a\sec\theta \text{ where } 0\le\theta<\frac{\pi}{2} \text{ or } \pi\le\theta<\frac{3\pi}{2}\right)\\
&= \sqrt{a^2\sec^2\theta-a^2}\\
&= \sqrt{a^2(\sec^2\theta-1)} && (\text{factoring out } a^2)\\
&= \sqrt{a^2\tan^2\theta} && (\text{Pythagorean Identity})\\
&= |a\tan\theta| && \left(\sqrt{\blacksquare^2}=|\blacksquare|\right)
\end{aligned}$$

Since $\tan\theta\ge 0$ on $0\le\theta<\frac{\pi}{2}$ and $\pi\le\theta<\frac{3\pi}{2}$, and because $a>0$, $|a\tan\theta|=a\tan\theta$.

Once more, by making the substitution $x=a\sec\theta$, we can convert an integral involving a radical into an integral involving trigonometric functions, where we have the added benefit of not worrying about absolute values. To convert our solution back to an expression involving $x$, we draw a reference triangle for $\theta$ (see Figure 7.2.5 below).

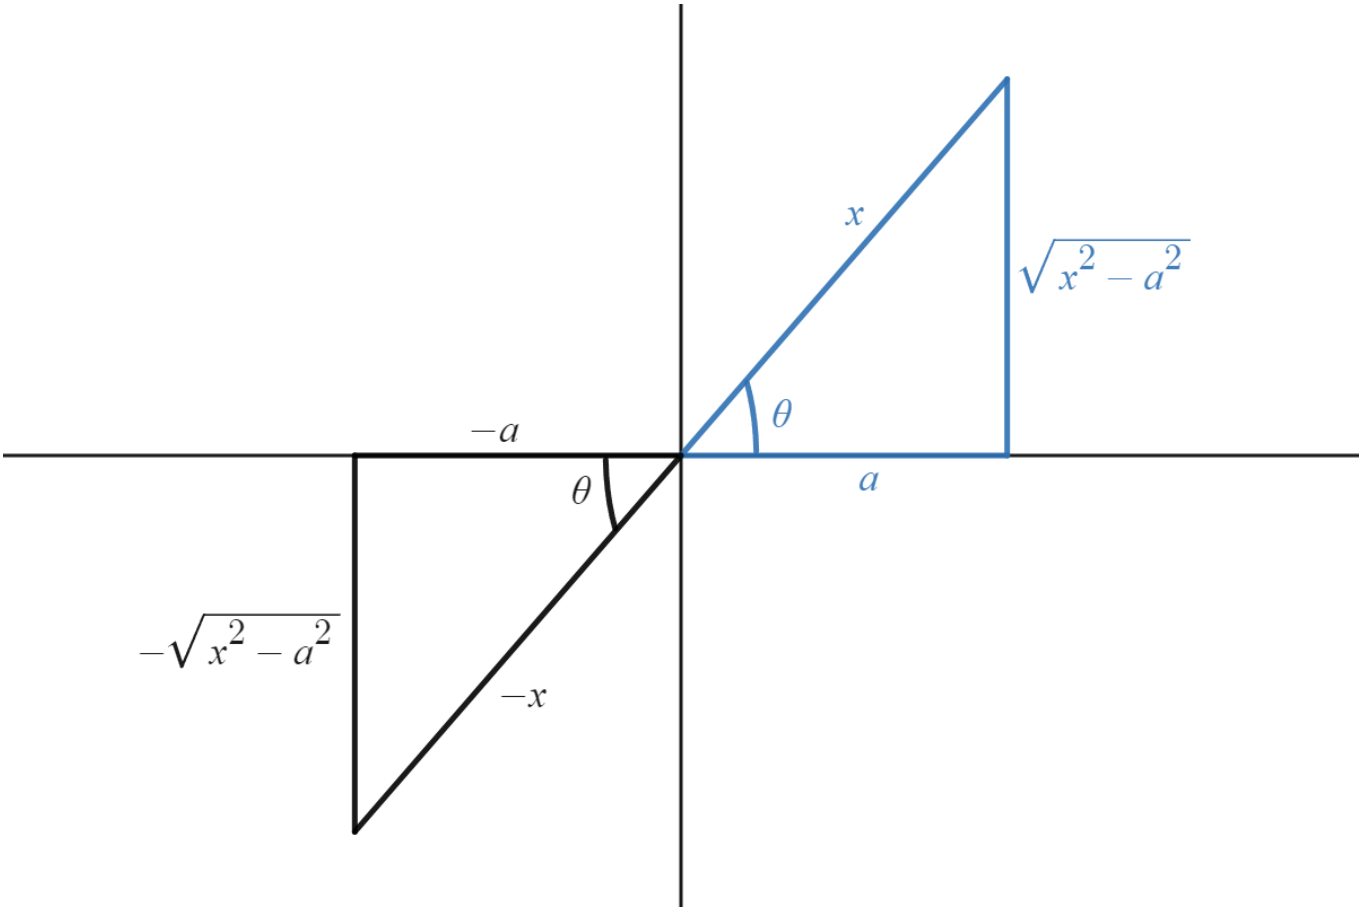

Figure 7.2.5: Use the appropriate reference triangle to express the trigonometric functions evaluated at $\theta$ in terms of $x$.

Since $\theta\in[0,\frac{\pi}{2})\cup[\pi,\frac{3\pi}{2})$, this reference triangle can only be drawn in quadrants I or III.[7] In either case,

$$\sin\theta = \frac{\sqrt{x^2-a^2}}{x}$$
$$\cos\theta = \frac{a}{x}$$
$$\tan\theta = \frac{\sqrt{x^2-a^2}}{a}.$$

Hence, no matter what trigonometric function is in the result of our evaluated integral, we can rewrite it as a function of $x$. Should $\theta$ appear by itself, we use $\theta = \sec^{-1}\left(\frac{x}{a}\right)$. The procedure for using this substitution is outlined in the following problem-solving strategy.

The procedure for using this substitution is outlined in the following problem-solving strategy.

### Problem-Solving Strategy: Integrals Involving $\sqrt{x^2-a^2}$

1. Check whether the integral cannot be evaluated using another method. If so, we may wish to consider applying an alternative technique.
2. Substitute $x = a\sec\theta$ and $dx = a\sec\theta\tan\theta\, d\theta$. This substitution yields
$$\sqrt{x^2-a^2} = \sqrt{(a\sec\theta)^2 - a^2} = \sqrt{a^2(\sec^2\theta - 1)} = \sqrt{a^2\tan^2\theta} = |a\tan\theta| = a\tan\theta.$$
3. Simplify the expression.
4. Evaluate the integral using techniques from the section on trigonometric integrals.
5. Use the reference triangles from Figure **7.2.5** to rewrite the result in terms of $x$.
6. You may also need to use some trigonometric identities and the relationship $\theta = \sec^{-1}\left(\frac{x}{a}\right)$.

### Example 7.2.7: Finding the Area of a Region

Find the area of the region between the graph of $f(x) = \frac{3\sqrt{x^2-25}}{x^4}$ and the x-axis over the interval $[5, 10]$.

**Solution**

First, we use graphing technology to obtain a graph of the region described in the problem, as shown in the following figure.

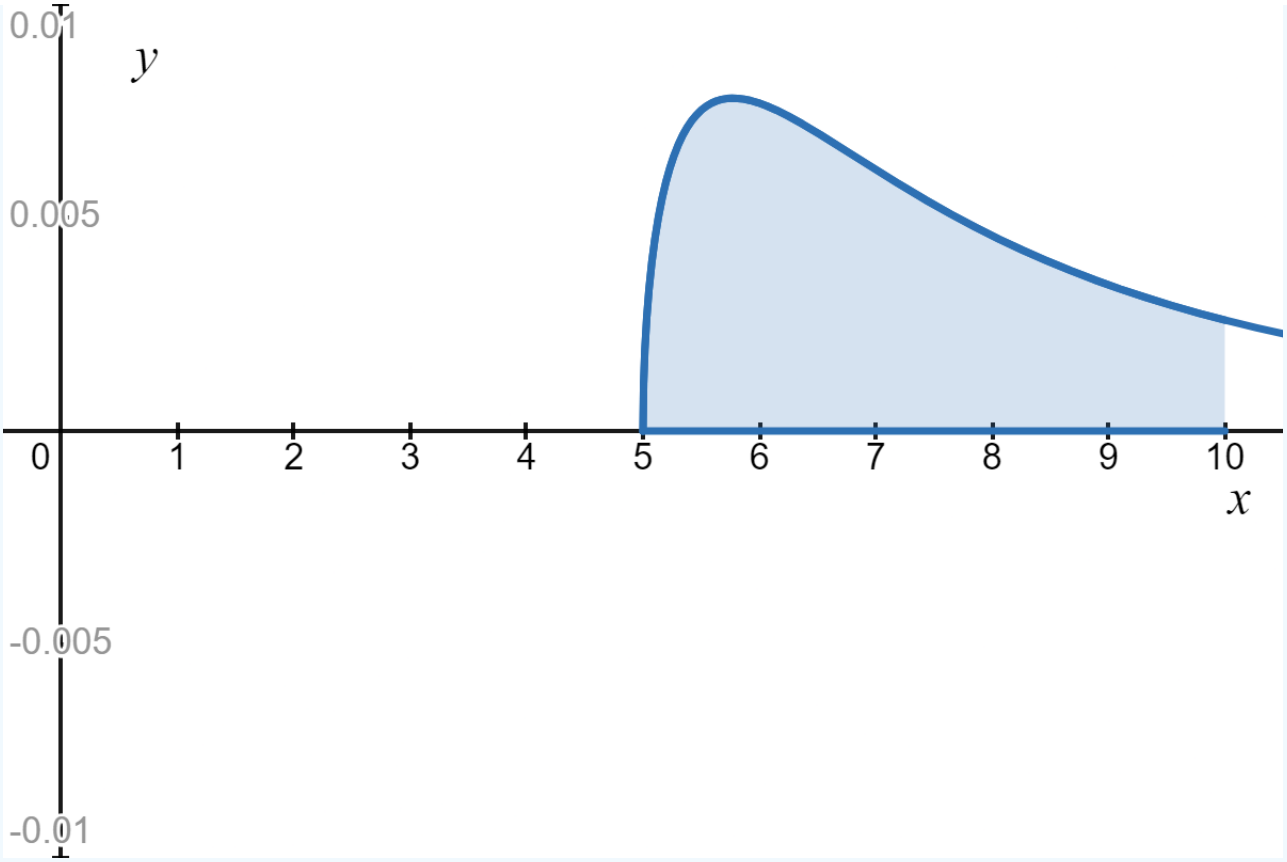

Figure 7.2.7

We can see that the area is $A = \int_5^{10} \frac{\sqrt{x^2-25}}{x^4}\,dx$.

☒ **Direct Integration**

☒ **Simple $u$-Substitution:** Letting $u = x^2 - 25$ results in $du = 2x\,dx$. I leave it to the reader to verify that this results in an uglier (and more difficult) integrand.

☒ **Radical Substitution**

☑ **Trigonometric Substitution:** We can substitute $x = 5\sec\theta$ so that $dx = 5\sec\theta\tan\theta\,d\theta$. We must also change the limits of integration. If $x = 5$, then $5 = 5\sec\theta$ and hence $\theta = 0$. If $x = 10$, then $10 = 5\sec\theta$ and so $\sec\theta = 2 \implies \theta = \frac{\pi}{3}$. After making these substitutions and simplifying, we have

$$
\begin{aligned}
\text{Area} &= \int_5^{10} \frac{\sqrt{x^2-25}}{x^4}\,dx \\
&= \int_0^{\pi/3} \frac{\sqrt{25\sec^2\theta-25}}{625\sec^4\theta}\cdot 5\sec\theta\tan\theta\,d\theta \\
&= \frac{5}{625}\int_0^{\pi/3} \frac{5\sqrt{\sec^2\theta-1}\cdot\tan\theta}{\sec^3\theta}\,d\theta \\
&= \frac{25}{625}\int_0^{\pi/3} \frac{\sqrt{\tan^2\theta}\cdot\tan\theta}{\sec^3\theta}\,d\theta && \text{(Pythagorean Identity)} \\
&= \frac{1}{25}\int_0^{\pi/3} \frac{\tan\theta\cdot\tan\theta}{\sec^3\theta}\,d\theta \\
&= \frac{1}{25}\int_0^{\pi/3} \frac{\tan^2\theta}{\sec^3\theta}\,d\theta \\
&= \frac{1}{25}\int_0^{\pi/3} \frac{\sin^2\theta/\cos^2\theta}{1/\cos^3\theta}\,d\theta && \text{(Ratio Identities)} \\
&= \frac{1}{25}\int_0^{\pi/3} \sin^2\theta\cos\theta\,d\theta \\
&= \frac{1}{25}\int_0^{\sqrt{3}/2} u^2\,du && (u=\sin\theta \implies du=\cos\theta\,d\theta) \\
&= \frac{1}{75}u^3\Big|_0^{\sqrt{3}/2} \\
&= \frac{3^{3/2}}{600} \\
&= \frac{3\cdot 3^{1/2}}{600} \\
&= \frac{3^{1/2}}{200}
\end{aligned}
$$

**? Checkpoint 7.2.7**

Evaluate

$$\int \frac{dx}{\sqrt{x^2-4}}.$$

Assume that $x > 2$.

**Answer**

$$\ln\left|\frac{x}{2}+\frac{\sqrt{x^2-4}}{2}\right|+C$$

## Rewriting Integrals to Use Trigonometric Substitution

There are many situations in which a given integral seems too challenging to be evaluated using known techniques. In these (and, in fact, in all) cases, you should remember the Mathematical Mantra:

> *Perform mathematics in the order you learned mathematics. That is, perform*
>
> *Arithmetic before Algebra,*
>
> *Algebra before Trigonometry,*
>
> *Trigonometry before Precalculus, and*
>
> *Precalculus before Differential Calculus.*

> *Always be willing to ask yourself, "Is there something I learned previously that can simplify my work here?"*

The following example illustrates how using the Mathematical Mantra can reduce a seemingly impossible problem into a more manageable one.

### Example 7.2.8: Completing the Square to Assist in Evaluating an Integral

Evaluate the integral.

$$\int \frac{x^2}{(3+4x-4x^2)^{3/2}}\,dx$$

**Solution**

☒ **Direct Integration:** Since the integrand is not the derivative of an established, well-known function, we cannot directly integrate.

☒ **Simple $u$-Substitution:**[8] If we let $u = 3+4x-4x^2$, then $du = (4-8x)\,dx$. At this point, we are experienced enough to recognize that this substitution will lead nowhere.

☒ **Radical Substitution:** Since a simple $u$-substitution will not work, a radical substitution is out of the question.

☒ **Trigonometric Substitution:** As written, this does not look to have a sum or difference of squares, so it doesn't *look* to be a candidate for a trigonometric substitution.

Now that we have exhausted all our integration techniques learned up to this point, we should realize that there must be some manipulation of the integrand using our previously learned mathematics to help us out. There are, in fact, *two* previously learned topics in Mathematics that can help here - both from Algebra; however, I will only mention completing the square as the other topic will lead to an integral we do not yet have a way to evaluate.

Back in Algebra, we learned how to complete the square for quadratic functions. This idea is beneficial with the given integral.

$$3+4x-4x^2 = -4(x^2-x)+3 = -4\left(x^2-x+\left(-\frac{1}{2}\right)^2\right)+3+4\left(-\frac{1}{2}\right)^2 = -4\left(x-\frac{1}{2}\right)^2+4 = 4-4\left(x-\frac{1}{2}\right)^2.$$

Therefore,

$$\int \frac{x^2}{(3+4x-4x^2)^{3/2}}\,dx = \int \frac{x^2}{\left(4-4\left(x-\frac{1}{2}\right)^2\right)^{3/2}}\,dx = \frac{1}{8}\int \frac{x^2}{\left(1-\left(x-\frac{1}{2}\right)^2\right)^{3/2}}\,dx.$$

The denominator of the integrand includes a difference of squares. This should encourage us to try a trigonometric substitution. The form is $a^2-x^2$, which reminds us of the trigonometric identity $1-\sin^2\theta = \cos^2\theta$. Hence, we want $\left(x-\frac{1}{2}\right)^2 = a^2\sin^2\theta = \sin^2\theta$, which gives $x-\frac{1}{2} = \sin\theta$. Moreover, this gives $dx = \cos\theta\,d\theta$. Finally, the numerator of the integrand has $x^2$, so it is necessary to determine $x$ as a function of $\theta$. Since $x-\frac{1}{2} = \sin\theta$, $x = \sin\theta+\frac{1}{2}$, and so $x^2 = \left(\sin\theta+\frac{1}{2}\right)^2$. Summarizing, we have

- $\left(x-\frac{1}{2}\right)^2 = \sin^2\theta$,
- $dx = \cos\theta\,d\theta$, and
- $x^2 = \left(\sin\theta+\frac{1}{2}\right)^2$.

Moreover, drawing a reference triangle at this point is a good idea. Figure 7.2.8 shows our reference triangle.

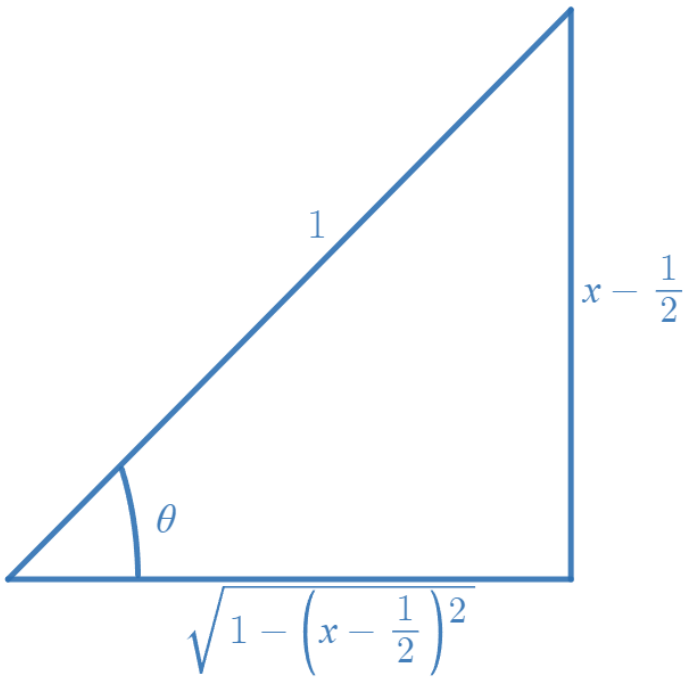

Figure **7.2.8**: The reference triangle.

Thus,

$$
\begin{aligned}
\int \frac{x^2}{(3+4x-4x^2)^{3/2}}\,dx &= \frac{1}{8}\int \frac{x^2}{\left(1-\left(x-\frac{1}{2}\right)^2\right)^{3/2}}\,dx \\
&= \frac{1}{8}\int \frac{\left(\sin\theta+\frac{1}{2}\right)^2}{(1-\sin^2\theta)^{3/2}}\cos\theta\,d\theta && \text{(completing the square)} \\
&= \frac{1}{8}\int \frac{\left(\sin\theta+\frac{1}{2}\right)^2}{(\cos^2\theta)^{3/2}}\cos\theta\,d\theta && \text{(Trigonometric substitutions)} \\
&= \frac{1}{8}\int \frac{\left(\sin\theta+\frac{1}{2}\right)^2}{\cos^3\theta}\cos\theta\,d\theta && \text{(Pythagorean Identity)} \\
&= \frac{1}{8}\int \frac{\left(\sin\theta+\frac{1}{2}\right)^2}{\cos^2\theta}\,d\theta \\
&= \frac{1}{8}\int \frac{\sin^2\theta+\sin\theta+\frac{1}{4}}{\cos^2\theta}\,d\theta \\
&= \frac{1}{8}\int \tan^2\theta+\sec\theta\tan\theta+\frac{1}{4}\sec^2\theta\,d\theta \\
&= \frac{1}{8}\int \sec^2\theta-1+\sec\theta\tan\theta+\frac{1}{4}\sec^2\theta\,d\theta && \text{(Pythagorean Identity)} \\
&= \frac{1}{8}\int -1+\sec\theta\tan\theta+\frac{5}{4}\sec^2\theta\,d\theta \\
&= -\frac{1}{8}\theta+\frac{1}{8}\sec\theta+\frac{5}{32}\tan\theta+C \\
&= -\frac{1}{8}\sin^{-1}\left(x-\frac{1}{2}\right)+\frac{1}{8\sqrt{1-\left(x-\frac{1}{2}\right)^2}}+\frac{5\left(x-\frac{1}{2}\right)}{32\sqrt{1-\left(x-\frac{1}{2}\right)^2}}+C && \text{(using the reference triangle)} \\
&= -\frac{1}{8}\sin^{-1}\left(x-\frac{1}{2}\right)+\frac{4+5\left(x-\frac{1}{2}\right)}{32\sqrt{1-\left(x-\frac{1}{2}\right)^2}}+C \\
&= -\frac{1}{8}\sin^{-1}\left(x-\frac{1}{2}\right)+\frac{5x+\frac{3}{2}}{32\sqrt{1-\left(x-\frac{1}{2}\right)^2}}+C \\
&= -\frac{1}{8}\sin^{-1}\left(x-\frac{1}{2}\right)+\frac{10x+3}{32\sqrt{4-4\left(x-\frac{1}{2}\right)^2}}+C \\
&= -\frac{1}{8}\sin^{-1}\left(x-\frac{1}{2}\right)+\frac{10x+3}{32\sqrt{3+4x-4x^2}}+C
\end{aligned}
$$

## Footnotes

[1] We will justify this assumption momentarily.

[2] After integrating the trigonometric integral as a function of $\theta$, you sometimes have a term of the form $k\theta$. If your original substitution was $x = a\sin\theta$, then it is a fact that $\theta = \arcsin\left(\frac{x}{a}\right)$. It is permissible to leave your final answer in this form *if and only if* $\frac{x}{a}$ is not a special trigonometric ratio. That is if evaluating a definite integral where you end up with $\arcsin\left(-\frac{1}{2}\right)$, you *must* use your prerequisite Trigonometry to simplify this to $-\frac{\pi}{6}$.

[3] The idea of constantly checking to see if something from the past will work first (i.e., a simple $u$-substitution) should not be new to you - especially if you took Differential Calculus using this text (well, the Calculus I version, at least). In that text, I continually referenced the Mathematical Mantra. The Mathematical Mantra boils down to doing mathematics in the order you learned mathematics - Arithmetic before Algebra, Algebra before Trigonometry, Trigonometry before Precalculus, Precalculus before Differential Calculus, and, in this case, Differential Calculus before Integral Calculus. In Differential Calculus, you learned about the Substitution Method. If you can evaluate an integral using the Substitution Method, then there is no need to get any fancier than that - don't jump to Trigonometric Substitutions or any other, more obscure technique if a good 'ol $u$-substitution does the job.

[4] As was stated previously, if given a definite integral, then you are expected to be able to evaluate the arctangent at special ratios.

[5] The reference triangle is based on the assumption that $x > 0$; however, the trigonometric ratios produced from the reference triangle are the same as the ratios for which $x \leq 0$.

[6] Of the three processes we have developed, it is important to pay close attention to this one in particular. The reason behind the choice of restriction for the range from Section 1.6 in the Differential Calculus textbook of the arcsecant should become apparent.

[7] Again, this is the distinct difference between the previous two derivations and this one. It is *very* important to note that we *could* have used the non-elegant range restriction of $\theta \in [0, \frac{\pi}{2}) \cup (\frac{\pi}{2}, \pi]$ for the arcsecant; however, doing so would result in a more complex derivation of this trigonometric substitution due to the sign of the tangent in quadrant II being negative - this would *not* allow for $|a \tan \theta| = a \tan \theta$.

[8] We have learned enough integration techniques at this point to realize that the Substitution Method is an "umbrella method" encapsulating at least two different "types" of substitution. The first was a simple $u$-substitution from our Differential Calculus course. We were introduced to the second in this section, trigonometric substitutions.

# 7.2E: Exercises

## Reading Questions

1. What are the three forms of radical expressions that indicate that a trigonometric substitution might be useful?
2. For an integral involving the expression $\sqrt{a^2-x^2}$, what is the standard trigonometric substitution for $x$, and what does the radical simplify to after this substitution?
3. For an integral involving the expression $\sqrt{a^2+x^2}$, what is the standard trigonometric substitution for $x$?
4. What is the purpose of drawing a reference triangle as part of the trigonometric substitution process?
5. What algebraic technique must be applied to an expression like $\sqrt{3+4x-4x^2}$ before a trigonometric substitution can be performed?
6. After making the substitution and evaluating the new integral in terms of $\theta$, what must be done to complete the problem?

**Simplify the expressions in exercises 1 - 5 by writing each one using a single trigonometric function.**

1) $4-4\sin^2\theta$

2) $9\sec^2\theta-9$

**Answer**

$9\sec^2\theta-9 \quad = \quad 9\tan^2\theta$

3) $a^2+a^2\tan^2\theta$

4) $a^2+a^2\sinh^2\theta$

**Answer**

$a^2+a^2\sinh^2\theta \quad = \quad a^2\cosh^2\theta$

5) $16\cosh^2\theta-16$

**Use the technique of completing the square to express each trinomial in exercises 6 - 8 as the square of a binomial.**

6) $4x^2-4x+1$

**Answer**

$4(x-\frac{1}{2})^2$

7) $2x^2-8x+3$

8) $-x^2-2x+4$

**Answer**

$-(x+1)^2+5$

**In exercises 9 - 26, integrate using the method of trigonometric substitution. Express the final answer in terms of the original variable.**

9) $\int \frac{dx}{\sqrt{4-x^2}}$

10) $\int \frac{dx}{\sqrt{x^2-a^2}}$

**Answer**

$\int \frac{dx}{\sqrt{x^2-a^2}} \quad = \quad \ln|x+\sqrt{-a^2+x^2}|+C$

11) $\int \sqrt{4-x^2}\,dx$

12) $\int \frac{dx}{\sqrt{1+9x^2}}$

**Answer**

$$\int \frac{dx}{\sqrt{1+9x^2}} = \frac{1}{3}\ln\left|\sqrt{9x^2+1}+3x\right|+C$$

13) $\int \frac{x^2\,dx}{\sqrt{1-x^2}}$

14) $\int \frac{dx}{x^2\sqrt{1-x^2}}$

**Answer**

$$\int \frac{dx}{x^2\sqrt{1-x^2}} = -\frac{\sqrt{1-x^2}}{x}+C$$

15) $\int \frac{dx}{(1+x^2)^2}$

16) $\int \frac{\sqrt{x^2-25}}{x}\,dx$

17) $\int \frac{\theta^3}{\sqrt{9-\theta^2}}\,d\theta$

**Answer**

$$\int \frac{\theta^3 d\theta}{\sqrt{9-\theta^2}}\,d\theta = -\frac{1}{3}\sqrt{9-\theta^2}(18+\theta^2)+C$$

18) $\int \frac{dx}{\sqrt{x^6-x^2}}$

19) $\int \sqrt{x^6-x^8}\,dx$

**Answer**

$$\int \sqrt{x^6-x^8}\,dx = \frac{(-1+x^2)(2+3x^2)\sqrt{x^6-x^8}}{15x^3}+C$$

20) $\int \frac{dx}{(1+x^2)^{3/2}}$

21) $\int \frac{dx}{(x^2-9)^{3/2}}$

**Answer**

$$\int \frac{dx}{(x^2-9)^{3/2}} = -\frac{x}{9\sqrt{x^2-9}}+C$$

22) $\int \frac{\sqrt{1+x^2}}{x}\,dx$

23) $\int \frac{x^2}{\sqrt{x^2-1}}\,dx$

**Answer**

$$\int \frac{x^2}{\sqrt{x^2-1}}\,dx = \frac{1}{2}\left(\ln\left|x+\sqrt{x^2-1}\right|+x\sqrt{x^2-1}\right)+C$$

24) $\int \frac{x^2}{x^2+4}\,dx$

25) $\int \frac{dx}{x^2\sqrt{x^2+1}}$

**Answer**

$$\int \frac{dx}{x^2\sqrt{x^2+1}} = -\frac{\sqrt{1+x^2}}{x} + C$$

26) $\int_{-1}^{1} (1-x^2)^{3/2}\,dx$

**Answer**

$$\int_{-1}^{1} (1-x^2)^{3/2}\,dx = \tfrac{1}{8}\left(x(5-2x^2)\sqrt{1-x^2} + 3\arcsin x\right) + C$$

**In exercises 27 - 32, use the substitutions $x = \sinh\theta$, $\cosh\theta$, or $\tanh\theta$. Express the final answers in terms of the variable $x$.**

27) $\int \frac{dx}{\sqrt{x^2-1}}$

28) $\int \frac{dx}{x\sqrt{1-x^2}}$

**Answer**

$$\int \frac{dx}{x\sqrt{1-x^2}} = \ln x - \ln|\,1+\sqrt{1-x^2}\,| + C$$

29) $\int \sqrt{x^2-1}\,dx$

30) $\int \frac{\sqrt{x^2-1}}{x^2}\,dx$

**Answer**

$$\int \frac{\sqrt{x^2-1}}{x^2}\,dx = -\frac{\sqrt{-1+x^2}}{x} + \ln\left|x+\sqrt{-1+x^2}\right| + C$$

31) $\int \frac{dx}{1-x^2}$

32) $\int \frac{\sqrt{1+x^2}}{x^2}\,dx$

**Answer**

$$\int \frac{\sqrt{1+x^2}}{x^2}\,dx = -\frac{\sqrt{1+x^2}}{x} + \operatorname{arcsinh} x + C$$

**Use the technique of completing the square to evaluate the integrals in exercises 33 - 37.**

33) $\int \frac{1}{x^2-6x}\,dx$

34) $\int \frac{1}{x^2+2x+1}\,dx$

**Answer**

$$\int \frac{1}{x^2+2x+1}\,dx = -\frac{1}{1+x} + C$$

35) $\int \frac{1}{\sqrt{-x^2+2x+8}}\,dx$

36) $\int \frac{1}{\sqrt{-x^2+10x}}\,dx$

**Answer**

$$\int \frac{1}{\sqrt{-x^2+10x}}\,dx = \arcsin\left(\frac{x-5}{5}\right) + C$$

37) $\int \frac{1}{\sqrt{x^2+4x-12}}\,dx$

38) Evaluate the integral without using calculus: $\int_{-3}^{3} \sqrt{9-x^2}\,dx$.

**Answer**

$\int_{-3}^{3} \sqrt{9-x^2}\,dx = \frac{9\pi}{2}$; area of a semicircle with radius 3

39) Find the area enclosed by the ellipse $\frac{x^2}{4}+\frac{y^2}{9}=1$.

40) Evaluate the integral $\int \frac{dx}{\sqrt{1-x^2}}$ using two different substitutions. First, let $x=\cos\theta$ and evaluate using trigonometric substitution. Second, let $x=\sin\theta$ and use trigonometric substitution. Are the answers the same?

**Answer**

$\int \frac{dx}{\sqrt{1-x^2}} = \arcsin(x)+C$ is the common answer.

41) Evaluate the integral $\int \frac{dx}{x\sqrt{x^2-1}}$ using the substitution $x=\sec\theta$. Next, evaluate the same integral using the substitution $x=\csc\theta$. Show that the results are equivalent.

42) Evaluate the integral $\int \frac{x}{x^2+1}\,dx$ using the form $\int \frac{1}{u}\,du$. Next, evaluate the same integral using $x=\tan\theta$. Are the results the same?

**Answer**

$\int \frac{x}{x^2+1}\,dx = \frac{1}{2}\ln(1+x^2)+C$ is the result using either method.

43) State the method of integration you would use to evaluate the integral $\int x\sqrt{x^2+1}\,dx$. Why did you choose this method?

44) State the method of integration you would use to evaluate the integral $\int x^2\sqrt{x^2-1}\,dx$. Why did you choose this method?

**Answer**

Use trigonometric substitution. Let $x=\sec(\theta)$.

45) Evaluate $\int_{-1}^{1} \frac{x}{x^2+1}\,dx$

46) Find the length of the arc of the curve over the specified interval: $y=\ln x, \quad [1,5]$. Round the answer to three decimal places.

**Answer**

$s=4.367$ units

47) Find the surface area of the solid generated by revolving the region bounded by the graphs of $y=x^2$, $y=0$, $x=0$, and $x=\sqrt{2}$ about the $x$-axis. (Round the answer to three decimal places).

48) The region bounded by the graph of $f(x)=\frac{1}{1+x^2}$ and the $x$-axis between $x=0$ and $x=1$ is revolved about the $x$-axis. Find the volume of the solid that is generated.

**Answer**

$V=\left(\frac{\pi^2}{8}+\frac{\pi}{4}\right)$ units$^3$

**In exercises 49 - 50, solve the initial-value problem for $y$ as a function of $x$.**

49) $(x^2+36)\frac{dy}{dx}=1, \quad y(6)=0$

50) $(64-x^2)\frac{dy}{dx}=1, \quad y(0)=3$

**Answer**

$$y = \frac{1}{16}\ln\left|\frac{x+8}{x-8}\right| + 3$$

51) Find the area bounded by $y = \dfrac{2}{\sqrt{64-4x^2}}$, $x = 0$, $y = 0$, and $x = 2$.

52) An oil storage tank can be described as the volume generated by revolving the area bounded by $y = \dfrac{16}{\sqrt{64+x^2}}$, $x = 0$, $y = 0$, $x = 2$ about the $x$-axis. Find the volume of the tank (in cubic meters).

**Answer**

$V = 24.6$ m$^3$

53) During each cycle, the velocity $v$ (in feet per second) of a robotic welding device is given by $v = 2t - \dfrac{14}{4+t^2}$, where $t$ is time in seconds. Find the expression for the displacement $s$ (in feet) as a function of $t$ if $s = 0$ when $t = 0$.

54) Find the length of the curve $y = \sqrt{16-x^2}$ between $x = 0$ and $x = 2$.

**Answer**

$s = \frac{2\pi}{3}$ units

# 7.3: Integration by Parts

**Note to the Instructor (click to expand)**

This is the standard Integration by Parts section with the inclusion of the integral of $\sec^3(\theta)$ and power reduction formulas. It's fun and no-frills.

---

The following is a list of learning objectives for this section.

**Learning Objectives (click to expand)**

- Recognize when to use Integration by Parts.
- Use the Integration by Parts formula to solve integration problems.
- Use the Integration by Parts formula for definite integrals.

Hawk A.I. Section-Specific Tutor

To access the Hawk A.I. Tutor, you will need to be logged into your campus Gmail account.

By now, we have a fairly thorough procedure for evaluating many basic integrals. However, although we can integrate $\int x\sin(x^2)\,dx$ by using the substitution, $u = x^2$, something as simple looking as $\int x\sin x\;dx$ defies us. Many students want to know whether there is a Product Rule for integration. There is not, but a technique based on the Product Rule for differentiation allows us to exchange one integral for another. We call this technique Integration by Parts.

## The Integration by Parts Formula

If, $h(x) = f(x)g(x)$, then by using the Product Rule, we obtain

$$h'(x) = f'(x)g(x) + g'(x)f(x). \tag{7.3.1}$$

Although at first it may seem counterproductive, let's now integrate both sides of Equation 7.3.1:

$$\int h'(x)\;dx = \int (g(x)f'(x) + f(x)g'(x))\;dx.$$

This gives us

$$h(x) = f(x)g(x) = \int g(x)f'(x)\,dx + \int f(x)g'(x)\;dx.$$

Now we solve for $\int f(x)g'(x)\;dx$:

$$\int f(x)g'(x)\,dx = f(x)g(x) - \int g(x)f'(x)\;dx.$$

By making the substitutions $u = f(x)$ and $v = g(x)$, which in turn make $du = f'(x)\,dx$ and $dv = g'(x)\,dx$, we have the more compact form

$$\int u\,dv = uv - \int v\,du.$$

**Theorem: Integration by Parts**

Let $u = f(x)$ and $v = g(x)$ be functions with continuous derivatives. Then, the **Integration by Parts** formula (also known as IbP) for the integral involving these two functions is:

$$\int u\,dv = uv - \int v\,du. \tag{7.3.2}$$

The advantage of using the Integration by Parts formula is that we can exchange one integral for another, possibly more accessible integral. The following example illustrates its use.

## Example 7.3.1: Using Integration by Parts

Use Integration by Parts with $u = x$ and $dv = \sin x\ dx$ to evaluate

$$\int x \sin x\ dx.$$

**Solution**

By choosing $u = x$, we have $du = 1\ dx$. Since $dv = \sin x\ dx$, we get

$$v = \int \sin x\ dx = -\cos x.$$

It is handy to keep track of these values in a table, as follows:

| $u = x$ | $dv = \sin x\, dx$ |
|---|---|
| $du = 1\, dx$ | $v = \int \sin x\, dx = -\cos x$ |

Applying the Integration by Parts formula (Equation 7.3.2) results in

$$\begin{aligned} \int x \sin x\ dx &= (x)(-\cos x) - \int (-\cos x)(1\ dx) && \text{(substitution)} \\ &= -x\cos x + \int \cos x\ dx && \text{(simplifying)} \end{aligned}$$

Then use

$$\int \cos x\ dx = \sin x + C$$

to obtain

$$\int x \sin x\ dx = -x\cos x + \sin x + C.$$

**Analysis**

At this point, a few items need clarification. First, what would have happened if we had chosen $u = \sin x$ and $dv = x,\ dx$? If we had done so, then we would have $du = \cos x\, dx$ and $v = \frac{1}{2}x^2$. Thus, after applying Integration by Parts (Equation 7.3.2), we have

$$\int x \sin x\ dx = \frac{1}{2}x^2 \sin x - \int \frac{1}{2}x^2 \cos x\ dx.$$

Unfortunately, we are in no better position than before with the new integral. It is important to remember that when we apply Integration by Parts, we may need to try several choices for $u$ and $dv$ before finding a choice that works.

Second, you may wonder why, when we find $v = \int \sin x\ dx = -\cos x$, we do not use $v = -\cos x + K$. To see that it makes no difference, we can rework the problem using $v = -\cos x + K$:

$$\begin{aligned} \int x \sin x\ dx &= (x)(-\cos x + K) - \int (-\cos x + K)(1\ dx) \\ &= -x\cos x + Kx + \int \cos x\ dx - \int K\ dx \\ &= -x\cos x + Kx + \sin x - Kx + C \\ &= -x\cos x + \sin x + C. \end{aligned}$$

As you can see, it makes no difference in the final solution.

Last, we can check to make sure that our antiderivative is correct by differentiating $-x\cos x+\sin x+C$:

$$\begin{aligned}\frac{d}{dx}(-x\cos x+\sin x+C) &= \cancel{(-1)\cos x}+(-x)(-\sin x)+\cancel{\cos x}\\ &= x\sin x\end{aligned}$$

Therefore, the antiderivative checks out.

**? Checkpoint 7.3.1**

Evaluate $\int xe^{2x}\,dx$ using the Integration by Parts formula (Equation 7.3.2) with $u=x$ and $dv=e^{2x}\,dx$.

**Answer**

$$\int xe^{2x}\,dx=\frac{1}{2}xe^{2x}-\frac{1}{4}e^{2x}+C$$

## Choosing $u$ and $dv$

The natural question to ask at this point is: How do we know what to choose for $u$ and $dv$?

Most authors will immediately give you a trick to picking the "right" choice for $u$; however, the trick they give is not flawless. It often fails. Therefore, it is best to develop an approach to Integration by Parts from the other direction - by asking, "What is a good choice for $dv$?

Our choice for $dv$ will immediately inform us as to what $u$ needs to be. Since we are going to have to integrate $dv$, you want to choose it to be something you actually *can* integrate. This is so important that it bears repeating:

> ***Integration by Parts boils down to selecting a factor, preferably the most complex, of the integrand that you can integrate either by direct integration or by the Substitution Method.***

That's it! The rest of this subsection discusses *why* we make certain choices for $dv$ and $u$. Still, in the end, it's all about asking yourself, "What's the most complex factor of this integrand I can integrate?"

Now, think of all of the "traditional" functions you have encountered up to this point in mathematics, and ask yourself which ones you can easily integrate.

| Basic Function Type | Easily Integrable? |
|---|---|
| Algebraic (e.g., $x^3$, $\sqrt{x}$, and $\frac{1}{x}$) | Yes |
| Exponential (e.g., $e^x$ and $2^x$) | Yes |
| Logarithmic (e.g., $\ln(x)$ and $\log_3(x)$) | No |
| Trigonometric (e.g., $\sin(x)$ and $\sec^2(x)$, but not $\sec(x)$) | Yes (in some cases) |
| Inverse Trigonometric (e.g., $\tan^{-1}(x)$ and $\csc^{-1}(x)$) | No |

Since we do not have integration formulas that allow us to integrate simple **L**ogarithmic functions and **I**nverse trigonometric functions,[1] it makes sense that they should not be chosen for $dv$. On the other hand, **E**xponential and **T**rigonometric functions are, in general, easy to integrate and make good choices for $dv$. Finally, we can always integrate basic **A**lgebraic functions. However,

their antiderivatives require slightly more work than the straightforward antiderivatives of the exponential and trigonometric functions. Therefore, if given the option, we would rather integrate exponential or trigonometric functions than algebraic functions.

Given that discussion, we have the following tactic.

**Tactic for Choosing $dv$**

Given an integral where you wish to use Integration by Parts, the order of preference for choosing $dv$ is as follows:

1. **E**xponential functions
2. **T**rigonometric functions
3. **A**lgebraic functions
4. **I**nverse trigonometric functions
5. **L**ogarithmic functions

As was mentioned previously, most authors approach this conversation by stating what your choice of $u$ should be rather than $dv$. To accommodate students with instructors who take this same approach, we could reverse the direction of our tactic for choosing $dv$ and, instead, create the commonly-taught tactic for choosing $u$. If logarithms are the worst choice for $dv$, then they will be our first choice for $u$, and so on. This gives us the following tactic for choosing $u$.

**Tactic for Choosing $u$**

Given an integral where you wish to use Integration by Parts, the order of preference for choosing $u$ is as follows:

1. **L**ogarithmic functions
2. **I**nverse trigonometric functions
3. **A**lgebraic functions
4. **T**rigonometric functions
5. **E**xponential functions

This last tactic gives a common mnemonic, **LIATE**, to take some of the guesswork out of our choices for $u$. The type of function in the integral that appears first in the list should be our first choice of $u$.[2] When we have chosen $u$, $dv$ is selected to be the remaining part of the integrand.

**Caution: My Approach**

I stick with finding $dv$ first instead of finding $u$ so that you get a more natural and understandable approach to Integration by Parts. All of the examples will reflect this.

Thus, if an integral contains the product of a logarithmic function and an algebraic function, we would choose $dv$ to be the algebraic function (because we don't know how to integrate a logarithm as of yet). Therefore, we would choose $u$ to be the logarithmic function. Following the typical textbook tactic, our choice for $u$ is correct because L comes before A in LIATE.

The integral in Example **7.3.1** has a trigonometric function, $\sin x$, and an algebraic function, $x$. Both of these are easily integrable, but we would rather integrate $\sin x$ over $x$ because antiderivatives of trigonometric functions are simple (as opposed to algebraic functions, which require raising powers and dividing by new powers). Thus, we would choose $dv = \sin x\,dx$ and $u = x$. Again, this coincides with our decision to use the common textbook tactic because A comes before T in LIATE.

There is a second, more important reason as to why we are selecting to differentiate the algebraic function and integrate the trigonometric function in Example **7.3.1**. When we tried to go the opposite direction (choosing to integrate the algebraic function and differentiate the trigonometric function), we arrived at an integral that got *worse* as we ended with an algebraic function of *higher* power and we *still* had a trigonometric function. A hidden goal when dealing with products of polynomials and other functions is to remove the polynomial. This can only be done if we take derivatives of the polynomial. While this might seem confusing right now, things will get more apparent as you use Integration by Parts.

Finally, here is the rule of thumb I tell my students:

**Rule of Thumb: Choosing $dv$ and $u$**

When using Integration by Parts:

- Choose $dv$ to be the *largest* factor of the integrand that you can integrate, either directly or by using the Substitution Method - $u$ will be the rest of the integrand. You will often need to rewrite the integrand to see this largest factor and, remember, $\int f(x)\,dx = \int f(x)\cdot 1\,dx$. This is especially useful if you cannot integrate any *obvious* factor within the integrand.
- If you can integrate *all* factors within the integrand, then switch gears and instead choose $u$ to be the factor whose derivative (or eventual, higher-order derivative) changes forms or becomes a constant.
- If you have to use Integration by Parts more than once while evaluating an integral, be sure to stay with the same "function type" choice for all Integrations by Parts.

The best way to understand this Rule of Thumb is through examples.

**Example 7.3.2: Using Integration by Parts**

Evaluate

$$\int \frac{\ln x}{x^3}\,dx.$$

**Solution**

☒ **Direct Integration:** Since the integrand is not the derivative of an established, well-known function, we cannot directly integrate.

☒ **Simple $u$-Substitution:** I leave it for the reader to try as they might to find a proper $u$-substitution - none will work.

☒ **Radical Substitution:** Since a simple $u$-substitution will not work, a radical substitution is out of the question.

☒ **Trigonometric Substitution:** As written, there isn't any obvious trigonometric substitution.

? **By Parts:** Since the integrand is the product of two different function types, it is a good candidate for Integration by Parts.[3]

It is helpful, at times, to begin by rewriting the integral:

$$\int \frac{\ln x}{x^3}\,dx = \int x^{-3}\ln x\,dx.$$

Consider the factors of the integrand - $x^{-3}$ and $\ln(x)$. Which one can we easily integrate? The obvious answer here is $x^{-3}$. Hence, we choose $dv = x^{-3}\,dx$ (don't forget the $dx$) and we let $u$ be the rest of the integrand. That is, $u = \ln(x)$.

**For the LIATE Folks**

We choose $u = \ln x$ and $dv = x^{-3}\,dx$, since L comes before A in LIATE.

Next, since $u = \ln x$, we have $du = \frac{1}{x}\,dx$. Also, $v = \int x^{-3}\,dx = -\frac{1}{2}x^{-2}$. Summarizing,

| | |
|---|---|
| $u = \ln(x)$ | $dv = x^{-3}\,dx$ |
| $du = \dfrac{1}{x}\,dx$ | $v = -\dfrac{1}{2}x^{-2}$ |

Substituting into the Integration by Parts formula (Equation 7.3.2) gives

$$\begin{aligned}\int \frac{\ln x}{x^3}\,dx &= \int x^{-3}\ln x\,dx \\ &= (\ln x)\left(-\frac{1}{2}x^{-2}\right) - \int \left(-\frac{1}{2}x^{-2}\right)\left(\frac{1}{x}\,dx\right) \\ &= -\frac{1}{2}x^{-2}\ln x + \int \frac{1}{2}x^{-3}\,dx \\ &= -\frac{1}{2}x^{-2}\ln x - \frac{1}{4}x^{-2} + C \\ &= -\frac{1}{2x^2}\ln x - \frac{1}{4x^2} + C\end{aligned}$$

**? Checkpoint 7.3.2**

Evaluate

$$\int x\ln x\,dx.$$

**Answer**

$$\int x\ln x\;dx = \frac{1}{2}x^2\ln x - \frac{1}{4}x^2 + C$$

## More Complex Uses of Integration by Parts

In some cases, as in the next two examples, it may be necessary to apply Integration by Parts more than once.

**✓ Example 7.3.3: Applying Integration by Parts More Than Once**

Evaluate

$$\int x^2 e^{3x}\,dx.$$

**Solution**

☒ **Direct Integration:** Since the integrand is not the derivative of an established, well-known function, we cannot directly integrate.

☒ **Simple $u$-Substitution:** I leave it for the reader to try as they might to find a proper $u$-substitution - none will work.

☒ **Radical Substitution:** Since a simple $u$-substitution will not work, a radical substitution is out of the question.

☒ **Trigonometric Substitution:** As written, there isn't any obvious trigonometric substitution.

? **By Parts:** Since the integrand is the product of two different function types, it is a good candidate for Integration by Parts.

Since we can easily integrate both $x^2$ and $e^{3x}$, we switch gears and ask ourselves which one has a derivative (or eventual, higher-order derivative) that will change forms. Thus, we choose $u = x^2$ because a couple of derivatives will result in the function completely devolving into a constant function. Therefore, $dv = e^{3x}\,dx$.

| $u = x^2$ | $dv = e^{3x}\,dx$ |
|---|---|
| $du = 2x\,dx$ | $v = \frac{1}{3}e^{3x}$ |

**For the LIATE Folks**

Choose $u = x^2$ and $dv = e^{3x}\,dx$ because A comes before E in LIATE.

Substituting into Equation 7.3.2 produces

$$\int x^2 e^{3x}\,dx = \frac{1}{3}x^2e^{3x} - \int \frac{2}{3}xe^{3x}\,dx = \frac{1}{3}x^2e^{3x} - \frac{2}{3}\int xe^{3x}\,dx. \tag{7.3.3}$$

We still cannot integrate $\int xe^{3x}\,dx$ directly, but the integral now has a lower power on $x$. We can evaluate this new integral by using Integration by Parts again. Since we have already started the Integration by Parts process on this integral, we stick with the same "function type" choices for $u$ and $dv$. We chose $u$ to be the algebraic function on our first Integration by Parts, so our choice of $u$ on this new Integration by Parts must also be an algebraic function.

**For the LIATE Folks**

Choose $u = x$ and $dv = e^{3x}\,dx$ because A comes before E in LIATE.

| | |
|---|---|
| $u = x$ | $dv = e^{3x}\,dx$ |
| $du = dx$ | $v = \frac{1}{3}e^{3x}$ |

Substituting back into Equation 7.3.3 yields

$$\int x^2 e^{3x}\,dx = \frac{1}{3}x^2e^{3x} - \frac{2}{3}\left(\frac{1}{3}xe^{3x} - \int \frac{1}{3}e^{3x}\,dx\right).$$

After evaluating the last integral and simplifying, we obtain

$$\int x^2 e^{3x}\,dx = \frac{1}{3}x^2e^{3x} - \frac{2}{9}xe^{3x} + \frac{2}{27}e^{3x} + C.$$

Example **7.3.3** showcases a vital difference between LIATE and having a more natural understanding of Integration by Parts using the Rule of Thumb. When using LIATE, we chose $u = x^2$ by rote memorization without understanding the consequences of the choice. The Rule of Thumb, on the other hand, delivered an extra bit of "hidden" knowledge - since we chose $u = x^2$ because it changes form after two derivatives, we could have immediately recognized that this integral would require *two* integrations (in this case, two applications of Integration by Parts).

**Example 7.3.4: Applying Integration by Parts When LIATE Does not Quite Work**

Evaluate

$$\int t^3 e^{t^2}\,dt.$$

**Solution**

☒ **Direct Integration:** Since the integrand is not the derivative of an established, well-known function, we cannot directly integrate.

? **Simple $u$-Substitution:** Letting $u = t^2$ *might* work.

☒ **Radical Substitution:** There is not a radical in the integrand.

☒ **Trigonometric Substitution:** As written, there isn't any obvious trigonometric substitution.

? **By Parts:** Since the integrand is the product of two different function types, it is a good candidate for Integration by Parts.

This is an excellent example of having many approaches to a problem that are all correct - welcome to the wonderful world of real integration!

**Approach #1 (Ineffective): Using LIATE**

For the LIATE-lovers out there, this one's for you. If we use a strict interpretation of the mnemonic LIATE to make our choice of $u$, we end up with $u = t^3$ and $dv = e^{t^2}\,dt$.

| $u = t^3$ | $dv = e^{t^2}\,dt$ |
|---|---|
| $du = 3t^2\,dt$ | $v = \ldots$ (we're stuck) |

Unfortunately, we cannot continue with this approach because we cannot integrate $e^{t^2}$.

**Approach #2: Starting with a Substitution**

Using the Substitution Method, we could let $w = t^2$ so that $dw = 2t\,dt$. This means $\frac{1}{2}dw = t\,dt$. Hence,

$$\begin{aligned}\int t^3 e^{t^2}\,dt &= \int t^2 e^{t^2} t\,dt \\ &= \frac{1}{2}\int we^w\,dw \qquad \left(\text{substituting } w = t^2 \implies \frac{1}{2}dw = t\,dt\right)\end{aligned}$$

We can integrate *both* $w$ and $e^w$, so we focus on choosing $u$ to be the factor whose derivative (or eventual derivative) changes form. This is $w$. Thus, we choose $u = w$ and $dv = e^w\,dw$.

| $u = w$ | $dv = e^w\,dw$ |
|---|---|
| $du = dw$ | $v = e^w$ |

Using Integration by Parts, we get

$$\begin{aligned}\int t^3 e^{t^2}\,dt &= \int t^2 e^{t^2} t\,dt \\ &= \frac{1}{2}\int we^w\,dw && \left(\text{substituting } w = t^2 \implies \frac{1}{2}dw = t\,dt\right) \\ &= \frac{1}{2}\left(we^w - \int e^w\,dw\right) && \text{(IbP)} \\ &= \frac{1}{2}\left(we^w - e^w + C_1\right) \\ &= \frac{1}{2}\left(t^2e^{t^2} - e^{t^2} + C_1\right) && \text{(resubstituting } w = t^2\text{)} \\ &= \frac{1}{2}t^2e^{t^2} - \frac{1}{2}e^{t^2} + C && \left(\frac{1}{2}C_1 \text{ is a constant, so we call it } C\right)\end{aligned}$$

**Approach #3 (Most Efficient): Starting with IBP by Choosing $dv$ to be the Largest Integrable Factor**

If we rewrite the given integral as

$$\int t^2\left(te^{t^2}\right)\,dt,$$

we can see that both $t^2$ and $te^{t^2}$ are integrable. Therefore, we choose $dv$ to be the "larger" (read as "more complex") of these two factors. Hence, we choose $dv = te^{t^2}\,dt$ and $u = t^2$.[4]

| $u = t^2$ | $dv = te^{t^2}\,dt$ |
|---|---|
| $du = 2t\,dt$ | $v = \frac{1}{2}e^{t^2}$ (Substitution Method) |

Therefore, we get

$$\begin{aligned}\int t^3e^{t^2}\,dt &= \int t^2\left(te^{t^2}\right)\,dt \\ &= \frac{1}{2}t^2e^{t^2} - \int te^{t^2}\,dt. \qquad \text{(IbP)} \\ &= \frac{1}{2}t^2e^{t^2} - \frac{1}{2}e^{t^2} + C\end{aligned}$$

There are a couple of things I want to mention about Example **7.3.4**. First, notice that LIATE failed us here, but a natural understanding of our goal - to find the largest factor of the integrand that we *can* integrate - still led us to a solution. This is why I do not teach LIATE in my classes (again, I only include it here because you will hear of it from students in other classes, and those students might have the illusion that it always works).

The second thing to mention is that Approach #3 in this example demonstrates the level of comfort with integration for which you want to strive. There is nothing wrong with Approach #2, but you *definitely* want to build the skill set to perform complex integrations like this. However, The only way you will build that skill is through lots of practice!

**Caution: Practice Makes Better**

Integration by Parts (and most other integration techniques) is almost a completely **heuristic** method. That is, you will only learn how to identify when to use a technique properly and what pitfalls to avoid by practicing.

**Example 7.3.5: Self-Relating Integration by Parts**

Evaluate

$$\int \sin(\ln x)\,dx.$$

**Solution**

☒ **Direct Integration:** Since the integrand is not the derivative of an established, well-known function, we cannot directly integrate.

☒ **Simple $u$-Substitution:** I leave it for the reader to try as they might to find a proper $u$-substitution - none will work.

☒ **Radical Substitution:** Since a simple $u$-substitution will not work, a radical substitution is out of the question.

☒ **Trigonometric Substitution:** As written, there isn't any obvious trigonometric substitution.

? **By Parts:** Since the integrand is *not* the product of two different function types, it doesn't *seem* to be a good candidate for Integration by Parts.[5]

Again, LIATE fails us here, but the Rule of Thumb is still helpful. We begin by rewriting the integral as

$$\int \sin(\ln x)\cdot 1\,dx.$$

We can integrate $1$, but not $\sin(\ln(x))$, so we let $dv = 1\,dx$.

| | |
|---|---|
| $u = \sin(\ln(x))$ | $dv = 1\,dx$ |
| $du = \dfrac{\cos(\ln(x))}{x}\,dx$ | $v = x$ |

Therefore, we have

$$\int \sin\left(\ln(x)\right)\,dx = x\sin(\ln(x)) - \int \cos(\ln(x))\,dx.$$

Unfortunately, this process leaves us with a new integral that is very similar to the original. However, let's see what happens when we apply Integration by Parts again.

Since we chose $u$ to be the composition of the trigonometric function and the logarithmic function on our first pass of the Integration by Parts method, we choose the same *style* of function for $u$ on our second pass.

| | |
|---|---|
| $u = \cos(\ln(x))$ | $dv = 1\,dx$ |
| $du = -\dfrac{\sin(\ln(x))}{x}\,dx$ | $v = x$ |

Substituting, we have

$$\int \sin(\ln(x))\,dx = x\sin(\ln x) - \left(x\cos(\ln(x)) - \int -\sin(\ln(x))\,dx\right).$$

After simplifying, we obtain

$$\int \sin(\ln(x))\,dx = x\sin(\ln(x)) - x\cos(\ln(x)) - \int \sin(\ln(x))\,dx.$$

The last integral is now the same as the original. It may seem that we have gone in circles, but now we can evaluate the integral. To see how to do this more clearly, substitute $I = \int \sin(\ln(x))\,dx$. Thus, the equation becomes

$$I = x\sin(\ln(x)) - x\cos(\ln(x)) - I.$$

First, add $I$ to both sides of the equation to obtain

$$2I = x\sin(\ln(x)) - x\cos(\ln(x)).$$

Next, divide by 2:

$$I = \frac{1}{2}x\sin(\ln(x)) - \frac{1}{2}x\cos(\ln(x)).$$

Substituting $I = \int \sin(\ln(x))\,dx$ again, we have

$$\int \sin(\ln(x))\,dx = \frac{1}{2}x\sin(\ln(x)) - \frac{1}{2}x\cos(\ln(x)).$$

From this we see that $\frac{1}{2}x\sin(\ln(x)) - \frac{1}{2}x\cos(\ln(x))$ is an antiderivative of $\sin(\ln(x))$. For the most general antiderivative, add $C$:

$$\int \sin(\ln(x))\,dx = \frac{1}{2}x\sin(\ln(x)) - \frac{1}{2}x\cos(\ln(x)) + C.$$

**Analysis**

If this method feels a little strange at first, we can check the answer by differentiation:

$$\frac{d}{dx}\left(\frac{1}{2}x\sin(\ln x)-\frac{1}{2}x\cos(\ln x)\right) = \frac{1}{2}(\sin(\ln x))+\cos(\ln x)\cdot\frac{1}{x}\cdot\frac{1}{2}x-\left(\frac{1}{2}\cos(\ln x)-\sin(\ln x)\cdot\frac{1}{x}\cdot\frac{1}{2}x\right)$$
$$= \sin(\ln x).$$

Example 7.3.5 is an integral I call a "Self-Relating Integration by Parts." This is because, when we use Integration by Parts, we obtain the original integral as part of our evaluated integral. This style of integration comes up frequently enough that you should practice it until it is comfortable.

**? Checkpoint 7.3.5**

Evaluate

$$\int x^2\sin x\,dx.$$

**Answer**

$$\int x^2\sin x\,dx = -x^2\cos x+2x\sin x+2\cos x+C$$

In Section 2.1, we introduced the following Problem-Solving Strategy for dealing with integrals involving products of powers of the tangent and secant functions. In this case, we complete the strategy by filling out the fourth tactic - one that requires Integration by Parts.

**Problem-Solving Strategy: Integrating $\int \tan^k(x)\sec^j(x)\,dx$**

To integrate $\int \tan^k(x)\sec^j(x)\,dx$, use the following strategies:

1. If $j$ is even and $j\geq 2$, rewrite $\sec^j(x)=\sec^{j-2}(x)\sec^2(x)$ and use $\sec^2(x)=\tan^2(x)+1$ to rewrite $\sec^{j-2}(x)$ in terms of $\tan(x)$. Let $u=\tan(x)$ and $du=\sec^2(x)\,dx$.
2. If $k$ is odd and $j\geq 1$, rewrite $\tan^k(x)\sec^j(x)=\tan^{k-1}(x)\sec^{j-1}(x)\sec(x)\tan(x)$ and use $\tan^2(x)=\sec^2(x)-1$ to rewrite $\tan^{k-1}(x)$ in terms of $\sec(x)$. Let $u=\sec(x)$ and $du=\sec(x)\tan(x)\,dx$. (Note: If $j$ is even and $k$ is odd, then either strategy 1 or strategy 2 may be used.)
3. If $k$ is odd where $k\geq 3$ and $j=0$, rewrite $\tan^k(x)=\tan^{k-2}(x)\tan^2(x)=\tan^{k-2}(x)(\sec^2(x)-1)=\tan^{k-2}(x)\sec^2(x)-\tan^{k-2}(x)$. It may be necessary to repeat this process on the $\tan^{k-2}(x)$ term.
4. If $k$ is even and $j$ is odd, then use $\tan^2(x)=\sec^2(x)-1$ to express $\tan^k(x)$ in terms of $\sec(x)$. Use Integration by Parts to integrate odd powers of $\sec(x)$.

**✓ Example 7.3.6: Integrating $\sec^3(x)$**

Evaluate $\int \sec^3(x)\,dx$.

**Solution**

☒ **Direct Integration:** Since the integrand is not the derivative of an established, well-known function, we cannot directly integrate.

☒ **Simple $u$-Substitution:** Any choice of substitution will lead nowhere. For example, letting $u=\tan(x)$ will definitely "steal" two powers off the secant (via $du=\sec^2(x)\,dx$); however, the secant would be left with an *odd* power - we don't want that. Letting $u=\sec(x)$ would steal a power off tangent (via $du=\sec(x)\tan(x)\,dx$), leaving $(\tan(x))^{-1}$; however, we would need that power on tangent to be even, and that's not going to happen. I leave it for the reader to try as they might to find a proper $u$-substitution - none will work.

☒ **Radical Substitution:** The integrand doesn't involve a radical.

☒ **Trigonometric Substitution:** As written, there isn't any obvious trigonometric substitution.

? **By Parts:** Since all other techniques have failed, we *might* be able to use Integration by Parts; however, as written, we have no clue where to start.

This integral is dangerously popular in some texts!

Since we are stuck from the get-go, let's use the Mathematical Mantra and see if there is anything from Trigonometry that might help. We would like to rewrite the integrand as the product of two functions (which is not technically always needed for Integration by Parts, but it is helpful here):

$$\int \sec^3(x)\,dx = \int \sec(x)\sec^2(x)\,dx.$$

We definitely can integrate $sec^2(x)$, so we choose $dv = \sec^2(x)\,dx$ and $u = \sec(x)$.

| $u = \sec(x)$ | $dv = \sec^2(x)\,dx$ |
|---|---|
| $du = \sec(x)\tan(x)\,dx$ | $v = \tan(x)$ |

Thus,

$$\begin{aligned}
\int \sec^3(x)\,dx &= \sec(x)\tan(x) - \int \tan(x)\sec(x)\tan(x)\,dx \\
&= \sec(x)\tan(x) - \int \tan^2(x)\sec(x)\,dx \\
&= \sec(x)\tan(x) - \int (\sec^2(x) - 1)\sec(x)\,dx \\
&= \sec(x)\tan(x) + \int \sec(x)\,dx - \int \sec^3(x)\,dx \\
&= \sec(x)\tan(x) + \ln|\sec(x) + \tan(x)| - \int \sec^3(x)\,dx.
\end{aligned}$$

We now have

$$\int \sec^3(x)\,dx = \sec(x)\tan(x) + \ln|\sec(x) + \tan(x)| - \int \sec^3(x)\,dx.$$

Since the integral $\int \sec^3(x)\,dx$ has reappeared on the right-hand side, we can solve for $\int \sec^3(x)\,dx$ by adding it to both sides. In doing so, we obtain

$$2\int \sec^3(x)\,dx = \sec(x)\tan(x) + \ln|\sec(x) + \tan(x)|.$$

Dividing by 2, we arrive at

$$\int \sec^3(x)\,dx = \frac{1}{2}\sec(x)\tan(x) + \frac{1}{2}\ln|\sec(x) + \tan(x)| + C.$$

**Interesting Pattern!**

While I love the derivation of this integral (and you could be expected to derive it on an exam), I cannot help but mention the cool pattern it generates. The integral of the cube of the secant is one-half the sum of the secant's derivative and the secant's integral.

## Integration by Parts for Definite Integrals

Now that we have used Integration by Parts successfully to evaluate indefinite integrals, we turn our attention to definite integrals. The integration technique is the same; we only add a step to evaluate the integral at the upper and lower limits of integration.

**Theorem: Integration by Parts for Definite Integrals**

Let $u = f(x)$ and $v = g(x)$ be functions with continuous derivatives on $[a, b]$. Then

$$\int_a^b u\,dv = uv\Big|_a^b - \int_a^b v\,du$$

**Example 7.3.7: Finding the Area of a Region**

Find the area of the region bounded above by the graph of $y = \tan^{-1} x$ and below by the $x$-axis over the interval $[0, 1]$.

**Solution**

This region is shown in Figure 7.3.1. To find the area, we must evaluate

$$\int_0^1 \tan^{-1} x\,dx.$$

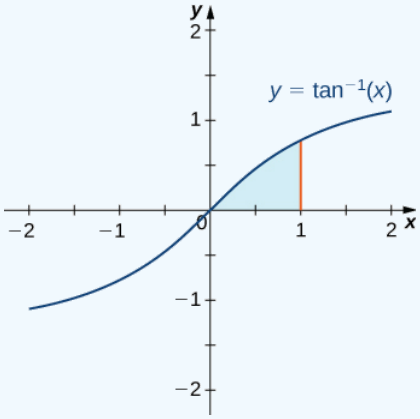

Figure 7.3.1

☒ **Direct Integration:** Since the integrand is not the derivative of an established, well-known function, we cannot directly integrate.

☒ **Simple $u$-Substitution:** I leave it for the reader to try as they might to find a proper $u$-substitution - none will work.

☒ **Radical Substitution:** Since a simple $u$-substitution will not work, a radical substitution is out of the question.

☒ **Trigonometric Substitution:** As written, there isn't any obvious trigonometric substitution.

? **By Parts:** Since all other integration techniques have been exhausted, Integration by Parts *might* be feasible.

Since we can integrate 1, this will be our choice for $dv$.

| $u = \tan^{-1}(x)$ | $dv = 1\,dx$ |
|---|---|
| $du = \dfrac{1}{1+x^2}\,dx$ | $v = x$ |

After applying the Integration by Parts formula (Equation 7.3.2) we obtain

$$\text{Area} = x\tan^{-1} x\Big|_0^1 - \int_0^1 \frac{x}{x^2+1}\,dx.$$

Use $u$-substitution to obtain

$$\int_0^1 \frac{x}{x^2+1}\,dx = \frac{1}{2}\ln\left(x^2+1\right)\Big|_0^1.$$

Thus,

$$\text{Area} = x\tan^{-1}x\Big|_0^1 - \frac{1}{2}\ln\left(x^2+1\right)\Big|_0^1 = \left(\frac{\pi}{4} - \frac{1}{2}\ln 2\right)\ \text{units}^2.$$

At this point, it might not be a bad idea to do a "reality check" on the reasonableness of our solution. Since $\frac{\pi}{4} - \frac{1}{2}\ln 2 \approx 0.4388\ \text{units}^2$, and from Figure 7.3.1 we expect our area to be slightly less than $0.5\ \text{units}^2$, this solution appears to be reasonable.

### Example 7.3.8: Finding a Volume of Revolution

Find the volume of the solid obtained by revolving the region bounded by the graph of $f(x) = e^{-x}$, the $x$-axis, the $y$-axis, and the line $x = 1$ about the $y$-axis.

**Solution**

The best solution to this problem is to use the Method of Cylindrical Shells. Begin by sketching the region to be revolved, along with a typical rectangle (Figure 7.3.2).

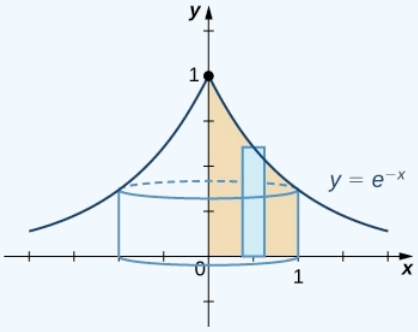

Figure 7.3.2: We can use the shell method to find a volume of revolution.

To find the volume using shells, we must evaluate

$$2\pi\int_0^1 xe^{-x}\,dx. \tag{7.3.4}$$

☒ **Direct Integration:** Since the integrand is not the derivative of an established, well-known function, we cannot directly integrate.

☒ **Simple $u$-Substitution:** I leave it for the reader to try as they might to find a proper $u$-substitution - none will work.

☒ **Radical Substitution:** Since a simple $u$-substitution will not work, a radical substitution is out of the question.

☒ **Trigonometric Substitution:** As written, there isn't any obvious trigonometric substitution.

? **By Parts:** The fact that the integrand is the product of two different types of functions is promising and invokes thoughts of using Integration by Parts.

Both $x$ and $e^{-x}$ are easily integrable, so we instead resort to choosing for $u$ the function whose form eventually changes through differentiation - this is $x$. Thus, we let $u = x$ and $dv = e^{-x}\,dx$.

| | |
|---|---|
| $u = x$ | $dv = e^{-x}\,dx$ |
| $du = dx$ | $v = -e^{-x}$ |

Using the Shell Method formula and substituting these values in, we obtain

$$\begin{aligned}
\text{Volume} &= 2\pi \int_0^1 xe^{-x}\,dx \\
&= 2\pi \left(-xe^{-x}\Big|_0^1 + \int_0^1 e^{-x}\,dx\right) \\
&= -2\pi \left(xe^{-x}\Big|_0^1 - \int_0^1 e^{-x}\,dx\right) \\
&= -2\pi \left(e^{-1} - 0 + e^{-x}\Big|_0^1\right) \\
&= -2\pi \left(e^{-1} + e^{-1} - 1\right) \\
&= -2\pi \left(2e^{-1} - 1\right) \\
&= 2\pi - \frac{4\pi}{e} \text{ units}^3.
\end{aligned}$$

**Analysis**

Again, it is a good idea to check the reasonableness of our solution. We observe that the solid has a volume slightly less than that of a cylinder of radius $1$ and height of $1/e$ added to the volume of a cone of base radius $1$ and height of $1 - \frac{1}{e}$. Consequently, the solid should have a volume a bit less than

$$\pi(1)^2 \frac{1}{e} + \left(\frac{\pi}{3}\right)(1)^2 \left(1 - \frac{1}{e}\right) = \frac{2\pi}{3e} + \frac{\pi}{3} \approx 1.8177 \text{ units}^3.$$

Since $2\pi - \frac{4\pi}{e} \approx 1.6603$, we see that our calculated volume is reasonable.

**? Checkpoint 7.3.8**

Evaluate

$$\int_0^{\pi/2} x \cos x\,dx.$$

**Answer**

$$\int_0^{\pi/2} x \cos x\,dx = \frac{\pi}{2} - 1$$

**✓ Example 7.3.9: Finding the Area of a Region**

Find the area of the region between the graph of $f(x) = \sqrt{x^2 - 9}$ and the x-axis over the interval $[3, 5]$.

**Solution**

First, sketch a rough graph of the region described in the problem, as shown in the following figure.

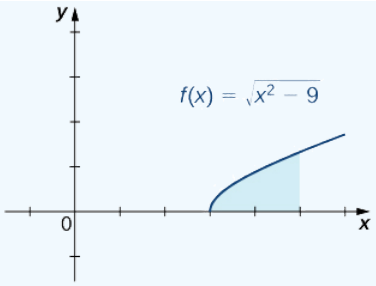

Figure 7.3.7: Calculating the area of the shaded region requires evaluating an integral with a trigonometric substitution.

We can see that the area is $A = \int_3^5 \sqrt{x^2-9}\,dx$. To evaluate this definite integral, substitute $x = 3\sec\theta$ and $dx = 3\sec\theta\tan\theta\,d\theta$. We must also change the limits of integration. If $x = 3$, then $3 = 3\sec\theta$ and hence $\theta = 0$. If $x = 5$, then $\theta = \sec^{-1}(\frac{5}{3})$. After making these substitutions and simplifying, we have

$$\begin{aligned}
\text{Area} &= \int_3^5 \sqrt{x^2-9}\,dx \\
&= \int_0^{\sec^{-1}(5/3)} 9\tan^2\theta\sec\theta\,d\theta \\
&= \int_0^{\sec^{-1}(5/3)} 9(\sec^2\theta-1)\sec\theta\,d\theta && \text{(Pythagorean Identity)} \\
&= \int_0^{\sec^{-1}(5/3)} 9(\sec^3\theta-\sec\theta)\,d\theta \\
&= \left(\frac{9}{2}\ln|\sec\theta+\tan\theta| + \frac{9}{2}\sec\theta\tan\theta - 9\ln|\sec\theta+\tan\theta|\right)\Big|_0^{\sec^{-1}(5/3)} \\
&= \left(\frac{9}{2}\sec\theta\tan\theta - \frac{9}{2}\ln|\sec\theta+\tan\theta|\right)\Big|_0^{\sec^{-1}(5/3)} \\
&= \frac{9}{2}\cdot\frac{5}{3}\cdot\frac{4}{3} - \frac{9}{2}\ln\left|\frac{5}{3}+\frac{4}{3}\right| - \left(\frac{9}{2}\cdot 1\cdot 0 - \frac{9}{2}\ln|1+0|\right) \\
&= 10 - \frac{9}{2}\ln 3
\end{aligned}$$

**? Checkpoint 7.3.9: Finding an Arc Length**

Find the length of the curve $y = x^2$ over the interval $[0, \frac{1}{2}]$.

**Answer**

$\frac{1}{4}\left(\sqrt{2}+\ln(\sqrt{2}+1)\right)$

## Reduction Formulas

Evaluating $\int \sec^n(x)\,dx$ for values of $n$ where $n$ is odd requires Integration by Parts. In addition, we must also know the value of $\int \sec^{n-2}(x)\,dx$ to evaluate $\int \sec^n(x)\,dx$. The evaluation of $\int \tan^n(x)\,dx$ also requires being able to integrate $\int \tan^{n-2}(x)\,dx$. We can derive and apply the following **Power Reduction Identities for Integration** to simplify the process. These rules allow us to replace the integral of a power of $\sec(x)$ or $\tan(x)$ with the integral of a lower power of $\sec(x)$ or $\tan(x)$.

**Theorem: Power Reduction Identities for $\int \sec^n(x)\,dx$ and $\int \tan^n(x)\,dx$**

$$\int \sec^n(x)\,dx = \frac{1}{n-1}\sec^{n-2}(x)\tan(x) + \frac{n-2}{n-1}\int \sec^{n-2}(x)\,dx$$

and

$$\int \tan^n(x)\,dx = \frac{1}{n-1}\tan^{n-1}(x) - \int \tan^{n-2}(x)\,dx.$$

**Note**

The Power Reduction Identity for Integrating Powers of Secant may be verified by applying Integration by Parts. The Power Reduction Identity for Integrating Powers of Tangent may be verified by following the strategy outlined for integrating odd powers of $\tan(x)$.

### Example 7.3.10: Revisiting $\int \sec^3(x)\,dx$

Apply a reduction formula to evaluate $\int \sec^3(x)\,dx$.

**Solution**

By applying the first reduction formula, we obtain

$$\begin{aligned}\int \sec^3(x)\,dx &= \frac{1}{2}\sec(x)\tan(x) + \frac{1}{2}\int \sec(x)\,dx \\ &= \frac{1}{2}\sec(x)\tan(x) + \frac{1}{2}\ln|\sec(x)+\tan(x)| + C.\end{aligned}$$

### Example 7.3.11: Using a Power Reduction Identity for Integration

Evaluate $\int \tan^4(x)\,dx$.

**Solution**

Applying the Power Reduction Identity for $\int \tan^4(x)\,dx$ we have

$$\begin{aligned}\int \tan^4(x)\,dx &= \frac{1}{3}\tan^3(x) - \int \tan^2(x)\,dx \\ &= \frac{1}{3}\tan^3(x) - (\tan(x) - \int \tan^0(x)\,dx) \\ &= \frac{1}{3}\tan^3(x) - \tan(x) + \int 1\,dx \\ &= \frac{1}{3}\tan^3(x) - \tan(x) + x + C\end{aligned}$$

### Checkpoint 7.3.11

Apply the Power Reduction Identity to $\int \sec^5(x)\,dx$.

**Answer**

$$\int \sec^5(x)\,dx = \frac{1}{4}\sec^3(x)\tan(x) + \frac{3}{4}\int \sec^3(x)\,dx$$

## Footnotes

[1] The capital, bold letters are purposeful here, we will see why momentarily.

[2] Note that we put **LI** at the beginning of the mnemonic; however, we could just as easily have started with **IL**, since these two types of functions won't appear together in an Integration by Parts problem and they are both terrible choices for $dv$.

[3] I use a $\boxed{?}$ instead of $\boxed{\checkmark}$ because having a product of two different types of functions within the integrand is *not* a guarantee that Integration by Parts will work.

[4] Another way we could have made our choice for $u$ and $dv$ here is to note that, since both $t^2$ and $te^{t^2}$ are integrable, we switch gears and choose $u$ to be the factor that will *eventually* change forms given enough derivatives. This will be $u = t^2$ because, after two derivatives, it will become a constant function.

[5] It turns out that Integration by Parts does not require the integrand to be a product of two different function types. It can be used to integrate compositions of functions and it is sometimes used to integrate *single* functions!

# 7.3E: EXERCISES

## READING QUESTIONS

1. The formula for Integration by Parts is derived from which rule in differential calculus?
2. What is the formula for Integration by Parts for indefinite integrals?
3. When choosing which part of the integrand will be $u$ and which will be $dv$, what is the most important characteristic of the expression chosen for $dv$?
4. What does the mnemonic LIATE stand for, and how is it used as a guideline for choosing $u$?
5. What is a "self-relating integral," and how do you solve it once the original integral reappears in your work?
6. If you need to apply Integration by Parts more than once to solve an integral, why is it important to be consistent with your choices of function types for $u$?
7. What is the purpose of a reduction formula?

**In using the technique of Integration by Parts, you must carefully choose which expression is $u$. For each of the following problems, use the guidelines in this section to choose $u$. Do not evaluate the integrals.**

1) $\int x^3 e^{2x}\,dx$

**Answer**

$u = x^3$

2) $\int x^3 \ln(x)\,dx$

3) $\int y^3 \cos y\,dy$

**Answer**

$u = y^3$

4) $\int x^2 \arctan x\,dx$

5) $\int e^{3x} \sin(2x)\,dx$

**Answer**

$u = \sin(2x)$

**In exercises 6 - 40, find the integral by using the simplest method. Not all problems require Integration by Parts.**

6) $\int v \sin v\,dv$

7) $\int \ln x\,dx$ (Hint: $\int \ln x\,dx$ is equivalent to $\int 1 \cdot \ln(x)\,dx$.)

**Answer**

$$\int \ln x\,dx \quad = \quad -x + x \ln x + C$$

8) $\int x \cos x\,dx$

9) $\int \tan^{-1} x\,dx$

**Answer**

$$\int \tan^{-1} x\,dx \quad = \quad x \tan^{-1} x - \tfrac{1}{2}\ln(1 + x^2) + C$$

10) $\int x^2 e^x\,dx$

11) $\int x \sin(2x)\,dx$

**Answer**

$$\int x\sin(2x)\,dx \quad = \quad -\tfrac{1}{2}x\cos(2x)+\tfrac{1}{4}\sin(2x)+C$$

12) $\int xe^{4x}\,dx$

13) $\int xe^{-x}\,dx$

**Answer**

$$\int xe^{-x}\,dx \quad = \quad e^{-x}(-1-x)+C$$

14) $\int x\cos 3x\,dx$

15) $\int x^2\cos x\,dx$

**Answer**

$$\int x^2\cos x\,dx \quad = \quad 2x\cos x+(-2+x^2)\sin x+C$$

16) $\int x\ln x\,dx$

17) $\int \sqrt{x^2+9}\,dx$

**Answer**

$$\int \sqrt{x^2+9}\,dx \quad = \quad 9\left[\frac{x\sqrt{x^2+9}}{18}+\tfrac{1}{2}\ln\left|\frac{\sqrt{x^2+9}}{3}+\frac{x}{3}\right|\right]+C$$

18) $\int \ln(2x+1)\,dx$

**Answer**

$$\int \ln(2x+1)\,dx \quad = \quad \tfrac{1}{2}(1+2x)(-1+\ln(1+2x))+C$$

19) $\int x^2e^{4x}\,dx$

20) $\int e^x\sin x\,dx$

**Answer**

$$\int e^x\sin x\,dx \quad = \quad \tfrac{1}{2}e^x(-\cos x+\sin x)+C$$

21) $\int e^x\cos x\,dx$

22) $\int xe^{-x^2}\,dx$

**Answer**

$$\int xe^{-x^2}\,dx \quad = \quad -\frac{e^{-x^2}}{2}+C$$

23) $\int x^2e^{-x}\,dx$

24) $\int \sin(\ln(2x))\,dx$

**Answer**

$$\int \sin(\ln(2x))\,dx \quad = \quad -\tfrac{1}{2}x\cos[\ln(2x)]+\tfrac{1}{2}x\sin[\ln(2x)]+C$$

25) $\int \cos(\ln x)\,dx$

26) $\int (\ln x)^2\,dx$

**Answer**

$$\int (\ln x)^2\,dx \quad = \quad 2x - 2x\ln x + x(\ln x)^2 + C$$

27) $\int \ln(x^2)\,dx$

28) $\int \dfrac{x^2}{\sqrt{1+x^2}}\,dx$

29) $\int x^2 \ln x\,dx$

**Answer**

$$\int x^2 \ln x\,dx \quad = \quad -\frac{x^3}{9} + \tfrac{1}{3}x^3 \ln x + C$$

30) $\int \sin^{-1} x\,dx$

31) $\int \cos^{-1}(2x)\,dx$

**Answer**

$$\int \cos^{-1}(2x)\,dx \quad = \quad -\tfrac{1}{2}\sqrt{1-4x^2} + x\cos^{-1}(2x) + C$$

32) $\int x \arctan x\,dx$

33) $\int x^2 \sin x\,dx$

**Answer**

$$\int x^2 \sin x\,dx \quad = \quad -(-2+x^2)\cos x + 2x\sin x + C$$

34) $\int x^3 \cos x\,dx$

35) $\int x^3 \sin x\,dx$

**Answer**

$$\int x^3 \sin x\,dx \quad = \quad -x(-6+x^2)\cos x + 3(-2+x^2)\sin x + C$$

36) $\int x^3 e^x\,dx$

37) $\int x \sec^{-1} x\,dx$

**Answer**

$$\int x \sec^{-1} x\,dx \quad = \quad \tfrac{1}{2}x\left(-\sqrt{1-\frac{1}{x^2}} + x\cdot \sec^{-1} x\right) + C$$

38) $\int x \sec^2 x\,dx$

39) $\int x \cosh x\,dx$

**Answer**

$$\int x \cosh x\,dx \quad = \quad -\cosh x + x\sinh x + C$$

40) $\int \tan^2 x \sec x\,dx$

**Answer**

$$\int \tan^2 x \sec x\,dx \quad = \quad \tfrac{1}{2}\sec x \tan x - \tfrac{1}{2}\ln(\sec x + \tan x) + C$$

**In exercises 41 - 50, compute the definite integrals. Use a graphing utility to confirm your answers.**

41) $\int_{1/e}^{1} \ln x \, dx$

42) $\int_{0}^{1} xe^{-2x} \, dx$ (Express the answer in exact form.)

**Answer**

$$\int_{0}^{1} xe^{-2x} \, dx \quad = \quad \frac{1}{4} - \frac{3}{4e^2}$$

43) $\int_{0}^{1} e^{\sqrt{x}} \, dx \quad (\text{let } u = \sqrt{x})$

44) $\int_{1}^{e} \ln(x^2) \, dx$

**Answer**

$$\int_{1}^{e} \ln(x^2) \, dx \quad = \quad 2$$

45) $\int_{0}^{\pi} x \cos x \, dx$

46) $\int_{-\pi}^{\pi} x \sin x \, dx$ (Express the answer in exact form.)

**Answer**

$$\int_{-\pi}^{\pi} x \sin x \, dx \quad = \quad 2\pi$$

47) $\int_{0}^{3} \ln(x^2 + 1) \, dx$ (Express the answer in exact form.)

48) $\int_{0}^{\pi/2} x^2 \sin x \, dx$ (Express the answer in exact form.)

**Answer**

$$\int_{0}^{\pi/2} x^2 \sin x \, dx \quad = \quad -2 + \pi$$

49) $\int_{0}^{1} x5^x \, dx$ (Express the answer using five significant digits.)

50) Evaluate $\int \cos x \ln(\sin x) \, dx$

**Answer**

$$\int \cos x \ln(\sin x) \, dx \quad = \quad -\sin(x) + \ln[\sin(x)] \sin x + C$$

**In exercises 51 - 53, derive the following formulas using the technique of Integration by Parts. Assume that $n$ is a positive integer. These formulas are called *reduction formulas* because the exponent in the $x$ term has been reduced by one in each case. The second integral is simpler than the original integral.**

51) $\int x^n e^x \, dx = x^n e^x - n \int x^{n-1} e^x \, dx$

52) $\int x^n \cos x \, dx = x^n \sin x - n \int x^{n-1} \sin x \, dx$

**Answer**

Answers vary

53) $\int x^n \sin x \, dx =$_____

54) Integrate $\int 2x\sqrt{2x-3} \, dx$ using two methods:

a. Using Integration by Parts, letting $dv = \sqrt{2x-3} \, dx$

b. Substitution Method, letting $u = 2x - 3$

**Answer**

a. $\int 2x\sqrt{2x-3}\,dx = \frac{2}{5}(1+x)(-3+2x)^{3/2}+C$

b. $\int 2x\sqrt{2x-3}\,dx = \frac{2}{5}(1+x)(-3+2x)^{3/2}+C$

**In exercises 55 - 60, state whether you would use Integration by Parts to evaluate the integral. If so, identify $u$ and $dv$. If not, describe the technique used to perform the integration without actually doing the problem.**

55) $\int x\ln x\,dx$

56) $\int \frac{\ln^2 x}{x}\,dx$

**Answer**

Do not use Integration by Parts. Choose $u$ to be $\ln x$, and the integral is of the form $\int u^2\,du$.

57) $\int xe^x\,dx$

58) $\int xe^{x^2-3}\,dx$

**Answer**

Do not use Integration by Parts. Let $u = x^2-3$, and the integral can be put into the form $\int e^u\,du$.

59) $\int x^2\sin x\,dx$

60) $\int x^2\sin(3x^3+2)\,dx$

**Answer**

Do not use Integration by Parts. Choose $u$ to be $u = 3x^3+2$ and the integral can be put into the form $\int \sin(u)\,du$.

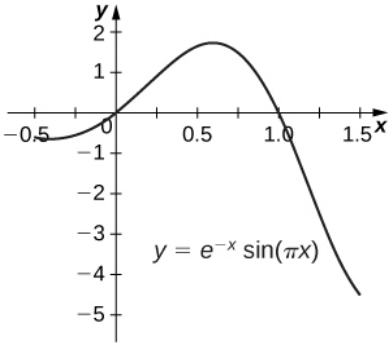
**In exercises 61 - 62, sketch the region bounded above by the curve, the $x$-axis, and $x = 1$, and find the area of the region. Provide the exact form or round answers to the number of places indicated.**

61) $y = 2xe^{-x}$ (Approximate answer to four decimal places.)

62) $y = e^{-x}\sin(\pi x)$ (Approximate answer to five decimal places.)

**Answer**

The area under graph is $0.39535\ \text{units}^2$.



**In exercises 63 - 64, find the volume generated by rotating the region bounded by the given curves about the specified line. Express the answers in exact form or approximate to the number of decimal places indicated.**

63) $y = \sin x$, $y = 0$, $x = 2\pi$, $x = 3\pi$; about the $y$-axis (Express the answer in exact form.)

64) $y = e^{-x}$, $y = 0$, $x = -1$, $x = 0$; about $x = 1$ (Express the answer in exact form.)

**Answer**

$V = 2\pi e\ \text{units}^3$

65) A particle moving along a straight line has a velocity of $v(t) = t^2e^{-t}$ after $t$ sec. How far does it travel in the first 2 sec? (Assume the units are in feet and express the answer in exact form.)

66) Find the area under the graph of $y = \sec^3 x$ from $x = 0$ to $x = 1$. (Round the answer to two significant digits.)

**Answer**

$A = 2.05 \text{ units}^2$

67) Find the area between $y = (x - 2)e^x$ and the $x$-axis from $x = 2$ to $x = 5$. (Express the answer in exact form.)

68) Find the area of the region enclosed by the curve $y = x \cos x$ and the $x$-axis for $\frac{11\pi}{2} \le x \le \frac{13\pi}{2}$. (Express the answer in exact form.)

**Answer**

$A = 12\pi \text{ units}^2$

69) Find the volume of the solid generated by revolving the region bounded by the curve $y = \ln x$, the $x$-axis, and the vertical line $x = e^2$ about the $x$-axis. (Express the answer in exact form.)

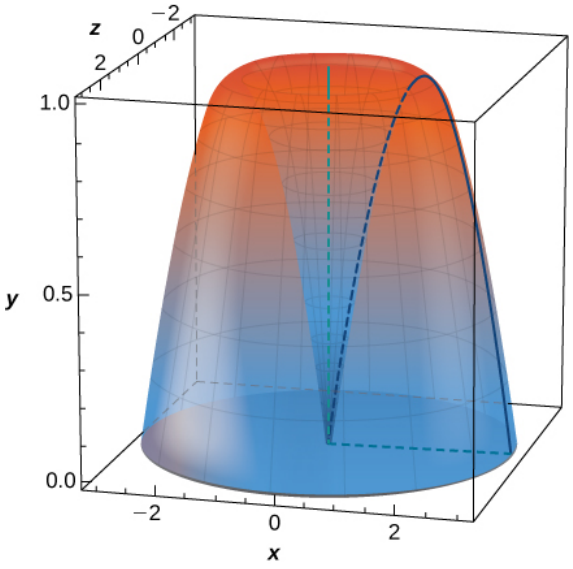
70) Find the volume of the solid generated by revolving the region bounded by the curve $y = 4 \cos x$ and the $x$-axis, $\frac{\pi}{2} \le x \le \frac{3\pi}{2}$, about the $x$-axis. (Express the answer in exact form.)

**Answer**

$V = 8\pi^2 \text{ units}^3$

71) Find the volume of the solid generated by revolving the region in the first quadrant bounded by $y = e^x$ and the $x$-axis, from $x = 0$ to $x = \ln(7)$, about the $y$-axis. (Express the answer in exact form.)

72) What is the volume of the Bundt cake that comes from rotating $y = \sin x$ around the $y$-axis from $x = 0$ to $x = \pi$?



**Answer**

$V = 2\pi^2$ units$^3$

73) Find the weight of a ruler that is $12$ in. long (starting at $x = 5$) and has a weight density function of $\gamma(x) = \ln(x) + (1/2)x^2$ oz/in. You should assume the ruler is a one-dimensional object.

**In exercises 74 - 75, find the weight of the two-dimensional object that is centered at the origin.**

74) A plate of radius $10$ in. with radial *weight* density function $\gamma(x) = 1 + \cos(\pi x)$ lb/in$^2$

**Answer**

$100\pi$ lbs.

75) A jar lid of radius $3$ in. with radial *weight* density function $\gamma(x) = \ln(x + 1)$ oz/in$^2$

**For each pair of integrals in exercises 76 - 77, determine which one is more difficult to evaluate. Explain your reasoning.**

76) $\int \sin^{456} x \cos x \, dx$ or $\int \sin^2 x \cos^2 x \, dx$

77) $\int \tan^{350} x \sec^2 x \, dx$ or $\int \tan^{350} x \sec x \, dx$

**Answer**

The second integral is more difficult because the first integral is simply a $u$-substitution type.

# 7.4: Chapter 2 Review Exercises

**In exercises 1 - 4, determine whether the statement is true or false. Justify your answer with a proof or a counterexample.**

1) $\int e^x \sin(x)\,dx$ cannot be integrated by parts.

2) $\int \frac{1}{x^4+1}\,dx$ cannot be integrated using partial fractions.

**Answer**

False

3) In numerical integration, increasing the number of points decreases the error.

4) Integration by parts can always yield the integral.

**Answer**

False

**In exercises 5 - 10, evaluate the integral using the specified method.**

5) $\int x^2 \sin(4x)\,dx$, using integration by parts

6) $\int \frac{1}{x^2\sqrt{x^2+16}}\,dx$, using trigonometric substitution

**Answer**

$$\int \frac{1}{x^2\sqrt{x^2+16}}\,dx = -\frac{\sqrt{x^2+16}}{16x} + C$$

7) $\int \sqrt{x}\ln x\,dx$, using integration by parts

8) $\int \frac{3x}{x^3+2x^2-5x-6}\,dx$, using partial fractions

**Answer**

$$\int \frac{3x}{x^3+2x^2-5x-6}\,dx = \frac{1}{10}\left(4\ln|2-x| + 5\ln|x+1| - 9\ln|x+3|\right) + C$$

9) $\int \frac{x^5}{(4x^2+4)^{5/2}}\,dx$, using trigonometric substitution

10) $\int \frac{\sqrt{4-\sin^2(x)}}{\sin^2(x)}\cos(x)\,dx$, using a table of integrals or a CAS

**Answer**

$$\int \frac{\sqrt{4-\sin^2(x)}}{\sin^2(x)}\cos(x)\,dx = -\frac{\sqrt{4-\sin^2(x)}}{\sin(x)} - \frac{x}{2} + C$$

**In exercises 11 - 15, integrate using whatever method you choose.**

11) $\int \sin^2 x \cos^2 x\,dx$

12) $\int x^3\sqrt{x^2+2}\,dx$

**Answer**

$$\int x^3\sqrt{x^2+2}\,dx = \frac{1}{15}(x^2+2)^{3/2}(3x^2-4) + C$$

13) $\int \frac{3x^2+1}{x^4-2x^3-x^2+2x}\,dx$

14) $\int \frac{1}{x^4+4}\,dx$

**Answer**

$$\int \frac{1}{x^4+4}\,dx = \frac{1}{16}\ln\left(\frac{x^2+2x+2}{x^2-2x+2}\right) - \frac{1}{8}\tan^{-1}(1-x) + \frac{1}{8}\tan^{-1}(x+1) + C$$

15) $\int \frac{\sqrt{3+16x^4}}{x^4}\,dx$

**In exercises 16 - 18, approximate the integrals using the midpoint rule, trapezoidal rule, and Simpson's rule using four subintervals, rounding to three decimals.**

16) [Technology Required] $\int_1^2 \sqrt{x^5+2}\,dx$

**Answer**

$M_4 = 3.312,$
$T_4 = 3.354,$
$S_4 = 3.326$

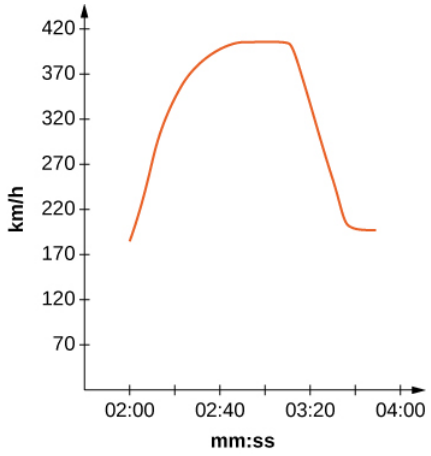
17) [Technology Required] $\int_0^{\sqrt{\pi}} e^{-\sin(x^2)}\,dx$

18) [Technology Required] $\int_1^4 \frac{\ln(1/x)}{x}\,dx$

**Answer**

$M_4 = -0.982,$
$T_4 = -0.917,$
$S_4 = -0.952$

The fastest car in the world, the Bugati Veyron, can reach a top speed of 408 km/h. The graph represents its velocity.



19) [Technology Required] Use the graph to estimate the velocity every 20 sec and fit to a graph of the form $v(t) = ae^{bx}\sin(cx) + d$. (Hint: Consider the time units.)

20) [Technology Required] Using your function from the previous problem, find exactly how far the Bugati Veyron traveled in the 1 min 40 sec included in the graph.

**Answer**

Answers may vary. Ex: $9.405$ km

# 7.5: Partial Fractions

https://math.libretexts.org/@go/page/175599

**Note to the Instructor (click to expand)**

This is the nuts and bolts of PFD.

---

To succeed in this section, you'll need to use some skills from previous courses. While you should already know them, this is the first time they've been required. You can review these skills in CRC's Corequisite Codex. If you have a support class, it might cover some, **but not all**, of these topics.

**Prerequisite Skills and Support Topics (click to expand)**

- **Factoring Techniques**
  - Greatest Common Factor: Factoring the denominator is a critical step, and it often begins with factoring out a greatest common factor, as seen in Example 2.4.2 where $x^3 - x^2 - 2x$ is factored.
  - Factoring Trinomials: After factoring out a GCF, the remaining polynomial often needs to be factored, such as factoring $x^2 - x - 2$ in Example 2.4.2.
  - Factoring Sums and Differences of Cubes: This technique is needed to factor denominators like $x^3 - 8$ in Example 2.4.7.
  - Factoring Expressions Using the Rational Roots Theorem: The homework mentions that this may be needed to factor higher-degree polynomials in the denominator.
- **Systems**
  - Solving 2x2 Systems of Linear Equations: The method of equating coefficients for finding the constants in the decomposition often results in a system of linear equations that must be solved.
  - Solving 3x3 Systems of Linear Equations: For decompositions with three or more unknown constants, solving a larger system of equations is necessary.
- **Quadratic Functions**
  - The Discriminant: The text mentions using the discriminant ($b^2 - 4ac$) to determine if a quadratic factor is irreducible.
- **Polynomial Functions**
  - The Basics of Polynomial Functions: Understanding the degree of a polynomial is fundamental to the first step of the process: comparing the degree of the numerator to the degree of the denominator.

---

The following is a list of learning objectives for this section.

**Learning Objectives (click to expand)**

- Integrate a rational function using the method of partial fractions.
- Recognize simple linear factors in a rational function.
- Recognize repeated linear factors in a rational function.
- Recognize quadratic factors in a rational function.

We have seen some techniques that allow us to integrate specific rational functions. For example, we know that

$$\int \frac{du}{u} = \ln|u| + C$$

and

$$\int \frac{du}{u^2 + a^2} = \frac{1}{a}\tan^{-1}\left(\frac{u}{a}\right) + C.$$

However, we do not yet have a technique that allows us to tackle arbitrary quotients of this type. Thus, it is not immediately obvious how to go about evaluating

$$\int \frac{3x}{x^2 - x - 2}\, dx.$$

However, we know from material previously developed that

$$\int \left(\frac{1}{x+1} + \frac{2}{x-2}\right) dx = \ln|x+1| + 2\ln|x-2| + C.$$

By getting a common denominator, we see that

$$\frac{1}{x+1} + \frac{2}{x-2} = \frac{3x}{x^2 - x - 2}.$$

Consequently,

$$\int \frac{3x}{x^2 - x - 2}\, dx = \int \left(\frac{1}{x+1} + \frac{2}{x-2}\right) dx.$$

In this section, we examine the method of **Partial Fraction Decomposition**, which allows us to decompose rational functions into sums of simpler, more easily integrated rational functions. Using this method, we can rewrite an expression such as:

$$\frac{3x}{x^2 - x - 2}$$

as an expression such as

$$\frac{1}{x+1} + \frac{2}{x-2}.$$

The key to the partial fraction decomposition method is anticipating the form that the decomposition of a rational function will take. As we shall see, this form is both predictable and highly dependent on the factorization of the denominator of the rational function. It is also imperative to keep in mind that partial fraction decomposition can be applied to a rational function $\frac{P(x)}{Q(x)}$ only if $\deg(P(x)) < \deg(Q(x))$. In the case when $\deg(P(x)) \geq \deg(Q(x))$, we must first perform long division to rewrite the quotient $\frac{P(x)}{Q(x)}$ in the form $A(x) + \frac{R(x)}{Q(x)}$, where $\deg(R(x)) < \deg(Q(x))$.[1] We then do a partial fraction decomposition on $\frac{R(x)}{Q(x)}$. The following example, although not requiring partial fraction decomposition, illustrates our approach to integrals of rational functions of the form $\int \frac{P(x)}{Q(x)}\, dx$, where $\deg(P(x)) \geq \deg(Q(x))$.

### ✔ Example 7.5.1: Evaluating $\int \frac{P(x)}{Q(x)}\, dx$, where $deg(P(x)) \geq deg(Q(x))$

Evaluate

$$\int \frac{x^2 + 3x + 5}{x+1}\, dx.$$

**Solution**

Since $\deg(x^2 + 3x + 5) \geq \deg(x+1)$, we perform long division to obtain

$$\frac{x^2+3x+5}{x+1} = x+2+\frac{3}{x+1}.$$

Thus,

$$\int \frac{x^2+3x+5}{x+1}\,dx = \int \left(x+2+\frac{3}{x+1}\right)\,dx = \frac{1}{2}x^2+2x+3\ln|x+1|+C.$$

**? Checkpoint 7.5.1**

Evaluate

$$\int \frac{x-3}{x+2}\,dx.$$

**Answer**

$$x-5\ln|x+2|+C$$

To integrate $\int \frac{P(x)}{Q(x)}\,dx$, where $\deg(P(x)) < \deg(Q(x))$, we must begin by factoring $Q(x)$.

## Nonrepeated Linear Factors

If $Q(x)$ can be factored as $(a_1x+b_1)(a_2x+b_2)\ldots(a_nx+b_n)$, where each linear factor is distinct, then it is possible to find constants $A_1$, $A_2$, ..., $A_n$ satisfying the following.[2]

$$\frac{P(x)}{Q(x)} = \frac{A_1}{a_1x+b_1}+\frac{A_2}{a_2x+b_2}+\cdots+\frac{A_n}{a_nx+b_n}. \tag{7.5.1}$$

In this next example, we see how to use partial fractions to integrate a rational function of this type.

**✓ Example 7.5.2: Partial Fractions with Nonrepeated Linear Factors**

Evaluate

$$\int \frac{3x+2}{x^3-x^2-2x}\,dx.$$

**Solution**

Since $\deg(3x+2) < \deg(x^3-x^2-2x)$, we begin by factoring the denominator of $\frac{3x+2}{x^3-x^2-2x}$.

We can see that $x^3-x^2-2x = x(x-2)(x+1)$. Thus, there are constants $A$, $B$, and $C$ satisfying Equation 7.5.1 such that

$$\frac{3x+2}{x(x-2)(x+1)} = \frac{A}{x}+\frac{B}{x-2}+\frac{C}{x+1}.$$

We must now find these constants. To do so, we begin by multiplying both sides of this equation by the least common denominator: $x(x-2)(x+1)$. Thus,

$$3x+2 = A(x-2)(x+1)+Bx(x+1)+Cx(x-2). \tag{7.5.2}$$

There are two different strategies for finding the coefficients $A$, $B$, and $C$. We refer to these as the **method of equating coefficients** and the **method of strategic substitution**.

### Strategy One: Method of Equating Coefficients

Rewrite Equation 7.5.2 in the form

$$3x+2 = (A+B+C)x^2+(-A+B-2C)x+(-2A).$$

Equating coefficients produces the system of equations

$$\begin{aligned} A+B+C &= 0 \\ -A+B-2C &= 3 \\ -2A &= 2. \end{aligned}$$

To solve this system, we first observe that $-2A=2 \implies A=-1$. Substituting this value into the first two equations gives us the system

$$\begin{aligned} B+C &= 1 \\ B-2C &= 2. \end{aligned}$$

Multiplying the second equation by $-1$ and adding the resulting equation to the first produces $-3C=1$, which in turn implies that $C=-\frac{1}{3}$. Substituting this value into the equation $B+C=1$ yields $B=\frac{4}{3}$. Thus, solving these equations yields $A=-1$, $B=\frac{4}{3}$, and $C=-\frac{1}{3}$.

It is important to note that the system produced by this method is consistent if and only if we have set up the decomposition correctly. If the system is inconsistent, there is an error in our decomposition.

### Strategy Two: Method of Strategic Substitution

The method of strategic substitution is also based on the assumption that we have set up the decomposition correctly. If the decomposition is set up correctly, then there must be values of $A$, $B$, and $C$ that satisfy Equation 7.5.2 for all values of $x$. This equation must be valid for any value of $x$ we care to substitute into it. Therefore, by choosing values of $x$ carefully and substituting them into the equation, we may find $A$, $B$, and $C$ easily.

For example, if we substitute $x=0$, the equation reduces to $2=A(-2)(1)$. Solving for $A$ yields $A=-1$. Next, by substituting $x=2$, the equation reduces to $8=B(2)(3)$, or equivalently $B=\frac{4}{3}$. Last, we substitute $x=-1$ into the equation and obtain $-1=C(-1)(-3)$. Solving, we have $C=-\frac{1}{3}$.

It is important to remember that if we attempt to use this method with a decomposition that has not been set up correctly, we can still find values for the constants, but these constants are meaningless. If we opt to use the method of strategic substitution, then it is a good idea to check the result by recombining the terms algebraically.

Now that we have the values of $A$, $B$, and $C$, we rewrite the original integral:

$$\int \frac{3x+2}{x^3-x^2-2x}\,dx = \int \left(-\frac{1}{x}+\frac{4}{3}\cdot\frac{1}{x-2}-\frac{1}{3}\cdot\frac{1}{x+1}\right)dx.$$

Evaluating the integral gives us

$$\int \frac{3x+2}{x^3-x^2-2x}\,dx = -\ln|x|+\frac{4}{3}\ln|x-2|-\frac{1}{3}\ln|x+1|+C.$$

In the next example, we integrate a rational function in which the degree of the numerator is not less than the degree of the denominator.

**Example 7.5.3: Dividing before Applying Partial Fractions**

Evaluate

$$\int \frac{x^2+3x+1}{x^2-4}\,dx.$$

**Solution**

Since $\deg(x^2+3x+1) \geq \deg(x^2-4)$, we must perform long division of polynomials. This results in

$$\frac{x^2+3x+1}{x^2-4} = 1+\frac{3x+5}{x^2-4}.$$

Next, we perform partial fraction decomposition on $\frac{3x+5}{x^2-4} = \frac{3x+5}{(x+2)(x-2)}$. We have

$$\frac{3x+5}{(x-2)(x+2)} = \frac{A}{x-2} + \frac{B}{x+2}.$$

Thus,

$$3x+5 = A(x+2) + B(x-2).$$

Solving for $A$ and $B$ using either method, we obtain $A = \frac{11}{4}$ and $B = \frac{1}{4}$.

Rewriting the original integral, we have

$$\int \frac{x^2+3x+1}{x^2-4}\,dx = \int \left(1 + \frac{11}{4}\cdot\frac{1}{x-2} + \frac{1}{4}\cdot\frac{1}{x+2}\right)dx.$$

Evaluating the integral produces

$$\int \frac{x^2+3x+1}{x^2-4}\,dx = x + \frac{11}{4}\ln|x-2| + \frac{1}{4}\ln|x+2| + C.$$

As we see in the following example, it may be possible to apply the technique of partial fraction decomposition to a nonrational function. To do so, we must first convert the nonrational function to a rational function through a substitution.

### Example 7.5.4: Applying Partial Fractions after a Substitution

Evaluate

$$\int \frac{\cos x}{\sin^2 x - \sin x}\,dx.$$

**Solution**

Let's begin by letting $u = \sin x$. Consequently, $du = \cos x\,dx$. After making these substitutions, we have

$$\int \frac{\cos x}{\sin^2 x - \sin x}\,dx = \int \frac{du}{u^2-u} = \int \frac{du}{u(u-1)}.$$

Applying partial fraction decomposition to $\frac{1}{u(u-1)}$ gives $\frac{1}{u(u-1)} = -\frac{1}{u} + \frac{1}{u-1}$.

Thus,

$$\int \frac{\cos x}{\sin^2 x - \sin x}\,dx = -\ln|u| + \ln|u-1| + C = -\ln|\sin x| + \ln|\sin x - 1| + C.$$

### Checkpoint 7.5.4

Evaluate

$$\int \frac{x+1}{(x+3)(x-2)}\,dx.$$

**Answer**

$$\frac{2}{5}\ln|x+3| + \frac{3}{5}\ln|x-2| + C$$

## Repeated Linear Factors

For some applications, we need to integrate rational expressions that have denominators with repeated linear factors - that is, rational functions with at least one factor of the form $(ax+b)^n$, where $n$ is a positive integer greater than or equal to 2. If the denominator contains the repeated linear factor $(ax+b)^n$, then the decomposition must contain

$$\frac{A_1}{ax+b} + \frac{A_2}{(ax+b)^2} + \cdots + \frac{A_n}{(ax+b)^n}. \tag{7.5.3}$$

As we see in our next example, the basic technique for solving the coefficients is the same. Still, more algebra is required to determine the numerators of the partial fractions.

### Example 7.5.5: Partial Fractions with Repeated Linear Factors

Evaluate

$$\int \frac{x-2}{(2x-1)^2(x-1)}\,dx.$$

**Solution**

We have $\deg(x-2) < \deg((2x-1)^2(x-1))$, so we can proceed with the decomposition. Since $(2x-1)^2$ is a repeated linear factor, include

$$\frac{A}{2x-1}+\frac{B}{(2x-1)^2}$$

in the decomposition in Equation 7.5.3. Thus,

$$\frac{x-2}{(2x-1)^2(x-1)}=\frac{A}{2x-1}+\frac{B}{(2x-1)^2}+\frac{C}{x-1}.$$

After multiplying both sides by the least common denominator, we have

$$x-2=A(2x-1)(x-1)+B(x-1)+C(2x-1)^2. \tag{7.5.4}$$

We then use the method of equating coefficients to find the values of $A, B$, and $C$.

$$x-2=(2A+4C)x^2+(-3A+B-4C)x+(A-B+C).$$

Equating coefficients yields $2A+4C=0$, $-3A+B-4C=1$, and $A-B+C=-2$. Solving this system yields $A=2$, $B=3$, and $C=-1$.

Alternatively, we can use the method of strategic substitution. In this case, substituting $x=1$ and $x=\frac{1}{2}$ into Equation 7.5.4 easily produces the values $B=3$ and $C=-1$. At this point, it may seem that we have run out of good choices for $x$; however, since we already have values for $B$ and $C$, we can substitute these values and choose any value for $x$ not previously used. The value $x=0$ is a good option. In this case, we obtain the equation $-2=A(-1)(-1)+3(-1)+(-1)(-1)^2$ or, equivalently, $A=2$.

Now that we have the values for $A$, $B$, and $C$, we rewrite the original integral and evaluate it:

$$\begin{aligned}\int \frac{x-2}{(2x-1)^2(x-1)}\,dx &= \int\left(\frac{2}{2x-1}+\frac{3}{(2x-1)^2}-\frac{1}{x-1}\right)dx\\ &= \ln|2x-1|-\frac{3}{2(2x-1)}-\ln|x-1|+C.\end{aligned}$$

### Checkpoint 7.5.5

Set up the partial fraction decomposition for

$$\int \frac{x+2}{(x+3)^3(x-4)^2}\,dx.$$

(Do not solve for the coefficients or complete the integration.)

**Answer**

$$\frac{x+2}{(x+3)^3(x-4)^2}=\frac{A}{x+3}+\frac{B}{(x+3)^2}+\frac{C}{(x+3)^3}+\frac{D}{(x-4)}+\frac{E}{(x-4)^2}$$

## The General Method

Now that we are beginning to understand how the partial fraction decomposition technique works let's outline the basic method in the following problem-solving strategy.

### Problem-Solving Strategy: Partial Fraction Decomposition

To decompose the rational function $\frac{P(x)}{Q(x)}$, use the following steps:

1. Make sure that $\deg(P(x)) < \deg(Q(x))$. If not, perform a long division of polynomials.
2. Factor $Q(x)$ into the product of linear and irreducible quadratic factors.[3]
3. Assuming that $\deg(P(x)) < \deg(Q(x))$, the factors of $Q(x)$ determine the form of the decomposition of $\frac{P(x)}{Q(x)}$.
   a. If $Q(x)$ can be factored as $(a_1x + b_1)(a_2x + b_2)\ldots(a_nx + b_n)$, where each linear factor is distinct, then it is possible to find constants $A_1, A_2, \ldots, A_n$ satisfying
   $$\frac{P(x)}{Q(x)} = \frac{A_1}{a_1x + b_1} + \frac{A_2}{a_2x + b_2} + \cdots + \frac{A_n}{a_nx + b_n}.$$
   b. If $Q(x)$ contains the repeated linear factor $(ax + b)^n$, then the decomposition must contain
   $$\frac{A_1}{ax + b} + \frac{A_2}{(ax + b)^2} + \cdots + \frac{A_n}{(ax + b)^n}.$$
   c. For each irreducible quadratic factor $ax^2 + bx + c$ that $Q(x)$ contains, the decomposition must include
   $$\frac{Ax + B}{ax^2 + bx + c}.$$
   d. For each repeated irreducible quadratic factor $(ax^2 + bx + c)^n$, the decomposition must include
   $$\frac{A_1x + B_1}{ax^2 + bx + c} + \frac{A_2x + B_2}{(ax^2 + bx + c)^2} + \cdots + \frac{A_nx + B_n}{(ax^2 + bx + c)^n}.$$
   e. After determining the appropriate decomposition, solve for the constants.
   f. Last, rewrite the integral in its decomposed form and evaluate it using previously developed techniques or integration formulas.

## Irreducible Quadratic Factors

Now, let's consider integrating a rational expression in which the denominator contains an irreducible quadratic factor. Recall that the quadratic $ax^2 + bx + c$ is irreducible if $ax^2 + bx + c = 0$ has no real zeros - that is, if $b^2 - 4ac$ (the discriminant) is less than $0$.

### Example 7.5.6: Rational Expressions with an Irreducible Quadratic Factor

Evaluate
$$\int \frac{2x - 3}{x^3 + x}\,dx.$$

**Solution**

Since $\deg(2x - 3) < \deg(x^3 + x)$, factor the denominator and proceed with partial fraction decomposition. In this case, $x^3 + x = x(x^2 + 1)$ contains the irreducible quadratic factor $x^2 + 1$. Therefore, we include $\frac{Ax+B}{x^2+1}$ as part of the decomposition, along with $\frac{C}{x}$ for the linear term $x$. Thus, the decomposition has the form
$$\frac{2x - 3}{x(x^2 + 1)} = \frac{Ax + B}{x^2 + 1} + \frac{C}{x}.$$

After multiplying both sides by the least common denominator, we obtain the equation
$$2x - 3 = (Ax + B)x + C(x^2 + 1).$$

Solving for $A$, $B$, and $C$, we get $A=3$, $B=2$, and $C=-3$.

Thus,

$$\frac{2x-3}{x^3+x}=\frac{3x+2}{x^2+1}-\frac{3}{x}.$$

Substituting back into the integral, we obtain

$$\begin{aligned}\int\frac{2x-3}{x^3+x}\,dx &= \int\left(\frac{3x+2}{x^2+1}-\frac{3}{x}\right)dx\\ &= 3\int\frac{x}{x^2+1}\,dx+2\int\frac{1}{x^2+1}\,dx-3\int\frac{1}{x}\,dx\\ &= \frac{3}{2}\ln\left|x^2+1\right|+2\tan^{-1}x-3\ln|x|+C.\end{aligned}$$

Note: We may rewrite $\ln\left|x^2+1\right|=\ln(x^2+1)$, if we wish to do so, since $x^2+1>0$; however, this is not required.

## Example 7.5.7: Partial Fractions with an Irreducible Quadratic Factor

Evaluate

$$\int\frac{dx}{x^3-8}.$$

**Solution**

We can start by factoring $x^3-8=(x-2)(x^2+2x+4)$. We see that the quadratic factor $x^2+2x+4$ is irreducible since $2^2-4(1)(4)=-12<0$. Using the decomposition described in the problem-solving strategy, we get

$$\frac{1}{(x-2)(x^2+2x+4)}=\frac{A}{x-2}+\frac{Bx+C}{x^2+2x+4}.$$

Multiplying both sides by the LCD, we arrive at

$$1=A(x^2+2x+4)+(Bx+C)(x-2).$$

Applying either method to find the constants, we get $A=\frac{1}{12}$, $B=-\frac{1}{12}$, and $C=-\frac{1}{3}$.

Rewriting $\int\frac{dx}{x^3-8}$, we have

$$\int\frac{dx}{x^3-8}=\frac{1}{12}\int\frac{1}{x-2}\,dx-\frac{1}{12}\int\frac{x+4}{x^2+2x+4}\,dx.$$

We can see that

$$\int\frac{1}{x-2}\,dx=\ln|x-2|+C,$$

but

$$\int\frac{x+4}{x^2+2x+4}\,dx$$

requires a bit more effort. Let's begin by completing the square on $x^2+2x+4$ to obtain

$$x^2+2x+4=(x+1)^2+3.$$

By letting $u=x+1$ and consequently $du=dx$, we see that

$$\begin{aligned}\int \frac{x+4}{x^2+2x+4}\,dx &= \int \frac{x+4}{(x+1)^2+3}\,dx \\ &= \int \frac{u+3}{u^2+3}\,du \\ &= \int \frac{u}{u^2+3}\,du + \int \frac{3}{u^2+3}\,du \\ &= \frac{1}{2}\ln\left|u^2+3\right| + \frac{3}{\sqrt{3}}\tan^{-1}\left(\frac{u}{\sqrt{3}}\right) + C \\ &= \frac{1}{2}\ln\left|x^2+2x+4\right| + \sqrt{3}\tan^{-1}\left(\frac{x+1}{\sqrt{3}}\right) + C\end{aligned}$$

Substituting back into the original integral and simplifying gives

$$\int \frac{dx}{x^3-8} = \frac{1}{12}\ln|x-2| - \frac{1}{24}\ln|x^2+2x+4| - \frac{\sqrt{3}}{12}\tan^{-1}\left(\frac{x+1}{\sqrt{3}}\right) + C.$$

Here again, we can drop the absolute value if we wish to do so, since $x^2+2x+4>0$ for all $x$.

### Example 7.5.8: Finding a Volume

Find the volume of the solid of revolution obtained by revolving the region enclosed by the graph of $f(x)=\frac{x^2}{(x^2+1)^2}$ and the $x$-axis over the interval $[0,1]$ about the $y$-axis.

**Solution**

Let's begin by sketching the region to be revolved (see Figure 7.5.1). The sketch shows that the shell method is a good choice for solving this problem.

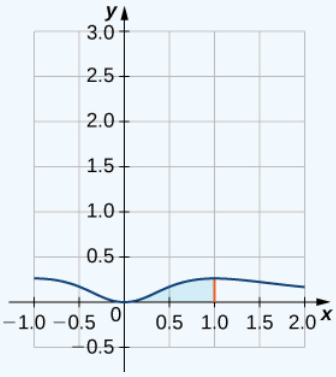

Figure 7.5.1: We can use the shell method to find the volume of revolution obtained by revolving the region shown about the $y$-axis.

The volume is given by

$$V = 2\pi\int_0^1 x\cdot\frac{x^2}{(x^2+1)^2}\,dx = 2\pi\int_0^1 \frac{x^3}{(x^2+1)^2}\,dx.$$

Since $\deg((x^2+1)^2)=4>3=\deg(x^3)$, we can proceed with partial fraction decomposition. Note that $(x^2+1)^2$ is a repeated irreducible quadratic. Using the decomposition described in the problem-solving strategy, we get

$$\frac{x^3}{(x^2+1)^2} = \frac{Ax+B}{x^2+1} + \frac{Cx+D}{(x^2+1)^2}.$$

Multiplying both sides by the LCD gives

$$x^3 = (Ax + B)(x^2 + 1) + Cx + D.$$

Solving, we obtain $A = 1$, $B = 0$, $C = -1$, and $D = 0$. Substituting back into the integral, we have

$$V = 2\pi \int_0^1 \frac{x^3}{(x^2+1)^2}\,dx = 2\pi \int_0^1 \left(\frac{x}{x^2+1} - \frac{x}{(x^2+1)^2}\right) dx = 2\pi \left(\frac{1}{2}\ln(x^2+1) + \frac{1}{2}\cdot\frac{1}{x^2+1}\right)\Big|_0^1 = \pi\left(\ln 2 - \tfrac{1}{2}\right).$$

**? Checkpoint 7.5.8**

Set up the partial fraction decomposition for

$$\int \frac{x^2+3x+1}{(x+2)(x-3)^2(x^2+4)^2}\,dx.$$

**Answer**

$$\frac{x^2+3x+1}{(x+2)(x-3)^2(x^2+4)^2} = \frac{A}{x+2} + \frac{B}{x-3} + \frac{C}{(x-3)^2} + \frac{Dx+E}{x^2+4} + \frac{Fx+G}{(x^2+4)^2}$$

## Footnotes

[1] Visit this website for a review of long division of polynomials.

[2] The proof that such constants exist is beyond the scope of this course.

[3] An irreducible quadratic is a quadratic that has no real zeros.

# 7.5E: Exercises

## Reading Questions

1. What condition must be met regarding the degrees of the numerator and denominator of a rational function before you can apply the method of partial fraction decomposition? What must you do if this condition is not met?
2. If the denominator of a rational function contains the nonrepeated linear factor $(x-3)$, what is the corresponding term in its partial fraction decomposition?
3. If the denominator contains the repeated linear factor $(x+5)^3$, what three terms must be included in the decomposition corresponding to this factor?
4. If the denominator contains the irreducible quadratic factor $(x^2+x+1)$, what is the form of the corresponding term in the decomposition?
5. What are the two algebraic strategies mentioned in the text for finding the unknown constants in a partial fraction decomposition?
6. What algebraic technique is often required to integrate a term with an irreducible quadratic factor in the denominator?

**Use partial fraction decomposition (or a simpler technique) to express the rational function as a sum or difference of two or more simpler rational expressions.**

1) $\dfrac{1}{(x-3)(x-2)}$

2) $\dfrac{x^2+1}{x(x+1)(x+2)}$

**Answer**

$$\frac{x^2+1}{x(x+1)(x+2)} = -\frac{2}{x+1}+\frac{5}{2(x+2)}+\frac{1}{2x}$$

3) $\dfrac{1}{x^3-x}$

4) $\dfrac{3x+1}{x^2}$

**Answer**

$$\frac{3x+1}{x^2} = \frac{1}{x^2}+\frac{3}{x}$$

5) $\dfrac{3x^2}{x^2+1}$ (Hint: Use long division first.)

6) $\dfrac{2x^4}{x^2-2x}$

**Answer**

$$\frac{2x^4}{x^2-2x} = 2x^2+4x+8+\frac{16}{x-2}$$

7) $\dfrac{1}{(x-1)(x^2+1)}$

8) $\dfrac{1}{x^2(x-1)}$

**Answer**

$$\frac{1}{x^2(x-1)} = -\frac{1}{x^2}-\frac{1}{x}+\frac{1}{x-1}$$

9) $\dfrac{x}{x^2-4}$

10) $\dfrac{1}{x(x-1)(x-2)(x-3)}$

**Answer**

**Answer**

$$\frac{1}{x(x-1)(x-2)(x-3)} = -\frac{1}{2(x-2)} + \frac{1}{2(x-1)} - \frac{1}{6x} + \frac{1}{6(x-3)}$$

11) $\dfrac{1}{x^4-1} = \dfrac{1}{(x+1)(x-1)(x^2+1)}$

12) $\dfrac{3x^2}{x^3-1} = \dfrac{3x^2}{(x-1)(x^2+x+1)}$

**Answer**

$$\frac{3x^2}{x^3-1} = \frac{1}{x-1} + \frac{2x+1}{x^2+x+1}$$

13) $\dfrac{2x}{(x+2)^2}$

14) $\dfrac{3x^4+x^3+20x^2+3x+31}{(x+1)(x^2+4)^2}$

**Answer**

$$\frac{3x^4+x^3+20x^2+3x+31}{(x+1)(x^2+4)^2} = \frac{2}{x+1} + \frac{x}{x^2+4} - \frac{1}{(x^2+4)^2}$$

**In exercises 15 - 25, use the method of partial fractions to evaluate each of the following integrals.**

15) $\displaystyle\int \frac{dx}{(x-3)(x-2)}$

16) $\displaystyle\int \frac{3x}{x^2+2x-8}\,dx$

**Answer**

$$\int \frac{3x}{x^2+2x-8}\,dx = 2\ln|x+4| + \ln|x-2| + C = \ln\left|(x+4)^2(x-2)\right| + C$$

17) $\displaystyle\int \frac{dx}{x^3-x}$

18) $\displaystyle\int \frac{x}{x^2-4}\,dx$

**Answer**

Note that you don't need Partial Fractions here. We use a simple $u$-substitution.

$$\int \frac{x}{x^2-4}\,dx = \tfrac{1}{2}\ln|4-x^2| + C$$

19) $\displaystyle\int \frac{dx}{x(x-1)(x-2)(x-3)}$

20) $\displaystyle\int \frac{2x^2+4x+22}{x^2+2x+10}\,dx$

**Answer**

Note that since the degree of the numerator is equal to the degree of the denominator, we need to start with long division. Then note that we will need to use completing the square to continue since we cannot factor the trinomial in the denominator.

$$\int \frac{2x^2+4x+22}{x^2+2x+10}\,dx = 2\left(x + \tfrac{1}{3}\arctan\left(\frac{1+x}{3}\right)\right) + C$$

21) $\displaystyle\int \frac{dx}{x^2-5x+6}$

22) $\displaystyle\int \frac{2-x}{x^2+x}\,dx$

**Answer**

$$\int \frac{2-x}{x^2+x}\,dx = 2\ln|x| - 3\ln|1+x| + C = \ln\left|\frac{x^2}{(1+x)^3}\right| + C$$

23) $\int \frac{2}{x^2-x-6}\,dx$

24) $\int \frac{dx}{x^3-2x^2-4x+8}$

**Answer**

$$\int \frac{dx}{x^3-2x^2-4x+8} \quad = \quad \tfrac{1}{16}\left(-\frac{4}{-2+x}-\ln|-2+x|+\ln|2+x|\right)+C = \tfrac{1}{16}\left(-\frac{4}{-2+x}+\ln\left|\frac{x+2}{x-2}\right|\right)+C$$

25) $\int \frac{dx}{x^4-10x^2+9}$

**In exercises 26 - 29, evaluate the integrals with irreducible quadratic factors in the denominators.**

26) $\int \frac{2}{(x-4)(x^2+2x+6)}\,dx$

**Answer**

$$\int \frac{2}{(x-4)(x^2+2x+6)}\,dx \quad = \quad \tfrac{1}{30}(-2\sqrt{5}\arctan\left[\frac{1+x}{\sqrt{5}}\right]+2\ln|-4+x|-\ln|6+2x+x^2|)+C$$

27) $\int \frac{x^2}{x^3-x^2+4x-4}\,dx$

28) $\int \frac{x^3+6x^2+3x+6}{x^3+2x^2}\,dx$

**Answer**

Note that we need to use long division first, since the degree of the numerator is greater than the degree of the denominator.

$$\int \frac{x^3+6x^2+3x+6}{x^3+2x^2}\,dx \quad = \quad -\frac{3}{x}+4\ln|x+2|+x+C$$

29) $\int \frac{x}{(x-1)(x^2+2x+2)^2}\,dx$

**In exercises 30 - 32, use the method of partial fractions to evaluate the integrals.**

30) $\int \frac{3x+4}{(x^2+4)(3-x)}\,dx$

**Answer**

$$\int \frac{3x+4}{(x^2+4)(3-x)}\,dx \quad = \quad -\ln|3-x|+\tfrac{1}{2}\ln|x^2+4|+C$$

31) $\int \frac{2}{(x+2)^2(2-x)}\,dx$

32) $\int \frac{3x+4}{x^3-2x-4}\,dx$ (Hint: Use the rational root theorem.)

**Answer**

$$\int \frac{3x+4}{x^3-2x-4}\,dx \quad = \quad \ln|x-2|-\tfrac{1}{2}\ln|x^2+2x+2|+C$$

**In exercises 33 - 46, use substitution to convert the integrals to integrals of rational functions. Then use partial fractions to evaluate the integrals.**

33) $\int_0^1 \frac{e^x}{36-e^{2x}}\,dx$ (Give the exact answer and the decimal equivalent. Round to five decimal places.)

34) $\int \frac{e^x\,dx}{e^{2x}-e^x}\,dx$

**Answer**

$$\int \frac{e^x\,dx}{e^{2x}-e^x}\,dx \quad = \quad -x+\ln|1-e^x|+C$$

35) $\int \frac{\sin x\,dx}{1-\cos^2 x}$

36) $\int \frac{\sin x}{\cos^2 x+\cos x-6}\,dx$

**Answer**

$$\int \frac{\sin x}{\cos^2 x+\cos x-6}\,dx \quad = \quad \tfrac{1}{5}\ln\left|\frac{\cos x+3}{\cos x-2}\right|+C$$

37) $\int \frac{1-\sqrt{x}}{1+\sqrt{x}}\,dx$

38) $\int \frac{dt}{(e^t-e^{-t})^2}$

**Answer**

$$\int \frac{dt}{(e^t-e^{-t})^2} \quad = \quad \frac{1}{2-2e^{2t}}+C$$

39) $\int \frac{1+e^x}{1-e^x}\,dx$

40) $\int \frac{dx}{1+\sqrt{x+1}}$

**Answer**

$$\int \frac{dx}{1+\sqrt{x+1}} \quad = \quad 2\sqrt{1+x}-2\ln|1+\sqrt{1+x}|+C$$

41) $\int \frac{dx}{\sqrt{x}+\sqrt[4]{x}}$

42) $\int \frac{\cos x}{\sin x(1-\sin x)}\,dx$

**Answer**

$$\int \frac{\cos x}{\sin x(1-\sin x)}\,dx \quad = \quad \ln\left|\frac{\sin x}{1-\sin x}\right|+C$$

43) $\int \frac{e^x}{(e^{2x}-4)^2}\,dx$

44) $\int_1^2 \frac{1}{x^2\sqrt{4-x^2}}\,dx$

**Answer**

$$\int_1^2 \frac{1}{x^2\sqrt{4-x^2}}\,dx \quad = \quad \frac{\sqrt{3}}{4}$$

45) $\int \frac{1}{2+e^{-x}}\,dx$

46) $\int \frac{1}{1+e^x}\,dx$

**Answer**

$$\int \frac{1}{1+e^x}\,dx \quad = \quad x-\ln(1+e^x)+C$$

**In exercises 47 - 48, use the given substitution to convert the integral to an integral of a rational function, then evaluate.**

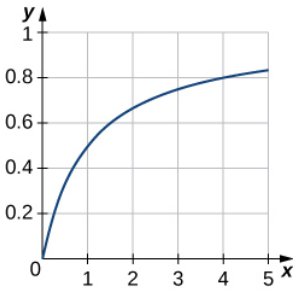
47) $\int \frac{1}{t-\sqrt[3]{t}}\,dt; \quad t=x^3$

48) $\int \frac{1}{\sqrt{x}+\sqrt[3]{x}}\,dx; \quad x=u^6$

**Answer**

$$\int \frac{1}{\sqrt{x}+\sqrt[3]{x}}\,dx \quad = \quad 6x^{1/6}-3x^{1/3}+2\sqrt{x}-6\ln(1+x^{1/6})+C$$

49) Graph the curve $y=\dfrac{x}{1+x}$ over the interval $[0,5]$. Then, find the area of the region bounded by the curve, the $x$-axis, and the line $x=4$.



50) Find the volume of the solid generated when the region bounded by $y=\dfrac{1}{\sqrt{x(3-x)}}$, $y=0$, $x=1$, and $x=2$ is revolved about the $x$-axis.

**Answer**

$V=\frac{4}{3}\pi\text{arctanh}\,\left[\frac{1}{3}\right]=\frac{1}{3}\pi\ln 4\,\text{units}^3$

51) The velocity of a particle moving along a line is a function of time given by $v(t)=\dfrac{88t^2}{t^2+1}$. Find the distance that the particle has traveled after $t=5$ sec.

**In exercises 52 - 54, solve the initial-value problem for $x$ as a function of $t$.**

52) $(t^2-7t+12)\dfrac{dx}{dt}=1, \quad t>4,\ x(5)=0$

**Answer**

$x=-\ln|t-3|+\ln|t-4|+\ln 2=\ln\left|\dfrac{2(t-4)}{t-3}\right|$

53) $(t+5)\dfrac{dx}{dt}=x^2+1, \quad t>-5,\ x(1)=\tan 1$

54) $(2t^3-2t^2+t-1)\dfrac{dx}{dt}=3, \quad x(2)=0$

**Answer**

$x=\ln|t-1|-\sqrt{2}\arctan(\sqrt{2}t)-\frac{1}{2}\ln(t^2+\frac{1}{2})+\sqrt{2}\arctan(2\sqrt{2})+\frac{1}{2}\ln 4.5$

55) Find the $x$-coordinate of the centroid of the area bounded by $y(x^2-9)=1$, $y=0$, $x=4$, and $x=5$. (Round the answer to two decimal places.)

56) Find the volume generated by revolving the area bounded by $y=\dfrac{1}{x^3+7x^2+6x}$, $x=1$, $x=7$, and $y=0$ about the $y$-axis.

**Answer**

$V=\frac{2}{5}\pi\ln\frac{28}{13}\,\text{units}^3$

57) Find the area bounded by $y=\dfrac{x-12}{x^2-8x-20}$, $y=0$, $x=2$, and $x=4$. (Round the answer to the nearest hundredth.)

58) Evaluate the integral $\displaystyle\int\frac{dx}{x^3+1}$.

**Answer**

$$\int\frac{dx}{x^3+1} \quad = \quad \frac{\arctan[\frac{-1+2x}{\sqrt{3}}]}{\sqrt{3}}+\frac{1}{3}\ln|1+x|-\frac{1}{6}\ln|\,1-x+x^2\,|+C$$

**For problems 59 - 62, use the substitutions $\tan\left(\frac{x}{2}\right)=t$, $dx=\frac{2}{1+t^2}\,dt$, $\sin x=\frac{2t}{1+t^2}$, and $\cos x=\frac{1-t^2}{1+t^2}$.**

59) $\int \frac{dx}{3-5\sin x}$

60) Find the area under the curve $y=\frac{1}{1+\sin x}$ between $x=0$ and $x=\pi$. (Assume the dimensions are in inches.)

**Answer**

2.0 in.$^2$

61) Given $\tan\left(\frac{x}{2}\right)=t$, derive the formulas $dx=\frac{2}{1+t^2}dt$, $\sin x=\frac{2t}{1+t^2}$, and $\cos x=\frac{1-t^2}{1+t^2}$.

62) Evaluate $\int \frac{\sqrt[3]{x-8}}{x}\,dx$.

**Answer**

$$\int \frac{\sqrt[3]{x-8}}{x}\,dx = 3(-8+x)^{1/3}-2\sqrt{3}\arctan\left[\frac{-1+(-8+x)^{1/3}}{\sqrt{3}}\right]-2\ln\left[2+(-8+x)^{1/3}\right]$$
$$+\ln\left[4-2(-8+x)^{1/3}+(-8+x)^{2/3}\right]+C$$

# 7.6: Numerical Integration

**Note to the Instructor (click to expand)**

We finally get to the final frontier of integration techniques. All of this is core content for Calculus II.

---

To succeed in this section, you'll need to use some skills from previous courses. While you should already know them, this is the first time they've been required. You can review these skills in CRC's Corequisite Codex. If you have a support class, it might cover some, **but not all**, of these topics.

**Prerequisite Skills and Support Topics (click to expand)**

- **Graphing Functions**
  - Local and Absolute Extrema: Finding the error bounds for the Midpoint, Trapezoidal, and Simpson's Rules requires finding the absolute maximum value of a function's second or fourth derivative over a closed interval

---

The following is a list of learning objectives for this section.

**Learning Objectives (click to expand)**

- Approximate the value of a definite integral by using the Midpoint and Trapezoidal Rules.
- Determine the absolute and relative error in using a numerical integration technique.
- Estimate the absolute and relative error using an error-bound formula.
- Recognize when the midpoint and Trapezoidal Rules over- or underestimate the true value of an integral.
- Use Simpson's Rule to approximate the value of a definite integral to a given accuracy.

Hawk A.I. Section-Specific Tutor

To access the Hawk A.I. Tutor, you will need to be logged into your campus Gmail account.

The antiderivatives of many functions either cannot be expressed or cannot be expressed easily in **closed form** (that is, in terms of known functions). Consequently, rather than directly evaluating definite integrals of these functions, we resort to various **numerical integration** techniques to approximate their values. In this section, we explore several of these techniques. In addition, we examine the process of estimating the error when using these techniques.

## The Midpoint Rule

Earlier in this text, we defined the definite integral of a function over an interval as the limit of Riemann sums. In general, any Riemann sum of a function $f(x)$ over an interval $[a, b]$ may be viewed as an estimate of $\int_a^b f(x)\,dx$. Recall that a Riemann sum of a function $f(x)$ over an interval $[a, b]$ is obtained by selecting a partition

$$P = \{x_0, x_1, x_2, \ldots, x_n\},$$

where $a = x_0 < x_1 < x_2 < \cdots < x_n = b$, and a set

$$S = \{x_1^*, x_2^*, \ldots, x_n^*\},$$

where $x_{i-1} \le x_i^* \le x_i$ **for all** $i = 1, 2, \ldots, n$.

The Riemann sum corresponding to the partition $P$ and the set $S$ is given by

$$\sum_{i=1}^{n} f(x_i^*)\Delta x_i,$$

where $\Delta x_i = x_i - x_{i-1}$ is the length of the $i^{\text{th}}$ subinterval.

In Differential Calculus, we learned the Left Endpoint and Right Endpoint approximation methods for estimating the value of a definite integral. The **Midpoint Rule** for estimating the value of a definite integral uses a Riemann sum with subintervals of equal width and the midpoints, $m_i$, of each subinterval in place of $x_i^*$. Formally, we state a theorem regarding the convergence of the Midpoint Rule as follows.

### Theorem: Midpoint Rule

Let $f(x)$ be continuous on $[a, b]$, $n$ be a positive integer, and $\Delta x = \frac{b-a}{n}$. If $[a, b]$ is divided into $n$ subintervals, each of length $\Delta x$, and $m_i = \frac{x_{i-1}+x_i}{2}$ is the midpoint of the $i^{\text{th}}$ subinterval, set

$$M_n = \sum_{i=1}^{n} f(m_i)\Delta x = \sum_{i=1}^{n} f\left(\frac{x_{i-1}+x_i}{2}\right)\Delta x.$$

Then

$$\lim_{n\to\infty} M_n = \int_a^b f(x)\,dx.$$

As we can see in Figure 7.6.1, if $f(x) \geq 0$ over $[a, b]$, then $\sum_{i=1}^{n} f(m_i)\Delta x$ corresponds to the sum of the areas of rectangles approximating the area between the graph of $f(x)$ and the $x$-axis over $[a, b]$. The graph shows the rectangles corresponding to $M_4$ for a nonnegative function over a closed interval $[a, b]$.

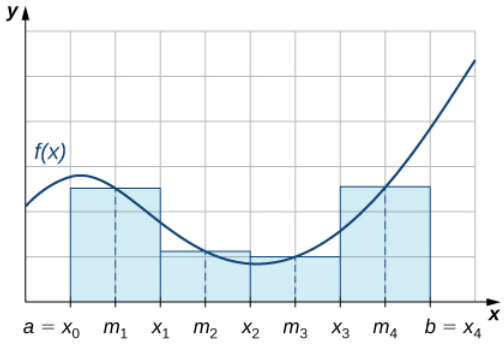

Figure 7.6.1: The Midpoint Rule approximates the area between the graph of $f(x)$ and the $x$-axis by summing the areas of rectangles with midpoints that are points on $f(x)$.

If we are lucky enough to know the exact value of a definite integral, then we can define the absolute error of an estimation as follows:

### Definition: Absolute Error

The **absolute error**, $E_*$, of a numerical approximation, $A$, to the true value of the quantity, $T$, is defined to be

$$E_* = |T - A|.$$

The notation "$*$" is reserved for the method being used. For example, the absolute error if using the Midpoint Rule with $n = 10$ to approximate the value of a definite integral is

$$E_M = |T - M_{10}|.$$

## Example 7.6.1: Using the Midpoint Rule with $M_4$

Use the Midpoint Rule to estimate

$$\int_0^1 x^2\,dx$$

using four subintervals. Compare the result with the actual value of this integral.

**Solution**

Each subinterval has length $\Delta x = \frac{1-0}{4} = \frac{1}{4}$. Therefore, the subintervals consist of

$$\left[0, \frac{1}{4}\right], \left[\frac{1}{4}, \frac{1}{2}\right], \left[\frac{1}{2}, \frac{3}{4}\right], \text{and } \left[\frac{3}{4}, 1\right].$$

The midpoints of these subintervals are $\left\{\frac{1}{8}, \frac{3}{8}, \frac{5}{8}, \frac{7}{8}\right\}$. Thus,

$$\begin{aligned} M_4 &= \frac{1}{4}\cdot f\left(\frac{1}{8}\right) + \frac{1}{4}\cdot f\left(\frac{3}{8}\right) + \frac{1}{4}\cdot f\left(\frac{5}{8}\right) + \frac{1}{4}\cdot f\left(\frac{7}{8}\right) \\ &= \frac{1}{4}\cdot\frac{1}{64} + \frac{1}{4}\cdot\frac{9}{64} + \frac{1}{4}\cdot\frac{25}{64} + \frac{1}{4}\cdot\frac{49}{64} \\ &= \frac{21}{64} \\ &= 0.328125. \end{aligned}$$

Since the true value of this definite integral is

$$T = \int_0^1 x^2\,dx = \frac{1}{3},$$

the absolute error in this approximation is

$$E_M = |T - M_4| = \left|\frac{1}{3} - \frac{21}{64}\right| = \frac{1}{192} \approx 0.0052,$$

and we see that the Midpoint Rule produces an estimate that is somewhat close to the actual value of the definite integral.

## Example 7.6.2: Using the Midpoint Rule with $M_6$

Use $M_6$ to estimate the length of the curve

$$y = \frac{1}{2}x^2,$$

on $[1, 4]$.

**Solution**

The length of $y = \frac{1}{2}x^2$ on $[1, 4]$ is

$$s = \int_1^4 \sqrt{1 + \left(\frac{dy}{dx}\right)^2}\,dx.$$

Since $\frac{dy}{dx} = x$, this integral becomes $\int_1^4 \sqrt{1 + x^2}\,dx$.

If $[1, 4]$ is divided into six subintervals, then each subinterval has length $\Delta x = \frac{4-1}{6} = \frac{1}{2}$. The midpoints of the subintervals are $\left\{\frac{5}{4}, \frac{7}{4}, \frac{9}{4}, \frac{11}{4}, \frac{13}{4}, \frac{15}{4}\right\}$. If we set $f(x) = \sqrt{1 + x^2}$, we get

$$\begin{aligned} M_6 &= \frac{1}{2}\cdot f\left(\frac{5}{4}\right)+\frac{1}{2}\cdot f\left(\frac{7}{4}\right)+\frac{1}{2}\cdot f\left(\frac{9}{4}\right)+\frac{1}{2}\cdot f\left(\frac{11}{4}\right)+\frac{1}{2}\cdot f\left(\frac{13}{4}\right)+\frac{1}{2}\cdot f\left(\frac{15}{4}\right) \\ &\approx \frac{1}{2}(1.6008+2.0156+2.4622+2.9262+3.4004+3.8810) \\ &= 8.1431 \text{ units.} \end{aligned}$$

**? Checkpoint 7.6.2**

Use $M_2$ to estimate

$$\int_1^2 \frac{1}{x}\,dx.$$

**Answer**

$\frac{24}{35} \approx 0.685714$

## The Trapezoidal Rule

We can also approximate the value of a definite integral by using trapezoids rather than rectangles (see Figure 7.6.2).

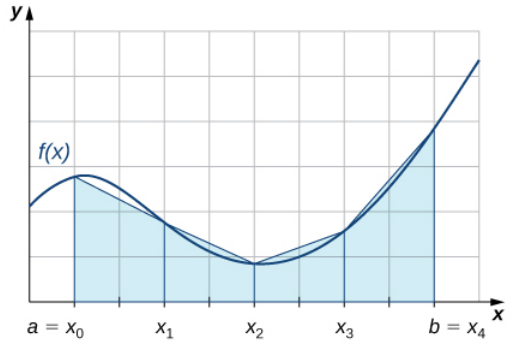

Figure 7.6.2: Trapezoids may be used to approximate the area under a curve, hence approximating the definite integral.

The **Trapezoidal Rule** for estimating definite integrals uses trapezoids rather than rectangles to approximate the area under a curve. Consider the trapezoids in Figure 7.6.2 to gain insight into the rule's final form. We assume that the length of each subinterval is given by $\Delta x$. First, recall that the area of a trapezoid with a height of $h$ and bases of length $b_1$ and $b_2$ is given by

$$\text{Area} = \frac{1}{2}h(b_1+b_2).$$

We see that the first trapezoid has a "height" $\Delta x$ and parallel "bases" of length $f(x_0)$ and $f(x_1)$. Thus, the area of the first trapezoid in Figure 7.6.2 is

$$\frac{1}{2}\Delta x\left(f(x_0)+f(x_1)\right).$$

The areas of the remaining three trapezoids are

$$\frac{1}{2}\Delta x\left(\left(f(x_1)+f(x_2)\right)\right),\ \frac{1}{2}\Delta x\left(f(x_2)+f(x_3)\right),\ \text{and}\ \frac{1}{2}\Delta x\left(f(x_3)+f(x_4)\right).$$

Consequently,

$$\begin{aligned} &\int_a^b f(x)\,dx \\ &\approx \frac{1}{2}\Delta x\left(f(x_0)+f(x_1)\right)+\frac{1}{2}\Delta x\left(f(x_1)+f(x_2)\right)+\frac{1}{2}\Delta x\left(f(x_2)+f(x_3)\right)+\frac{1}{2}\Delta x\left(f(x_3)+f(x_4)\right). \end{aligned}$$

After taking out a common factor of $\frac{1}{2}\Delta x$ and combining like terms, we have

$$\int_a^b f(x)\,dx \approx \frac{\Delta x}{2}\left[f(x_0)+2f(x_1)+2f(x_2)+2f(x_3)+f(x_4)\right].$$

Generalizing, we formally state the following rule.

**Theorem: The Trapezoidal Rule**

Let $f(x)$ be continuous over $[a,b]$, $n$ be a positive integer, and $\Delta x = \frac{b-a}{n}$. If $[a,b]$ is divided into $n$ subintervals, each of length $\Delta x$, with endpoints at $P = \{x_0, x_1, x_2, \ldots, x_n\}$, set

$$T_n = \frac{\Delta x}{2}\left[f(x_0)+2f(x_1)+2f(x_2)+\cdots+2f(x_{n-1})+f(x_n)\right].$$

Then,

$$\lim_{n\to\infty} T_n = \int_a^b f(x)\,dx.$$

Before continuing, let's make a few observations about the Trapezoidal Rule. First of all, it is useful to note that

$$T_n = \frac{1}{2}(L_n + R_n), \text{ where } L_n = \sum_{i=1}^{n} f(x_{i-1})\Delta x \text{ and } R_n = \sum_{i=1}^{n} f(x_i)\Delta x.$$

That is, the Trapezoidal Rule is the average of the Left Endpoint Approximation, $L_n$, and the Right Endpoint Approximation, $R_n$. In addition, a careful examination of Figure **7.6.3** (see below) leads us to make the following observations about using the Trapezoidal Rules and Midpoint Rules to estimate the definite integral of a nonnegative function. The Trapezoidal Rule tends to overestimate the value of a definite integral systematically over intervals where the function is concave up and to underestimate the value systematically over intervals where the function is concave down. On the other hand, the Midpoint Rule averages out these errors somewhat by partially overestimating and underestimating the value of the definite integral over these same types of intervals. This leads us to hypothesize that, in general, the Midpoint Rule tends to be more accurate than the Trapezoidal Rule.

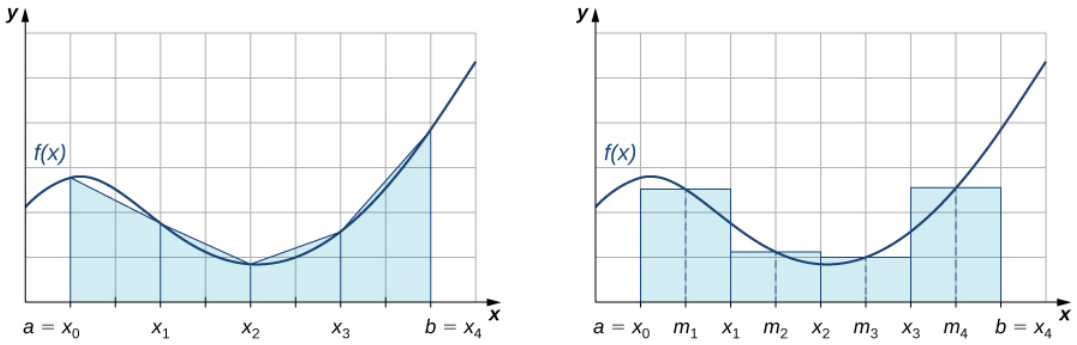

Figure **7.6.3**: The Trapezoidal Rule tends to be less accurate than the Midpoint Rule.

**Example 7.6.3: Using the Trapezoidal Rule**

Use the Trapezoidal Rule to estimate

$$\int_0^1 x^2\,dx$$

using four subintervals.

**Solution**

The endpoints of the subintervals consist of elements of the set $P = \{0, \frac{1}{4}, \frac{1}{2}, \frac{3}{4}, 1\}$ and $\Delta x = \frac{1-0}{4} = \frac{1}{4}$. Thus,

$$\begin{aligned}\int_0^1 x^2\,dx &\approx \frac{1}{2}\cdot\frac{1}{4}\left[f(0)+2f\left(\frac{1}{4}\right)+2f\left(\frac{1}{2}\right)+2f\left(\frac{3}{4}\right)+f(1)\right]\\ &= \frac{1}{8}\left(0+2\cdot\frac{1}{16}+2\cdot\frac{1}{4}+2\cdot\frac{9}{16}+1\right)\\ &= \frac{11}{32}\\ &= 0.34375\end{aligned}$$

**Checkpoint 7.6.3**

Use $T_2$ to estimate

$$\int_1^2 \frac{1}{x}\,dx.$$

**Answer**

$\frac{17}{24} \approx 0.708333$

## Absolute and Relative Error

An important aspect to consider when using numerical integration techniques is calculating their errors from the true value of their associated definite integrals. As mentioned, a method's absolute error is given by

$$E_* = |T - A|\,.$$

Another important measure is the **relative error** of an approximation.

**Definition: Relative Error**

The **relative error** of an approximation is the error as a percentage of the actual value and is given by

$$\left|\frac{T - A_*}{T}\right| \cdot 100\% = \frac{E_*}{|T|} \cdot 100\%.$$

**Example 7.6.4: Calculating Error in the Midpoint Rule**

Calculate the relative error in the estimate of $\int_0^1 x^2\,dx$ using the Midpoint Rule, found in Example 7.6.1.

**Solution**

We computed the absolute error to be $E_M = \frac{1}{192} \approx 0.0052$. Therefore, the relative error is

$$\left|\frac{T - M_4}{T}\right| = \frac{E_M}{|T|} = \frac{1/192}{1/3} = \frac{1}{64} \approx 0.015625 \approx 1.6\%.$$

**Example 7.6.5: Calculating Error in the Trapezoidal Rule**

Calculate the absolute and relative error in the estimate of $\int_0^1 x^2\,dx$ using the Trapezoidal Rule, found in Example 7.6.3.

**Solution**

The true value is $\int_0^1 x^2\,dx = \frac{1}{3}$, and our estimate from the example is $T_4 = \frac{11}{32}$. Thus, the absolute error is given by

$$E_T = |T - T_4| = \left|\frac{1}{3} - \frac{11}{32}\right| = \frac{1}{96} \approx 0.0104.$$

The relative error is given by

$$\left|\frac{T - T_4}{T}\right| = \frac{E_T}{|T|} = \frac{1/96}{1/3} = 0.03125 \approx 3.1\%.$$

**? Checkpoint 7.6.5**

In an earlier checkpoint, we estimated $\int_1^2 \frac{1}{x}\,dx$ to be $\frac{24}{35}$ using $M_2$. The actual value of this integral is $\ln 2$. Using $\frac{24}{35} \approx 0.6857$ and $\ln 2 \approx 0.6931$, calculate the absolute error and the relative error.

**Answer**

The absolute error is $\approx 0.0074$, and the relative error is $\approx 1.1\%$.

## Error Bounds on the Midpoint and Trapezoidal Rules

In the two previous examples, we could compare our estimate of an integral with the actual value of the integral; however, we do not typically have this luxury. In general, if we are approximating an integral, we are doing so because we cannot easily compute the exact value of the integral. Therefore, determining an upper bound for the error in an approximation of an integral is often helpful. The following theorem provides error bounds for the Midpoint and Trapezoidal Rules. The theorem is stated without proof.[1]

**Theorem: Error Bounds for the Midpoint and Trapezoidal Rules**

Let $f(x)$ be a continuous function over $[a, b]$, where $f''(x)$ exists over this same interval interval. If $M$ is the maximum value of $|f''(x)|$ over $[a, b]$, then the upper bounds for the error in using $M_n$ and $T_n$ to estimate $\int_a^b f(x)\,dx$ are

$$E_M \le \frac{M(b-a)^3}{24n^2} \tag{7.6.1}$$

and

$$E_T \le \frac{M(b-a)^3}{12n^2}. \tag{7.6.2}$$

We can use these bounds to determine the value of $n$ necessary to guarantee that the error in an estimate is less than a specified value.

**✓ Example 7.6.6: Determining the Number of Intervals to Use**

What value of $n$ should be used to guarantee that an estimate of

$$\int_0^1 e^{x^2}\,dx$$

is accurate to within $0.01$ if we use the Midpoint Rule?

**Solution**

We begin by determining the value of $M$, the maximum value of $|f''(x)|$ over $[0, 1]$ for $f(x) = e^{x^2}$.

Since $f'(x) = 2xe^{x^2}$, we have

$$f''(x) = 2e^{x^2} + 4x^2e^{x^2}.$$

Thus,

$$|f''(x)| = 2e^{x^2}(1+2x^2) \le 2 \cdot e \cdot 3 = 6e.$$

From the error-bound Equation 7.6.1, we have

$$E_M \le \frac{M(b-a)^3}{24n^2} \le \frac{6e(1-0)^3}{24n^2} = \frac{6e}{24n^2}.$$

Now we solve the following inequality for $n$:

$$\frac{6e}{24n^2} \le 0.01.$$

Thus, $n \ge \sqrt{\frac{600e}{24}} \approx 8.24$. Since $n$ must be an *integer* satisfying this inequality, a choice of $n = 9$ would guarantee that

$$E_M = |T - M_n| = \left| \int_0^1 e^{x^2}\,dx - M_n \right| < 0.01.$$

**Analysis**

We might have been tempted to round $8.24$ down and choose $n = 8$, but this would be incorrect because we must have an integer greater than or equal to $8.24$. We must remember that the error estimates provide an upper bound only for the error. The actual estimate may be a much better approximation than the error bound indicates.

**? Checkpoint 7.6.6**

Use Equation 7.6.1 to find an upper bound for the error in using $M_4$ to estimate $\int_0^1 x^2\,dx$.

**Answer**

$\frac{1}{192}$

## Simpson's Rule

With the Midpoint Rule, we estimated areas of regions under curves by using rectangles. In a sense, we approximated the curve with piecewise *constant* functions. With the Trapezoidal Rule, we approximated the curve using piecewise *linear* functions. What if we were to approximate a curve using piecewise quadratic functions instead? With **Simpson's Rule,** we do just this. Consider the function in Figure 7.6.4.

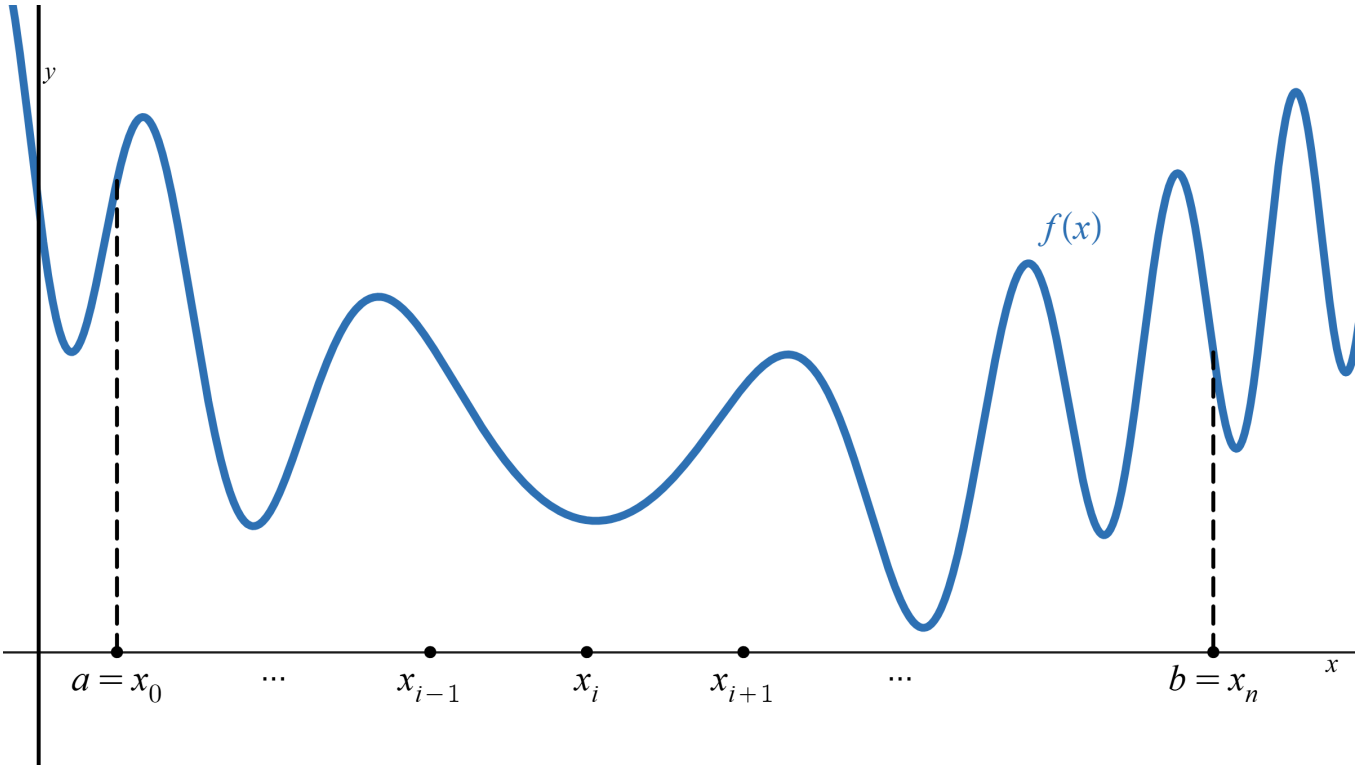

Figure 7.6.4

We partition the interval into an *even* number of subintervals of equal width (the necessity of the even number of subintervals will be revealed shortly). If we wish to string together quadratic functions to help us approximate the area under this curve, we face a new challenge - the Left Endpoint, Right Endpoint, Midpoint, and Trapezoidal Rules each required "tops" to our slices that were linear functions (horizontal lines in all cases but the Trapezoidal Rule). Since we only need two points to build a line, we only needed our subintervals to include neighboring points in the partition - namely, $(x_{i-1}, f(x_{i-1}))$ and $(x_i, f(x_i))$. This is why the $i^{\text{th}}$ subinterval was $[x_{i-1}, x_i]$ in each of these methods; however, quadratic functions graph as parabolas, and from our Algebra, we know we need *three* points to find the equation of a parabola. Hence, we need an "expanded" interval containing *three* neighboring points to uniquely find the approximating parabola, as see in Figure 7.6.5.

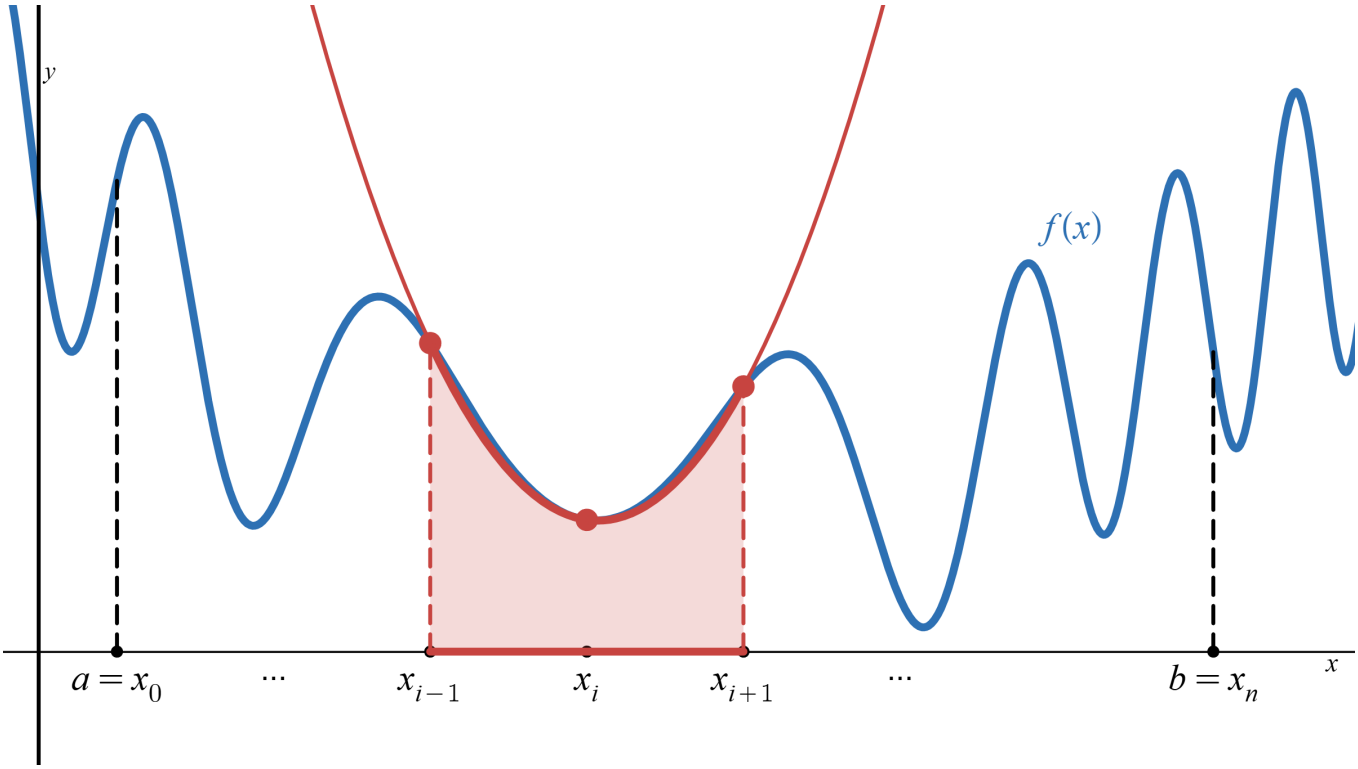

Figure **7.6.5**

Our goal is to derive a formula for the area of this $i^{\text{th}}$ slice over the interval $[x_{i-1}, x_{i+1}]$. Before continuing, let's make sure we all agree that the red points in Figure **7.6.5** are $(x_{i-1}, f(x_{i-1}))$, $(x_i, f(x_i))$, and $(x_{i+1}, f(x_{i+1}))$. For notational simplicity, let's replace those function values with a cleaner notation - $(x_{i-1}, y_{i-1})$, $(x_i, y_i)$, and $(x_{i+1}, y_{i+1})$.

There are several ways to approach this, however, we will use the simple concept that shifting a function left or right does not affect the area between the function and the $x$-axis (another way to say this is that the area under the curve on a given interval is **invariant** under horizontal translations). Therefore, we shift the function so $x_i = 0$ and temporarily let $h = \Delta x$. Figure **7.6.6** reflects this change.

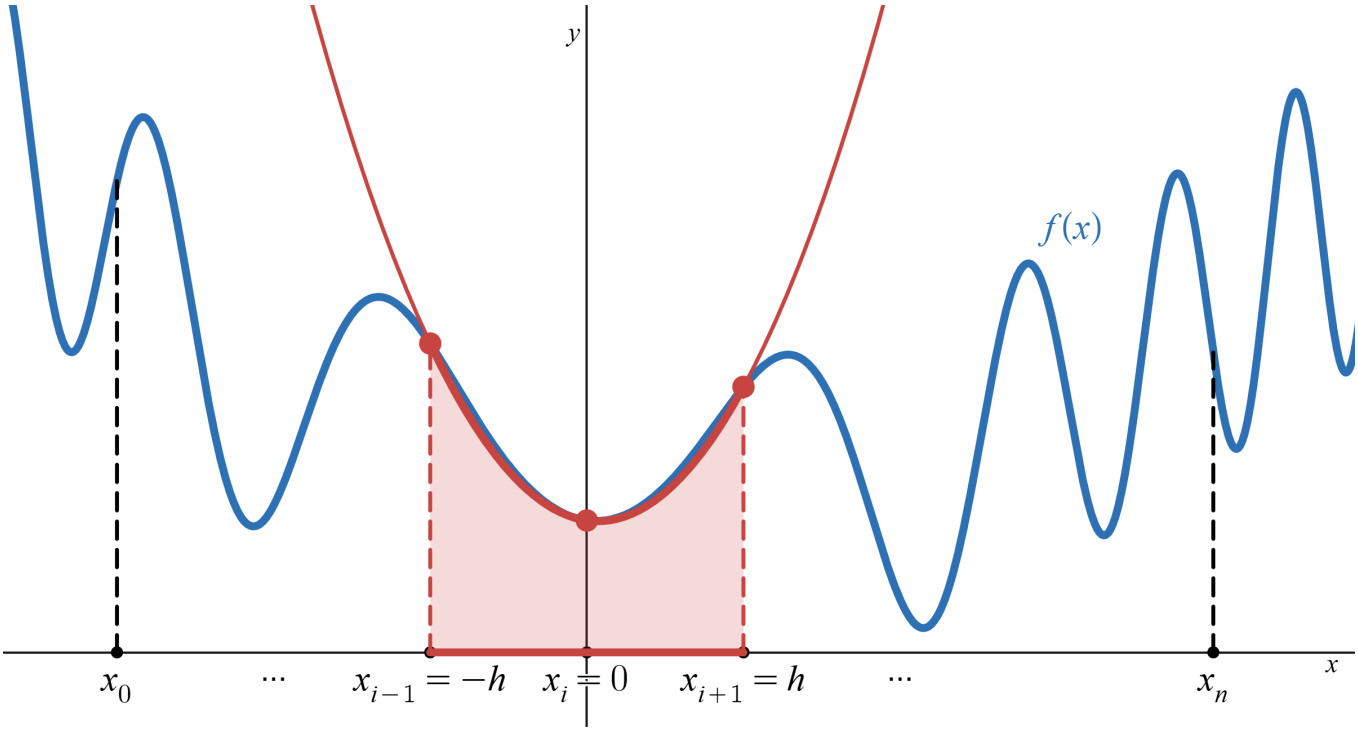

Figure 7.6.6

As mentioned, computationally, this shift has no effect; however, it simplifies our derivation quite a bit. The most important part we note is that the $y$-values of those points are still $y_{i-1}$, $y_i$, and $y_{i+1}$. Thus, the three red points in Figure 7.6.6 are $(-h, y_{i-1})$, $(0, y_i)$, and $(h, y_{i+1})$. We know the equation of a parabola is

$$y = Ax^2 + Bx + C.$$

Substituting in the three points, we get the equations

$$\begin{aligned} y_{i-1} &= Ah^2 - Bh + C \\ y_i &= C \\ y_{i+1} &= Ah^2 + Bh + C \end{aligned} \tag{7.6.3}$$

We now turn our focus to computing the approximated area under $f$ on the interval $[x_{i-1}, x_{i+1}]$.

$$\text{Area of the } i^{\text{th}} \text{ slice} \approx \int_{x_{i-1}}^{x_{i+1}} Ax^2 + Bx + C\,dx = \int_{-h}^{h} Ax^2 + Bx + C\,dx$$
$$= \left(\frac{A}{3}x^3 + \frac{B}{2}x^2 + Cx\right)\Big|_{-h}^{h} = \frac{2A}{3}h^3 + 2Ch = \frac{h}{3}\left(2Ah^2 + 6C\right).$$

A little ingenuity reveals that the expression $2Ah^2 + 6C$ is a combination of the equations in 7.6.3. Specifically, if you took one of the first equation, four of the second, and one of the third, you would get

$$\begin{aligned} & y_{i-1} &= Ah^2 - Bh + C \\ & 4y_i &= 4C \\ + \quad & y_{i+1} &= Ah^2 + Bh + C \\ \hline & y_{i-1} + 4y_i + y_{i+1} &= 2Ah^2 + 6C \end{aligned}$$

Does this look familiar? I hope so because we just spent a little while deriving that right side! This leads to a clean approximation to the area of the $i^{\text{th}}$ slice:

$$\text{Area of the } i^{\text{th}} \text{ slice} \approx \frac{h}{3}\left(2Ah^2 + 6C\right) = \frac{h}{3}\left(y_{i-1} + 4y_i + y_{i+1}\right) = \frac{h}{3}\left(f(x_{i-1}) + 4f(x_i) + f(x_{i+1})\right).$$

Now that we have an explicit formula for the area of the $i^{\text{th}}$ slice, we can use a Riemann sum to approximate the area under the curve from $x_0$ to $x_n$. Before we setup the summation, however, it is important to visualize that the edges of the $i^{\text{th}}$ slice occur at $x = x_{i-1}$ and $x_{i+1}$. Hence, our summation will go from $i = 1$ to $i = n - 1$ (the $(n-1)^{\text{st}}$ slice having $x_n$ as its rightmost edge). Moreover, the center of the first slice is at $x_1$, the second at $x_3$, the third at $x_5$, and so on. The rightmost edge of the entire interval must be $x_n$, where $n$ is even (thus, the requirement for an even number of slices). Thus,

$$\begin{aligned} A &\approx \left[\frac{h}{3}\left(f(x_0)+4f(x_1)+f(x_2)\right)+\frac{h}{3}\left(f(x_2)+4f(x_3)+f(x_4)\right)\right. \\ &\quad +\frac{h}{3}\left(f(x_4)+4f(x_5)+f(x_6)\right)+\cdots \\ &\quad \left.+\frac{h}{3}\left(f(x_{n-4})+4f(x_{n-3})+f(x_{n-2})\right)+\frac{h}{3}\left(f(x_{n-2})+4f(x_{n-1})+f(x_n)\right)\right] \\ &= \frac{h}{3}\left[\left(f(x_0)+4f(x_1)+f(x_2)\right)+\left(f(x_2)+4f(x_3)+f(x_4)\right)+\left(f(x_4)+4f(x_5)+f(x_6)\right)+\cdots\right. \\ &\quad \left.+\left(f(x_{n-4})+4f(x_{n-3})+f(x_{n-2})\right)+\left(f(x_{n-2})+4f(x_{n-1})+f(x_n)\right)\right] \\ &= \frac{\Delta x}{3} \\ &\quad \left[\left(f(x_0)+4f(x_1)+f(x_2)\right)+\left(f(x_2)+4f(x_3)+f(x_4)\right)+\left(f(x_4)+4f(x_5)+f(x_6)\right)+\cdots\right. \\ &\quad \left.+\left(f(x_{n-4})+4f(x_{n-3})+f(x_{n-2})\right)+\left(f(x_{n-2})+4f(x_{n-1})+f(x_n)\right)\right] \\ &= \frac{\Delta x}{3}\left(f(x_0)+4f(x_1)+2f(x_2)+4f(x_3)+2f(x_4)+\cdots+2f(x_{n-2})+4f(x_{n-1})+f(x_n)\right) \end{aligned}$$

Other than the outer edges of the main interval, the doubling of the function values at even indexed partition values occurs because the edges of *two* parabolas meet there and their function values get double-counted. The general rule may be stated as follows.

**Theorem: Simpson's Rule**

Assume that $f(x)$ is continuous over $[a, b]$. Let $n$ be a positive even integer and $\Delta x = \frac{b-a}{n}$. Let $[a, b]$ be divided into $n$ subintervals, each of length $\Delta x$, with endpoints at $P = \{x_0, x_1, x_2, \ldots, x_n\}$. Set

$$S_n = \frac{\Delta x}{3}\left[f(x_0)+4f(x_1)+2f(x_2)+4f(x_3)+2f(x_4)+\cdots+2f(x_{n-2})+4f(x_{n-1})+f(x_n)\right].$$

Then,

$$\lim_{n\to\infty} S_n = \int_a^b f(x)\,dx.$$

Just as the Trapezoidal Rule is the average of the Left Endpoint and Right Endpoint approximations for estimating definite integrals, Simpson's Rule may be obtained using a weighted average from the Midpoint and Trapezoidal Rules. It can be shown that $S_{2n} = \left(\frac{2}{3}\right) M_n + \left(\frac{1}{3}\right) T_n$.

It is also possible to put a bound on the error when using Simpson's Rule to approximate a definite integral. The bound in the error is given by the following rule:

**Theorem: Error Bound for Simpson's Rule**

Let $f(x)$ be a continuous function over $[a, b]$ having a fourth derivative, $f^{(4)}(x)$, over this interval. If $M$ is the maximum value of $\left|f^{(4)}(x)\right|$ over $[a, b]$, then the upper bound for the error in using $S_n$ to estimate $\int_a^b f(x)\,dx$ is given by

$$E_S \leq \frac{M(b-a)^5}{180n^4}.$$

### Example 7.6.7: Applying Simpson's Rule 1

Use $S_2$ to approximate

$$\int_0^1 x^3\,dx.$$

Estimate a bound for the error in $S_2$.

**Solution**

Since $[0,1]$ is divided into two intervals, each subinterval has length $\Delta x = \frac{1-0}{2} = \frac{1}{2}$. The endpoints of these subintervals are $\left\{0, \frac{1}{2}, 1\right\}$. If we set $f(x) = x^3$, then

$$S_2 = \frac{1/2}{3}\left(f(0) + 4f\left(\frac{1}{2}\right) + f(1)\right) = \frac{1}{6}\left(0 + 4\cdot\frac{1}{8} + 1\right) = \frac{1}{4}.$$

Since $f^{(4)}(x) = 0$ and consequently $M = 0$, we see that

$$E_S \leq \frac{0(1)^5}{180\cdot 2^4} = 0.$$

This bound indicates that the value obtained through Simpson's Rule is exact. A quick check will verify that, in fact, $\int_0^1 x^3\,dx = \frac{1}{4}$.

### Example 7.6.8: Applying Simpson's Rule 2

Use $S_6$ to estimate the length of the curve

$$y = \frac{1}{2}x^2$$

over $[1,4]$

**Solution**

The length of $y = \frac{1}{2}x^2$ over $[1,4]$ is $\int_1^4 \sqrt{1+x^2}\,dx$. If we divide $[1,4]$ into six subintervals, then each subinterval has length $\Delta x = \frac{4-1}{6} = \frac{1}{2}$, and the endpoints of the subintervals are $\left\{1, \frac{3}{2}, 2, \frac{5}{2}, 3, \frac{7}{2}, 4\right\}$. Setting $f(x) = \sqrt{1+x^2}$,

$$S_6 = \frac{1/2}{3}\left(f(1) + 4f\left(\frac{3}{2}\right) + 2f(2) + 4f\left(\frac{5}{2}\right) + 2f(3) + 4f\left(\frac{7}{2}\right) + f(4)\right).$$

After substituting, we have

$$S_6 = \frac{1}{6}\left(1.4142 + 4\cdot 1.80278 + 2\cdot 2.23607 + 4\cdot 2.69258 + 2\cdot 3.16228 + 4\cdot 3.64005 + 4.12311\right) \approx 8.14594 \text{ units}.$$

### Checkpoint 7.6.8

Use $S_2$ to estimate

$$\int_1^2 \frac{1}{x}\,dx.$$

**Answer**

$\frac{25}{36} \approx 0.694444$

## Footnotes

[1] The exploration of numerical methods, their error bounds, and the trade-off between the accuracy of the method and its computational expense is the realm of a subfield of Mathematics called Numerical Analysis. If you are intrigued by how such methods (and their errors) are developed, I recommend taking a series of upper-division courses in Numerical Analysis.

# 7.6E: Exercises

## Reading Questions

1. What is the primary reason for using numerical integration methods like the Midpoint, Trapezoidal, or Simpson's Rule?
2. What geometric shapes are used to approximate the area under a curve in the Trapezoidal Rule and Simpson's Rule, respectively?
3. What is the difference between absolute error and relative error in a numerical approximation?
4. The error bound formula for the Midpoint Rule depends on finding the maximum value of which derivative of the function being integrated?
5. What specific requirement does Simpson's Rule have for the number of subintervals, $n$?
6. The Trapezoidal Rule approximation, $T_n$, can be found by taking the average of which two other Riemann sum approximations?
7. For a function that is concave up over an interval, will the Trapezoidal Rule produce an overestimate or an underestimate of the definite integral?

**In exercises 1 - 5, approximate the following integrals using either the Midpoint Rule, Trapezoidal Rule, or Simpson's Rule as indicated. (Round answers to three decimal places.)**

1) $\int_1^2 \frac{dx}{x}$; Trapezoidal Rule; $n = 5$

**Answer**

0.696

2) $\int_0^3 \sqrt{4+x^3}\ dx$; Trapezoidal Rule; $n = 6$

3) $\int_0^3 \sqrt{4+x^3}\ dx$; Simpson's Rule; $n = 6$

**Answer**

9.279

4) $\int_0^{12} x^2\ dx$; Midpoint Rule; $n = 6$

5) $\int_0^1 \sin^2(\pi x)\ dx$; Midpoint Rule; $n = 3$

**Answer**

0.500

6) Use the Midpoint Rule with eight subdivisions to estimate $\int_2^4 x^2\ dx$.

7) Use the Trapezoidal Rule with four subdivisions to estimate $\int_2^4 x^2\ dx$.

**Answer**

$T_4 = 18.75$

8) Find the exact value of $\int_2^4 x^2\ dx$. Find the error of approximation between the exact value and the value calculated using the Trapezoidal Rule with four subdivisions. Draw a graph to illustrate.

**Approximate the integral to four decimal places using the indicated rule.**

9) $\int_0^1 \sin^2(\pi x)\ dx$; Trapezoidal Rule; $n = 6$

**Answer**

0.5000

10) $\int_0^3 \frac{1}{1+x^3}\,dx$; Trapezoidal Rule; $n=6$

11) $\int_0^3 \frac{1}{1+x^3}\,dx$; Simpson's Rule; $n=6$

**Answer**

1.1614

12) $\int_0^{0.8} e^{-x^2}\,dx$; Trapezoidal Rule; $n=4$

13) $\int_0^{0.8} e^{-x^2}\,dx$; Simpson's Rule; $n=4$

**Answer**

0.6577

14) $\int_0^{0.4} \sin(x^2)\,dx$; Trapezoidal Rule; $n=4$

15) $\int_0^{0.4} \sin(x^2)\,dx$; Simpson's Rule; $n=4$

**Answer**

0.0213

16) $\int_{0.1}^{0.5} \frac{\cos x}{x}\,dx$; Trapezoidal Rule; $n=4$

17) $\int_{0.1}^{0.5} \frac{\cos x}{x}\,dx$; Simpson's Rule; $n=4$

**Answer**

1.5629

18) Evaluate $\int_0^1 \frac{dx}{1+x^2}$ exactly and show that the result is $\pi/4$. Then, find the approximate value of the integral using the Trapezoidal Rule with $n=4$ subdivisions. Use the result to approximate the value of $\pi$.

19) Approximate $\int_2^4 \frac{1}{\ln x}\,dx$ using the Midpoint Rule with four subdivisions to four decimal places.

**Answer**

1.9133

20) Approximate $\int_2^4 \frac{1}{\ln x}\,dx$ using the Trapezoidal Rule with eight subdivisions to four decimal places.

21) Use the Trapezoidal Rule with four subdivisions to estimate $\int_0^{0.8} x^3\,dx$ to four decimal places.

**Answer**

$T(4)=0.1088$

22) Use the Trapezoidal Rule with four subdivisions to estimate $\int_0^{0.8} x^3\,dx$. Compare this value with the exact value and find the error estimate.

23) Using Simpson's Rule with four subdivisions, find $\int_0^{\pi/2} \cos(x)\,dx$.

**Answer**

$\int_0^{\pi/2} \cos(x)\, dx \approx \quad 1.0$

24) Show that the exact value of $\int_0^1 xe^{-x}\, dx = 1 - \frac{2}{e}$. Find the absolute error if you approximate the integral using the Midpoint Rule with 16 subdivisions.

25) Given $\int_0^1 xe^{-x}\, dx = 1 - \frac{2}{e}$, use the Trapezoidal Rule with 16 subdivisions to approximate the integral and find the absolute error.

**Answer**

Approximate error is **0.000325.**

26) Find an upper bound for the error in estimating $\int_0^3 (5x + 4)\, dx$ using the Trapezoidal Rule with six steps.

27) Find an upper bound for the error in estimating $\int_4^5 \frac{1}{(x-1)^2}\, dx$ using the Trapezoidal Rule with seven subdivisions.

**Answer**

$\frac{1}{7938}$

28) Find an upper bound for the error in estimating $\int_0^3 (6x^2 - 1)\, dx$ using Simpson's Rule with $n = 10$ steps.

29) Find an upper bound for the error in estimating $\int_2^5 \frac{1}{x-1}\, dx$ using Simpson's Rule with $n = 10$ steps.

**Answer**

$\frac{81}{25{,}000}$

30) Find an upper bound for the error in estimating $\int_0^{\pi} 2x\cos(x)\, dx$ using Simpson's Rule with four steps.

31) Estimate the minimum number of subintervals needed to approximate the integral $\int_1^4 (5x^2 + 8)\, dx$ with an error magnitude of less than 0.0001 using the Trapezoidal Rule.

**Answer**

**475**

32) Determine a value of n such that the Trapezoidal Rule will approximate $\int_0^1 \sqrt{1 + x^2}\, dx$ with an error of no more than 0.01.

33) Estimate the minimum number of subintervals needed to approximate the integral $\int_2^3 (2x^3 + 4x)\, dx$ with an error of magnitude less than 0.0001 using the Trapezoidal Rule.

**Answer**

**174**

34) Estimate the minimum number of subintervals needed to approximate the integral $\int_3^4 \frac{1}{(x-1)^2}\, dx$ with an error magnitude of less than 0.0001 using the Trapezoidal Rule.

35) Use Simpson's Rule with four subdivisions to approximate the area under the probability density function $y = \frac{1}{\sqrt{2\pi}} e^{-x^2/2}$ from $x = 0$ to $x = 0.4$.

**Answer**

**0.1544**

36) Use Simpson's Rule with $n = 14$ to approximate (to three decimal places) the area of the region bounded by the graphs of $y = 0, x = 0$, and $x = \pi/2$.

37) The length of one arch of the curve $y = 3\sin(2x)$ is given by $L = \int_0^{\pi/2} \sqrt{1 + 36\cos^2(2x)}\ dx$. Estimate L using the Trapezoidal Rule with $n = 6$.

**Answer**

6.2807

38) The length of the ellipse $x = a\cos(t), y = b\sin(t), 0 \le t \le 2\pi$ is given by $L = 4a\int_0^{\pi/2} \sqrt{1 - e^2\cos^2(t)}dt$, where e is the eccentricity of the ellipse. Use Simpson's Rule with $n = 6$ subdivisions to estimate the length of the ellipse when $a = 2$ and $e = 1/3$.

39) Estimate the area of the surface generated by revolving the curve $y = \cos(2x), 0 \le x \le \frac{\pi}{4}$ about the x-axis. Use the Trapezoidal Rule with six subdivisions.

**Answer**

4.606

40) Estimate the area of the surface generated by revolving the curve $y = 2x^2, 0 \le x \le 3$ about the x-axis. Use Simpson's Rule with $n = 6$.

41) The growth rate of a certain tree (in feet) is given by $y = \dfrac{2}{t+1} + e^{-t^2/2}$, where t is time in years. Estimate the growth of the tree through the end of the second year by using Simpson's Rule, using two subintervals. (Round the answer to the nearest hundredth.)

**Answer**

3.41 ft

42) [Technology Required] Use a calculator to approximate $\int_0^1 \sin(\pi x)\ dx$ using the Midpoint Rule with 25 subdivisions. Compute the relative error of approximation.

43) [Technology Required] Given $\int_1^5 (3x^2 - 2x)\ dx = 100$, approximate the value of this integral using the Midpoint Rule with 16 subdivisions and determine the absolute error.

**Answer**

$T_{16} = 100.125$; absolute error = 0.125

44) Given that we know the Fundamental Theorem of Calculus, why would we want to develop numerical methods for definite integrals?

45) The table represents the coordinates $(x, y)$ that give the boundary of a lot. The units of measurement are meters. Use the Trapezoidal Rule to estimate the number of square meters of land that is in this lot.

| $x$ | $y$ | $x$ | $y$ |
|---|---|---|---|
| 0 | 125 | 600 | 95 |
| 100 | 125 | 700 | 88 |
| 200 | 120 | 800 | 75 |
| 300 | 112 | 900 | 35 |
| 400 | 90 | 1000 | 0 |
| 500 | 90 | | |

**Answer**

about 89,250 $m^2$

46) Choose the correct answer. When Simpson's Rule is used to approximate the definite integral, it is necessary that the number of partitions be____

a. an even number

b. odd number

c. either an even or an odd number

d. a multiple of 4

47) The “Simpson” sum is based on the area under a ____.

**Answer**

parabola

48) The error formula for Simpson's Rule depends on___.

a. $f(x)$

b. $f'(x)$

c. $f^{(4)}(x)$

d. the number of steps

# CHAPTER OVERVIEW

## 8: Sequences and Series

The topic of infinite series may seem unrelated to differential and integral calculus. In fact, an infinite series whose terms involve powers of a variable is a powerful tool that we can use to express functions as “infinite polynomials.” We can use infinite series to evaluate complicated functions, approximate definite integrals, and create new functions. In addition, infinite series are used to solve differential equations that model physical behavior, from tiny electronic circuits to Earth-orbiting satellites.

# 8.1: Improper Integrals

**Learning Objectives**

- Evaluate an integral over an infinite interval.
- Evaluate an integral over a closed interval with an infinite discontinuity within the interval.
- Use the comparison theorem to determine whether a definite integral is convergent.

Before we dive too deeply into the focus of this chapter (sequences and series), we must investigate the concept of integrals with infinite upper and/or lower limits - this will significantly help us with the material for the rest of this chapter.

Is the area between the graph of $f(x) = \frac{1}{x}$ and the $x$-axis over the interval $[1, \infty)$ finite or infinite? If this same region is revolved about the $x$-axis, is the volume finite or infinite? Surprisingly, the area of the region described is infinite, but the volume of the solid obtained by revolving this region about the $x$-axis is finite.

In this section, we define integrals over an infinite interval and integrals of functions containing a discontinuity on the interval. Integrals of these types are called improper integrals. We examine several techniques for evaluating improper integrals, all involving taking limits.

## Integrating over an Infinite Interval

How should we go about defining an integral of the type $\int_a^\infty f(x)\,dx$? We can integrate $\int_a^t f(x)\,dx$ for any value of $t$, so it is reasonable to look at the behavior of this integral as we substitute larger values of $t$. Figure 8.1.1 shows that $\int_a^t f(x)\,dx$ may be interpreted as area for various values of $t$. In other words, we may define an **improper integral** as a limit, taken as one of the limits of integration increases or decreases without bound.

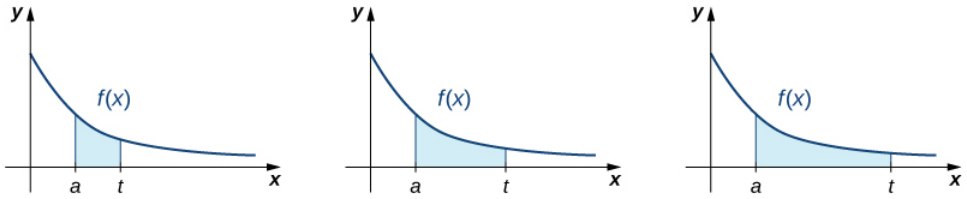

Figure 8.1.1: To integrate a function over an infinite interval, we consider the limit of the integral as the upper limit increases without bound.

**Definition: Improper Integral**

1. Let $f(x)$ be continuous over an interval of the form $[a, \infty)$. Then $\int_a^\infty f(x)\,dx$ is called an **improper integral**, and

$$\int_a^\infty f(x)\,dx \equiv \lim_{t\to\infty} \int_a^t f(x)\,dx, \tag{8.1.1}$$

provided this limit exists.[1,2]

2. Let $f(x)$ be continuous over an interval of the form $(-\infty, b]$. Then $\int_{-\infty}^b f(x)\,dx$ is also called an improper integral, and

$$\int_{-\infty}^b f(x)\,dx \equiv \lim_{t\to-\infty} \int_t^b f(x)\,dx, \tag{8.1.2}$$

provided this limit exists.

In each case, if the limit exists, then the improper integral is said to **converge**. If the limit does not exist, then the improper integral is said to **diverge**.

3. Let $f(x)$ be continuous over $(-\infty, \infty)$. Then $\int_{-\infty}^\infty f(x)\,dx$ is also called an improper integral, and

$$\int_{-\infty}^{\infty} f(x)\,dx \equiv \int_{-\infty}^{a} f(x)\,dx + \int_{a}^{\infty} f(x)\,dx \tag{8.1.3}$$

for any value of $a$, provided that $\int_{-\infty}^{a} f(x)\,dx$ *and* $\int_{a}^{\infty} f(x)\,dx$ both converge.

If *either* of these two integrals diverge, then $\int_{-\infty}^{\infty} f(x)\,dx$ diverges.

In our first example, we return to the question we posed at the start of this section: Is the area between the graph of $f(x) = \frac{1}{x}$ and the $x$-axis over the interval $[1, \infty)$ finite or infinite?

### Example 8.1.1: Finding an Area

Determine whether the area between the graph of $f(x) = \frac{1}{x}$ and the $x$-axis over the interval $[1, \infty)$ is finite or infinite.

**Solution**

We first do a quick sketch of the region in question, as shown in Figure 8.1.2.

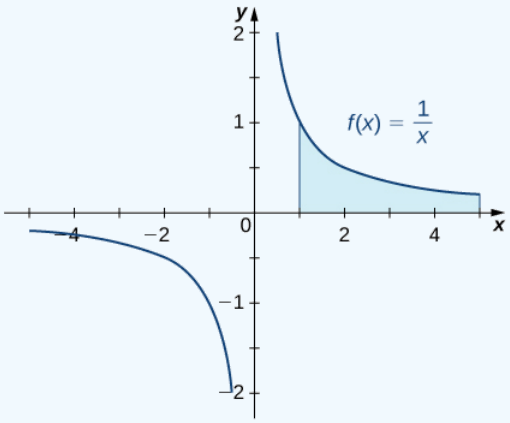

Figure 8.1.2: We can find the area between the curve $f(x) = 1/x$ and the $x$-axis on an infinite interval.

We can see that the area of this region is given by

$$A = \int_{1}^{\infty} \frac{1}{x}\,dx.$$

which can be evaluated using Equation 8.1.1:

$$\begin{aligned} A &= \int_{1}^{\infty} \frac{1}{x}\,dx \\ &= \lim_{t\to\infty} \int_{1}^{t} \frac{1}{x}\,dx \\ &= \lim_{t\to\infty} \ln|x|\Big|_{1}^{t} \\ &= \lim_{t\to\infty} (\ln|t| - \ln 1) \\ &= \infty. \end{aligned}$$

Since the limit tends to $\infty$, it technically does not exist (as a finite number).[2] Thus, the improper integral is divergent. In fact, it diverges to infinity, and so the area of the region is infinite.

https://math.libretexts.org/@go/page/175605

**Caution: Anything Involving $\infty$ in Calculus Requires Limits!!!**

A *very* lousy habit that some students get into is to evaluate an improper integral without using limit notation. To be clear:

**To evaluate an improper integral, you *must* use limits!**

That is, in Example 8.1.1, it would be incorrect to write

$$A = \int_1^{\infty} \frac{1}{x}\,dx = \ln|x|\Big|_1^{\infty} = \ln|\infty| - \ln|1| = \infty - 0 = \infty.$$

This makes no sense mathematically since $\infty$ is not a number and, as such, you cannot directly evaluate *any* function "at $\infty$." Hence, $\ln|\infty|$ has no meaning. On the other hand, $\lim_{t\to\infty} \ln|t| = \infty$ makes complete sense.

**Example 8.1.2: Finding a Volume**

Find the volume of the solid obtained by revolving the region bounded by the graph of $f(x) = \frac{1}{x}$ and the $x$-axis over the interval $[1, \infty)$ about the $x$-axis.

**Solution**

The solid is shown in Figure 8.1.3. Using the Disk Method, we see that the volume $V$ is

$$V = \pi \int_1^{\infty} \frac{1}{x^2}\,dx.$$

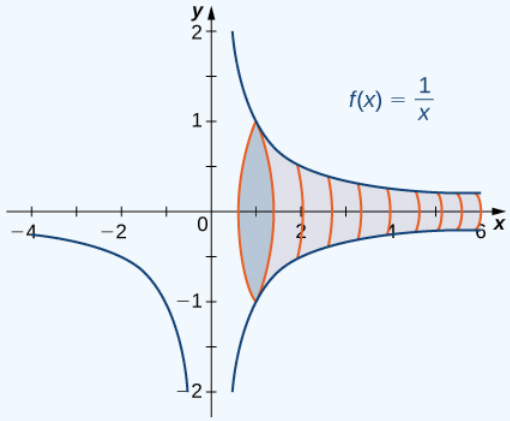

Figure 8.1.3: The solid of revolution can be generated by rotating an infinite area about the $x$-axis.

Then we have

$$\begin{aligned} V &= \pi \int_1^{\infty} \frac{1}{x^2}\,dx \\ &= \pi \lim_{t\to\infty} \int_1^t \frac{1}{x^2}\,dx \\ &= \pi \lim_{t\to\infty} -\frac{1}{x}\Big|_1^t \\ &= \pi \lim_{t\to\infty} \left(-\frac{1}{t}+1\right) \\ &= \pi \lim_{t\to\infty} \left(-\frac{1}{\not t^{\,0}}+1\right) \\ &= \pi \end{aligned}$$

Since this limit exists, the improper integral converges. In fact, it converges to $\pi$. Therefore, the volume of the solid of revolution is $\pi$.

In conclusion, although the area of the region between the $x$-axis and the graph of $f(x) = \frac{1}{x}$ over the interval $[1, \infty)$ is infinite, the volume of the solid generated by revolving this region about the $x$-axis is finite. The solid generated is known as **Gabriel's Horn**.[3]

### Example 8.1.3: Traffic Accidents in a City

Suppose that at a busy intersection, traffic accidents occur at an average rate of one every three months. After residents complained, changes were made to the traffic lights at the intersection. It has been eight months since the changes were made, and no accidents have occurred. Were the changes effective, or is the 8-month interval without an accident a result of chance?

Figure 8.1.4: Modification of work by David McKelvey, Flickr.

Probability theory tells us that if the *average* time between events is $k$, then the probability that the *actual* time between events is between $a$ and $b$ is given by

$$P(a \le X \le b) = \int_a^b f(x)\,dx,$$

where

$$f(x) = \begin{cases} 0, & \text{if } x < 0 \\ ke^{-kx}, & \text{if } x \ge 0 \end{cases}.$$

Thus, if accidents are occurring at a rate of one every 3 months, then the probability that *actual* time between accidents is between $a$ and $b$ is given by

$$P(a \le X \le b) = \int_a^b f(x)\,dx,$$

where

$$f(x) = \begin{cases} 0, & \text{if } x < 0 \\ \\ 3e^{-3x}, & \text{if } x \geq 0 \end{cases}.$$

To answer the question, we must ask ourselves, "What is the probability that the first accident in the intersection occurs after 8 months?" Hence, we need to compute $P(X \geq 8) = \int_8^{\infty} 3e^{-3x}\,dx$ and decide whether it is likely that 8 months could have passed without an accident if there had been no improvement in the traffic situation.

**Solution**

We need to calculate the probability as an improper integral:

$$\begin{aligned} P(X \geq 8) &= \int_8^{\infty} 3e^{-3x}\,dx \\ &= \lim_{t\to\infty} \int_8^t 3e^{-3x}\,dx \\ &= \lim_{t\to\infty} -e^{-3x}\Big|_8^t \\ &= \lim_{t\to\infty} (-e^{-3t} + e^{-24}) \\ &\approx 3.8 \times 10^{-11}. \end{aligned}$$

The value $3.8 \times 10^{-11}$ represents the probability of no accidents in 8 months under the initial conditions. Since this value is very small, concluding the changes were effective is reasonable.

### Example 8.1.4: Evaluating an Improper Integral over an Infinite Interval

Evaluate

$$\int_{-\infty}^{0} \frac{1}{x^2+4}\,dx.$$

State whether the improper integral converges or diverges.

**Solution**

Begin by rewriting $\int_{-\infty}^{0} \frac{1}{x^2+4}\,dx$ as a limit using Equation 8.1.2 from the definition. Thus,

$$\begin{aligned} \int_{-\infty}^{0} \frac{1}{x^2+4}\,dx &= \lim_{t\to-\infty} \int_t^0 \frac{1}{x^2+4}\,dx \\ &= \lim_{t\to-\infty} \frac{1}{2}\tan^{-1}\frac{x}{2}\Big|_t^0 \\ &= \lim_{t\to-\infty} \left(\frac{1}{2}\tan^{-1}0 - \frac{1}{2}\tan^{-1}\frac{t}{2}\right) \\ &= \frac{\pi}{4} \end{aligned}$$

Therefore, the improper integral converges to $\frac{\pi}{4}$.

## Example 8.1.5: Evaluating an Improper Integral on $(-\infty, \infty)$

Evaluate

$$\int_{-\infty}^{\infty} xe^x\,dx.$$

State whether the improper integral converges or diverges.

**Solution**

Start by splitting up the integral:

$$\int_{-\infty}^{\infty} xe^x\,dx = \int_{-\infty}^{0} xe^x\,dx + \int_{0}^{\infty} xe^x\,dx.$$

If either $\int_{-\infty}^{0} xe^x\,dx$ or $\int_{0}^{\infty} xe^x\,dx$ diverges, then $\int_{-\infty}^{\infty} xe^x\,dx$ diverges.

For the first integral,

$$\begin{aligned}\int_{-\infty}^{0} xe^x\,dx &= \lim_{t\to-\infty}\int_{t}^{0} xe^x\,dx \\ &= \lim_{t\to-\infty}(xe^x - e^x)\Big|_{t}^{0} \\ &= \lim_{t\to-\infty}(-1 - te^t + e^t) \\ &= -1.\end{aligned}$$

Note: $\lim_{t\to-\infty} te^t$ is indeterminate of the form $0\cdot\infty$. Thus,

$$\lim_{t\to-\infty} te^t = \lim_{t\to-\infty}\frac{t}{e^{-t}} \overset{\text{l'H}}{=} \lim_{t\to-\infty}\frac{-1}{e^{-t}} = \lim_{t\to-\infty} -e^t = 0$$

by l'Hospital's Rule. Hence, the first improper integral converges.

For the second integral,

$$\begin{aligned}\int_{0}^{\infty} xe^x\,dx &= \lim_{t\to\infty}\int_{0}^{t} xe^x\,dx \\ &= \lim_{t\to\infty}(xe^x - e^x)\Big|_{0}^{t} \\ &= \lim_{t\to\infty}(te^t - e^t + 1) \\ &= \lim_{t\to\infty}((t-1)e^t + 1) \\ &= \infty.\end{aligned}$$

Thus, $\int_{0}^{\infty} xe^x\,dx$ diverges. Since this integral diverges, $\int_{-\infty}^{\infty} xe^x\,dx$ diverges as well.

## Checkpoint 8.1.5

Evaluate

$$\int_{-3}^{\infty} e^{-x}\,dx.$$

State whether the improper integral converges or diverges.

**Answer**

It converges to $e^3$.

## Integrating a Discontinuous Integrand

Now, let's examine integrals of functions containing an infinite discontinuity in the interval over which the integration occurs. Consider an integral of the form $\int_a^b f(x)\,dx$, where $f(x)$ is continuous over $[a,b)$ and discontinuous at $b$. Since the function $f(x)$ is continuous over $[a,t]$ for all values of $t$ satisfying $a \le t < b$, the integral $\int_a^t f(x)\,dx$ is defined for all such values of $t$. Thus, it makes sense to consider the values of $\int_a^t f(x)\,dx$ as $t$ approaches $b$ for $a \le t < b$. That is, we define $\int_a^b f(x)\,dx \equiv \lim_{t\to b^-} \int_a^t f(x)\,dx$, provided this limit exists. Figure 8.1.5 illustrates $\int_a^t f(x)\,dx$ as areas of regions for values of $t$ approaching $b$.

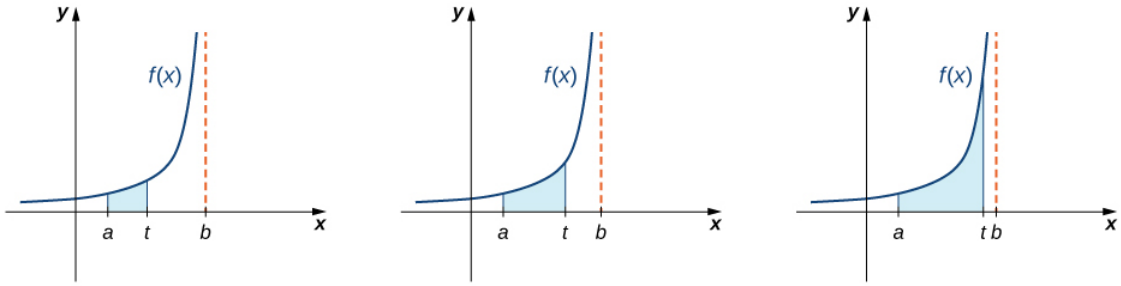

Figure 8.1.5: As t approaches b from the left, the value of the area from a to t approaches the area from a to b.

We use a similar approach to define $\int_a^b f(x)\,dx$, where $f(x)$ is continuous over $(a,b]$ and discontinuous at $a$. We now proceed with a formal definition.

**Definition: Converging and Diverging Improper Integral**

1. Let $f(x)$ be continuous over $[a,b)$. Then,

$$\int_a^b f(x)\,dx \equiv \lim_{t\to b^-} \int_a^t f(x)\,dx, \tag{8.1.4}$$

provided this limit exists.

2. Let $f(x)$ be continuous over $(a,b]$. Then,

$$\int_a^b f(x)\,dx = \lim_{t\to a^+} \int_t^b f(x)\,dx, \tag{8.1.5}$$

provided this limit exists.

3. If $f(x)$ is continuous over $[a,b]$ except at a point $c$ in $(a,b)$, then

$$\int_a^b f(x)\,dx \equiv \int_a^c f(x)\,dx + \int_c^b f(x)\,dx, \tag{8.1.6}$$

provided both $\int_a^c f(x)\,dx$ and $\int_c^b f(x)\,dx$ converge. If either of these integrals diverges, then $\int_a^b f(x)\,dx$ diverges.

In each case, if the limit exists, then the improper integral is said to converge. If the limit does not exist, then the improper integral is said to diverge.

The following examples demonstrate the application of this definition.

### Example 8.1.6: Integrating a Discontinuous Integrand

Evaluate

$$\int_0^4 \frac{1}{\sqrt{4-x}}\,dx,$$

if possible. State whether the integral converges or diverges.

**Solution**

The function $f(x) = \frac{1}{\sqrt{4-x}}$ is continuous over $[0,4)$ and discontinuous at 4. Using Equation 8.1.4 from the definition, rewrite $\int_0^4 \frac{1}{\sqrt{4-x}}\,dx$ as a limit:

$$\begin{aligned}\int_0^4 \frac{1}{\sqrt{4-x}}\,dx &= \lim_{t\to 4^-}\int_0^t \frac{1}{\sqrt{4-x}}\,dx \\ &= \lim_{t\to 4^-}\left(-2\sqrt{4-x}\right)\Big|_0^t \\ &= \lim_{t\to 4^-}\left(-2\sqrt{4-t}+4\right) \\ &= 4.\end{aligned}$$

The improper integral converges (to 4).

### Example 8.1.7: Integrating a Discontinuous Integrand

Evaluate

$$\int_0^2 x\ln x\,dx.$$

State whether the integral converges or diverges.

**Solution**

Since $f(x) = x\ln x$ is continuous over $(0,2]$ and is discontinuous at zero, we can rewrite the integral in limit form using Equation 8.1.5:

$$\begin{aligned}\int_0^2 x\ln x\,dx &= \lim_{t\to 0^+}\int_t^2 x\ln x\,dx \\ &= \lim_{t\to 0^+}\left(\frac{1}{2}x^2\ln x - \frac{1}{4}x^2\right)\Big|_t^2 \\ &= \lim_{t\to 0^+}\left(2\ln 2 - 1 - \frac{1}{2}t^2\ln t + \frac{1}{4}t^2\right) \\ &= 2\ln 2 - 1\end{aligned}$$

Note that $\lim_{t\to 0^+} t^2\ln t$ is indeterminate of the form $0\cdot\infty$. Therefore,

$$\lim_{t\to 0^+} t^2 \ln t = \lim_{t\to 0^+} \frac{\ln t}{t^{-2}} \qquad \left(\text{indeterminate of the form } \frac{\infty}{\infty}\right)$$

$$\overset{\text{l'H}}{=} \lim_{t\to 0^+} \frac{t^{-1}}{-2t^{-3}}$$

$$= \lim_{t\to 0^+} -\frac{t^2}{2}$$

$$= 0$$

Thus, the improper integral converges to $2\ln 2 - 1$.

### Example 8.1.8: Integrating a Discontinuous Integrand

Evaluate

$$\int_{-1}^{1} \frac{1}{x^3}\,dx.$$

State whether the improper integral converges or diverges.

**Solution**

Since $f(x) = \frac{1}{x^3}$ is discontinuous at zero, using Equation 8.1.6, we can write

$$\int_{-1}^{1} \frac{1}{x^3}\,dx = \int_{-1}^{0} \frac{1}{x^3}\,dx + \int_{0}^{1} \frac{1}{x^3}\,dx.$$

If either of the two integrals diverges, the original integral diverges. Begin with $\int_{-1}^{0} \frac{1}{x^3}\,dx$:

$$\int_{-1}^{0} \frac{1}{x^3}\,dx = \lim_{t\to 0^-} \int_{-1}^{t} \frac{1}{x^3}\,dx$$

$$= \lim_{t\to 0^-} \left(-\frac{1}{2x^2}\right)\Big|_{-1}^{t}$$

$$= \lim_{t\to 0^-} \left(-\frac{1}{2t^2} + \frac{1}{2}\right)$$

$$= \infty.$$

Therefore, $\int_{-1}^{0} \frac{1}{x^3}\,dx$ diverges.

Since $\int_{-1}^{0} \frac{1}{x^3}\,dx$ diverges, $\int_{-1}^{1} \frac{1}{x^3}\,dx$ also diverges.

### Checkpoint 8.1.8

Evaluate

$$\int_{0}^{2} \frac{1}{x}\,dx.$$

State whether the integral converges or diverges.

**Answer**

$\infty$, It diverges.

## The Comparison Test for Improper Integrals

It is not always easy, or even possible, to evaluate an improper integral directly; however, by comparing it with another carefully chosen integral, it may be possible to determine its convergence or divergence. To see this, consider two continuous functions $f(x)$ and $g(x)$ satisfying $0 \le f(x) \le g(x)$ for $x \ge a$ (Figure 8.1.6). In this case, we may view integrals of these functions over intervals of the form $[a, t]$ as areas, so we have the relationship

$$0 \le \int_a^t f(x)\,dx \le \int_a^t g(x)\,dx$$

for $t \ge a$.

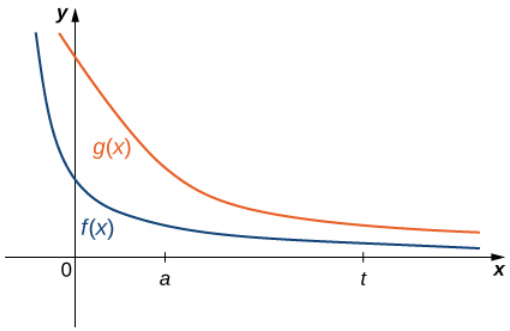

Figure 8.1.6: If $0 \le f(x) \le g(x)$ for $x \ge a$, then for $t \ge a$, $\int_a^t f(x)\,dx \le \int_a^t g(x)\,dx$.

Thus, if

$$\int_a^\infty f(x)\,dx = \lim_{t\to\infty} \int_a^t f(x)\,dx = \infty,$$

then

$$\int_a^\infty g(x)\,dx = \lim_{t\to\infty} \int_a^t g(x)\,dx = \infty$$

as well. That is, if the area of the region between the graph of $f(x)$ and the $x$-axis over $[a, \infty)$ is infinite, then the area of the region between the graph of $g(x)$ and the $x$-axis over $[a, \infty)$ is infinite too.

On the other hand, if

$$\int_a^\infty g(x)\,dx = \lim_{t\to\infty} \int_a^t g(x)\,dx = L$$

for some real number $L$, then

$$\int_a^\infty f(x)\,dx = \lim_{t\to\infty} \int_a^t f(x)\,dx$$

must converge to some value *less than or equal to* $L$, since $\int_a^t f(x)\,dx$ increases as $t$ increases and $\int_a^t f(x)\,dx \le L$ for all $t \ge a$.

If the area of the region between the graph of $g(x)$ and the $x$-axis over $[a, \infty)$ is finite, then the area of the region between the graph of $f(x)$ and the $x$-axis over $[a, \infty)$ is also finite.

These conclusions are summarized in the following theorem.

**Theorem: Comparison Test for Improper Integrals**

Let $f(x)$ and $g(x)$ be continuous over $[a, \infty)$. Assume that $0 \le f(x) \le g(x)$ for $x \ge a$.

i. If

$$\int_a^\infty f(x)\,dx = \lim_{t\to\infty}\int_a^t f(x)\,dx = \infty,$$

then

$$\int_a^\infty g(x)\,dx = \lim_{t\to\infty}\int_a^t g(x)\,dx = \infty.$$

That is, if the area between $f(x)$ and the $x$-axis is divergent (in this case, infinite), then so is the area between $g(x)$ and the $x$-axis.

ii. If

$$\int_a^\infty g(x)\,dx = \lim_{t\to\infty}\int_a^t g(x)\,dx = L,$$

where $L$ is a real number, then

$$\int_a^\infty f(x)\,dx = \lim_{t\to\infty}\int_a^t f(x)\,dx = M$$

for some real number $M \le L$. That is, if the area between $g(x)$ and the $x$-axis is convergent (i.e., finite), then so is the area between $f(x)$ and the $x$-axis.

### Example 8.1.9: Applying the Comparison Theorem

Use the Comparison Test for Improper Integrals to show that

$$\int_1^\infty \frac{1}{xe^x}\,dx$$

converges.

**Solution**

We can see that $0 \le \frac{1}{xe^x} \le \frac{1}{e^x} = e^{-x}$, so if $\int_1^\infty e^{-x}\,dx$ converges, then so does $\int_1^\infty \frac{1}{xe^x}\,dx$.

To evaluate $\int_1^\infty e^{-x}\,dx$, first rewrite it as a limit:

$$\begin{aligned}\int_1^\infty e^{-x}\,dx &= \lim_{t\to\infty}\int_1^t e^{-x}\,dx \\ &= \lim_{t\to\infty}\left(-e^{-x}\right)\Big|_1^t \\ &= \lim_{t\to\infty}\left(-e^{-t}+e^{-1}\right) \\ &= e^{-1}.\end{aligned}$$

Since $\int_1^\infty e^{-x}\,dx$ converges, so does $\int_1^\infty \frac{1}{xe^x}\,dx$. Note that we do not know the value the improper integral converges to, but we know it is less than or equal to $e^{-1}$.

Finding a function to compare an integrand to is an art form. I always advise my students to look for a *similar* function that they can integrate. Be sure to set up the bounding behavior. That is, once you find a function to compare your integrand with, be sure to develop an inequality relating the two functions.

The Comparison Test for Improper Integrals gives us the following very useful theorem.

### Theorem: $p$-Integral Test

The improper integral

$$\int_a^\infty \frac{1}{x^p}\,dx$$

where $a > 0$, converges for $p > 1$ and diverges otherwise.

**Proof**

Assuming for now that $p \neq 1$,

$$\begin{aligned}\int_a^\infty \frac{1}{x^p}\,dx &= \lim_{t\to\infty}\int_a^t \frac{1}{x^p}\,dx \\ &= \lim_{t\to\infty}\left(\frac{x^{-p+1}}{-p+1}\right)\Big|_a^t \\ &= \frac{1}{1-p}\lim_{t\to\infty}\left(t^{1-p}-a^{1-p}\right)\end{aligned}$$

If $p > 1$, then $0 > 1-p$ and so $\lim_{t\to\infty} t^{1-p} = 0$. Hence, the improper integral converges (specifically, it converges to $\frac{a^{1-p}}{p-1}$).

On the other hand, if $p < 1$, then $0 < 1-p$ and so $\lim_{t\to\infty} t^{1-p} = \infty$. Hence, the improper integral diverges.

Finally, if $p = 1$, then

$$\begin{aligned}\int_a^\infty \frac{1}{x^p}\,dx &= \lim_{t\to\infty}\int_a^t \frac{1}{x}\,dx \\ &= \lim_{t\to\infty}\left(\ln(x)\right)\Big|_a^t \\ &= \lim_{t\to\infty}\left(\ln(t)-\ln(a)\right)\end{aligned}$$

However, $\lim_{t\to\infty}\ln(t) = \infty$. Hence, the improper integral diverges.

Therefore,

$$\int_a^\infty \frac{1}{x^p}\,dx$$

where $a > 0$, converges for $p > 1$ and diverges otherwise.

### Example 8.1.10: Applying the Comparison Theorem

Determine whether the improper integral is convergent or divergent.

$$\int_3^\infty \frac{\sin^2(x)}{x^2+x+1}\,dx$$

**Solution**

For $x \geq 3$,

$$x^2 \leq x^2 + x + 1.$$

Therefore,

$$\frac{1}{x^2} \geq \frac{1}{x^2+x+1}.$$

Moreover, since $1 \geq \sin^2(x) \geq 0$,

$$\frac{1}{x^2} \geq \frac{1}{x^2+x+1} \geq \frac{\sin^2(x)}{x^2+x+1} \geq 0.$$

Thus,

$$0 \leq \frac{\sin^2(x)}{x^2+x+1} \leq \frac{1}{x^2}.$$

Since $\int_3^\infty \frac{1}{x^2}\,dx$ converges by the $p$-Integral Test, the Comparison Test for Improper Integrals implies

$$\int_3^\infty \frac{\sin^2(x)}{x^2+x+1}\,dx$$

converges as well.

## Checkpoint 8.1.10

Show that

$$\int_e^\infty \frac{\ln x}{x}\,dx$$

diverges.

**Answer**

Since $\int_e^\infty \frac{1}{x}\,dx = \infty$, $\int_e^\infty \frac{\ln x}{x}\,dx$ diverges.

## Laplace Transforms

In the last chapter, we have looked at several ways to use integration for solving real-world problems. For this next project, we will explore a more advanced application of integration: **integral transforms**. Specifically, we describe the Laplace transform and some of its properties.

The **Laplace transform** is used in engineering and physics to simplify the computations needed to solve some problems. It takes functions expressed in terms of time and *transforms* them to functions expressed in terms of frequency. In many cases, the computations needed to solve problems in the frequency domain are much simpler than those required in the time domain.

The Laplace transform is defined in terms of an integral as

$$\mathscr{L}(f(t)) = F(s) = \int_0^\infty e^{-st} f(t)\,dt.$$

Note that the input to a Laplace transform is a function of time, $f(t)$, and the output is a function of frequency, $F(s)$. Although many real-world examples require the use of complex numbers (involving the imaginary number $i = \sqrt{-1}$), in this project, we limit ourselves to functions of real numbers.

Let's start with a simple example. We calculate the Laplace transform of $f(t) = t$. We have

$$\mathscr{L}(t) = \int_0^\infty te^{-st}\,dt.$$

This is an improper integral, so we express it in terms of a limit, which gives

$$\mathscr{L}(t) = \int_0^\infty te^{-st}\,dt = \lim_{z\to\infty} \int_0^z te^{-st}\,dt.$$

We use Integration by Parts to evaluate the integral. Note that we are integrating with respect to $t$, so we treat the variable $s$ as a constant. We have

$$u = t \qquad dv = e^{-st}\,dt$$

$$du = dt \quad v = -\frac{1}{s}e^{-st}$$

Then we obtain

$$\begin{aligned}
\lim_{z\to\infty}\int_0^z te^{-st}\,dt &= \lim_{z\to\infty}\left[-\frac{t}{s}e^{-st}\Big|_0^z + \frac{1}{s}\int_0^z e^{-st}\,dt\right] \\
&= \lim_{z\to\infty}\left[\left(-\frac{z}{s}e^{-sz} + \frac{0}{s}e^{-0s}\right) + \frac{1}{s}\int_0^z e^{-st}\,dt\right] \\
&= \lim_{z\to\infty}\left[\left(-\frac{z}{s}e^{-sz} + 0\right) - \frac{1}{s}\left(\frac{e^{-st}}{s}\right)\Big|_0^z\right] \\
&= \lim_{z\to\infty}\left[-\frac{z}{s}e^{-sz} - \frac{1}{s^2}\left(e^{-sz} - 1\right)\right] \\
&= \lim_{z\to\infty}\left[-\frac{z}{se^{sz}}\right] - \lim_{z\to\infty}\frac{1}{s^2e^{sz}} + \lim_{z\to\infty}\frac{1}{s^2} \\
&= 0 - 0 + \frac{1}{s^2} \\
&= \frac{1}{s^2}.
\end{aligned}$$

Note, $\lim\limits_{z\to\infty}\left[-\frac{z}{se^{sz}}\right]$ is indeterminate of the form $-\frac{\infty}{\infty}$ and requires l'Hospital's Rule to evaluate. Using l'Hospital's Rule,

$$\lim_{z\to\infty}\left[-\frac{z}{se^{sz}}\right] = \lim_{z\to\infty}\left[-\frac{1}{s^2e^{sz}}\right] = 0.$$

Laplace transforms are often used to solve differential equations. While we saw some differential equations as homework problems in Differential Calculus, they are not covered in detail until later in this book; but, for now, let's look at the relationship between the Laplace transform of a function and the Laplace transform of its derivative.

Let's start with the definition of the Laplace transform. We have

$$\mathscr{L}\big(f(t)\big) = \int_0^\infty e^{-st}f(t)\,dt = \lim_{z\to\infty}\int_0^z e^{-st}f(t)\,dt.$$

Use Integration by Parts to evaluate $\lim\limits_{z\to\infty}\int_0^z e^{-st}f(t)\,dt$. (Let $u = f(t)$ and $dv = e^{-st}dt$.)

After integrating by parts and evaluating the limit, you should see that

$$\mathscr{L}\big(f(t)\big) = \frac{f(0)}{s} + \frac{1}{s}\left[\mathscr{L}\big(f'(t)\big)\right].$$

Then,

$$\mathscr{L}\big(f'(t)\big) = s\mathscr{L}\big(f(t)\big) - f(0).$$

Thus, differentiation in the time domain simplifies to multiplication by $s$ in the frequency domain.

The final thing we look at in this project is how the Laplace transforms of $f(t)$ and its antiderivative are related. Let $g(t) = \int_0^t f(u)\,du$.

Then,

$$\mathscr{L}\big(g(t)\big) = \int_0^{\infty} e^{-st} g(t)\, dt = \lim_{z\to\infty} \int_0^{z} e^{-st} g(t)\, dt.$$

Use Integration by Parts to evaluate $\lim_{z\to\infty} \int_0^{z} e^{-st} g(t)\, dt$. (Let $u = g(t)$ and $dv = e^{-st} dt$. Note, by the way that we have defined $g(t)$, $du = f(t)\, dt$.)

As you might expect, you should see that

$$\mathscr{L}\big(g(t)\big) = \frac{1}{s} \cdot \mathscr{L}\big(f(t)\big).$$

Integration in the time domain simplifies to division by $s$ in the frequency domain.

Now it's your turn.

1. Calculate the Laplace transform of $f(t) = 1$.
2. Calculate the Laplace transform of $f(t) = e^{-3t}$.
3. Calculate the Laplace transform of $f(t) = t^2$. (Note: you will have to integrate by parts twice.)

## Footnotes

[1] Recall that the notation "$\equiv$" means "is equivalent to," and is often used in Mathematics to clearly state that an expression is *defined* to be some other expression. In this case, $\int_a^{\infty} f(x)\, dx$ is *defined* to be $\lim_{t\to\infty} \int_a^{t} f(x)\, dx$.

[2] In your Differential Calculus class, your instructor should have been very clear that the words "provided this limit exists" means "provided this limit exists as a *finite number*." That is, if $\lim_{t\to a} g(t) = \infty$, we would say that this limit does not exist (as a finite number). We still use the notation $\lim_{t\to a} g(t) = \infty$ to describe the divergent behavior of the limit, but, in truth, the limit does not exist. This distinction will be critical when dealing with improper integrals.

[3] Gabriel's horn (also called **Torricelli's Trumpet**) is a geometric figure which has infinite surface area, but finite volume. The name refers to the tradition identifying the Archangel Gabriel as the angel who blows the horn to announce Judgment Day, associating the divine, or infinite, with the finite. Italian physicist and mathematician Evangelista Torricelli first studied the properties of this figure in the 17$^{th}$ century.

## Key Concepts

- Integrals of functions over infinite intervals are defined in terms of limits.
- Integrals of functions over an interval for which the function has a discontinuity at an endpoint may be defined in terms of limits.
- The convergence or divergence of an improper integral may be determined by comparing it with the value of an improper integral for which the convergence or divergence is known.

## Key Equations

- **Improper integrals**

$$\int_a^{+\infty} f(x)\, dx = \lim_{t\to+\infty} \int_a^{t} f(x)\, dx$$

$$\int_{-\infty}^{b} f(x)\, dx = \lim_{t\to-\infty} \int_t^{b} f(x)\, dx$$

$$\int_{-\infty}^{+\infty} f(x)\, dx = \int_{-\infty}^{0} f(x)\, dx + \int_0^{+\infty} f(x)\, dx$$

## Glossary

**improper integral**

an integral over an infinite interval or an integral of a function containing an infinite discontinuity on the interval; an improper integral is defined as a limit. The improper integral converges if this limit is a finite real number; otherwise, the improper integral diverges

## 8.1.1: Exercises

**In exercises 1 - 8, evaluate the following integrals. If the integral is not convergent, answer "It diverges."**

1) $\int_2^4 \frac{dx}{(x-3)^2}$

**Answer**

It diverges.

2) $\int_0^\infty \frac{1}{4+x^2}\,dx$

3) $\int_0^2 \frac{1}{\sqrt{4-x^2}}\,dx$

**Answer**

Converges to $\frac{\pi}{2}$

4) $\int_1^\infty \frac{1}{x\ln x}\,dx$

5) $\int_1^\infty xe^{-x}\,dx$

**Answer**

Converges to $\frac{2}{e}$

6) $\int_{-\infty}^\infty \frac{x}{x^2+1}\,dx$

7) Without integrating, determine whether the integral $\int_1^\infty \frac{1}{\sqrt{x^3+1}}\,dx$ converges or diverges by comparing the function $f(x) = \frac{1}{\sqrt{x^3+1}}$ with $g(x) = \frac{1}{\sqrt{x^3}}$.

**Answer**

It converges.

8) Without integrating, determine whether the integral $\int_1^\infty \frac{1}{\sqrt{x+1}}\,dx$ converges or diverges.

**In exercises 9 - 25, determine whether the improper integrals converge or diverge. If possible, determine the value of the integrals that converge.**

9) $\int_0^\infty e^{-x}\cos x\,dx$

**Answer**

Converges to $\frac{1}{2}$.

10) $\int_1^\infty \frac{\ln x}{x}\,dx$

11) $\int_0^1 \frac{\ln x}{\sqrt{x}}\,dx$

**Answer**

Converges to $-4$.

12) $\int_0^1 \ln x\,dx$

13) $\int_{-\infty}^\infty \frac{1}{x^2+1}\,dx$

**Answer**

Converges to $\pi$.

14) $\int_1^5 \frac{dx}{\sqrt{x-1}}$

15) $\int_{-2}^2 \frac{dx}{(1+x)^2}$

**Answer**

It diverges.

16) $\int_0^\infty e^{-x}\,dx$

17) $\int_0^\infty \sin x\,dx$

**Answer**

It diverges.

18) $\int_{-\infty}^\infty \frac{e^x}{1+e^{2x}}\,dx$

19) $\int_0^1 \frac{dx}{\sqrt[3]{x}}$

**Answer**

Converges to $1.5$.

20) $\int_0^2 \frac{dx}{x^3}$

21) $\int_{-1}^2 \frac{dx}{x^3}$

**Answer**

It diverges.

22) $\int_0^1 \frac{dx}{\sqrt{1-x^2}}$

23) $\int_0^3 \frac{1}{x-1}\,dx$

**Answer**

It diverges.

24) $\int_1^\infty \frac{5}{x^3}\,dx$

25) $\int_3^5 \frac{5}{(x-4)^2}\,dx$

**Answer**

It diverges.

**In exercises 26 and 27, determine the convergence of each of the following integrals by comparison with the given integral. If the integral converges, find the number to which it converges.**

26) $\int_1^\infty \frac{dx}{x^2+4x}$; compare with $\int_1^\infty \frac{dx}{x^2}$.

27) $\int_1^\infty \frac{dx}{\sqrt{x}+1}$; compare with $\int_1^\infty \frac{dx}{2\sqrt{x}}$.

**Answer**

Both integrals diverge.

**In exercises 28 - 38, evaluate the integrals. If the integral diverges, answer "It diverges."**

28) $\int_1^{\infty} \frac{dx}{x^e}$

29) $\int_0^1 \frac{dx}{x^{\pi}}$

**Answer**

It diverges.

30) $\int_0^1 \frac{dx}{\sqrt{1-x}}$

31) $\int_0^1 \frac{dx}{1-x}$

**Answer**

It diverges.

32) $\int_{-\infty}^0 \frac{dx}{x^2+1}$

33) $\int_{-1}^1 \frac{dx}{\sqrt{1-x^2}}$

**Answer**

Converges to $\pi$.

34) $\int_0^1 \frac{\ln x}{x}\, dx$

35) $\int_0^e \ln(x)\, dx$

**Answer**

Converges to **0**.

36) $\int_0^{\infty} xe^{-x}\, dx$

37) $\int_{-\infty}^{\infty} \frac{x}{(x^2+1)^2}\, dx$

**Answer**

Converges to **0**.

38) $\int_0^{\infty} e^{-x}\, dx$

**In exercises 39 - 44, evaluate the improper integrals. Each of these integrals has an infinite discontinuity either at an endpoint or at an interior point of the interval.**

39) $\int_0^9 \frac{dx}{\sqrt{9-x}}$

**Answer**

Converges to **6**.

40) $\int_{-27}^1 \frac{dx}{x^{2/3}}$

41) $\int_0^3 \frac{dx}{\sqrt{9-x^2}}$

**Answer**

Converges to $\frac{\pi}{2}$.

42) $\int_6^{24} \frac{dt}{t\sqrt{t^2-36}}$

43) $\int_0^4 x\ln(4x)\,dx$

**Answer**

Converges to $8\ln(16)-4$.

44) $\int_0^3 \frac{x}{\sqrt{9-x^2}}\,dx$

45) Evaluate $\int_{.5}^t \frac{dx}{\sqrt{1-x^2}}$. (Be careful!) (Express your answer using three decimal places.)

**Answer**

Converges to about $1.047$.

46) Evaluate $\int_1^4 \frac{dx}{\sqrt{x^2-1}}$. (Express the answer in exact form.)

47) Evaluate $\int_2^\infty \frac{dx}{(x^2-1)^{3/2}}$.

**Answer**

Converges to $-1+\frac{2}{\sqrt{3}}$.

48) Find the area of the region in the first quadrant between the curve $y=e^{-6x}$ and the $x$-axis.

49) Find the area of the region bounded by the curve $y=\frac{7}{x^2}$, the $x$-axis, and on the left by $x=1$.

**Answer**

$A=7.0$ units.$^2$

50) Find the area under the curve $y=\frac{1}{(x+1)^{3/2}}$, bounded on the left by $x=3$.

51) Find the area under $y=\frac{5}{1+x^2}$ in the first quadrant.

**Answer**

$A=\frac{5\pi}{2}$ units.$^2$

52) Find the volume of the solid generated by revolving about the $x$-axis the region under the curve $y=\frac{3}{x}$ from $x=1$ to $x=\infty$.

53) Find the volume of the solid generated by revolving about the $y$-axis the region under the curve $y=6e^{-2x}$ in the first quadrant.

**Answer**

$V=3\pi$ units$^3$

54) Find the volume of the solid generated by revolving about the $x$-axis the area under the curve $y=3e^{-x}$ in the first quadrant.

The **Laplace transform** of a continuous function over the interval $[0,\infty)$ is defined by $F(s)=\int_0^\infty e^{-sx}f(x)\,dx$ (see the Student Project). This definition is used to solve some important initial-value problems in differential equations, as discussed later. The

domain of $F$ is the set of all real numbers s such that the improper integral converges. Find the Laplace transform $F$ of each of the following functions and give the domain of $F$.

55) $f(x) = 1$

**Answer**

$\frac{1}{s}, \quad s > 0$

56) $f(x) = x$

57) $f(x) = \cos(2x)$

**Answer**

$\frac{s}{s^2 + 4}, \quad s > 0$

58) $f(x) = e^{ax}$

59) Use the formula for arc length to show that the circumference of the circle $x^2 + y^2 = 1$ is $2\pi$.

**Answer**

Answers will vary.

A function is a **probability density function** if it satisfies the following definition: $\int_{-\infty}^{\infty} f(t)\,dt = 1$. The probability that a random variable $x$ lies between a and b is given by $P(a \le x \le b) = \int_a^b f(t)\,dt$.

60) Show that $f(x) = \begin{cases} 0, & \text{if } x < 0 \\ 7e^{-7x}, & \text{if } x \ge 0 \end{cases}$ is a probability density function.

61) Find the probability that $x$ is between 0 and 0.3. (Use the function defined in the preceding problem.) Use four-place decimal accuracy.

**Answer**

0.8775

# 8.2: Sequences

**Learning Objectives**

- Find the formula for the general term of a sequence.
- Calculate the limit of a sequence if it exists.
- Determine the convergence or divergence of a given sequence.

In this section, we reintroduce the concept of sequences that you learned back in Algebra. The calculus of sequences allows us to define what it means for a sequence to converge or diverge. We show how to find limits of sequences that converge, often by using the properties of limits for functions discussed in Calculus I. We close this section with the Monotone Convergence Theorem, a tool we can use to prove that certain types of sequences converge.

## Terminology of Sequences

We need new terms and definitions for this topic. First, an **infinite sequence** is an ordered list of numbers of the form

$$a_1, a_2, a_3, \ldots, a_n, \ldots.$$

Each of the numbers in the sequence is called a **term**. The symbol $n$ is called the **index variable** for the sequence. We use the notation

$$\{a_n\}_{n=1}^{\infty},$$

or simply $\{a_n\}$, to denote this sequence.[1] Because, in general, a particular number $a_n$ exists for each positive integer $n$, we can also define a sequence as a function whose domain is the set of positive integers.

Let's consider the infinite, ordered list

$$2, 4, 8, 16, 32, \ldots.$$

This is a sequence in which the first, second, and third terms are given by $a_1 = 2$, $a_2 = 4$, and $a_3 = 8$. You can probably see that the terms in this sequence have the following pattern:

$$a_1 = 2^1,\ a_2 = 2^2,\ a_3 = 2^3,\ a_4 = 2^4 \text{ and } a_5 = 2^5.$$

Assuming this pattern continues, we can write the $n^{\text{th}}$ term in the sequence by the explicit formula $a_n = 2^n$. Using this notation, we can write this sequence as

$$\{2^n\}_{n=1}^{\infty},$$

or

$$\{2^n\},$$

or

$$a_n = 2^n. \tag{8.2.1}$$

The formula in Equation 8.2.1 is called an **explicit formula** (or **explicit relation**) for the sequence.

Alternatively, we can describe this sequence differently. Since each term is twice the previous term, this sequence can be defined **recursively** by expressing the $n^{\text{th}}$ term, $a_n$, in terms of the previous term, $a_{n-1}$. In particular, we can define this sequence as the sequence $\{a_n\}$ where $a_1 = 2$ and, for all $n \geq 2$, each term $a_n$ is defined by the **recurrence relation**

$$a_n = 2a_{n-1}.$$

In a recurrence relation, one term (or more) of the sequence is given explicitly, and subsequent terms are defined in terms of earlier terms in the sequence.

Note that the index does not have to start at $n = 1$ but could start with other integers. For example, a sequence given by the explicit formula $a_n = f(n)$ could start at $n = 0$, in which case the sequence would be

$$a_0,\ a_1,\ a_2, \ldots .$$

Similarly, for a sequence defined by a recurrence relation, the term $a_0$ may be given explicitly, and the terms $a_n$ for $n \geq 1$ may be defined in terms of $a_{n-1}$.

The graph of a sequence $\{a_n\}$ consists of all points $(n, a_n)$ for all positive integers $n$.[2] Figure 8.2.1 shows the graph of $2^n$.

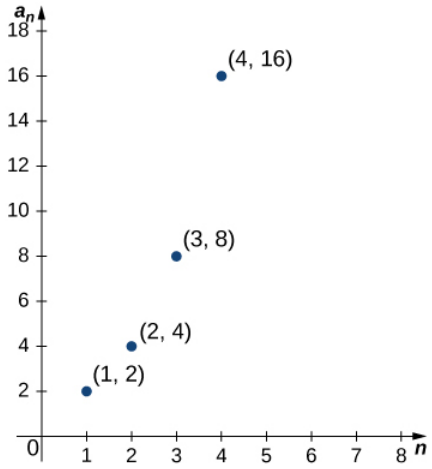

Figure 8.2.1: The plotted points are a graph of the sequence $\{2^n\}$.

Two types of sequences occur often and are given special names: **arithmetic sequences** and **geometric sequences**. The difference between every pair of consecutive terms is the same in an arithmetic sequence. For example, consider the sequence

$$3,\ 7,\ 11,\ 15, 19, \ldots .$$

You can see that the difference between every consecutive pair of terms is 4. Assuming that this pattern continues, this sequence is an arithmetic sequence. It can be described by using the recurrence relation

$$\begin{cases} a_1 = 3 \\ a_n = a_{n-1} + 4, \text{ for } n \geq 2 \end{cases}.$$

Note that

$$\begin{aligned} a_2 &= 3 + 4 \\ a_3 &= 3 + 4 + 4 = 3 + 2 \cdot 4 \\ a_4 &= 3 + 4 + 4 + 4 = 3 + 3 \cdot 4 \end{aligned}$$

Thus, the sequence can also be described using the explicit formula

$$a_n = 3 + 4(n-1) = 4n - 1.$$

In general, an arithmetic sequence is any sequence that can be written in the form $a_n = cn + b$.

In a geometric sequence, the ratio of every pair of consecutive terms is the same. For example, consider the sequence

$$2, -\frac{2}{3}, \frac{2}{9}, -\frac{2}{27}, \frac{2}{81}, \ldots .$$

We see that the ratio of any term to the preceding term is $-\frac{1}{3}$. Assuming this pattern continues, this sequence is geometric. It can be defined recursively as

$$\begin{cases} a_1 = 2 \\ a_n = -\dfrac{1}{3} \cdot a_{n-1}, \text{ for } n \geq 2 \end{cases}$$

Alternatively, since

$$a_2 = -\frac{1}{3}\cdot(2)$$

$$a_3 = \left(-\frac{1}{3}\right)\left(-\frac{1}{3}\right)(2) = \left(-\frac{1}{3}\right)^2\cdot(2)$$

$$a_4 = \left(-\frac{1}{3}\right)\left(-\frac{1}{3}\right)\left(-\frac{1}{3}\right)(2) = \left(-\frac{1}{3}\right)^3\cdot(2),$$

we see that the sequence can be described by using the explicit formula[3]

$$a_n = 2\left(-\frac{1}{3}\right)^{n-1}.$$

The sequence $\{2^n\}$ that we discussed earlier is a geometric sequence where the ratio of any term to the previous term is $2$. Generally, a geometric sequence is any sequence that can be written in the form $a_n = cr^n$.

### ✔ Example 8.2.1: Finding Explicit Formulas

For each of the following sequences, find an explicit formula for the $n^{\text{th}}$ term of the sequence.

a. $-\frac{1}{2}, \frac{2}{3}, -\frac{3}{4}, \frac{4}{5}, -\frac{5}{6}, \ldots$
b. $\frac{3}{4}, \frac{9}{7}, \frac{27}{10}, \frac{81}{13}, \frac{243}{16}, \ldots$.

**Solutions**

a. First, note that the sequence alternates from negative to positive. The odd terms in the sequence are negative, and the even terms are positive. Therefore, the $n^{\text{th}}$ term includes a factor of $(-1)^n$. Next, consider the sequence of numerators $1, 2, 3, \ldots$ and the sequence of denominators $2, 3, 4, \ldots$. We can see that both of these sequences are arithmetic sequences. The $n^{\text{th}}$ term in the sequence of numerators is $n$, and the $n^{\text{th}}$ term in the sequence of denominators is $n+1$. Therefore, the sequence can be described by the explicit formula

$$a_n = \frac{(-1)^n n}{n+1}.$$

b. The sequence of numerators $3, 9, 27, 81, 243, \ldots$ is a geometric sequence. The numerator of the $n^{\text{th}}$ term is $3^n$. The sequence of denominators $4, 7, 10, 13, 16, \ldots$ is an arithmetic sequence. The denominator of the $n^{\text{th}}$ term is $4 + 3(n-1) = 3n+1$. Therefore, we can describe the sequence by the explicit formula

$$a_n = \frac{3^n}{3n+1}.$$

### ? Checkpoint 8.2.1

Find an explicit formula for the $n^{\text{th}}$ term of the sequence $\left\{\frac{1}{5}, -\frac{1}{7}, \frac{1}{9}, -\frac{1}{11}, \ldots\right\}$.

**Answer**

$$a_n = \frac{(-1)^{n+1}}{3+2n}$$

### ✔ Example 8.2.2: Defined by Recurrence Relations

For each of the following recursively defined sequences, find an explicit formula for the sequence.

a. $a_1 = 2, a_n = -3a_{n-1}$ for $n \geq 2$
b. $a_1 = \left(\frac{1}{2}\right), a_n = a_{n-1} + \left(\frac{1}{2}\right)^n$ for $n \geq 2$

**Solutions**

a. Writing out the first few terms, we have

$$\begin{aligned} a_1 &= 2 \\ a_2 &= -3a_1 = -3(2) \\ a_3 &= -3a_2 = (-3)^2(2) \\ a_4 &= -3a_3 = (-3)^3(2). \end{aligned}$$

In general,

$$a_n = 2(-3)^{n-1}.$$

b. Write out the first few terms:

$$a_1 = \frac{1}{2}$$

$$a_2 = a_1 + \left(\frac{1}{2}\right)^2 = \frac{1}{2} + \frac{1}{4} = \frac{3}{4}$$

$$a_3 = a_2 + \left(\frac{1}{2}\right)^3 = \frac{3}{4} + \frac{1}{8} = \frac{7}{8}$$

$$a_4 = a_3 + \left(\frac{1}{2}\right)^4 = \frac{7}{8} + \frac{1}{16} = \frac{15}{16}.$$

From this pattern, we derive the explicit formula

$$a_n = \frac{2^n - 1}{2^n} = 1 - \frac{1}{2^n}.$$

**? Checkpoint 8.2.2**

Find an explicit formula for the sequence defined recursively such that $a_1 = -4$ and $a_n = a_{n-1} + 6$.

**Answer**

$a_n = 6n - 10$

## Limit of a Sequence

A fundamental question regarding infinite sequences is the behavior of the terms as $n$ gets larger. Since a sequence is a function defined on the positive integers, it makes sense to discuss the limit of the terms as $n \to \infty$. For example, consider the following four sequences and their different behaviors as $n \to \infty$ (Figure 8.2.2):

a. $\{1 + 3n\} = \{4, 7, 10, 13, ...\}$. The terms $1 + 3n$ become arbitrarily large as $n \to \infty$. In this case, we say that $1 + 3n \to \infty$ as $n \to \infty$.
b. $\{1 - (\frac{1}{2})^n\} = \{\frac{1}{2}, \frac{3}{4}, \frac{7}{8}, \frac{15}{16} ...\}$. The terms $1 - (\frac{1}{2})^n \to 1$ as $n \to \infty$.
c. $\{(-1)^n\} = \{-1, 1, -1, 1, ...\}$. The terms alternate but do not approach one value as $n \to \infty$.
d. $\left\{\frac{(-1)^n}{n}\right\} = \{-1, \frac{1}{2}, -\frac{1}{3}, \frac{1}{4}, ...\}$. The terms alternate for this sequence as well, but $\frac{(-1)^n}{n} \to 0$ as $n \to \infty$.

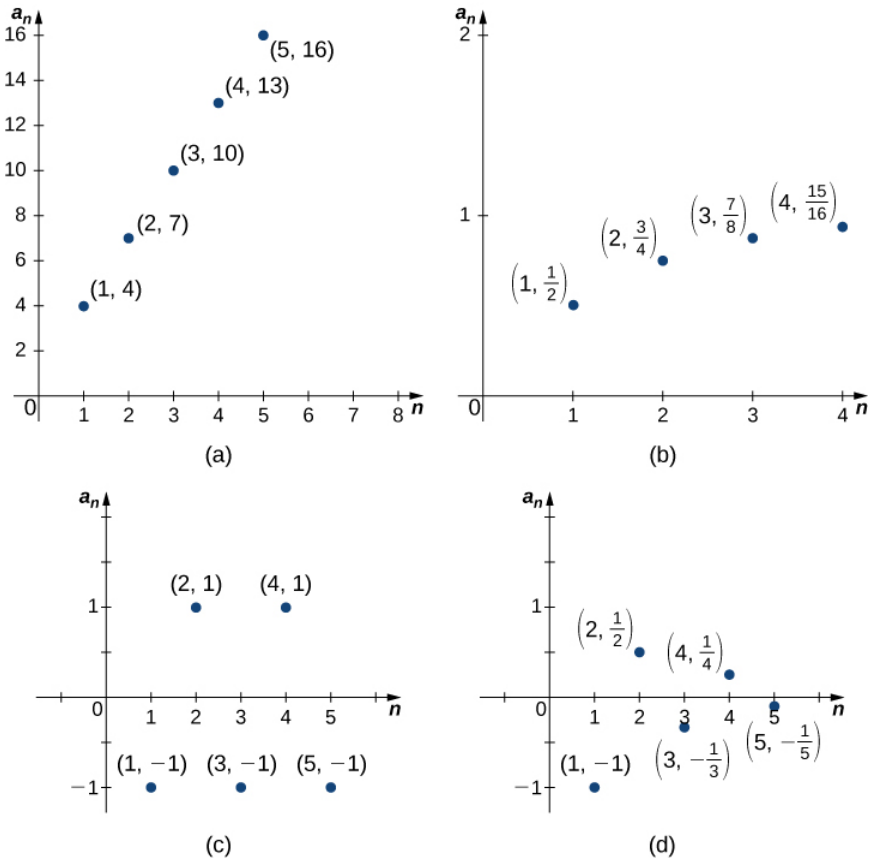

Figure 8.2.2(*a*): The terms in the sequence become arbitrarily large as $n \to \infty$.

Figure 8.2.2(*b*): The terms in the sequence approach 1 as $n \to \infty$.

Figure 8.2.2(*c*): The terms in the sequence alternate between 1 and $-1$ as $n \to \infty$.

Figure 8.2.2(*d*): The terms in the sequence alternate between positive and negative values but approach 0 as $n \to \infty$.

From these examples, we see several possibilities for the behavior of the terms of a sequence as $n \to \infty$. The terms approach a finite number in two sequences as $n \to \infty$. In the other two sequences, the terms do not. If the terms of a sequence approach a finite number $L$ as $n \to \infty$, we say that the sequence is a **convergent sequence** and the real number $L$ is the limit of the sequence. We can give an informal definition here.

### Definition: The Informal Definition of the Limit of a Sequence

Given a sequence $\{a_n\}$, if the terms $a_n$ become arbitrarily close to a finite number $L$ as $n$ becomes sufficiently large, we say $\{a_n\}$ is a **convergent sequence** and $L$ is the **limit of the sequence**. In this case, we write

$$\lim_{n\to\infty} a_n = L.$$

If a sequence $\{a_n\}$ is not convergent, we say it is a **divergent sequence.**

From Figure 8.2.2(*b*), we see that the terms in the sequence $\left\{1-\left(\frac{1}{2}\right)^n\right\}$ are becoming arbitrarily close to 1 as $n$ becomes very large. We conclude that $\left\{1-\left(\frac{1}{2}\right)^n\right\}$ is a convergent sequence and its limit is 1. In contrast, from Figure 8.2.2(*a*), we see that the terms in the sequence $1+3n$ are not approaching a finite number as $n$ becomes larger. We say that $\{1+3n\}$ is a divergent sequence.

In the informal definition for the limit of a sequence, we used the terms "arbitrarily close" and "sufficiently large." Although these phrases help illustrate the meaning of a converging sequence, they could be more specific. To be more precise, we now present the more formal definition of limit for a sequence and show these ideas graphically in Figure 8.2.2.

**Definition: The Precise Definition of the Limit of a Sequence**

A sequence $\{a_n\}$ converges to a real number $L$ if for all $\epsilon > 0$, there exists an integer $N$ such that for all $n \geq N$, $|a_n - L| < \epsilon$. The number $L$ is the limit of the sequence, and we write

$$\lim_{n\to\infty} a_n = L \text{ or } a_n \to L.$$

In this case, we say the sequence $\{a_n\}$ is a convergent sequence. If a sequence does not converge, it is divergent, and we say the limit does not exist.[4]

Figure 8.2.3 illustrates the precise definition of the limit of a convergent sequence.

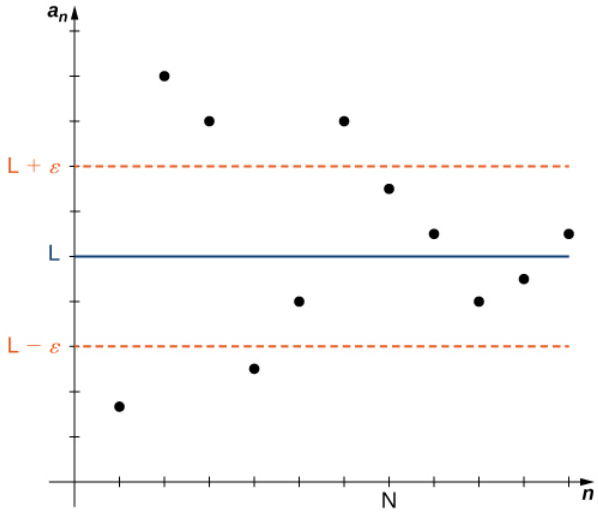

Figure 8.2.3: As $n$ increases, the terms $a_n$ become closer to $L$. For values of $n \geq N$, the distance between each point $(n, a_n)$ and the line $y = L$ is less than $\epsilon$.

We remark that the convergence or divergence of a sequence $\{a_n\}$ depends only on what happens to the terms $a_n$ as $n \to \infty$. Therefore, if a finite number of terms $b_1, b_2, \ldots, b_N$ are placed before $a_1$ to create a new sequence

$$b_1,\ b_2,\ \ldots,\ b_N,\ a_1,\ a_2,\ \ldots,$$

this new sequence will converge if $\{a_n\}$ converges and diverge if $\{a_n\}$ diverges. Furthermore, if the sequence $\{a_n\}$ converges to $L$, this new sequence will also converge to $L$.

As defined above, if a sequence does not converge, it is considered a divergent sequence. For example, the sequences $\{1 + 3n\}$ and $\{(-1)^n\}$ shown in Figure 8.2.2 diverge. However, different sequences can diverge in different ways. The sequence $\{(-1)^n\}$ diverges because the terms alternate between 1 and $-1$, but do not approach one value as $n \to \infty$. On the other hand, the sequence $\{1 + 3n\}$ diverges because the terms $1 + 3n \to \infty$ as $n \to \infty$. We say the sequence $\{1 + 3n\}$ **diverges to infinity** and write $\lim_{n\to\infty}(1 + 3n) = \infty$. It is important to recognize that this notation does not imply the limit of the sequence $\{1 + 3n\}$ exists. The sequence is, in fact, divergent. Writing that the limit is infinite is intended only to provide more information about why the sequence is divergent. A sequence can also diverge to negative infinity. For example, the sequence $\{-5n + 2\}$ diverges to negative infinity because $-5n + 2 \to -\infty$ as $n \to \infty$. We write this as $\lim_{n\to\infty}(-5n + 2) = -\infty$.

Because a sequence is a function whose domain is the set of positive integers, we can use properties of limits of functions to determine whether a sequence converges. For example, consider a sequence $\{a_n\}$ and a related function $f$ defined on all positive real numbers such that $f(n) = a_n$ for all integers $n \geq 1$. Since the domain of the sequence is a subset of the domain of $f$, if $\lim_{x\to\infty} f(x)$ exists, then the sequence converges and has the same limit. For example, consider the sequence $\left\{\frac{1}{n}\right\}$ and the related function $f(x) = \frac{1}{x}$. Since the function $f$ defined on all real numbers $x > 0$ satisfies $f(x) = \frac{1}{x} \to 0$ as $x \to \infty$, the sequence $\left\{\frac{1}{n}\right\}$ must satisfy $\frac{1}{n} \to 0$ as $n \to \infty$. We summarize this result as a theorem.

**Theorem**

Consider a sequence $\{a_n\}$ such that $a_n = f(n)$ for all $n \geq 1$. If there exists a real number $L$ such that

$$\lim_{x\to\infty} f(x) = L,$$

then $\{a_n\}$ converges and

$$\lim_{n\to\infty} a_n = L.$$

**Caution: The Converse of this Theorem is NOT True (in general)**

In general, the converse of this theorem is *not* true. For example, consider the sequence $\{\sin(\pi n)\}$. For all integer values of $n$, the value of this sequence is $0$. Hence, $\lim_{n\to\infty} \sin(\pi n) = 0$; however, from our work in Calculus I, we know that $\lim_{x\to\infty} \sin(\pi x)$ does not exist.

It's best to think of this theorem as follows:

> *If the infinite limit of the related function exists (and is finite), then the sequence converges (to the same value).*

We can use this theorem to evaluate $\lim_{n\to\infty} r^n$ for $0 \leq r \leq 1$. For example, consider the sequence $\{(1/2)^n\}$ and the related exponential function $f(x) = (1/2)^x$. Since $\lim_{x\to\infty} (1/2)^x = 0$, we conclude that the sequence $\{(1/2)^n\}$ converges and its limit is $0$. Similarly, for any real number $r$ such that $0 \leq r < 1$, $\lim_{x\to\infty} r^x = 0$, and therefore the sequence $\{r^n\}$ converges (to $0$). On the other hand, if $r = 1$, then $\lim_{x\to\infty} r^x = 1$, and therefore the limit of the sequence $\{1^n\}$ is $1$. If $r > 1$, $\lim_{x\to\infty} r^x = \infty$, and therefore we cannot apply this theorem. However, in this case, just as the function $r^x$ grows without bound as $n \to \infty$, the terms $r^n$ in the sequence become arbitrarily large as $n \to \infty$, and we conclude that the sequence $\{r^n\}$ diverges to infinity if $r > 1$.

We summarize these results regarding the geometric sequence $r^n$:

$$\begin{array}{lcll} r^n & \to & 0 & \text{if } 0 < r < 1 \\ r^n & \to & 1 & \text{if } r = 1 \\ r^n & \to & \infty & \text{if } r > 1 \end{array}$$

Later in this section we consider the case when $r < 0$.

We now consider slightly more complicated sequences. For example, consider the sequence $\{(2/3)^n + (1/4)^n\}$. The terms in this sequence are more complicated than other sequences we have discussed, but luckily the limit of this sequence is determined by the limits of the two sequences $\{(2/3)^n\}$ and $\{(1/4)^n\}$. As we describe in the following algebraic Limit Laws, since $\{(2/3)^n\}$ and $\{1/4)^n\}$ both converge to $0$, the sequence $\{(2/3)^n + (1/4)^n\}$ converges to $0 + 0 = 0$. Just as we were able to evaluate a limit involving an algebraic combination of functions $f$ and $g$ by looking at the limits of $f$ and $g$ in Calculus I, we can evaluate the limit of a sequence whose terms are algebraic combinations of $a_n$ and $b_n$ by evaluating the limits of $\{a_n\}$ and $\{b_n\}$.

**Theorem: Algebraic Limit Laws**

Given sequences $\{a_n\}$ and $\{b_n\}$ and any real number $c$, if there exist constants $A$ and $B$ such that $\lim_{n\to\infty} a_n = A$ and $\lim_{n\to\infty} b_n = B$, then

i. $\lim_{n\to\infty} c = c$
ii. $\lim_{n\to\infty} ca_n = c \lim_{n\to\infty} a_n = cA$
iii. $\lim_{n\to\infty} (a_n \pm b_n) = \lim_{n\to\infty} a_n \pm \lim_{n\to\infty} b_n = A \pm B$
iv. $\lim_{n\to\infty} (a_n \cdot b_n) = \left(\lim_{n\to\infty} a_n\right) \cdot \left(\lim_{n\to\infty} b_n\right) = A \cdot B$
v. $\lim_{n\to\infty} \left(\frac{a_n}{b_n}\right) = \frac{\lim_{n\to\infty} a_n}{\lim_{n\to\infty} b_n} = \frac{A}{B}$, provided $B \neq 0$ and each $b_n \neq 0$.

**Proof of part iii.**

Let $\epsilon > 0$. Since $\lim_{n\to\infty} a_n = A$, there exists a constant positive integer $N_1$ such that $|a_n - A| < \frac{\epsilon}{2}$ for all $n \geq N_1$. Since $\lim_{n\to\infty} b_n = B$, there exists a constant $N_2$ such that $|b_n - B| < \epsilon/2$ for all $n \geq N_2$. Let $N = \max\{N_1, N_2\}$. Therefore, for all $n \geq N$, $|(a_n + b_n) - (A + B)| \leq |a_n - A| + |b_n - B| < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon$.

The Algebraic Limit Laws allow us to evaluate limits for many sequences. For example, consider the sequence $a_n = \frac{1}{n^2}$. As shown earlier, $\lim_{n\to\infty} \frac{1}{n} = 0$. Similarly, for any positive integer $k$, we can conclude that

$$\lim_{n\to\infty} \frac{1}{n^k} = 0.$$

In the next example, we make use of this fact along with the Algebraic Limit Laws to evaluate limits for other sequences.

### Example 8.2.3: Determining Convergence and Finding Limits

For each of the following sequences, determine whether or not the sequence converges. If it converges, find its limit.

a. $\left\{5 - \frac{3}{n^2}\right\}$
b. $\left\{\frac{3n^4 - 7n^2 + 5}{6 - 4n^4}\right\}$
c. $\left\{\frac{2^n}{n^2}\right\}$
d. $\left\{\left(1 + \frac{4}{n}\right)^n\right\}$

**Solutions**

a. We know that $\lim_{n\to\infty} \frac{1}{n} = 0$. Using this fact, we conclude that

$$\lim_{n\to\infty} \frac{1}{n^2} = \lim_{n\to\infty} \frac{1}{n} \cdot \lim_{n\to\infty} \frac{1}{n} = 0.$$

Therefore,

$$\lim_{n\to\infty} \left(5 - \frac{3}{n^2}\right) = \lim_{n\to\infty} 5 - 3 \lim_{n\to\infty} \frac{1}{n^2} = 5 - 3.0 = 5.$$

The sequence converges and its limit is $5$.

b. By factoring $n^4$ out of the numerator and denominator and using the Algebraic Limit Laws above, we have

$$\begin{aligned}
\lim_{n\to\infty}\frac{3n^4-7n^2+5}{6-4n^4} &= \lim_{n\to\infty}\frac{3-\frac{7}{n^2}+\frac{5}{n^4}}{\frac{6}{n^4}-4}\\
&= \frac{\lim_{n\to\infty}(3-\frac{7}{n^2}+\frac{5}{n^4})}{\lim_{n\to\infty}(\frac{6}{n^4}-4)}\\
&= \frac{\lim_{n\to\infty}(3)-\lim_{n\to\infty}\frac{7}{n^2}+\lim_{n\to\infty}\frac{5}{n^4}}{\lim_{n\to\infty}\frac{6}{n^4}-\lim_{n\to\infty}(4)}\\
&= \frac{\lim_{n\to\infty}(3)-7\cdot\lim_{n\to\infty}\frac{1}{n^2}+5\cdot\lim_{n\to\infty}\frac{1}{n^4}}{6\cdot\lim_{n\to\infty}\frac{1}{n^4}-\lim_{n\to\infty}(4)}\\
&= \frac{3-7\cdot 0+5\cdot 0}{6\cdot 0-4}\\
&= -\frac{3}{4}.
\end{aligned}$$

The sequence converges and its limit is $-3/4$.

c. Consider the related function $f(x)=2^x/x^2$ defined on all real numbers $x>0$. Since $2^x\to\infty$ and $x^2\to\infty$ as $x\to\infty$, apply l'Hospital's Rule and write

$$\begin{aligned}
\lim_{x\to\infty}\frac{2^x}{x^2} &\overset{\text{L.R.}}{=} \lim_{x\to\infty}\frac{2^x\ln 2}{2x}\\
&\overset{\text{L.R.}}{=} \lim_{x\to\infty}\frac{2^x(\ln 2)^2}{2}\\
&= \infty.
\end{aligned}$$

We conclude that the sequence diverges.

d. Consider the function $f(x)=\left(1+\frac{4}{x}\right)^x$ defined on all real numbers $x>0$. We start by letting

$$y=\left(1+\frac{4}{x}\right)^x.$$

Hence,

$$\begin{aligned}
\ln(y) &= \ln\left[\left(1+\frac{4}{x}\right)^x\right]\\
&= x\ln\left(1+\frac{4}{x}\right) \qquad \text{(Properties of Logarithms)}
\end{aligned}$$

Taking the limit of both sides, we get

$$\begin{aligned}\lim_{x\to\infty}\ln(y) &= \lim_{x\to\infty} x\ln\left(1+\frac{4}{x}\right)\\ &= \lim_{x\to\infty}\frac{\ln\left(1+\frac{4}{x}\right)}{\frac{1}{x}} \qquad \text{(rewriting as the indeterminate form } \tfrac{0}{0}\text{)}\\ &\overset{\text{L.R.}}{=} \lim_{x\to\infty}\frac{4}{1+4/x}\\ &= 4\end{aligned}$$

Hence,

$$\begin{aligned}\lim_{x\to\infty}\left(1+\frac{4}{x}\right)^x &= \lim_{x\to\infty} y\\ &= \lim_{x\to\infty} e^{\ln(y)}\\ &= e^{\lim_{x\to\infty}\ln(y)}\\ &= e^4\end{aligned}$$

Hence, since $\lim_{x\to\infty}\left(1+\frac{4}{x}\right)^x = e^4$, we can conclude that the sequence $\left\{\left(1+\frac{4}{n}\right)^n\right\}$ converges to $e^4$.

**Checkpoint 8.2.3**

Consider the sequence $\{(5n^2+1)/e^n\}$. Determine whether or not the sequence converges. If it converges, find its limit.

**Answer**

The sequence converges, and its limit is $0$

Recall that if $f$ is a continuous function at a value $L$, then $f(x)\to f(L)$ as $x\to L$. This idea applies to sequences as well. Suppose a sequence $a_n\to L$, and a function $f$ is continuous at $L$. Then $f(a_n)\to f(L)$. This property often enables us to find limits for complicated sequences. For example, consider the sequence $\sqrt{5-\frac{3}{n^2}}$. From Example 8.2.3a. we know the sequence $5-\frac{3}{n^2}\to 5$. Since $\sqrt{x}$ is a continuous function at $x=5$,

$$\lim_{n\to\infty}\sqrt{5-\frac{3}{n^2}} = \sqrt{\lim_{n\to\infty}(5-\frac{3}{n^2})} = \sqrt{5}.$$

**Theorem**

Consider a sequence $\{a_n\}$ and suppose there exists a real number $L$ such that the sequence $\{a_n\}$ converges to $L$. Suppose $f$ is a continuous function at $L$. Then there exists an integer $N$ such that $f$ is defined at all values an for $n\geq N$, and the sequence $\{f(a_n)\}$ converges to $f(L)$ (see Figure 8.2.4).

**Proof**

Let $\epsilon>0$. Since $f$ is continuous at $L$, there exists $\delta>0$ such that $|f(x)-f(L)|<\epsilon$ if $|x-L|<\delta$. Since the sequence $\{a_n\}$ converges to $L$, there exists $N$ such that $|a_n-L|<\delta$ for all $n\geq N$. Therefore, for all $n\geq N$, $|a_n-L|<\delta$, which implies $|f(a_n)-f(L)|<\epsilon$. We conclude that the sequence $\{f(a_n)\}$ converges to $f(L)$.

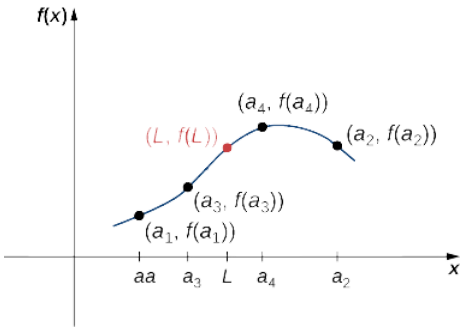

Figure 8.2.4: Because $f$ is a continuous function as the inputs $a_1, a_2, a_3, \ldots$ approach $L$, the outputs $f(a_1), f(a_2), f(a_3), \ldots$ approach $f(L)$.

### Example 8.2.4: Limits Involving Continuous Functions Defined on Convergent Sequences

Determine whether the sequence $\{\cos(3/n^2)\}$ converges. If it converges, find its limit.

**Solution**

Since the sequence $\{3/n^2\}$ converges to $0$ and $\cos x$ is continuous at $x = 0$, we can conclude that the sequence $\{\cos(3/n^2)\}$ converges and

$$\lim_{n\to\infty} \cos\left(\frac{3}{n^2}\right) = \cos 0 = 1.$$

### Checkpoint 8.2.4

Determine if the sequence $\left\{\sqrt{\frac{2n+1}{3n+5}}\right\}$ converges. If it converges, find its limit.

**Answer**

The sequence converges, and its limit is $\sqrt{2/3}$.

Another theorem involving limits of sequences is an extension of the Squeeze Theorem for limits discussed in Calculus I.

### Theorem: Squeeze Theorem for Sequences

Consider sequences $\{a_n\}$, $\{b_n\}$, and $\{c_n\}$. Suppose there exists an integer $N$ such that

$$a_n \le b_n \le c_n \text{ for all } n \ge N.$$

If there exists a real number $L$ such that

$$\lim_{n\to\infty} a_n = L = \lim_{n\to\infty} c_n,$$

then $\{b_n\}$ converges and $\lim_{n\to\infty} b_n = L$ (see Figure 8.2.5).

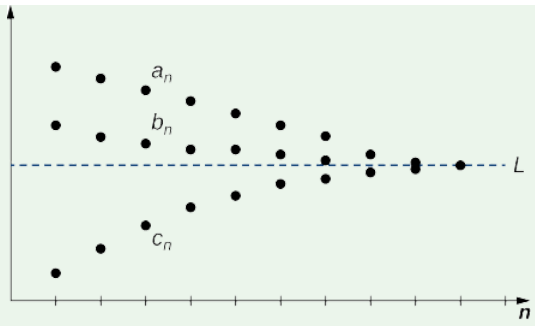

Figure 8.2.5: Each term $b_n$ satisfies $a_n \le b_n \le c_n$ and the sequences $\{a_n\}$ and $\{c_n\}$ converge to the same limit, so the sequence $\{b_n\}$ must converge to the same limit as well.

**Proof**

Let $\epsilon > 0$. Since the sequence $\{a_n\}$ converges to $L$, there exists an integer $N_1$ such that $|a_n - L| < \epsilon$ for all $n \ge N_1$. Similarly, since $\{c_n\}$ converges to $L$, there exists an integer $N_2$ such that $|c_n - L| < \epsilon$ for all $n \ge N_2$. By assumption, there exists an integer $N$ such that $a_n \le b_n \le c_n$ for all $n \ge N$. Let $M = \max\{N_1, N_2, N\}$. We must show that $|b_n - L| < \epsilon$ for all $n \ge M$.

For all $n \ge M$,

$$-\epsilon < -|a_n - L| \le a_n - L \le b_n - L \le c_n - L \le |c_n - L| < \epsilon.$$

Therefore, $-\epsilon < b_n - L < \epsilon$, and we conclude that $|b_n - L| < \epsilon$ for all $n \ge M$, and we conclude that the sequence $b_n$ converges to $L$.

## Example 8.2.5: Using the Squeeze Theorem

Use the Squeeze Theorem to find the limit of each of the following sequences.

a. $\left\{\frac{\cos n}{n^2}\right\}$
b. $\left\{\left(-\frac{1}{2}\right)^n\right\}$

**Solutions**

a. Since $-1 \le \cos n \le 1$ for all integers $n$, we have

$$-\frac{1}{n^2} \le \frac{\cos n}{n^2} \le \frac{1}{n^2}.$$

Since $-1/n^2 \to 0$ and $1/n^2 \to 0$ as $n \to \infty$, we conclude that $\cos n/n^2 \to 0$ by the Squeeze Theorem.

b. Since

$$-\frac{1}{2^n} \le \left(-\frac{1}{2}\right)^n \le \frac{1}{2^n}$$

for all positive integers $n$, $-1/2^n \to 0$ and $1/2^n \to 0$ as $n \to \infty$, we can conclude that $(-1/2)^n \to 0$ by the Squeeze Theorem.

## Checkpoint 8.2.5

Find $\lim\limits_{n\to\infty} \dfrac{2n - \sin n}{n}$.

**Answer**

2

https://math.libretexts.org/@go/page/175607

Using the idea from Example 8.2.5b we conclude that $r^n \to 0$ for any real number $r$ such that $-1 < r < 0$. If $r < -1$, the sequence $r^n$ diverges because the terms oscillate and become arbitrarily large in magnitude. If $r = -1$, the sequence $r^n = (-1)^n$ diverges, as discussed earlier. Here is a summary of the properties for geometric sequences.

$$\begin{aligned} r^n &\to 0 \quad \text{if} \quad |r| < 1 \\ r^n &\to 1 \quad \text{if} \quad r = 1 \\ r^n &\to \infty \quad \text{if} \quad r > 1 \\ \{r^n\} &\text{ diverges} \quad \text{if} \quad r \leq -1 \end{aligned}$$

## Bounded Sequences

We now focus on one of the most important theorems involving sequences: the Monotone Convergence Theorem. Before stating the theorem, we need to introduce some terminology and motivation. We begin by defining what it means for a sequence to be bounded.

**Definition: Bound Sequences**

A sequence $\{a_n\}$ is **bounded above** if there exists a real number $M$ such that

$$a_n \leq M$$

for all $n \in \mathbb{N}$.

A sequence $\{a_n\}$ is **bounded below** if there exists a real number $m$ such that

$$m \leq a_n$$

for all $n \in \mathbb{N}$.

A sequence $\{a_n\}$ is a **bounded sequence** if it is bounded above and bounded below.

If a sequence is not bounded, it is an **unbounded sequence.**

For example, the sequence $\{1/n\}$ is bounded above because $1/n \leq 1$ for all $n \in \mathbb{N}$. It is also bounded below because $1/n \geq 0$ for all $n \in \mathbb{N}$. Therefore, $\{1/n\}$ is a bounded sequence. On the other hand, consider the sequence $\{2^n\}$. Because $2^n \geq 2$ for all $n \in \mathbb{N}$, the sequence is bounded below. However, the sequence is not bounded above. Therefore, $\{2^n\}$ is an unbounded sequence.

We now discuss the relationship between boundedness and convergence. Suppose a sequence $\{a_n\}$ is unbounded. Then, it is not bounded above or below. In any case, there are terms $a_n$ that are arbitrarily large in magnitude as $n$ gets larger. As a result, the sequence $\{a_n\}$ cannot converge. Therefore, being bounded is a *necessary* condition for a sequence to converge.[5]

**Theorem**

If a sequence $\{a_n\}$ converges, then it is bounded.

Note that a sequence being bounded is not a sufficient condition for a sequence to converge. For example, the sequence $\{(-1)^n\}$ is bounded, but the sequence diverges because the sequence oscillates between $1$ and $-1$ and never approaches a finite number. We now discuss a sufficient (but not necessary) condition for a bounded sequence to converge.

Consider a bounded sequence $\{a_n\}$. Suppose the sequence $\{a_n\}$ is increasing. That is, $a_1 \leq a_2 \leq a_3 \ldots$. Since the sequence is increasing, the terms are not oscillating. Therefore, there are two possibilities - the sequence could diverge to infinity or converge. However, since the sequence is bounded above, it cannot diverge to infinity. We conclude that $\{a_n\}$ converges. For example, consider the sequence

$$\left\{\frac{1}{2}, \frac{2}{3}, \frac{3}{4}, \frac{4}{5}, \ldots\right\}.$$

Since this sequence is increasing and bounded above, it converges. Next, consider the sequence

$$\left\{2, 0, 3, 0, 4, 0, 1, -\frac{1}{2}, -\frac{1}{3}, -\frac{1}{4}, \ldots\right\}.$$

Even though the sequence is not increasing for all values of $n \in \mathbb{N}$, we see that $-1/2 < -1/3 < -1/4 < \cdots$. Therefore, starting with the eighth term, $a_8 = -1/2$, the sequence is increasing. In this case, we say the sequence is *eventually* increasing. Since the sequence is bounded above, it converges. It is also true that if a sequence is decreasing (or eventually decreasing) and bounded below, it also converges.

### Definition: Increasing, Decreasing, and Monotone Sequences

A sequence $\{a_n\}$ is said to be **increasing** for all $n \geq n_0$ if

$$a_n \leq a_{n+1} \text{ for all } n \geq n_0.$$

A sequence $\{a_n\}$ is said to be **decreasing** for all $n \geq n_0$ if

$$a_n \geq a_{n+1} \text{ for all } n \geq n_0.$$

A sequence $\{a_n\}$ is called a **monotone sequence** for all $n \geq n_0$ if it is increasing for all $n \geq n_0$ or decreasing for all $n \geq n_0$.

We now have the necessary definitions to state the Monotone Convergence Theorem, which gives a sufficient condition for sequence convergence.

### Theorem: Monotone Convergence Theorem

If $\{a_n\}$ is a bounded sequence and there exists a $n_0 \in \mathbb{N}$ such that $\{a_n\}$ is monotone for all $n \geq n_0$, then $\{a_n\}$ converges.

The proof of this theorem is beyond the scope of this text. Instead, we provide a graph to show intuitively why this theorem makes sense (Figure 8.2.6).

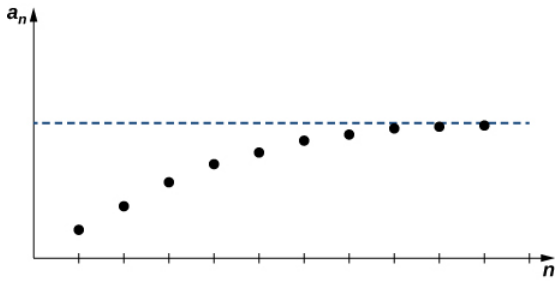

Figure 8.2.6: Since the sequence $\{a_n\}$ is increasing and bounded above, it must converge.

In the following example, we show how the Monotone Convergence Theorem can be used to prove the convergence of a sequence.

### Example 8.2.6: Using the Monotone Convergence Theorem

For each of the following sequences, use the Monotone Convergence Theorem to show the sequence converges and find its limit.

a. $\left\{\frac{4^n}{n!}\right\}$
b. $\{a_n\}$ defined recursively such that

$$a_1 = 2 \text{ and } a_{n+1} = \frac{a_n}{2} + \frac{1}{2a_n} \text{ for all } n \geq 2.$$

**Solutions**

a. Writing out the first few terms, we see that

$$\left\{\frac{4^n}{n!}\right\} = \left\{4, 8, \frac{32}{3}, \frac{32}{3}, \frac{128}{15}, \ldots\right\}.$$

At first, the terms increase. However, after the third term, the terms decrease. In fact, the terms decrease for all $n \geq 3$. We can show this as follows.

$$a_{n+1} = \frac{4^{n+1}}{(n+1)!} = \frac{4}{n+1} \cdot \frac{4^n}{n!} = \frac{4}{n+1} \cdot a_n \leq a_n \text{ if } n \geq 3.$$

Therefore, the sequence is decreasing for all $n \geq 3$. Further, the sequence is bounded below by $0$ because $4n/n! \geq 0$ for all $n \in \mathbb{N}$. Therefore, by the Monotone Convergence Theorem, the sequence converges.

To find the limit, we use the fact that the sequence converges and let $L = \lim_{n\to\infty} a_n$. Now note this important observation. Consider $\lim_{n\to\infty} a_{n+1}$. Since

$$\{a_{n+1}\} = \{a_2, a_3, a_4, ...\},$$

the only difference between the sequences $\{a_{n+1}\}$ and $\{a_n\}$ is that $\{a_{n+1}\}$ omits the first term. Since a finite number of terms does not affect the convergence of a sequence,

$$\lim_{n\to\infty} a_{n+1} = \lim_{n\to\infty} a_n = L.$$

Combining this fact with the equation

$$a_{n+1} = \frac{4}{n+1} a_n$$

and taking the limit of both sides of the equation

$$\lim_{n\to\infty} a_{n+1} = \lim_{n\to\infty} \frac{4}{n+1} a_n,$$

we can conclude that

$$L = 0.$$

b. Writing out the first several terms,

$$\left\{2, \frac{5}{4}, \frac{41}{40}, \frac{3281}{3280}, ...\right\}.$$

we can conjecture that the sequence is decreasing and bounded below by $1$. To show that the sequence is bounded below by $1$, we can show that

$$\frac{a_n}{2} + \frac{1}{2a_n} \geq 1.$$

To show this, first rewrite

$$\frac{a_n}{2} + \frac{1}{2a_n} = \frac{a_n^2 + 1}{2a_n}.$$

Since $a_1 > 0$ and $a_2$ is defined as a sum of positive terms, $a_2 > 0$. Similarly, all terms $a_n > 0$. Therefore,

$$\frac{a^2 n + 1}{2a_n} \geq 1$$

if and only if

$$a_n^2 + 1 \geq 2a_n.$$

Rewriting the inequality $a_n^2 + 1 \geq 2a_n$ as $a_n^2 - 2a_n + 1 \geq 0$ and using the fact that

$$a_n^2 - 2a_n + 1 = (a_n - 1)^2 \geq 0$$

because the square of any real number is nonnegative, we can conclude that

$$\frac{a^n}{2} + \frac{1}{2a_n} \geq 1.$$

To show that the sequence is decreasing, we must show that $a_{n+1} \leq a_n$ for all $n \geq 1$. Since $1 \leq a_n^2$, it follows that

$$a_n^2 + 1 \leq 2a_n^2.$$

Dividing both sides by $2a_n$, we obtain

$$\frac{a_n}{2} + \frac{1}{2a_n} \leq a_n.$$

Using the definition of $a_{n+1}$, we conclude that

$$a_{n+1} = \frac{a_n}{2} + \frac{1}{2a_n} \leq a_n.$$

Since $\{a_n\}$ is bounded below and decreasing, by the Monotone Convergence Theorem, it converges.

To find the limit, let $L = \lim_{n\to\infty} a_n$. Then using the recurrence relation and the fact that $\lim_{n\to\infty} a_n = \lim_{n\to\infty} a_{n+1}$, we have

$$\lim_{n\to\infty} a_{n+1} = \lim_{n\to\infty} \left(\frac{a_n}{2} + \frac{1}{2a_n}\right),$$

and therefore

$$L = \frac{L}{2} + \frac{1}{2L}.$$

Multiplying both sides of this equation by $2L$, we arrive at the equation

$$2L^2 = L^2 + 1.$$

Solving this equation for $L$, we conclude that $L^2 = 1$, which implies $L = \pm 1$. Since all the terms are positive, the limit $L = 1$.

**? Checkpoint 8.2.6**

Consider the sequence $\{a_n\}$ defined recursively such that $a_1 = 1$, $a_n = a_{n-1}/2$. Use the Monotone Convergence Theorem to show that this sequence converges and find its limit.

**Answer**

0.

**Definition: Fibonacci Numbers**

The **Fibonacci numbers** are defined recursively by the sequence $\{F_n\}$ where $F_0 = 0$, $F_1 = 1$, and for $n \geq 2$,

$$F_n = F_{n-1} + F_{n-2}.$$

Here, we look at the properties of the Fibonacci numbers.

1. Write out the first twenty Fibonacci numbers.

2. Find a closed formula for the Fibonacci sequence by using the following steps.

   a. Consider the recursively defined sequence $x_n$ where $x_0 = c$ and $x_{n+1} = ax_n$. Show that this sequence can be described by the closed formula $x_n = ca^n$ for all $n \geq 0$.

   b. Using the result from part a. as motivation, look for a solution of the equation

   $$F_n = F_{n-1} + F_{n-2}$$

   of the form $F_n = c\lambda^n$. Determine what two values for $\lambda$ will allow $F_n$ to satisfy this equation.

   c. Consider the two solutions from part b.: $\lambda_1$ and $\lambda_2$. Let $F_n = c_1\lambda_1^n + c_2\lambda_2^n$. Use the initial conditions $F_0$ and $F_1$ to determine the values for the constants $c_1$ and $c_2$ and write the closed formula $F_n$.

3. Use the answer in 2 c. to show that

$$\lim_{n\to\infty}\frac{F_{n+1}}{F_n}=\frac{1+\sqrt{5}}{2}.$$

The number $\phi=(1+\sqrt{5})/2$ is known as the **golden ratio** (Figure 8.2.7 and Figure 8.2.8).

Figure 8.2.7: The seeds in a sunflower exhibit spiral patterns curving to the left and the right. The number of spirals in each direction is always a Fibonacci number. (credit: modification of work by Esdras Calderan, Wikimedia Commons)

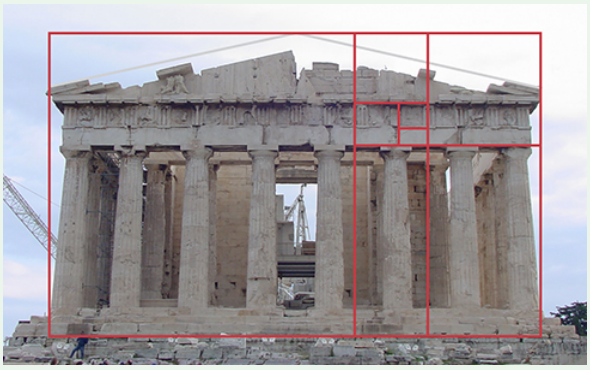

Figure 8.2.8: The proportion of the golden ratio appears in many famous examples of art and architecture. The ancient Greek temple, the Parthenon, was designed with these proportions, and the ratio appears again in many smaller details. (credit: modification of work by TravelingOtter, Flickr).

## Footnotes

[1] A similar notation is used for sets, but a sequence is an ordered list, whereas a set is not ordered.

[2] Remember, the domain of a sequence, in general, is the set of natural numbers (also called the positive integers). As such, the graph of a sequence will not be continuous.

[3] Since pattern recognition is an important skill when working with sequences (and it's sister-subject, series), it is often best to *not* simplify your arithmetic when writing out computations. This allows you to see the "hidden" patterns that make the sequence simple to write succinctly.

[4] This definition should be hauntingly familiar - you worked with the precise definition of a limit in Calculus I.

[5] When it comes to conditions for something to be true, the words "necessary" and "sufficient" are important in mathematics, and understanding the difference between the two will be helpful.

If a condition is *necessary* for a result to be true, it means that the necessary condition must exist for the result to even be possible. It does not mean, however, that the necessary condition immediately implies the result is true. For example, a necessary condition for you to pass this class is to attend all of the exams; however, you need more than just attending the exams to guarantee you will pass the course.

A *sufficient* condition, on the other hand, means that, as long as the sufficient condition is met, the result will be true. For example, scoring 80% on all of the exams and assignments in this class is a sufficient condition to pass the class. Note, however, that you can pass this class in other ways. For example, earning 96% on all of the exams and assignments will allow you to pass as well.

The takeaway:

- A sufficient condition guarantees the truth of another condition but is not necessary for that other condition to happen.
- A necessary condition is required for something else to happen. Still, it does not guarantee that the something else happens.

Much confusion can be had with necessary and sufficient conditions. Still, that investigation is left for a course in logic.

## Key Concepts

- To determine the convergence of a sequence given by an explicit formula $a_n = f(n)$, we use the properties of limits for functions.
- If $\{a_n\}$ and $\{b_n\}$ are convergent sequences that converge to $A$ and $B$, respectively, and $c$ is any real number, then the sequence $\{ca_n\}$converges to $c \cdot A$, the sequences $\{a_n \pm b_n\}$ converge to $A \pm B$, the sequence $\{a_n \cdot b_n\}$ converges to $A \cdot B$, and the sequence $\{a_n/b_n\}$ converges to $A/B$, provided $B \neq 0$.
- If a sequence is bounded and monotone, it converges, but not all convergent sequences are monotone.
- If a sequence is unbounded, it diverges, but not all divergent sequences are unbounded.
- The geometric sequence $\{r^n\}$ converges if and only if $|r| < 1$ or $r = 1$.

## Glossary

**arithmetic sequence**

a sequence in which the difference between every pair of consecutive terms is the same is called an arithmetic sequence

**bounded above**

a sequence $\{a_n\}$ is bounded above if there exists a constant $M$ such that $a_n \leq M$ for all positive integers $n$

**bounded below**

a sequence $\{a_n\}$ is bounded below if there exists a constant $M$ such that $M \leq a_n$ for all positive integers $n$

**bounded sequence**

a sequence $\{a_n\}$ is bounded if there exists a constant $M$ such that $|a_n| \leq M$ for all positive integers $n$

**convergent sequence**

a convergent sequence is a sequence $\{a_n\}$ for which there exists a real number $L$ such that $a_n$ is arbitrarily close to $L$ as long as $n$ is sufficiently large

**divergent sequence**

a sequence that is not convergent is divergent

**explicit formula**

a sequence may be defined by an explicit formula such that $a_n = f(n)$

**geometric sequence**

a sequence $\{a_n\}$ in which the ratio $a_{n+1}/a_n$ is the same for all positive integers $n$ is called a geometric sequence

**index variable**

the subscript used to define the terms in a sequence is called the index

**limit of a sequence**

the real number $L$ to which a sequence converges is called the limit of the sequence

**monotone sequence**

an increasing or decreasing sequence

**recurrence relation**

a recurrence relation is a relationship in which a term $a_n$ in a sequence is defined in terms of earlier terms in the sequence

**sequence**

an ordered list of numbers of the form $a_1, a_2, a_3, \ldots$ is a sequence

**term**

the number $a_n$ in the sequence $\{a_n\}$ is called the $n^{\text{th}}$ term of the sequence

**unbounded sequence**

a sequence that is not bounded is called unbounded

# 8.2E: Exercises

**In exercises 1 - 4, find the first six terms of each sequence, starting with $n = 1$.**

1) $a_n = 1 + (-1)^n$ for $n \geq 1$

**Answer**

$a_n = 0$ if $n$ is odd and $a_n = 2$ if $n$ is even

2) $a_n = n^2 - 1$ for $n \geq 1$

3) $a_1 = 1$ and $a_n = a_{n-1} + n$ for $n \geq 2$

**Answer**

$a_n = 1, 3, 6, 10, 15, 21, ...$

4) $a_1 = 1, a_2 = 1$ and $a_n + 2 = a_n + a_{n+1}$ for $n \geq 1$

5) Find an explicit formula for $a_n$ where $a_1 = 1$ and $a_n = a_{n-1} + n$ for $n \geq 2$.

**Answer**

$$a_n = \frac{n(n+1)}{2}$$

6) Find a formula $a_n$ for the $n^{\text{th}}$ term of the arithmetic sequence whose first term is $a_1 = 1$ such that $a_{n-1} - a_n = 17$ for $n \geq 1$.

7) Find a formula $a_n$ for the $n^{\text{th}}$ term of the arithmetic sequence whose first term is $a_1 = -3$ such that $a_{n-1} - a_n = 4$ for $n \geq 1$.

**Answer**

$a_n = 4n - 7$

8) Find a formula $a_n$ for the $n^{\text{th}}$ term of the geometric sequence whose first term is $a_1 = 1$ such that $\frac{a_{n+1}}{a_n} = 10$ for $n \geq 1$.

9) Find a formula $a_n$ for the $n^{\text{th}}$ term of the geometric sequence whose first term is $a_1 = 3$ such that $\frac{a_{n+1}}{a_n} = 1/10$ for $n \geq 1$.

**Answer**

$a_n = 3.10^{1-n} = 30.10^{-n}$

10) Find an explicit formula for the $n^{\text{th}}$ term of the sequence whose first several terms are $0, 3, 8, 15, 24, 35, 48, 63, 80, 99, ....$ (Hint: First add one to each term.)

11) Find an explicit formula for the $n^{\text{th}}$ term of the sequence satisfying $a_1 = 0$ and $a_n = 2a_{n-1} + 1$ for $n \geq 2$.

**Answer**

$a_n = 2^n - 1$

**In exercises 12 and 13, find a formula for the general term $a_n$ of each of the following sequences.**

12) $1, 0, -1, 0, 1, 0, -1, 0, ...$ (Hint: Find where $\sin x$ takes these values)

13) $1, -1/3, 1/5, -1/7, ...$

**Answer**

$$a_n = \frac{(-1)^{n-1}}{2n-1}$$

**In exercises 14-18, find a function $f(n)$ that identifies the $n^{\text{th}}$ term $a_n$ of the following recursively defined sequences, as $a_n = f(n)$.**

14) $a_1 = 1$ and $a_{n+1} = -a_n$ for $n \geq 1$

15) $a_1 = 2$ and $a_{n+1} = 2a_n$ for $n \geq 1$

**Answer**

$f(n) = 2^n$

16) $a_1 = 1$ and $a_{n+1} = (n+1)a_n$ for $n \geq 1$

17) $a_1 = 2$ and $a_{n+1} = (n+1)a_n/2$ for $n \geq 1$

**Answer**

$f(n) = \dfrac{n!}{2^{n-2}}$

18) $a_1 = 1$ and $a_{n+1} = a_n/2^n$ for $n \geq 1$

**In exercises 19 - 22, plot the first $N$ terms of the given sequence. State whether the graphical evidence suggests that the sequence converges or diverges.**

19) [Technology Required] $a_1 = 1, a_2 = 2$, and for $n \geq 2, a_n = \frac{1}{2}(a_{n-1} + a_{n-2})$; $N = 30$

20) [Technology Required] $a_1 = 1, a_2 = 2, a_3 = 3$ and for $n \geq 4, a_n = \frac{1}{3}(a_{n-1} + a_{n-2} + a_{n-3}), N = 30$

21) [Technology Required] $a_1 = 1, a_2 = 2$, and for $n \geq 3, a_n = \sqrt{a_{n-1}a_{n-2}}; N = 30$

22) [Technology Required] $a_1 = 1, a_2 = 2, a_3 = 3$, and for $n \geq 4, a_n = \sqrt{a_{n-1}a_{n-2}a_{n-3}}; N = 30$

**In exercises 23 - 16, suppose that $\lim_{n\to\infty} a_n = 1$, $\lim_{n\to\infty} b_n = -1$, and $0 < -b_n < a_n$ for all $n$.**

**Using this information, evaluate each of the following limits, state that the limit does not exist, or state that there is not enough information to determine whether the limit exists.**

23) $\lim_{n\to\infty} 3a_n - 4b_n$

**Answer**

$\lim_{n\to\infty} 3a_n - 4b_n \quad = \quad 7$

24) $\lim_{n\to\infty} \dfrac{1}{2}b_n - \dfrac{1}{2}a_n$

25) $\lim_{n\to\infty} \dfrac{a_n + b_n}{a_n - b_n}$

**Answer**

$\lim_{n\to\infty} \dfrac{a_n + b_n}{a_n - b_n} \quad = \quad 0$

26) $\lim_{n\to\infty} \dfrac{a_n - b_n}{a_n + b_n}$

**In exercises 27 - 30, find the limit of each of the following sequences, using L'Hôpital's rule when appropriate.**

27) $\dfrac{n^2}{2^n}$

**Answer**

$\lim_{n\to\infty} \dfrac{n^2}{2^n} \quad = \quad 0$

28) $\dfrac{(n-1)^2}{(n+1)^2}$

29) $\dfrac{\sqrt{n}}{\sqrt{n+1}}$

**Answer**

$$\lim_{n\to\infty}\frac{\sqrt{n}}{\sqrt{n+1}} = 1$$

30) $n^{1/n}$ (Hint: $n^{1/n} = e^{\frac{1}{n}\ln n}$)

**In exercises 31 - 37, state whether each sequence is bounded and whether it is eventually monotone, increasing, or decreasing.**

31) $n/2^n, n \geq 2$

**Answer**

bounded, decreasing for $n \geq 1$

32) $\ln\left(1+\frac{1}{n}\right)$

33) $\sin n$

**Answer**

bounded, not monotone

34) $\cos(n^2)$

35) $n^{1/n}, \quad n \geq 3$

**Answer**

bounded, decreasing

36) $n^{-1/n}, \quad n \geq 3$

37) $\tan n$

**Answer**

not monotone, not bounded

**In exercises 38 - 39, determine whether the given sequence has a limit. If it does, find the limit.**

38) $a_1 = \sqrt{2}, a_2 = \sqrt{2\sqrt{2}}.a_3 = \sqrt{2\sqrt{2\sqrt{2}}}$ etc.

39) $a_1 = 3, a_n = \sqrt{2a_{n-1}}, n = 2, 3, \ldots.$

**Answer**

$a_n$ is decreasing and bounded below by 2. The limit a must satisfy $a = \sqrt{2a}$ so $a = 2$, independent of the initial value.

**Use the Squeeze Theorem to find the limit of each sequence in exercises 40 - 43.**

40) $n\sin(1/n)$

41) $\frac{\cos(1/n)-1}{1/n}$

**Answer**

0

42) $a_n = \frac{n!}{n^n}$

43) $a_n = \sin n \sin(1/n)$

**Answer**

0 since $|\sin x| \leq |x|$ and $|\sin x| \leq 1$ so $-\frac{1}{n} \leq a_n \leq \frac{1}{n}$).

**For the sequences in exercises 44 and 45, plot the first 25 terms of the sequence and state whether the graphical evidence suggests that the sequence converges or diverges.**

44) [Technology Required] $a_n = \sin n$

45) [Technology Required] $a_n = \cos n$

**In exercises 46 - 52, determine the limit of the sequence or show that the sequence diverges. If it converges, find its limit.**

46) $a_n = \tan^{-1}(n^2)$

47) $a_n = (2n)^{1/n} - n^{1/n}$

**Answer**

$n^{1/n} \to 1$ and $2^{1/n} \to 1$, so $a_n \to 0$

48) $a_n = \dfrac{\ln(n^2)}{\ln(2n)}$

49) $a_n = \left(1 - \frac{2}{n}\right)^n$

**Answer**

Since $(1 + 1/n)^n \to e$, one has $(1 - 2/n)^n \approx (1 + k)^{-2k} \to e^{-2}$ as $k \to \infty$.

50) $a_n = \ln\left(\dfrac{n+2}{n^2-3}\right)$

51) $a_n = \dfrac{2^n + 3^n}{4^n}$

**Answer**

$2^n + 3^n \le 2 \cdot 3^n$ and $3^n/4^n \to 0$ as $n \to \infty$, so $a_n \to 0$ as $n \to \infty$.

52) $a_n = \dfrac{(1000)^n}{n!}$

53) $a_n = \dfrac{(n!)^2}{(2n)!}$

**Answer**

$\dfrac{a_{n+1}}{a_n} = n!/(n+1)(n+2)\cdots(2n) = \dfrac{1 \cdot 2 \cdot 3 \cdots n}{(n+1)(n+2)\cdots(2n)} < 1/2^n$. In particular, $a_{n+1}/a_n \le 1/2$, so $a_n \to 0$ as $n \to \infty$.

**Newton's method seeks to approximate a solution $f(x) = 0$ that starts with an initial approximation $x_0$ and successively defines a sequence $x_{n+1} = x_n - \dfrac{f(x_n)}{f'(x_n)}$. For the given choice of $f$ and $x_0$, write out the formula for $x_{n+1}$. If the sequence appears to converge, give an exact formula for the solution $x$, then identify the limit $x$ accurate to four decimal places and the smallest $n$ such that $x_n$ agrees with $x$ up to four decimal places.**

54) [Technology Required] $f(x) = x^2 - 2, \quad x_0 = 1$

55) [Technology Required] $f(x) = (x-1)^2 - 2, \quad x_0 = 2$

**Answer**

$x_{n+1} = x_n - ((x_n - 1)^2 - 2)/2(x_n - 1);\ x = 1 + \sqrt{2},\ x \approx 2.4142,\ n = 5$

56) [Technology Required] $f(x) = e^x - 2, \quad x_0 = 1$

57) [Technology Required] $f(x) = \ln x - 1, \quad x_0 = 2$

**Answer**

$x_{n+1} = x_n - x_n(\ln(x_n) - 1);\ x = e,\ x \approx 2.7183,\ n = 5$

58) [Technology Required] Suppose you start with one liter of vinegar and repeatedly remove $0.1$ L, replace with water, mix, and repeat.

a. Find a formula for the concentration after $n$ steps.

b. After how many steps does the mixture contain less than $10\%$ vinegar?

59) [Technology Required] A lake initially contains $2000$ fish. Suppose that in the absence of predators or other causes of removal, the fish population increases by $6\%$ each month. However, factoring in all causes, $150$ fish are lost each month.

a. Explain why the fish population after $n$ months is modeled by $P_n = 1.06P_{n-1} - 150$ with $P_0 = 2000$.

b. How many fish will be in the pond after one year?

**Answer**

a. Without losses, the population would obey $P_n = 1.06P_{n-1}$. The subtraction of $150$ accounts for fish losses.
b. After $12$ months, we have $P_{12} \approx 1494$.

60) [Technology Required] A bank account earns $5\%$ interest compounded monthly. Suppose that $\$1000$ is initially deposited into the account, but that $\$10$ is withdrawn each month.

a. Show that the amount in the account after $n$ months is $A_n = (1 + .05/12)A_{n-1} - 10;\ A_0 = 1000$.

b. How much money will be in the account after $1$ year?

c. Is the amount increasing or decreasing?

d. Suppose that instead of $\$10$, a fixed amount $d$ dollars is withdrawn each month. Find a value of $d$ such that the amount in the account after each month remains $\$1000$.

e. What happens if $d$ is greater than this amount?

61) [Technology Required] A student takes out a college loan of $\$10,000$ at an annual percentage rate of $6\%$, compounded monthly.

a. If the student makes payments of $\$100$ per month, how much does the student owe after $12$ months?

b. After how many months will the loan be paid off?

**Answer**

a. The student owes $\$9383$ after $12$ months.
b. The loan will be paid in full after $139$ months or eleven and a half years.

62) [Technology Required] Consider a series combining geometric growth and arithmetic decrease. Let $a_1 = 1$. Fix $a > 1$ and $0 < b < a$. Set $a_{n+1} = a.a_n - b$. Find a formula for $a_{n+1}$ in terms of $a_n, a$, and $b$ and a relationship between $a$ and $b$ such that $a_n$ converges.

63) [Technology Required] The binary representation $x = 0.b_1b_2b_3...$ of a number $x$ between $0$ and $1$ can be defined as follows. Let $b_1 = 0$ if $x < 1/2$ and $b_1 = 1$ if $1/2 \le x < 1$. Let $x_1 = 2x - b_1$. Let $b_2 = 0$ if $x_1 < 1/2$ and $b_2 = 1$ if $1/2 \le x < 1$. Let $x_2 = 2x_1 - b_2$ and in general, $x_n = 2x_{n-1} - b_n$ and $b_n{-}1 = 0$ if $x_n < 1/2$ and $b_{n-1} = 1$ if $1/2 \le x_n < 1$. Find the binary expansion of $1/3$.

**Answer**

$b_1 = 0, x_1 = 2/3, b_2 = 1, x_2 = 4/3 - 1 = 1/3$, so the pattern repeats, and $1/3 = 0.010101\ldots$.

64) [Technology Required] To find an approximation for $\pi$, set $a_0 = \sqrt{2+1}, a_1 = \sqrt{2+a_0}$, and, in general, $a_{n+1} = \sqrt{2+a_n}$. Finally, set $p_n = 3.2^n\sqrt{2-a_n}$. Find the first ten terms of $p_n$ and compare the values to $\pi$.

For the following two exercises, assume that you have access to a computer program or Internet source that can generate a list of zeros and ones of any desired length. Pseudo-random number generators (PRNGs) play an important role in simulating random noise in physical systems by creating sequences of zeros and ones that appear like the result of flipping a coin repeatedly. One of the simplest types of PRNGs recursively defines a random-looking sequence of $N$ integers $a_1, a_2, \ldots, a_N$ by fixing two special integers ($K$ and $M$ and letting $a_{n+1}$ be the remainder after dividing $K.a_n$ into $M$, then creates a bit sequence of zeros and ones

whose $n^{\text{th}}$ term $b_n$ is equal to one if $a_n$ is odd and equal to zero if $a_n$ is even. If the bits $b_n$ are pseudo-random, then the behavior of their average $(b_1 + b_2 + \cdots + b_N)/N$ should be similar to behavior of averages of truly randomly generated bits.

65) [Technology Required] Starting with $K = 16,807$ and $M = 2,147,483,647$, using ten different starting values of $a_1$, compute sequences of bits $b_n$ up to $n = 1000$, and compare their averages to ten such sequences generated by a random bit generator.

**Answer**

For the starting values $a_1 = 1, a_2 = 2, \ldots, a_1 = 10$, the corresponding bit averages calculated by the method indicated are $0.5220, 0.5000, 0.4960, 0.4870, 0.4860, 0.4680, 0.5130, 0.5210, 0.5040$, and $0.4840$. Here is an example of ten corresponding averages of strings of $1000$ bits generated by a random number generator:
$0.4880, 0.4870, 0.5150, 0.5490, 0.5130, 0.5180, 0.4860, 0.5030, 0.5050, 0.4980$. There is no real pattern in either type of average. The random-number-generated averages range between $0.4860$ and $0.5490$, a range of $0.0630$, whereas the calculated PRNG bit averages range between $0.4680$ and $0.5220$, a range of $0.0540$.

66) [Technology Required] Find the first $1000$ digits of $\pi$ using either a computer program or Internet resource. Create a bit sequence $b_n$ by letting $b_n = 1$ if the $n^{\text{th}}$ digit of $\pi$ is odd and $b_n = 0$ if the $n^{\text{th}}$ digit of $\pi$ is even. Compute the average value of $b_n$ and the average value of $d_n = |b_{n+1} - b_n|, n = 1, \ldots, 999$. Does the sequence $b_n$ appear random? Do the differences between successive elements of $b_n$ appear random?

# 8.3: Infinite Series

**Learning Objectives**

- Explain the meaning of the sum of an infinite series.
- Calculate the sum of a geometric series.
- Evaluate a telescoping series.

We have seen that a sequence is an ordered set of terms. Adding these terms together gives you a **series**. In this section, we define an infinite series and show how series are related to sequences. We also define what it means for a series to converge or diverge. We introduce one of the most important series types: the geometric series. In the next chapter, we will use geometric series to write certain functions as polynomials with infinite terms. This process is important because it allows us to evaluate, differentiate, and integrate complicated functions by using easier to handle polynomials. We also discuss the harmonic series, arguably the most interesting divergent series.

## Sums and Series

An **infinite series** is a sum of infinitely many terms and is written in the form

$$\sum_{n=1}^{\infty} a_n = a_1 + a_2 + a_3 + \cdots.$$

But what does this mean? We cannot add an infinite number of terms like we can add a finite number of terms. Instead, the value of an infinite series is defined in terms of the limit of partial sums. A **partial sum** of an infinite series is a finite sum of the form

$$\sum_{n=1}^{k} a_n = a_1 + a_2 + a_3 + \cdots + a_k.$$

To see how we use partial sums to evaluate infinite series, consider the following example. Suppose oil is seeping into a lake such that $1000$ gallons enters the lake the first week. During the second week, an additional $500$ gallons of oil enters the lake. The third week, $250$ more gallons enters the lake. Assume this pattern continues so that half as much oil enters the lake each week as did the previous week. If this continues forever, what can we say about the amount of oil in the lake? Will the amount of oil continue to get arbitrarily large, or is it possible that it approaches some finite amount? To answer this question, we look at the amount of oil in the lake after $k$ weeks. Letting $S_k$ denote the amount of oil in the lake (measured in thousands of gallons) after $k$ weeks, we see that

$$\begin{aligned}
S_1 &= 1 \\
S_2 &= 1 + 0.5 = 1 + \frac{1}{2} \\
S_3 &= 1 + 0.5 + 0.25 = 1 + \frac{1}{2} + \frac{1}{4} \\
S_4 &= 1 + 0.5 + 0.25 + 0.125 = 1 + \frac{1}{2} + \frac{1}{4} + \frac{1}{8} \\
S_5 &= 1 + 0.5 + 0.25 + 0.125 + 0.0625 = 1 + \frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \frac{1}{16}
\end{aligned}$$

Looking at this pattern, we see that the amount of oil in the lake (in thousands of gallons) after $k$ weeks is

$$S_k = 1 + \frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \frac{1}{16} + \cdots + \frac{1}{2^{k-1}} = \sum_{n=1}^{k} \left(\frac{1}{2}\right)^{n-1}.$$

We are interested in what happens as $k \to \infty$. Symbolically, the amount of oil in the lake as $k \to \infty$ is given by the infinite series

$$\lim_{k\to\infty} \sum_{n=1}^{k} \left(\frac{1}{2}\right)^{n-1} \equiv \sum_{n=1}^{\infty} \left(\frac{1}{2}\right)^{n-1} = 1 + \frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \frac{1}{16} + \cdots.$$

Before we continue, it is important to note that we are *defining* $\lim\limits_{k\to\infty}\sum\limits_{n=1}^{k}\left(\frac{1}{2}\right)^{n-1}$ with the more succinct (and slightly less rigorous) notation $\sum\limits_{n=1}^{\infty}\left(\frac{1}{2}\right)^{n-1}$. With that being cleared up, we can get back to the example.

At the same time, as $k\to\infty$, the amount of oil in the lake can be calculated by evaluating $\lim\limits_{k\to\infty}S_k$. Therefore, the behavior of the infinite series can be determined by looking at the behavior of the sequence of partial sums $\{S_k\}$. If the sequence of partial sums, $\{S_k\}$, converges, we say that the infinite series converges. Its sum is given by $\lim\limits_{k\to\infty}S_k$. If the sequence $\{S_k\}$ diverges, we say the infinite series diverges. We now turn our attention to determining the limit of this sequence $\{S_k\}$.

First, simplifying some of these partial sums, we see that

$$\begin{aligned} S_1 &= 1 \\ S_2 &= 1+\frac{1}{2} &&= \frac{3}{2} \\ S_3 &= 1+\frac{1}{2}+\frac{1}{4} &&= \frac{7}{4} \\ S_4 &= 1+\frac{1}{2}+\frac{1}{4}+\frac{1}{8} &&= \frac{15}{8} \\ S_5 &= 1+\frac{1}{2}+\frac{1}{4}+\frac{1}{8}+\frac{1}{16} &&= \frac{31}{16} \end{aligned}$$

Plotting some of these values in Figure 8.3.1, it appears that the sequence $\{S_k\}$ could be approaching 2.

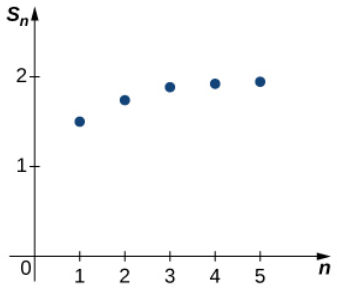

Figure 8.3.1: The graph shows the sequence of partial sums $\{S_k\}$. The sequence appears to be approaching the value 2.

Let's look for more convincing evidence. In the following table, we list the values of $S_k$ for several values of $k$.

| $k$ | 5 | 10 | 15 | 20 |
|---|---|---|---|---|
| $S_k$ | 1.9375 | 1.998 | 1.999939 | 1.999998 |

These data supply more evidence suggesting that the sequence $\{S_k\}$ converges to 2. Later, we will provide an analytic argument that can be used to prove that $\lim\limits_{k\to\infty}S_k=2$. For now, we rely on the numerical and graphical data to convince ourselves that the sequence of partial sums does converge to 2. Since this sequence of partial sums converges to 2, we say the infinite series converges to 2 and write

$$\sum_{n=1}^{\infty}\left(\frac{1}{2}\right)^{n-1}=2.$$

Returning to the question about the oil in the lake, since this infinite series converges to 2, we conclude that the amount of oil in the lake will get arbitrarily close to 2000 gallons as the amount of time gets sufficiently large.

This series is an example of a geometric series. We discuss geometric series in more detail later in this section. First, we summarize what it means for an infinite series to converge.

### Definition: Infinite Series

An **infinite series** is an expression of the form

$$\sum_{n=1}^{\infty} a_n = a_1 + a_2 + a_3 + \cdots.$$

For each positive integer, $k$, the sum

$$S_k = \sum_{n=1}^{k} a_n = a_1 + a_2 + a_3 + \cdots + a_k$$

is called the $k^{\text{th}}$ **partial sum** of the infinite series. The partial sums form a sequence $\{S_k\}$. The infinite series converges if the sequence of partial sums converges to a real number $S$. If we can describe the **convergence** of a series to $S$, we call $S$ the **sum of the series**, and we write

$$\sum_{n=1}^{\infty} a_n = S.$$

If the sequence of partial sums diverges, we say the series **diverges** (or is **divergent**).

Note that the index for a series need not begin with $n = 1$ but can begin with any value. For example, the series

$$\sum_{n=1}^{\infty} \left(\frac{1}{2}\right)^{n-1}$$

can also be written as

$$\sum_{n=0}^{\infty} \left(\frac{1}{2}\right)^{n} \text{ or } \sum_{n=5}^{\infty} \left(\frac{1}{2}\right)^{n-5}.$$

Often, it is convenient for the index to begin at $1$. If, for some reason, it begins at a different value, we can **re-index** by changing variables. For example, consider the series

$$\sum_{n=2}^{\infty} \frac{1}{n^2}.$$

By introducing the variable $m = n - 1$ so that $n = m + 1$, we can rewrite the series as

$$\sum_{m=1}^{\infty} \frac{1}{(m+1)^2}.$$

### Example 8.3.1: Evaluating Limits of Sequences of Partial Sums

For each of the following series, use the sequence of partial sums to determine whether the series converges or diverges.

a. $\displaystyle\sum_{n=1}^{\infty} \frac{n}{n+1}$

b. $\displaystyle\sum_{n=1}^{\infty} (-1)^n$

c. $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n(n+1)}$

**Solutions**

a. The sequence of partial sums $\{S_k\}$ satisfies

$$\begin{aligned} S_1 &= \frac{1}{2} \\ S_2 &= \frac{1}{2}+\frac{2}{3} \\ S_3 &= \frac{1}{2}+\frac{2}{3}+\frac{3}{4} \\ S_4 &= \frac{1}{2}+\frac{2}{3}+\frac{3}{4}+\frac{4}{5} \end{aligned}$$

Notice that each term added is greater than $1/2$. As a result, we see that

$$\begin{aligned} S_1 &= \frac{1}{2} \\ S_2 &= \frac{1}{2}+\frac{2}{3} &&> \frac{1}{2}+\frac{1}{2} &&= 2\left(\frac{1}{2}\right) \\ S_3 &= \frac{1}{2}+\frac{2}{3}+\frac{3}{4} &&> \frac{1}{2}+\frac{1}{2}+\frac{1}{2} &&= 3\left(\frac{1}{2}\right) \\ S_4 &= \frac{1}{2}+\frac{2}{3}+\frac{3}{4}+\frac{4}{5} &&> \frac{1}{2}+\frac{1}{2}+\frac{1}{2}+\frac{1}{2} &&= 4\left(\frac{1}{2}\right) \end{aligned}$$

From this pattern we can see that $S_k > k\left(\frac{1}{2}\right)$ for every integer $k$. Therefore, $\{S_k\}$ is unbounded and, consequently, diverges. Hence, the infinite series $\sum_{n=1}^{\infty} \frac{n}{n+1}$ diverges.

b. The sequence of partial sums $\{S_k\}$ satisfies

$$\begin{aligned} S_1 &= -1 \\ S_2 &= -1+1 &&= 0 \\ S_3 &= -1+1-1 &&= -1 \\ S_4 &= -1+1-1+1 &&= 0 \end{aligned}$$

From this pattern, we can see the sequence of partial sums is

$$\{S_k\} = -1, 0, -1, 0, \ldots.$$

Since this sequence diverges, the infinite series $\sum_{n=1}^{\infty} (-1)^n$ diverges.

c. The sequence of partial sums $\{S_k\}$ satisfies

$$\begin{aligned} S_1 &= \frac{1}{1\cdot 2} &&= \frac{1}{2} \\ S_2 &= \frac{1}{1\cdot 2}+\frac{1}{2\cdot 3} &&= \frac{2}{3} \\ S_3 &= \frac{1}{1\cdot 2}+\frac{1}{2\cdot 3}+\frac{1}{3\cdot 4} &&= \frac{3}{4} \\ S_4 &= \frac{1}{1\cdot 2}+\frac{1}{2\cdot 3}+\frac{1}{3\cdot 4}+\frac{1}{4\cdot 5} &&= \frac{4}{5} \\ S_5 &= \frac{1}{1\cdot 2}+\frac{1}{2\cdot 3}+\frac{1}{3\cdot 4}+\frac{1}{4\cdot 5}+\frac{1}{5\cdot 6} &&= \frac{5}{6} \end{aligned}$$

From this pattern, we can see that the $k^{\text{th}}$ partial sum is given by the explicit formula

$$S_k = \frac{k}{k+1}.$$

Since $k/(k+1) \to 1$, we conclude that the sequence of partial sums converges, and therefore the infinite series converges to $1$. We have

$$\sum_{n=1}^{\infty} \frac{1}{n(n+1)} = 1.$$

**Checkpoint 8.3.1**

Determine whether the series $\sum_{n=1}^{\infty} \frac{n+1}{n}$ converges or diverges.

**Answer**

The series diverges because the $k^{\text{th}}$ partial sum $S_k > k$.

## The Harmonic Series

A useful series to know about is the **harmonic series.** The harmonic series is defined as

$$\sum_{n=1}^{\infty} \frac{1}{n} = 1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \cdots.$$

This series is interesting because it diverges, but it diverges *very* slowly. By this, we mean that the terms in the sequence of partial sums $\{S_k\}$ approach infinity but do so very slowly. We will show that the series diverges, but first, we illustrate the slow growth of the terms in the sequence $\{S_k\}$ in the following table.

| $k$ | 10 | 100 | 1000 | 10,00 | 100,000 | 1,000,000 |
|---|---|---|---|---|---|---|
| $S_k$ | 2.92897 | 5.18738 | 7.48547 | 9.78761 | 12.09015 | 14.39273 |

Even after $1,000,000$ terms, the partial sum is still relatively small. From this table, it is not clear that this series diverges. However, we can show analytically that the sequence of partial sums diverges, and therefore the series diverges.

To show that the sequence of partial sums diverges, we show that the sequence of partial sums is unbounded. We begin by writing the first several partial sums:

$$\begin{aligned} S_1 &= 1 \\ S_2 &= 1 + \frac{1}{2} \\ S_3 &= 1 + \frac{1}{2} + \frac{1}{3} \\ S_4 &= 1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} \end{aligned}$$

Notice that for the last two terms in $S_4$,

$$\frac{1}{3} + \frac{1}{4} > \frac{1}{4} + \frac{1}{4}.$$

Therefore, we conclude that

$$S_4 > 1 + \frac{1}{2} + \left(\frac{1}{4} + \frac{1}{4}\right) = 1 + \frac{1}{2} + \frac{1}{2} = 1 + 2\left(\frac{1}{2}\right).$$

Using the same idea for $S_8$ we see that

$$\begin{aligned} S_8 &= 1+\frac{1}{2}+\frac{1}{3}+\frac{1}{4}+\frac{1}{5}+\frac{1}{6}+\frac{1}{7}+\frac{1}{8} \\ &> 1+\frac{1}{2}+\left(\frac{1}{4}+\frac{1}{4}\right)+\left(\frac{1}{8}+\frac{1}{8}+\frac{1}{8}+\frac{1}{8}\right) \\ &= 1+\frac{1}{2}+\frac{1}{2}+\frac{1}{2} \\ &= 1+3\left(\frac{1}{2}\right) \end{aligned}$$

From this pattern, we see that $S_1 = 1$, $S_2 = 1 + 1/2$, $S_4 > 1 + 2(1/2)$, and $S_8 > 1 + 3(1/2)$. More generally, it can be shown that $S_{2^j} > 1 + j(1/2)$ for all $j > 1$. Since $1 + j(1/2) \to \infty$, we conclude that the sequence, $\{S_k\}$, is unbounded. In the previous section, we stated that convergent sequences are bounded. Consequently, it diverges since $\{S_k\}$ is unbounded. Thus, the harmonic series diverges.

## Algebraic Properties of Convergent Series

Since the sum of a convergent infinite series is defined as a limit of a sequence, the algebraic properties for series listed below follow directly from the Algebraic Properties for Sequences.

**Theorem: Algebraic Properties of Convergent Series**

Let $\sum_{n=1}^{\infty} a_n$ and $\sum_{n=1}^{\infty} b_n$ be convergent series. Then, the following algebraic properties hold.

i. The series $\sum_{n=1}^{\infty}(a_n + b_n)$ converges, and $\sum_{n=1}^{\infty}(a_n + b_n) = \sum_{n=1}^{\infty} a_n + \sum_{n=1}^{\infty} b_n$. (Sum Rule for Convergent Series)

ii. The series $\sum_{n=1}^{\infty}(a_n - b_n)$ converges, and $\sum_{n=1}^{\infty}(a_n - b_n) = \sum_{n=1}^{\infty} a_n - \sum_{n=1}^{\infty} b_n$. (Difference Rule for Convergent Series)

iii. For any real number $c$, the series $\sum_{n=1}^{\infty} ca_n$ converges, and $\sum_{n=1}^{\infty} ca_n = c\sum_{n=1}^{\infty} a_n$. (Constant Multiple Rule for Convergent Series)

**Example 8.3.2: Using Algebraic Properties of Convergent Series**

Evaluate $\sum_{n=1}^{\infty}\left[\frac{3}{n(n+1)} + \left(\frac{1}{2}\right)^{n-2}\right]$.

**Solution**

We showed earlier that

$$\sum_{n=1}^{\infty} \frac{1}{n(n+1)} = 1$$

and

$$\sum_{n=1}^{\infty} \left(\frac{1}{2}\right)^{n-1} = 2.$$

Since both of those series converge, we can apply the Algebraic Properties of Convergent Series to evaluate

$$\sum_{n=1}^{\infty}\left[\frac{3}{n(n+1)} + \left(\frac{1}{2}\right)^{n-2}\right].$$

Using the Sum Rule for Convergent Series, write

$$\sum_{n=1}^{\infty}\left[\frac{3}{n(n+1)} + \left(\frac{1}{2}\right)^{n-2}\right] = \sum_{n=1}^{\infty} \frac{3}{n(n+1)} + \sum_{n=1}^{\infty} \left(\frac{1}{2}\right)^{n-2}.$$

Then, using the Constant Multiple Rule for Convergent Series and the sums above, we can conclude that

$$\sum_{n=1}^{\infty}\frac{3}{n(n+1)}+\sum_{n=1}^{\infty}\left(\frac{1}{2}\right)^{n-2}=3\sum_{n=1}^{\infty}\frac{1}{n(n+1)}+\left(\frac{1}{2}\right)^{-1}\sum_{n=1}^{\infty}\left(\frac{1}{2}\right)^{n-1}=3(1)+\left(\frac{1}{2}\right)^{-1}(2)=3+2(2)=7.$$

**? Checkpoint 8.3.2**

Evaluate $\sum_{n=1}^{\infty}\frac{5}{2^{n-1}}$.

**Answer**

10

## Geometric Series

A **geometric series** is any series that we can write in the form

$$a+ar+ar^2+ar^3+\cdots=\sum_{n=1}^{\infty}ar^{n-1}.$$

Because the ratio of each term in this series to the previous term is $r$, the number $r$ is called the **common ratio**. We refer to $a$ as the initial term because it is the first term in the series. For example, the series

$$\sum_{n=1}^{\infty}\left(\frac{1}{2}\right)^{n-1}=1+\frac{1}{2}+\frac{1}{4}+\frac{1}{8}+\cdots$$

is a geometric series with initial term $a=1$ and common ratio $r=1/2$.

In general, when does a geometric series converge? Consider the geometric series

$$\sum_{n=1}^{\infty}ar^{n-1}$$

when $a>0$. Its sequence of partial sums $\{S_k\}$ is given by

$$S_k=\sum_{n=1}^{k}ar^{n-1}=a+ar+ar^2+\cdots+ar^{k-1}. \tag{8.3.1}$$

Consider the case when $r=1$. In that case,

$$S_k=a+a(1)+a(1)^2+\cdots+a(1)^{k-1}=ak.$$

Since $a>0$, we know $ak\to\infty$ as $k\to\infty$. Therefore, the sequence of partial sums is unbounded and thus diverges. Consequently, the infinite series diverges for $r=1$. For $r\neq 1$, to find the limit of $\{S_k\}$, multiply Equation 8.3.1 by $1-r$. Doing so, we see that

$$\begin{aligned}(1-r)S_k&=a(1-r)(1+r+r^2+r^3+\cdots+r^{k-1})\\&=a[(1+r+r^2+r^3+\cdots+r^{k-1})-(r+r^2+r^3+\cdots+r^k)]=a(1-r^k).\end{aligned}$$

All the other terms cancel out.

Therefore,

$$S_k=\frac{a(1-r^k)}{1-r}\text{ for }r\neq 1.$$

From our discussion in the previous section, we know that the geometric sequence $r^k\to 0$ if $|r|<1$, and that $r^k$ diverges if $|r|>1$ or $r=\pm 1$. Therefore, for $|r|<1$, $S_k\to\frac{a}{1-r}$ and we have

$$\sum_{n=1}^{\infty}ar^{n-1}=\frac{a}{1-r}\text{ if }|r|<1.$$

If $|r|\geq 1$, $S_k$ diverges, and therefore

$$\sum_{n=1}^{\infty} ar^{n-1} \text{ diverges if } |r| \geq 1.$$

**Theorem: Convergence of Geometric Series**

A **geometric series** is a series of the form

$$\sum_{n=1}^{\infty} ar^{n-1} = a + ar + ar^2 + ar^3 + \cdots. \tag{8.3.2}$$

If $|r| < 1$ the series **converges**, and

$$\sum_{n=1}^{\infty} ar^{n-1} = \frac{a}{1-r} \text{ for } |r| < 1.$$

If $|r| \geq 1$ the series **diverges**.

Geometric series sometimes appear in slightly different forms. For example, sometimes the index begins at a value other than $n = 1$, or the exponent involves a linear expression for $n$ other than $n - 1$. As long as we can rewrite the series in the form given by Equation 8.3.2, it is a geometric series. For example, consider the series

$$\sum_{n=0}^{\infty} \left(\frac{2}{3}\right)^{n+2}.$$

To see that this is a geometric series, we write out the first several terms:

$$\begin{aligned} \sum_{n=0}^{\infty} \left(\frac{2}{3}\right)^{n+2} &= \left(\frac{2}{3}\right)^2 + \left(\frac{2}{3}\right)^3 + \left(\frac{2}{3}\right)^4 + \cdots \\ &= \frac{4}{9} + \frac{4}{9} \cdot \left(\frac{2}{3}\right) + \frac{4}{9} \cdot \left(\frac{2}{3}\right)^2 + \cdots \end{aligned}$$

We see that the initial term is $a = 4/9$ and the ratio is $r = 2/3$. Therefore, the series can be written as

$$\sum_{n=1}^{\infty} \frac{4}{9} \cdot \left(\frac{2}{3}\right)^{n-1}.$$

Since $|r| = |2/3| = 2/3 < 1$, this series converges, and its sum is given by

$$\sum_{n=1}^{\infty} \frac{4}{9} \cdot \left(\frac{2}{3}\right)^{n-1} = \frac{4/9}{1 - 2/3} = \frac{4}{3}.$$

**Example 8.3.3: Determining Convergence or Divergence of a Geometric Series**

Determine whether each of the following geometric series converges or diverges, and if it converges, find its sum.

a. $\displaystyle\sum_{n=1}^{\infty} \frac{(-3)^{n+1}}{4^{n-1}}$

b. $\displaystyle\sum_{n=1}^{\infty} e^{2n}$

**Solutions**

a. Writing out the first several terms in the series, we have

$$\sum_{n=1}^{\infty} \frac{(-3)^{n+1}}{4^{n-1}} = \frac{(-3)^2}{4^0} + \frac{(-3)^3}{4} + \frac{(-3)^4}{4^2} + \cdots$$
$$= (-3)^2 + (-3)^2 \cdot \left(\frac{-3}{4}\right) + (-3)^2 \cdot \left(\frac{-3}{4}\right)^2 + \cdots$$
$$= 9 + 9 \cdot \left(\frac{-3}{4}\right) + 9 \cdot \left(\frac{-3}{4}\right)^2 + \cdots$$

The initial term is $a = 9$ and the ratio is $r = -3/4$. Since $|r| = 3/4 < 1$, the series converges to

$$\frac{9}{1-(-3/4)} = \frac{9}{7/4} = \frac{36}{7}.$$

b. Writing this series as

$$e^2 \sum_{n=1}^{\infty} (e^2)^{n-1},$$

we can see that this is a geometric series where $|r| = e^2 > 1$. Therefore, the series diverges.

## Checkpoint 8.3.3

Determine whether the series $\sum_{n=1}^{\infty} \left(\frac{-2}{5}\right)^{n-1}$ converges or diverges. If it converges, find its sum.

**Answer**

$5/7$

We now turn our attention to a nice application of geometric series. We show how they can be used to write repeating decimals as fractions of integers.

## Example 8.3.4: Writing Repeating Decimals as Fractions of Integers

Use a geometric series to write $3.\overline{26}$ as a fraction of integers.

**Solution**

Since $3.\overline{26} = 3.262626\ldots$, first we write

$$3.262626\ldots = 3 + \frac{26}{100} + \frac{26}{1000} + \frac{26}{100,000} + \cdots$$
$$= 3 + \frac{26}{10^2} + \frac{26}{10^4} + \frac{26}{10^6} + \cdots$$

Ignoring the term $3$, the rest of this expression is a geometric series with initial term $a = 26/10^2$ and ratio $r = 1/10^2$. Therefore, the sum of this series is

$$\frac{26/10^2}{1-(1/10^2)} = \frac{26/10^2}{99/10^2} = \frac{26}{99}.$$

Thus,

$$3.262626\ldots = 3 + \frac{26}{99} = \frac{323}{99}.$$

**Checkpoint 8.3.4**

Write $5.2\overline{7}$ as a fraction of integers.

**Answer**

$475/90$

**Example 8.3.5: Finding the Area of the Koch Snowflake**

Define a sequence of figures $\{F_n\}$ recursively as follows (Figure 8.3.2). Let $F_0$ be an equilateral triangle with sides of length 1. For $n \geq 1$, let $F_n$ be the curve created by removing the middle third of each side of $F_{n-1}$ and replacing it with an equilateral triangle pointing outward. The limiting figure as $n \to \infty$ is known as **Koch's snowflake**.

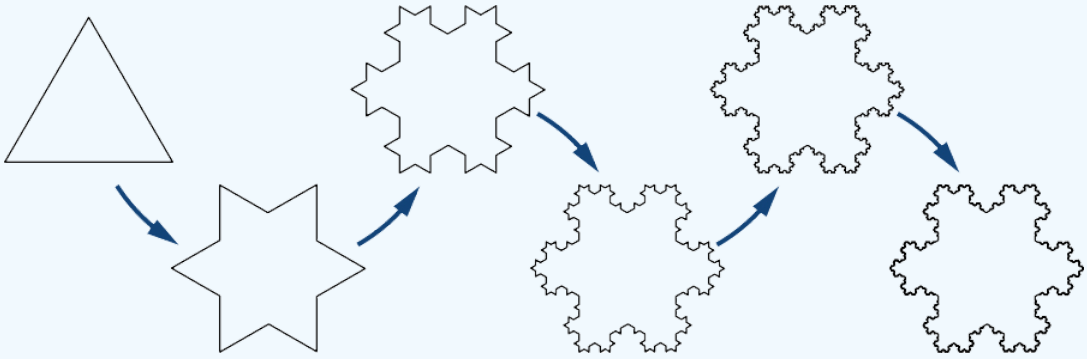

Figure 8.3.2: The first four figures, $F_0, F_1, F_2$ and $F_3$ in the construction of the Koch snowflake.

a. Find the length $L_n$ of the perimeter of $F_n$. Evaluate $\lim_{n\to\infty} L_n$ to find the length of the perimeter of Koch's snowflake.

b. Find the area $A_n$ of figure $F_n$. Evaluate $\lim_{n\to\infty} A_n$ to find the area of Koch's snowflake.

**Solutions**

a. Let $N_n$ denote the number of sides of figure $F_n$. Since $F_0$ is a triangle, $N_0 = 3$. Let ln denote the length of each side of $F_n$. Since $F_0$ is an equilateral triangle with sides of length $l_0 = 1$, we now need to determine $N_1$ and $l_1$. Since $F_1$ is created by removing the middle third of each side and replacing that line segment with two line segments, for each side of $F_0$, we get four sides in $F_1$. Therefore, the number of sides for $F_1$ is

$$N_1 = 4 \cdot 3.$$

Since the length of each of these new line segments is $1/3$ the length of the line segments in $F_0$, the length of the line segments for $F_1$ is given by

$$l_1 = \frac{1}{3} \cdot 1 = \frac{1}{3}.$$

Similarly, for $F_2$, since the middle third of each side of $F_1$ is removed and replaced with two line segments, the number of sides in $F_2$ is given by

$$N_2 = 4N_1 = 4(4 \cdot 3) = 4^2 \cdot 3.$$

Since the length of each of these sides is $1/3$ the length of the sides of $F_1$, the length of each side of figure $F_2$ is given by

$$l_2 = \frac{1}{3} \cdot l_1 = \frac{1}{3} \cdot \frac{1}{3} = \left(\frac{1}{3}\right)^2.$$

More generally, since $F_n$ is created by removing the middle third of each side of $F_{n-1}$ and replacing that line segment with two line segments of length $\frac{1}{3}|_{n-1}$ in the shape of an equilateral triangle, we know that $N_n = 4N_{n-1}$ and $l_n = \frac{l_{n-1}}{3}$. Therefore, the number of sides of figure $F_n$ is

$$N_n = 4^n \cdot 3$$

and the length of each side is

$$l_n = \left(\frac{1}{3}\right)^n.$$

Therefore, to calculate the perimeter of $F_n$, we multiply the number of sides $N_n$ and the length of each side $l_n$. We conclude that the perimeter of $F_n$ is given by

$$L_n = N_n \cdot l_n = 3 \cdot \left(\frac{4}{3}\right)^n$$

Therefore, the length of the perimeter of Koch's snowflake is

$$L = \lim_{n\to\infty} L_n = \infty.$$

b. Let $T_n$ denote the area of each new triangle created when forming $F_n$. For $n = 0$, $T_0$ is the area of the original equilateral triangle. Therefore, $T_0 = A_0 = \sqrt{3}/4$. For $n \geq 1$, since the lengths of the sides of the new triangle are $1/3$ the length of the sides of $F_{n-1}$, we have

$$T_n = \left(\frac{1}{3}\right)^2 \cdot T_{n-1} = \frac{1}{9} \cdot T_{n-1}.$$

Therefore, $T_n = \left(\frac{1}{9}\right)^n \cdot \frac{\sqrt{3}}{4}$. Since a new triangle is formed on each side of $F_{n-1}$,

$$\begin{aligned} A_n &= A_{n-1} + N_{n-1} \cdot T_n \\ &= A_{n-1} + (3 \cdot 4_{n-1}) \cdot \left(\frac{1}{9}\right)^n \cdot \frac{\sqrt{3}}{4} \\ &= A_{n-1} + \frac{3}{4} \cdot \left(\frac{4}{9}\right)^n \cdot \frac{\sqrt{3}}{4} \end{aligned}$$

Writing out the first few terms, we see that

$$\begin{aligned} A_0 &= \frac{\sqrt{3}}{4} \\ A_1 &= A_0 + \frac{3}{4} \cdot \left(\frac{4}{9}\right) \cdot \frac{\sqrt{3}}{4} = \frac{\sqrt{3}}{4} + \frac{3}{4} \cdot \left(\frac{4}{9}\right) \cdot \frac{\sqrt{3}}{4} = \frac{\sqrt{3}}{4}\left[1 + \frac{3}{4} \cdot \left(\frac{4}{9}\right)\right] \\ A_2 &= A_1 + \frac{3}{4} \cdot (\frac{4}{9})^2 \cdot \frac{\sqrt{3}}{4} = \frac{\sqrt{3}}{4}\left[1 + \frac{3}{4} \cdot \left(\frac{4}{9}\right)\right] + \frac{3}{4} \cdot \left(\frac{4}{9}\right)^2 \cdot \frac{\sqrt{3}}{4} = \frac{\sqrt{3}}{4}[1 + \frac{3}{4} \cdot (\frac{4}{9}) + \frac{3}{4} \cdot \left(\frac{4}{9}\right)^2] \end{aligned}$$

More generally,

$$A_n = \frac{\sqrt{3}}{4}\left[1 + \frac{3}{4}\left(\frac{4}{9} + \left(\frac{4}{9}\right)^2 + \cdots + \left(\frac{4}{9}\right)^n\right)\right].$$

Factoring $4/9$ out of each term inside the inner parentheses, we rewrite our expression as

$$A_n = \frac{\sqrt{3}}{4}\left[1 + \frac{1}{3}\left(1 + \frac{4}{9} + \left(\frac{4}{9}\right)^2 + \cdots + \left(\frac{4}{9}\right)^{n-1}\right)\right].$$

The expression $1 + \left(\frac{4}{9}\right) + \left(\frac{4}{9}\right)^2 + \cdots + \left(\frac{4}{9}\right)^{n-1}$ is a geometric sum. As shown earlier, this sum satisfies

$$1 + \frac{4}{9} + \left(\frac{4}{9}\right)^2 + \cdots + \left(\frac{4}{9}\right)^{n-1} = \frac{1 - (4/9)^n}{1 - (4/9)}.$$

Substituting this expression into the expression above and simplifying, we conclude that

$$A_n = \frac{\sqrt{3}}{4}\left[1 + \frac{1}{3}(\frac{1 - (4/9)^n}{1 - (4/9)})\right] = \frac{\sqrt{3}}{4}\left[\frac{8}{5} - \frac{3}{5}\left(\frac{4}{9}\right)^n\right].$$

Therefore, the area of Koch's snowflake is

$$A = \lim_{n\to\infty} A_n = \frac{2\sqrt{3}}{5}.$$

**Analysis**

The Koch snowflake is interesting because it has a finite area yet an infinite perimeter. Although this may seem impossible initially, recall that you have seen similar examples earlier in the text. For example, consider the region bounded by the curve $y = 1/x^2$ and the $x$-axis on the interval $[1, \infty)$. Since the improper integral

$$\int_1^\infty \frac{1}{x^2}\,dx$$

converges, the area of this region is finite, even though the perimeter is infinite.

## Telescoping Series

Consider the series $\sum_{n=1}^{\infty} \frac{1}{n(n+1)}$. We discussed this series in Example 8.3.1, showing that the series converges by writing out the first several partial sums $S_1$, $S_2$, ..., $S_6$, and noticing that they are all of the form $S_k = \frac{k}{k+1}$. Here, we use a different technique to show that this series converges. By using partial fractions, we can write

$$\frac{1}{n(n+1)} = \frac{1}{n} - \frac{1}{n+1}.$$

Therefore, the series can be written as

$$\sum_{n=1}^{\infty}\left[\frac{1}{n} - \frac{1}{n+1}\right] = \left(1 + \frac{1}{2}\right) + \left(\frac{1}{2} - \frac{1}{3}\right) + \left(\frac{1}{3} - \frac{1}{4}\right) + \cdots.$$

Writing out the first several terms in the sequence of partial sums $\{S_k\}$, we see that

$$\begin{aligned} S_1 &= 1 - \frac{1}{2} \\ S_2 &= \left(1 - \frac{1}{2}\right) + \left(\frac{1}{2} - \frac{1}{3}\right) &&= 1 - \frac{1}{3} \\ S_3 &= \left(1 - \frac{1}{2}\right) + \left(\frac{1}{2} - \frac{1}{3}\right) + \left(\frac{1}{3} - \frac{1}{4}\right) &&= 1 - \frac{1}{4} \end{aligned}$$

In general,

$$S_k = \left(1 - \frac{1}{2}\right) + \left(\frac{1}{2} - \frac{1}{3}\right) + \left(\frac{1}{3} - \frac{1}{4}\right) + \cdots + \left(\frac{1}{k} - \frac{1}{k+1}\right) = 1 - \frac{1}{k+1}.$$

We notice that the middle terms cancel each other out, leaving only the first and last terms. The series collapses like a spyglass with tubes that disappear into each other to shorten the telescope. For this reason, we call a series with this property a **telescoping series**. For this series, since $S_k = 1 - 1/(k+1)$ and $1/(k+1) \to 0$ as $k \to \infty$, the sequence of partial sums converges to 1, and therefore the series converges to 1.

**Definition: Telescoping Series**

A **telescoping series** is a series in which most of the terms cancel in each of the partial sums, leaving only some of the first terms and some of the last terms.

For example, any series of the form

$$\sum_{n=1}^{\infty}[b_n - b_{n+1}] = (b_1 - b_2) + (b_2 - b_3) + (b_3 - b_4) + \cdots$$

is a telescoping series. We can see this by writing out some of the partial sums. In particular, we see that

$$\begin{aligned} S_1 &= b_1 - b_2 \\ S_2 &= (b_1 - b_2) + (b_2 - b_3) &&= b_1 - b_3 \\ S_3 &= (b_1 - b_2) + (b_2 - b_3) + (b_3 - b_4) &&= b_1 - b_4. \end{aligned}$$

In general, the $k^{\text{th}}$ partial sum of this series is

$$S_k = b_1 - b_{k+1}.$$

Since the $k^{\text{th}}$ partial sum can be simplified to the difference of these two terms, the sequence of partial sums $\{S_k\}$ will converge if and only if the sequence $\{b_{k+1}\}$ converges. Moreover, if the sequence $b_{k+1}$ converges to some finite number $B$ then the sequence of partial sums converges to $b_1 - B$ and therefore

$$\sum_{n=1}^{\infty}[b_n - b_{n+1}] = b_1 - B.$$

In the next example, we show how to use these ideas to analyze a telescoping series of this form.

### Example 8.3.6: Evaluating a Telescoping Series

Determine whether the telescoping series

$$\sum_{n=1}^{\infty}\left[\cos\left(\frac{1}{n}\right) - \cos\left(\frac{1}{n+1}\right)\right]$$

converges or diverges. If it converges, find its sum.

**Solution**

By writing out terms in the sequence of partial sums, we can see that

$$\begin{aligned} S_1 &= \cos(1) - \cos\left(\frac{1}{2}\right) \\ S_2 &= \left(\cos(1) - \cos\left(\frac{1}{2}\right)\right) + \left(\cos\left(\frac{1}{2}\right) - \cos\left(\frac{1}{3}\right)\right) &&= \cos(1) - \cos\left(\frac{1}{3}\right) \\ S_3 &= \left(\cos(1) - \cos\left(\frac{1}{2}\right)\right) + \left(\cos\left(\frac{1}{2}\right) - \cos\left(\frac{1}{3}\right)\right) + \left(\cos\left(\frac{1}{3}\right) - \cos\left(\frac{1}{4}\right)\right) &&= \cos(1) - \cos\left(\frac{1}{4}\right) \end{aligned}$$

In general,

$$S_k = \cos(1) - \cos\left(\frac{1}{k+1}\right).$$

Since $1/(k+1) \to 0$ as $k \to \infty$ and $\cos x$ is a continuous function, $\cos(1/(k+1)) \to \cos(0) = 1$. Therefore, we conclude that $S_k \to \cos(1) - 1$. The telescoping series converges and the sum is given by

$$\sum_{n=1}^{\infty}\left[\cos\left(\frac{1}{n}\right) - \cos\left(\frac{1}{n+1}\right)\right] = \cos(1) - 1.$$

### Checkpoint 8.3.5

Determine whether $\sum_{n=1}^{\infty}[e^{1/n} - e^{1/(n+1)}]$ converges or diverges. If it converges, find its sum.

**Answer**

$e - 1$

### Euler's Constant

We have shown that the harmonic series $\sum_{n=1}^{\infty}\frac{1}{n}$ diverges. Here, we investigate the behavior of the partial sums $S_k$ as $k \to \infty$. In particular, we show that they behave like the natural logarithm function by showing that there exists a constant $\gamma$ such that\[ \sum_{n=1}^k\left(\dfrac{1}{n}−\ln k\right) \to \gamma \) as $k \to \infty$.

This constant, $\gamma$, is known as **Euler's constant.**

1. Let $T_k = \sum_{n=1}^{k} \left(\frac{1}{n} - \ln k\right)$. Evaluate $T_k$ for various values of $k$.
2. For $T_k$ as defined in part 1. show that the sequence $T_k$ converges by using the following steps.
   a. Show that the sequence $\{T_k\}$ is monotone decreasing. (Hint: Show that $\ln(1 + 1/k > 1/(k+1))$
   b. Show that the sequence $\{T_k\}$ is bounded below by zero. (Hint: Express $\ln k$ as a definite integral.)
   c. Use the Monotone Convergence Theorem to conclude that the sequence $\{T_k\}$ converges. The limit, $\gamma$, is Euler's constant.
3. Now, estimate how far $T_k$ is from $\gamma$ for a given integer $k$. Prove that for $k \geq 1, 0 < T_k - \gamma \leq 1/k$ by using the following steps.
   a. Show that $\ln(k+1) - \ln k < 1/k$.
   b. Use the result from part a. to show that for any integer $k$

$$T_k - T_{k+1} < \frac{1}{k} - \frac{1}{k+1}.$$

   c. For any integers $k$ and $j$ such that $j > k$ express $T_k - T_j$ as a telescoping sum by writing

$$T_k - T_j = (T_k - T_{k+1}) + (T_{k+1} - T_{k+2}) + (T_{k+2} - T_{k+3}) + \cdots + (T_{j-1} - T_j).$$

   Use the result from part b. combined with this telescoping sum to conclude that

$$T_k - T_j < \frac{1}{k} - \frac{1}{j}.$$

   d. Apply the limit to both sides of the inequality in part c. to conclude that

$$T_k - \gamma \leq \frac{1}{k}.$$

   e. Estimate $\gamma$ to an accuracy of within 0.001.

## Key Concepts

- Given the infinite series

$$\sum_{n=1}^{\infty} a_n = a_1 + a_2 + a_3 + \cdots$$

  and the corresponding sequence of partial sums $\{S_k\}$ where

$$S_k = \sum_{n=1}^{k} a_n = a_1 + a_2 + a_3 + \cdots + a_k$$

  The series converges if and only if the sequence $\{S_k\}$ converges.
- The geometric series $\sum_{n=1}^{\infty} ar^{n-1}$ converges if $|r| < 1$, and diverges if $|r| \geq 1$. For $|r| < 1$,

$$\sum_{n=1}^{\infty} ar^{n-1} = \frac{a}{1-r}.$$

- The harmonic series

$$\sum_{n=1}^{\infty} \frac{1}{n} = 1 + \frac{1}{2} + \frac{1}{3} + \cdots$$

  diverges.
- A series of the form $\sum_{n=1}^{\infty} [b_n - b_{n+1}] = [b_1 - b_2] + [b_2 - b_3] + [b_3 - b_4] + \cdots + [b_n - b_{n+1}] + \cdots$ is a telescoping series. The $k^{\text{th}}$ partial sum of this series is given by $S_k = b_1 - b_{k+1}$. The series will converge if and only if $\lim_{k \to \infty} b_{k+1}$ exists. In that case,

$$\sum_{n=1}^{\infty}[b_n - b_{n+1}] = b_1 - \lim_{k\to\infty}(b_{k+1}).$$

## Key Equations

- **Harmonic series**

$$\sum_{n=1}^{\infty}\frac{1}{n} = 1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \cdots$$

- **Sum of a geometric series**

$$\sum_{n=1}^{\infty} ar^{n-1} = \frac{a}{1-r} \text{ for } |r| < 1$$

## Glossary

**convergence of a series**

a series converges if the sequence of partial sums for that series converges

**divergence of a series**

a series diverges if the sequence of partial sums for that series diverges

**geometric series**

a geometric series is a series that can be written in the form

$$\sum_{n=1}^{\infty} ar^{n-1} = a + ar + ar^2 + ar^3 + \cdots$$

**harmonic series**

the harmonic series takes the form

$$\sum_{n=1}^{\infty}\frac{1}{n} = 1 + \frac{1}{2} + \frac{1}{3} + \cdots$$

**infinite series**

an infinite series is an expression of the form

$$a_1 + a_2 + a_3 + \cdots = \sum_{n=1}^{\infty} a_n$$

**partial sum**

the $kth$ partial sum of the infinite series $\sum_{n=1}^{\infty} a_n$ is the finite sum

$$S_k = \sum_{n=1}^{k} a_n = a_1 + a_2 + a_3 + \cdots + a_k$$

**telescoping series**

a telescoping series is one in which most of the terms cancel in each of the partial sums

# 8.3E: Exercises

**In exercises 1 - 4, use sigma notation to write each expressions as an infinite series.**

1) $1+\frac{1}{2}+\frac{1}{3}+\frac{1}{4}+\cdots$

**Answer**

$$\sum_{n=1}^{\infty}\frac{1}{n}$$

2) $1-1+1-1+\cdots$

3) $1-\frac{1}{2}+\frac{1}{3}-\frac{1}{4}+...$

**Answer**

$$\sum_{n=1}^{\infty}\frac{(-1)^{n-1}}{n}$$

4) $\sin 1+\sin\frac{1}{2}+\sin\frac{1}{3}+\sin\frac{1}{4}+\cdots$

**In exercises 5 - 8, compute the first four partial sums $S_1,\ldots,S_4$ for the series having $n^{\text{th}}$ term $a_n$ starting with $n=1$ as follows.**

5) $a_n=n$

**Answer**

$1,3,6,10$

6) $a_n=1/n$

7) $a_n=\sin\frac{n\pi}{2}$

**Answer**

$1,1,0,0$

8) $a_n=(-1)^n$

**In exercises 9 - 12, compute the general term $a_n$ of the series with the given partial sum $S_n$. If the sequence of partial sums converges, find its limit $S$.**

9) $S_n=1-\frac{1}{n},\quad n\geq 2$

**Answer**

$a_n=S_n-S_{n-1}=\frac{1}{n-1}-\frac{1}{n}$. Since $S=\lim\limits_{n\to\infty}S_n=\lim\limits_{n\to\infty}\left(1-\frac{1}{n}\right)=1$, the series converges to $S=1$.

10) $S_n=\frac{n(n+1)}{2},\quad n\geq 1$

11) $S_n=\sqrt{n},\quad n\geq 2$

**Answer**

$a_n=S_n-S_{n-1}=\sqrt{n}-\sqrt{n-1}=\frac{1}{\sqrt{n-1}+\sqrt{n}}$.

The series diverges because the partial sums are unbounded.

That is, $\lim\limits_{n\to\infty}S_n=\lim\limits_{n\to\infty}\sqrt{n}=\infty$.

12) $S_n=2-\frac{n+2}{2^n},\quad n\geq 1$

**For each series in exercises 13 - 16, use the sequence of partial sums to determine whether the series converges or diverges.**

13) $\sum_{n=1}^{\infty} \frac{n}{n+2}$

**Answer**

$S_1 = 1/3,$
$S_2 = 1/3 + 2/4 > 1/3 + 1/3 = 2/3,$
$S_3 = 1/3 + 2/4 + 3/5 > 3 \cdot (1/3) = 1.$
In general $S_k > k/3,$ so the series diverges.
Note that the $n^{\text{th}}$ Term Test for Divergence could also be used to prove that this series diverges.

14) $\sum_{n=1}^{\infty}(1-(-1)^n))$

15) $\sum_{n=1}^{\infty} \frac{1}{(n+1)(n+2)}$

(Hint: Use a partial fraction decomposition like that for $\sum_{n=1}^{\infty} \frac{1}{n(n+1)}$.)

**Answer**

$S_1 = 1/(2 \cdot 3) = 1/6 = 2/3 - 1/2,$

$S_2 = 1/(2 \cdot 3) + 1/(3 \cdot 4) = 2/12 + 1/12 = 1/4 = 3/4 - 1/2,$

$S_3 = 1/(2 \cdot 3) + 1/(3 \cdot 4) + 1/(4 \cdot 5) = 10/60 + 5/60 + 3/60 = 3/10 = 4/5 - 1/2,$

$S_4 = 1/(2 \cdot 3) + 1/(3 \cdot 4) + 1/(4 \cdot 5) + 1/(5 \cdot 6) = 10/60 + 5/60 + 3/60 + 2/60 = 1/3 = 5/6 - 1/2.$

The pattern is $S_k = \frac{k+1}{k+2} - \frac{1}{2}.$
Then $\lim_{n\to\infty} S_n = \lim_{n\to\infty} \left(\frac{k+1}{k+2} - \frac{1}{2}\right) = \frac{1}{2}$, so the series converges to $1/2$.

16) $\sum_{n=1}^{\infty} \frac{1}{2n+1}$

(Hint: Follow the reasoning for $\sum_{n=1}^{\infty} \frac{1}{n}$.)

**Suppose that $\sum_{n=1}^{\infty} a_n = 1$, that $\sum_{n=1}^{\infty} b_n = -1$, that $a_1 = 2$, and $b_1 = -3$. Use this information to find the sum of the indicated series in exercises 17 - 20.**

17) $\sum_{n=1}^{\infty}(a_n + b_n)$

**Answer**

$$\sum_{n=1}^{\infty}(a_n + b_n) \quad = \quad \sum_{n=1}^{\infty} a_n + \sum_{n=1}^{\infty} b_n \quad = \quad 1 + (-1) \quad = \quad 0$$

18) $\sum_{n=1}^{\infty}(a_n - 2b_n)$

19) $\sum_{n=2}^{\infty}(a_n - b_n)$

**Answer**

$$\sum_{n=2}^{\infty}(a_n - b_n) \quad = \quad \sum_{n=2}^{\infty} a_n - \sum_{n=2}^{\infty} b_n \quad = \quad \left(\sum_{n=1}^{\infty} a_n - a_1\right) - \left(\sum_{n=1}^{\infty} b_n - b_1\right) \quad = \quad (1-2) - (-1-(-3)) = -1 - 2 \quad = \quad -3$$

20) $\sum_{n=1}^{\infty}(3a_{n+1} - 4b_{n+1})$

**In exercises 21 - 26, state whether the given series converges or diverges and explain why.**

21) $\sum_{n=1}^{\infty} \frac{1}{n+1000}$ (Hint: Rewrite using a change of index.)

**Answer**

The series diverges, $\sum_{n=1001}^{\infty} \frac{1}{n}$

22) $\sum_{n=1}^{\infty} \frac{1}{n+10^{80}}$ (Hint: Rewrite using a change of index.)

23) $1+\frac{1}{10}+\frac{1}{100}+\frac{1}{1000}+\cdots$

**Answer**

This is a convergent geometric series, since $r=\frac{1}{10}<1$

24) $1+\frac{e}{\pi}+\frac{e^2}{\pi^2}+\frac{e^3}{\pi^3}+\cdots$

25) $1+\frac{\pi}{e^2}+\frac{\pi^2}{e^4}+\frac{\pi^3}{e^6}+\frac{\pi^4}{e^8}+\cdots$

**Answer**

This is a convergent geometric series, since $r=\pi/e^2<1$

26) $1-\sqrt{\frac{\pi}{3}}+\sqrt{\frac{\pi^2}{9}}-\sqrt{\frac{\pi^3}{27}}+\cdots$

**For each $a_n$ in exercises 27 - 30, write its sum as a geometric series of the form $\sum_{n=1}^{\infty} ar^n$. State whether the series converges and if it does, find the exact value of its sum.**

27) $a_1=-1$ and $\frac{a_n}{a_{n+1}}=-5$ for $n\geq 1$.

**Answer**

$\sum_{n=1}^{\infty} 5\cdot(-1/5)^n$, converges to $-5/6$

28) $a_1=2$ and $\frac{a_n}{a_{n+1}}=1/2$ for $n\geq 1$.

29) $a_1=10$ and $\frac{a_n}{a_{n+1}}=10$ for $n\geq 1$.

**Answer**

$\sum_{n=1}^{\infty} 100\cdot(1/10)^n$, converges to $\frac{100}{9}$

30) $a_1=\frac{1}{10}$ and $a_n/a_{n+1}=-10$ for $n\geq 1$.

**In exercises 31 - 34, use the identity $\frac{1}{1-y}=\sum_{n=0}^{\infty} y^n$ (which is true for $|y|<1$) to express each function as a geometric series in the indicated term.**

31) $\frac{x}{1+x}$ in $x$

**Answer**

$x\sum_{n=0}^{\infty}(-x)^n=\sum_{n=1}^{\infty}(-1)^{n-1}x^n$

32) $\frac{\sqrt{x}}{1-x^{3/2}}$ in $\sqrt{x}$

33) $\frac{1}{1+\sin^2 x}$ in $\sin x$

**Answer**

$$\sum_{n=0}^{\infty}(-1)^n \sin^{2n}(x)$$

34) $\sec^2 x$ in $\sin x$

**In exercises 35 - 38, evaluate the telescoping series or state whether the series diverges.**

35) $\sum_{n=1}^{\infty} 2^{1/n} - 2^{1/(n+1)}$

**Answer**

$S_k = 2 - 2^{1/(k+1)} \to 1$ as $k \to \infty$.

36) $\sum_{n=1}^{\infty} \frac{1}{n^{13}} - \frac{1}{(n+1)^{13}}$

37) $\sum_{n=1}^{\infty} (\sqrt{n} - \sqrt{n+1})$

**Answer**

$S_k = 1 - \sqrt{k+1}$ diverges

38) $\sum_{n=1}^{\infty} (\sin n - \sin(n+1))$

**Express each series in exercises 39 - 42 as a telescoping sum and evaluate its $n^{\text{th}}$ partial sum.**

39) $\sum_{n=1}^{\infty} \ln\left(\frac{n}{n+1}\right)$

**Answer**

$\sum_{n=1}^{\infty} [\ln n - \ln(n+1)]$,
$S_k = -\ln(k+1)$

40) $\sum_{n=1}^{\infty} \frac{2n+1}{(n^2+n)^2}$ (Hint: Factor denominator and use partial fractions.)

41) $\sum_{n=2}^{\infty} \frac{\ln\left(1+\frac{1}{n}\right)}{(\ln n)\ln(n+1)}$

**Answer**

$a_n = \frac{1}{\ln n} - \frac{1}{\ln(n+1)}$ and $S_k = \frac{1}{\ln(2)} - \frac{1}{\ln(k+1)} \to \frac{1}{\ln(2)}$

42) $\sum_{n=1}^{\infty} \frac{(n+2)}{n(n+1)2^{n+1}}$ (Hint: Look at $1/(n2^n)$.

**A general telescoping series is one in which all but the first few terms cancel out after summing a given number of successive terms.**

43) Let $a_n = f(n) - 2f(n+1) + f(n+2)$, in which $f(n) \to 0$ as $n \to \infty$. Find $\sum_{n=1}^{\infty} a_n$.

**Answer**

$$\sum_{n=1}^{\infty} a_n = f(1) - f(2)$$

44) $a_n = f(n) - f(n+1) - f(n+2) + f(n+3)$, in which $f(n) \to 0$ as $n \to \infty$. Find $\sum_{n=1}^{\infty} a_n$.

45) Suppose that $a_n = c_0 f(n) + c_1 f(n+1) + c_2 f(n+2) + c_3 f(n+3) + c_4 f(n+4)$, where $f(n) \to 0$ as $n \to \infty$. Find a condition on the coefficients $c_0, \ldots, c_4$ that make this a general telescoping series.

**Answer**

$c_0 + c_1 + c_2 + c_3 + c_4 = 0$

46) Evaluate $\sum_{n=1}^{\infty} \frac{1}{n(n+1)(n+2)}$ (Hint: $\frac{1}{n(n+1)(n+2)} = \frac{1}{2n} - \frac{1}{n+1} + \frac{1}{2(n+2)}$)

47) Evaluate $\sum_{n=2}^{\infty} \frac{2}{n^3 - n}$.

**Answer**

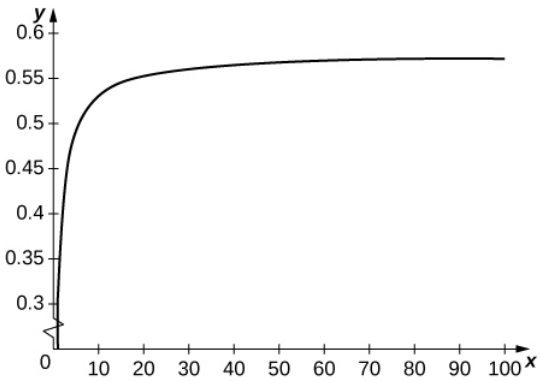
$\frac{2}{n^3-1} = \frac{1}{n-1} - \frac{2}{n} + \frac{1}{n+1}$,
$S_n = (1 - 1 + 1/3) + (1/2 - 2/3 + 1/4) + (1/3 - 2/4 + 1/5) + (1/4 - 2/5 + 1/6) + \cdots = 1/2$

48) Find a formula for $\sum_{n=1}^{\infty} \frac{1}{n(n+N)}$ where $N$ is a positive integer.

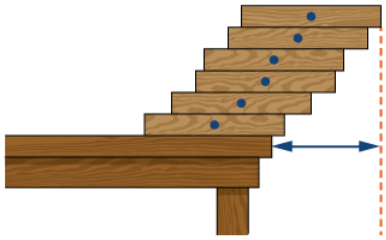
49) [Technology Required] Define a sequence $t_k = \sum_{n=1}^{k-1} (1/k) - \ln k$. Use the graph of $1/x$ to verify that $t_k$ is increasing. Plot $t_k$ for $k = 1 \ldots 100$ and state whether it appears that the sequence converges.

**Answer**

$t_k$ converges to $0.57721 \ldots t_k$ is a sum of rectangles of height $1/k$ over the interval $[k, k+1]$ which lie above the graph of $1/x$.



50) [Technology Required] Suppose that $N$ equal uniform rectangular blocks are stacked one on top of the other, allowing for some overhang. Archimedes' law of the lever implies that the stack of $N$ blocks is stable as long as the center of mass of the top $(N-1)$ blocks lies at the edge of the bottom block. Let $x$ denote the position of the edge of the bottom block, and think of its position as relative to the center of the next-to-bottom block. This implies that $(N-1)x = \left(\frac{1}{2} - x\right)$ or $x = 1/(2N)$. Use this expression to compute the maximum overhang (the position of the edge of the top block over the edge of the bottom block.) See the following figure.



Each of the following infinite series converges to the given multiple of $\pi$ or $1/\pi$.

**In each case, find the minimum value of $N$ such that the $Nth$ partial sum of the series accurately approximates the left-hand side to the given number of decimal places, and give the desired approximate value. Up to 15 decimals place, $\pi = 3.141592653589793....$**

51) [Technology Required] $\pi = -3 + \sum_{n=1}^{\infty} \frac{n2^n n!^2}{(2n)!}$, error $< 0.0001$

**Answer**

$N = 22,$

$S_N = 6.1415$

52) [Technology Required] $\frac{\pi}{2} = \sum_{k=0}^{\infty} \frac{k!}{(2k+1)!!} = \sum_{k=0}^{\infty} \frac{2^k k!^2}{(2k+1)!}$, error $< 10^{-4}$

53) [Technology Required] $\frac{9801}{2\pi} = \frac{4}{9801} \sum_{k=0}^{\infty} \frac{(4k)!(1103+26390k)}{(k!)^4 396^{4k}}$, error $< 10^{-12}$

**Answer**

$N = 3,$

$S_N = 1.559877597243667...$

54) [Technology Required] $\frac{1}{12\pi} = \sum_{k=0}^{\infty} \frac{(-1)^k (6k)!(13591409+545140134k)}{(3k)!(k!)^3 640320^{3k+3/2}}$, error $< 10^{-15}$

55) [Technology Required] A fair coin is one that has probability $1/2$ of coming up heads when flipped.

a. What is the probability that a fair coin will come up tails $n$ times in a row?

b. Find the probability that a coin comes up heads for the first time after an even number of coin flips.

**Answer**

a. The probability of any given ordered sequence of outcomes for $n$ coin flips is $1/2^n$.

b. The probability of coming up heads for the first time on the $n$ th flip is the probability of the sequence $TT...TH$ which is $1/2^n$. The probability of coming up heads for the first time on an even flip is $\sum_{n=1}^{\infty} 1/2^{2n}$ or $1/3$.

56) [Technology Required] Find the probability that a fair coin is flipped a multiple of three times before coming up heads.

57) [Technology Required] Find the probability that a fair coin will come up heads for the second time after an even number of flips.

**Answer**

$5/9$

58) [Technology Required] Find a series that expresses the probability that a fair coin will come up heads for the second time on a multiple of three flips.

59) [Technology Required] The expected number of times that a fair coin will come up heads is defined as the sum over $n = 1, 2, ...$ of $n$ times the probability that the coin will come up heads exactly $n$ times in a row, or $\frac{n}{2^{n+1}}$. Compute the expected number of consecutive times that a fair coin will come up heads.

**Answer**

$E = \sum_{n=1}^{\infty} \frac{n}{2^{n+1}} = 1,$ as can be shown using summation by parts

60) [Technology Required] A person deposits $\$10$ at the beginning of each quarter into a bank account that earns $4$ annual interest compounded quarterly (four times a year).

a. Show that the interest accumulated after $n$ quarters is $\$10(\frac{1.01^{n+1}-1}{0.01} - n)$.

b. Find the first eight terms of the sequence.

c. How much interest has accumulated after $2$ years?

61) [Technology Required] Suppose that the amount of a drug in a patient's system diminishes by a multiplicative factor $r < 1$ each hour. Suppose that a new dose is administered every $N$ hours. Find an expression that gives the amount $A(n)$ in the patient's system after $n$ hours for each $n$ in terms of the dosage $d$ and the ratio $r$. (Hint: Write $n = mN + k$, where $0 \le k < N$, and sum over values from the different doses administered.)

**Answer**

The part of the first dose after $n$ hours is $dr^n$, the part of the second dose is $dr^{n-N}$, and, in general, the part remaining of the $m^{\text{th}}$ dose is $dr^{n-mN}$, so $A(n) = \sum_{l=0}^{m} dr^{n-lN} = \sum_{l=0}^{m} dr^{k+(m-l)N} = \sum_{q=0}^{m} dr^{k+qN} = dr^k \sum_{q=0}^{m} r^{Nq} = dr^k \frac{1-r^{(m+1)N}}{1-r^N}$, where $n = k + mN$.

62) [Technology Required] A certain drug is effective for an average patient only if there is at least $1$ mg per kg in the patient's system, while it is safe only if there is at most $2$ mg per kg in an average patient's system. Suppose that the amount in a patient's system diminishes by a multiplicative factor of $0.9$ each hour after a dose is administered. Find the maximum interval $N$ of hours between doses, and corresponding dose range $d$ (in mg/kg) for this $N$ that will enable use of the drug to be both safe and effective in the long term.

63) Suppose that $a_n \ge 0$ is a sequence of numbers. Explain why the sequence of partial sums of $a_n$ is increasing.

**Answer**

$S_{N+1} = a_{N+1} + S_N \ge S_N$

64) [Technology Required] Suppose that $a_n$ is a sequence of positive numbers and the sequence $S_n$ of partial sums of $a_n$ is bounded above. Explain why $\sum_{n=1}^{\infty} a_n$ converges. Does the conclusion remain true if we remove the hypothesis $a_n \ge 0$?

65) [Technology Required] Suppose that $a_1 = S_1 = 1$ and that, for given numbers $S > 1$ and $0 < k < 1$, one defines $a_{n+1} = k(S - S_n)$ and $S_{n+1} = a_{n+1} + S_n$. Does $S_n$ converge? If so, to what? (Hint: First argue that $S_n < S$ for all $n$ and $S_n$ is increasing.)

**Answer**

Since $S > 1, a_2 > 0$, and since $k < 1, S_2 = 1 + a_2 < 1 + (S - 1) = S$. If $S_n > S$ for some $n$, then there is a smallest $n$. For this $n, S > S_{n-1}$, so $S_n = S_{n-1} + k(S - S_{n-1}) = kS + (1 - k)S_{n-1} < S$, a contradiction. Thus $S_n < S$ and $a_{n+1} > 0$ for all $n$, so $S_n$ is increasing and bounded by $S$. Let $S_* = \lim S_n$. If $S_* < S$, then $\Delta = k(S - S_*) > 0$, but we can find n such that $S_* - S_n < \Delta/2$, which implies that $S_{n+1} = S_n + k(S - S_n) > S_* + \Delta/2$, contradicting that Sn is increasing to $S_*$. Thus $S_n \to S$.

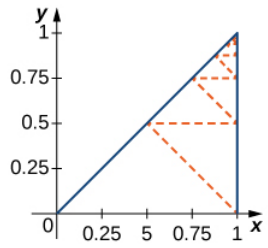
66) [Technology Required] A version of **von Bertalanffy growth** can be used to estimate the age of an individual in a homogeneous species from its length if the annual increase in year $n + 1$ satisfies $a_{n+1} = k(S - S_n)$, with $S_n$ as the length at year $n, S$ as a limiting length, and $k$ as a relative growth constant. If $S_1 = 3, S = 9$, and $k = 1/2$, numerically estimate the smallest value of n such that $S_n \ge 8$. Note that $S_{n+1} = S_n + a_{n+1}$. Find the corresponding $n$ when $k = 1/4$.

67) [Technology Required] Suppose that $\sum_{n=1}^{\infty} a_n$ is a convergent series of positive terms. Explain why $\lim_{N\to\infty} \sum_{n=N+1}^{\infty} a_n = 0$.

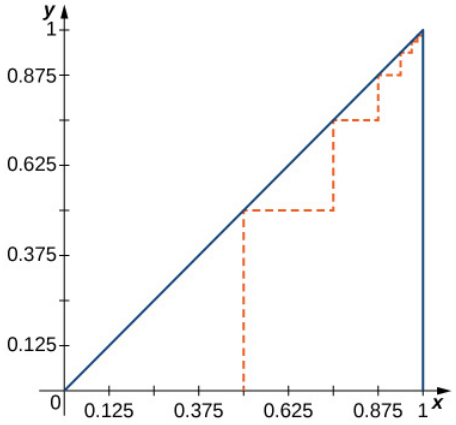
**Answer**

Let $S_k = \sum_{n=1}^{k} a_n$ and $S_k \to L$. Then $S_k$ eventually becomes arbitrarily close to $L$, which means that $L - S_N = \sum_{n=N+1}^{\infty} a_n$ becomes arbitrarily small as $N \to \infty$.

68) [Technology Required] Find the length of the dashed zig-zag path in the following figure.



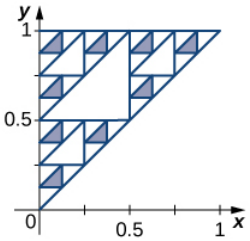
69) [Technology Required] Find the total length of the dashed path in the following figure.



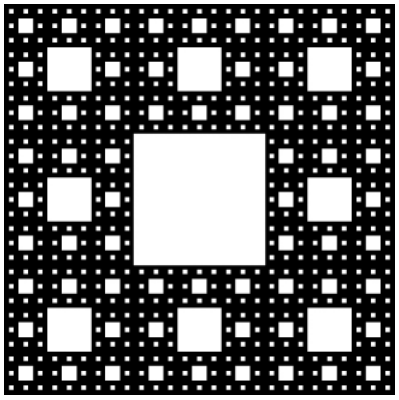
**Answer**

$$L = \left(1 + \frac{1}{2}\right) \sum_{n=1}^{\infty} \frac{1}{2^n} = \frac{3}{2}.$$

70) [Technology Required] The **Sierpinski triangle** is obtained from a triangle by deleting the middle fourth as indicated in the first step, by deleting the middle fourths of the remaining three congruent triangles in the second step, and in general deleting the middle fourths of the remaining triangles in each successive step. Assuming that the original triangle is shown in the figure, find the areas of the remaining parts of the original triangle after $N$ steps and find the total length of all of the boundary triangles after $N$ steps.



71) [Technology Required] The Sierpinski gasket is obtained by dividing the unit square into nine equal sub-squares, removing the middle square, then doing the same at each stage to the remaining sub-squares. The figure shows the remaining set after four iterations. Compute the total area removed after $N$ stages, and compute the length the total perimeter of the remaining set after $N$ stages.



**Answer**

At stage one a square of area $1/9$ is removed, at stage $2$ one removes $8$ squares of area $1/9^2$, at stage three one removes $8^2$ squares of area $1/9^3$, and so on. The total removed area after $N$ stages is $\sum_{n=0}^{N-1} \frac{8^N}{9^{N+1}} = \frac{1}{8} \cdot \frac{1-(8/9)^N}{1-8/9} \to 1$ as $N \to \infty$. The total perimeter is $4 + 4\sum_{n=0}^{\infty} \frac{8^N}{3^{N+1}} \to \infty$.

# 8.4: The Divergence and Integral Tests

**Learning Objectives**

- Use the Divergence Test to determine whether a series converges or diverges.
- Use the Integral Test to determine the convergence of a series.
- Estimate the value of a series by finding bounds on its remainder term.

In the previous section, we determined the convergence or divergence of several series by explicitly calculating the limit of the sequence of partial sums $\{S_k\}$. In practice, explicitly calculating this limit can be difficult or impossible. Luckily, several tests exist that allow us to determine convergence or divergence for many types of series. This section discusses two tests: the Divergence Test and the Integral Test. We will examine several other tests in the rest of this chapter and then summarize how and when to use them.

## Divergence Test

We begin our exploration of tests for the convergence or divergence of series with the test that is the quickest to use.

**Theorem: Divergence Test**

If $\lim\limits_{n\to\infty} a_n \neq 0$, then the series $\sum\limits_{n=1}^{\infty} a_n$ diverges.

**Proof by Contraposition**[1]

Suppose $\sum\limits_{n=1}^{\infty} a_n$ *converges*. Let $S_n = a_1 + a_2 + \cdots + a_n$. Then $a_n = S_n - S_{n-1}$.[2] Since we have assumed $\sum\limits_{n=1}^{\infty} a_n$ converges, the sequence of partial sums, $\{S_n\}$ must be convergent. Let $\lim\limits_{n\to\infty} S_n = S$. Since $n-1 \to \infty$ as $n \to \infty$, we also have $\lim\limits_{n\to\infty} S_{n-1} = S$. Therefore

$$\lim_{n\to\infty} a_n = \lim_{n\to\infty} (S_n - S_{n-1}) = \lim_{n\to\infty} S_n - \lim_{n\to\infty} S_{n-1} = S - S = 0.$$

Hence, the limit $\lim_{n\to\infty} a_n$ exists *and* is $0$.[3]

As with all of the proofs in Calculus, it is worthwhile to read through the proof of the Divergence Test and try to understand it. The method (proof by contraposition) is a wonderful indirect proof style.

**Caution: The Converse in NOT True**

It is important to note that the converse of the Divergence Test is *not true*. That is, if $\lim\limits_{n\to\infty} a_n = 0$, we cannot make any conclusion about the convergence of $\sum\limits_{n=1}^{\infty} a_n$.

To illustrate that cautionary statement, consider the harmonic series $\sum\limits_{n=1}^{\infty} \frac{1}{n}$.

$\lim\limits_{n\to 0} \frac{1}{n} = 0$, but the harmonic series $\sum\limits_{n=1}^{\infty} \frac{1}{n}$ diverges. From this point forward, we show many more examples of such series. Consequently, although we can use the Divergence Test to show that a series diverges, we cannot use it to prove that a series converges. Specifically, if $a_n \to 0$, the Divergence Test is inconclusive.

**Example 8.4.1: Using the Divergence Test**

For each of the following series, apply the Divergence Test. If the Divergence Test proves that the series diverges, state so. Otherwise, indicate that the Divergence Test is inconclusive.

a. $\sum\limits_{n=1}^{\infty} \frac{n}{2n-1}$

b. $\sum_{n=1}^{\infty} \frac{1}{n^3}$

c. $\sum_{n=1}^{\infty} e^{1/n^2}$

**Solutions**

a. Since $\lim_{n\to\infty} \frac{n}{3n-1} = \frac{1}{3} \neq 0$, by the Divergence Test, we can conclude that $\sum_{n=1}^{\infty} \frac{n}{3n-1}$ diverges.

b. Since $\lim_{n\to\infty} \frac{1}{n^3} = 0$, the Divergence Test is inconclusive.

c. Since $\lim_{n\to\infty} e^{1/n^2} = 1 \neq 0$, by the Divergence Test, the series $\sum_{n=1}^{\infty} e^{1/n^2}$ diverges.

**? Checkpoint 8.4.1**

What does the Divergence Test tell us about the series $\sum_{n=1}^{\infty} \cos(1/n^2)$?

**Answer**

The series diverges.

## Integral Test

In the previous section, we proved that the harmonic series diverges by looking at the sequence of partial sums $\{S_k\}$ and showing that $S_{2^k} > 1 + k/2$ for all $k \in \mathbb{N}$. In this section, we use a different technique to prove the divergence of the harmonic series. This technique is important because it is used to prove the divergence or convergence of many other series. This test, called the **Integral Test**, compares an infinite sum to an improper integral. It is important to note that this test can only be applied when considering a series with positive terms.

To illustrate how the Integral Test works, use the harmonic series as an example. In Figure 8.4.1, we depict the harmonic series by sketching a sequence of rectangles with areas $1, 1/2, 1/3, 1/4, \ldots$ along with the function $f(x) = 1/x$.

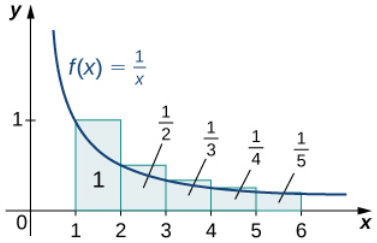

Figure 8.4.1: The sum of the areas of the rectangles is greater than the area between the curve $f(x) = 1/x$ and the $x$-axis for $x \geq 1$. Since the area bounded by the curve is infinite (as calculated by an improper integral), the sum of the areas of the rectangles is also infinite.

From the graph, we see that

$$\sum_{n=1}^{k} \frac{1}{n} = 1 + \frac{1}{2} + \frac{1}{3} + \cdots + \frac{1}{k} > \int_1^{k+1} \frac{1}{x}\, dx.$$

Therefore, for each $k$, the $k^{\text{th}}$ partial sum $S_k$ satisfies

$$\begin{aligned} S_k &= \sum_{n=1}^{k} \frac{1}{n} \\ &> \int_1^{k+1} \frac{1}{x}\,dx \\ &= \ln x\big|_1^{k+1} \\ &= \ln(k+1) - \ln(1) \\ &= \ln(k+1). \end{aligned}$$

Since $\lim_{k\to\infty} \ln(k+1) = \infty$, we see that the sequence of partial sums $\{S_k\}$ is unbounded. Therefore, $\{S_k\}$ diverges, and, consequently, the series $\sum_{n=1}^{\infty} \frac{1}{n}$ also diverges.

Now consider the series $\sum_{n=1}^{\infty} \frac{1}{n^2}$. We show how an integral can be used to prove that this series converges. In Figure 8.4.2, we sketch a sequence of rectangles with areas $1, 1/2^2, 1/3^2, \ldots$ along with the function $f(x) = \frac{1}{x^2}$.

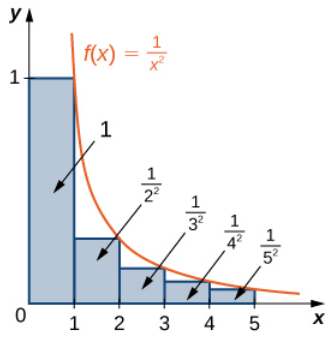

Figure 8.4.2: The sum of the areas of the rectangles is less than the sum of the area of the first rectangle and the area between the curve $f(x) = 1/x^2$ and the $x$-axis for $x \geq 1$. Since the area bounded by the curve is finite, the sum of the areas of the rectangles is also finite.

From the graph we see that

$$\sum_{n=1}^{k} \frac{1}{n^2} = 1 + \frac{1}{2^2} + \frac{1}{3^2} + \cdots + \frac{1}{k^2} < 1 + \int_1^k \frac{1}{x^2}\,dx.$$

Therefore, for each $k$, the $k^{\text{th}}$ partial sum $S_k$ satisfies

$$\begin{aligned} S_k &= \textstyle\sum_{n=1}^{k} \frac{1}{n^2} \\ &< 1 + \textstyle\int_1^k \frac{1}{x^2}\,dx \\ &= 1 - \frac{1}{x}\Big|_1^k \\ &= 1 - \frac{1}{k} + 1 \\ &= 2 - \frac{1}{k} \\ &< 2. \end{aligned}$$

We conclude that the sequence of partial sums $\{S_k\}$ is bounded. Moreover, since

$$S_k = S_{k-1} + \frac{1}{k^2}$$

for $k \geq 2$, the sequence of partial sums is also increasing. Therefore, by the Monotone Convergence Theorem, it converges. Thus, the series $\sum_{n=1}^{\infty} \frac{1}{n^2}$ converges.

We can extend this idea to prove convergence or divergence for many different series. Suppose $\sum_{n=1}^{\infty} a_n$ is a series with positive terms $a_n$ such that there exists a continuous, positive, decreasing function $f$ where $f(n) = a_n$ for all positive integers. Then, as in Figure 8.4.3*a*, for any integer $k$, the $k^{\text{th}}$ partial sum $S_k$ satisfies

$$S_k = a_1 + a_2 + a_3 + \cdots + a_k < a_1 + \int_1^k f(x)\,dx < 1 + \int_1^{\infty} f(x)\,dx.$$

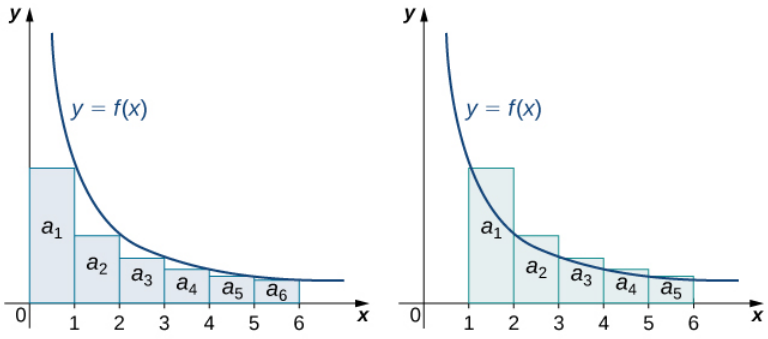

Figure 8.4.3*a*: If we can inscribe rectangles inside a region bounded by a curve $y = f(x)$ and the $x$-axis, and the area bounded by those curves for $x \geq 1$ is finite, then the sum of the areas of the rectangles is also finite.

Figure 8.4.3*b*: If a set of rectangles circumscribes the region bounded by $y = f(x)$ and the $x$ axis for $x \geq 1$ and the region has infinite area, then the sum of the areas of the rectangles is also infinite.

Therefore, if $\int_1^{\infty} f(x)\,dx$ converges, then the sequence of partial sums $\{S_k\}$ is bounded. Since $\{S_k\}$ is an increasing sequence, it converges by the Monotone Convergence Theorem if it is also a bounded sequence. We conclude that if $\int_1^{\infty} f(x)\,dx$ converges, then the series $\sum_{n=1}^{\infty} a_n$ also converges.

On the other hand, from Figure 8.4.3*b*, for any integer $k$, the $k^{\text{th}}$ partial sum $S_k$ satisfies

$$S_k = a_1 + a_2 + a_3 + \cdots + a_k > \int_1^{k+1} f(x)\,dx.$$

If

$$\lim_{k\to\infty} \int_1^{k+1} f(x)\,dx = \infty,$$

then $\{S_k\}$ is an unbounded sequence and therefore diverges. As a result, the series $\sum_{n=1}^{\infty} a_n$ also diverges. Since $f$ is a positive function, if $\int_1^{\infty} f(x)\,dx$ diverges, then

$$\lim_{k\to\infty} \int_1^{k+1} f(x)\,dx = \infty.$$

We conclude that if $\int_1^{\infty} f(x)\,dx$ diverges, then $\sum_{n=1}^{\infty} a_n$ diverges.

**Theorem: Integral Test**

Suppose $\sum_{n=1}^{\infty} a_n$ is a series with positive terms $a_n$. Suppose there exists a function $f$ and a positive integer $N$ such that the following three conditions are satisfied:

i. $f$ is continuous,
ii. $f$ is decreasing, and
iii. $f(n) = a_n$ for all integers $n \geq N$.

Then

$$\sum_{n=1}^{\infty} a_n$$

and

$$\int_N^{\infty} f(x)\,dx$$

both converge or both diverge (Figure 8.4.3).

**Caution: The Sequence Must EVENTUALLY be Non-Negative**

The base sequence, $\{a_n\}$, in the Integral Test must *eventually* consist of non-negative terms only. That is, to be able to use the Integral Test, there must exist $N$ such that $f(n) = a_n \geq 0$ for all $n \geq N$. This (along with the need to evaluate an improper integral) is a weakness of the Integral Test and a reason we will eventually need to consider other tests for convergence.

Although the convergence of $\int_N^{\infty} f(x)\,dx$ implies convergence of the related series $\sum_{n=1}^{\infty} a_n$, it does not imply that the value of the integral and the series are the same. They may be different and often are. For example,

$$\sum_{n=1}^{\infty} \left(\frac{1}{e}\right)^n = \frac{1}{e} + \left(\frac{1}{e}\right)^2 + \left(\frac{1}{e}\right)^3 + \cdots$$

is a geometric series with initial term $a = 1/e$ and ratio $r = 1/e$, which converges to

$$\frac{1/e}{1-(1/e)} = \frac{1/e}{(e-1)/e} = \frac{1}{e-1}.$$

However, the related integral $\int_1^{\infty} (1/e)^x\,dx$ satisfies

$$\int_1^{\infty} \left(\frac{1}{e}\right)^x dx = \int_1^{\infty} e^{-x}\,dx = \lim_{b\to\infty} \int_1^b e^{-x}\,dx = \lim_{b\to\infty} -e^{-x}\Big|_1^b = \lim_{b\to\infty} [-e^{-b} + e^{-1}] = \frac{1}{e}.$$

**Example 8.4.2: Using the Integral Test**

For each of the following series, use the Integral Test to determine whether the series converges or diverges.

a. $\sum_{n=1}^{\infty} \frac{1}{n^3}$
b. $\sum_{n=1}^{\infty} \frac{1}{\sqrt{2n-1}}$

**Solutions**

a. Compare

$$\sum_{n=1}^{\infty} \frac{1}{n^3} \text{ and } \int_1^{\infty} \frac{1}{x^3}\,dx.$$

We have

$$\begin{aligned}\int_1^\infty \frac{1}{x^3}\,dx &= \lim_{b\to\infty}\int_1^b \frac{1}{x^3}\,dx \\ &= \lim_{b\to\infty}\left[-\frac{1}{2x^2}\Big|_1^b\right] \\ &= \lim_{b\to\infty}\left[-\frac{1}{2b^2}+\frac{1}{2}\right] \\ &= \frac{1}{2}.\end{aligned}$$

Thus the integral $\int_1^\infty \frac{1}{x^3}\,dx$ converges, and therefore so does the series

$$\sum_{n=1}^\infty \frac{1}{n^3}.$$

b. Compare

$$\sum_{n=1}^\infty \frac{1}{\sqrt{2n-1}} \text{ and } \int_1^\infty \frac{1}{\sqrt{2x-1}}\,dx.$$

Since

$$\begin{aligned}\int_1^\infty \frac{1}{\sqrt{2x-1}}\,dx &= \lim_{b\to\infty}\int_1^b \frac{1}{\sqrt{2x-1}}\,dx \\ &= \lim_{b\to\infty}\sqrt{2x-1}\Big|_1^b \\ &= \lim_{b\to\infty}\left[\sqrt{2b-1}-1\right] \\ &= \infty,\end{aligned}$$

the integral $\int_1^\infty \frac{1}{\sqrt{2x-1}}\,dx$ diverges, and therefore

$$\sum_{n=1}^\infty \frac{1}{\sqrt{2n-1}}$$

diverges.

**? Checkpoint 8.4.2**

Use the Integral Test to determine whether the series $\sum_{n=1}^\infty \frac{n}{3n^2+1}$ converges or diverges.

**Answer**

The series diverges.

## The $p$-Series

The harmonic series $\sum_{n=1}^\infty 1/n$ and the series $\sum_{n=1}^\infty 1/n^2$ are both examples of a type of series called a $p$-series.

**Definition: $p$-series**

For any real number $p$, the series

$$\sum_{n=1}^\infty \frac{1}{n^p}$$

is called a $p$-**series**.

We know the $p$-series converges if $p = 2$ and diverges if $p = 1$. What about other values of $p$? In general, it is difficult, if not impossible, to compute the exact value of most $p$-series. However, we can use the tests presented thus far to prove whether a $p$-series converges or diverges.

If $p < 0$, then $1/n^p \to \infty$, and if $p = 0$, then $1/n^p \to 1$. Therefore, by the Divergence Test,

$$\sum_{n=1}^{\infty} \frac{1}{n^p}$$

diverges if $p \leq 0$.

If $p > 0$, then $f(x) = 1/x^p$ is a positive, continuous, decreasing function. Therefore, for $p > 0$, we use the Integral Test, comparing

$$\sum_{n=1}^{\infty} \frac{1}{n^p} \text{ and } \int_1^{\infty} \frac{1}{x^p}\, dx.$$

We have already considered the case when $p = 1$. We consider the case when $p > 0, p \neq 1$. For this case,

$$\begin{aligned} \int_1^{\infty} \frac{1}{x^p}\, dx &= \lim_{b\to\infty} \int_1^b \frac{1}{x^p}\, dx \\ &= \lim_{b\to\infty} \frac{1}{1-p} x^{1-p}\Big|_1^b \\ &= \lim_{b\to\infty} \frac{1}{1-p}[b^{1-p} - 1]. \end{aligned}$$

Because $b^{1-p} \to 0$ if $p > 1$ and $b^{1-p} \to \infty$ if $p < 1$, we conclude that

$$\int_1^{\infty} \frac{1}{x^p}\, dx = \begin{cases} \frac{1}{p-1}, \text{if } p > 1 \\ \infty, \text{if } p < 1. \end{cases}$$

Therefore, $\sum_{n=1}^{\infty} 1/n^p$ converges if $p > 1$ and diverges if $0 < p < 1$. We summarize this as a theorem.

**Theorem: $p$-series Test**

The $p$-series

$$\sum_{n=1}^{\infty} \frac{1}{n^p}$$

converges if and only if $p > 1$. It diverges otherwise.

**Example 8.4.3: Testing for Convergence of p-series**

For each of the following series, determine whether it converges or diverges.

a. $\sum_{n=1}^{\infty} \frac{1}{n^4}$

b. $\sum_{n=1}^{\infty} \frac{1}{n^{2/3}}$

**Solutions**

a. This is a $p$-series with $p = 4 > 1$, so the series converges.

b. Since $p = 2/3 < 1$, the series diverges.

**Checkpoint 8.4.3**

Does the series $\sum_{n=1}^{\infty} \frac{1}{n^{5/4}}$ converge or diverge?

**Answer**

The series converges.

## Estimating the Value of a Series

Suppose we know that a series $\sum_{n=1}^{\infty} a_n$ converges, and we want to estimate the sum of that series. Certainly we can approximate that sum using any finite sum $\sum_{n=1}^{N} a_n$ where $N \in \mathbb{N}$. The question we address here is, for a convergent series $\sum_{n=1}^{\infty} a_n$, how good is the approximation $\sum_{n=1}^{N} a_n$?

More specifically, if we let

$$R_N = \sum_{n=1}^{\infty} a_n - \sum_{n=1}^{N} a_n$$

be the **remainder** when the sum of an infinite series is approximated by the $N^{\text{th}}$ partial sum, how large is $R_N$? For some types of series, we can use the ideas from the Integral Test to estimate $R_N$.

**Theorem: Remainder Estimate from the Integral Test**

Suppose $\sum_{n=1}^{\infty} a_n$ is a *convergent* series with *positive* terms.[4] Also suppose there exists a function $f$ satisfying the following three conditions:

i. $f$ is continuous,
ii. $f$ is decreasing, and
iii. $f(n) = a_n$ for all integers $n \geq 1$.

Let $S_N$ be the $N^{\text{th}}$ partial sum of $\sum_{n=1}^{\infty} a_n$. For all $N \in \mathbb{N}$,

$$S_N + \int_{N+1}^{\infty} f(x)\,dx < \sum_{n=1}^{\infty} a_n < S_N + \int_{N}^{\infty} f(x)\,dx.$$

In other words, the remainder $R_N = \sum_{n=1}^{\infty} a_n - S_N = \sum_{n=N+1}^{\infty} a_n$ satisfies the following estimate:

$$\int_{N+1}^{\infty} f(x)\,dx < R_N < \int_{N}^{\infty} f(x)\,dx.$$

This is known as the **remainder estimate**.

The remainder estimate can be considered the error in approximating the series value.

We illustrate this theorem in Figure 8.4.4.

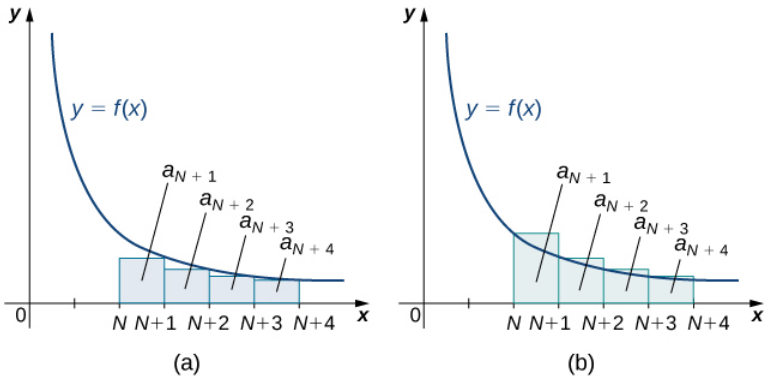

Figure 8.4.4: Given a continuous, positive, decreasing function $f$ and a sequence of positive terms $a_n$ such that $a_n = f(n)$ for all $n \in \mathbb{N}$, (a) the areas $a_{N+1} + a_{N+2} + a_{N+3} + \cdots < \int_N^\infty f(x)\,dx$, or (b) the areas $a_{N+1} + a_{N+2} + a_{N+3} + \cdots > \int_{N+1}^\infty f(x)\,dx$. Therefore, the integral is either an overestimate or an underestimate of the error.

In particular, by representing the remainder $R_N = a_{N+1} + a_{N+2} + a_{N+3} + \cdots$ as the sum of areas of rectangles, we see that the area of those rectangles is bounded above by $\int_N^\infty f(x)\,dx$ and bounded below by $\int_{N+1}^\infty f(x)\,dx$. In other words,

$$R_N = a_{N+1} + a_{N+2} + a_{N+3} + \cdots > \int_{N+1}^\infty f(x)\,dx$$

and

$$R_N = a_{N+1} + a_{N+2} + a_{N+3} + \cdots < \int_N^\infty f(x)\,dx.$$

We conclude that

$$\int_{N+1}^\infty f(x)\,dx < R_N < \int_N^\infty f(x)\,dx.$$

Since

$$\sum_{n=1}^\infty a_n = S_N + R_N,$$

where $S_N$ is the $N^{\text{th}}$ partial sum, we conclude that

$$S_N + \int_{N+1}^\infty f(x)\,dx < \sum_{n=1}^\infty a_n < S_N + \int_N^\infty f(x)\,dx.$$

The ability to approximate a series's value is important, and we will use different approximation methods for different convergence tests as we move forward.

### Example 8.4.4: Estimating the Value of a Series

Consider the series $\sum_{n=1}^\infty \frac{1}{n^3}$.

a. Calculate $S_{10} = \sum_{n=1}^{10} \frac{1}{n^3}$ and estimate the error.

b. Determine the least value of $N$ necessary such that $S_N$ will estimate $\sum_{n=1}^\infty \frac{1}{n^3}$ to within $0.001$.

**Solutions**

a. Using technology, we have

$$S_{10} = 1 + \frac{1}{2^3} + \frac{1}{3^3} + \frac{1}{4^3} + \cdots + \frac{1}{10^3} \approx 1.19753.$$

By the remainder estimate, we know

$$R_N < \int_N^\infty \frac{1}{x^3}\,dx.$$

We have

$$\begin{aligned}\int_{10}^\infty \frac{1}{x^3}\,dx &= \lim_{b\to\infty}\int_{10}^b \frac{1}{x^3}\,dx \\ &= \lim_{b\to\infty}\left[-\frac{1}{2x^2}\right]_N^b \\ &= \lim_{b\to\infty}\left[-\frac{1}{2b^2}+\frac{1}{2N^2}\right] \\ &= \frac{1}{2N^2}.\end{aligned}$$

Therefore, the error is $R_{10} < \frac{1}{2(10)^2} = 0.005$.

b. We want to find $N$ such that $R_N < 0.001$. In part a. we showed that $R_N < 1/2N^2$. Therefore, the remainder $R_N < 0.001$ as long as $\frac{1}{2N^2} < 0.001$. That is, we need $2N^2 > 1000$. Solving this inequality for $N$, we see that we need $N > 22.36$. We need to round up to the nearest integer to ensure the remainder is within the desired amount. Therefore, the minimum necessary value is $N = 23$.

**? Checkpoint 8.4.4**

For $\sum_{n=1}^\infty \frac{1}{n^4}$, calculate $S_5$ and estimate the error $R_5$.

**Answer**

$S_5 \approx 1.09035, R_5 < 0.00267$

## Footnotes

[1] Most theorems can be stated symbolically as the conditional proposition$P \implies Q$, where $P$ is a statement called the **antecedent**, and $Q$ is a statement called the **consequent**. Instead of directly proving $P \implies Q$, it is sometimes easier to prove it indirectly. There are two kinds of indirect proofs: **proof by contradiction**, and **proof by contraposition**.

You have already seen proofs by contradiction (see the uses of Rolle's Theorem in Calculus I for proving that a given equation has *exactly* one root). In a proof by contraposition, we use the fact that an implication, "if $P$, then $Q$," is equivalent to its contrapositive, "if *not* $Q$, then *not* $P$" (the notation, $\sim P$, is called the **negation** of $P$). Therefore, instead of proving $P \implies Q$, we may prove its contrapositive $\sim Q \implies \sim P$. Since it is an implication, we could use a direct proof at this point:

Assume $\sim Q$ is true (hence, assume $Q$ is false). Show that $\sim P$ is true (that is, show that $P$ is false).

[2] It can be useful at times to remember that $S_n = S_{n-1} + a_n$.

[3] The negation of "$A$ *or* $B$" is "not $A$ *and* not $B$."

[4] Remember, when dealing with the Integral Test, the terms of your base sequence, $\{a_n\}$ must *eventually* be non-negative.

## Key Concepts

- If $\lim_{n\to\infty} a_n \neq 0$, then the series $\sum_{n=1}^\infty a_n$ diverges.
- If $\lim_{n\to\infty} a_n = 0$, the series $\sum_{n=1}^\infty a_n$ may converge or diverge.

- If $\sum_{n=1}^{\infty} a_n$ is a series with positive terms $a_n$ and $f$ is a continuous, decreasing function such that $f(n) = a_n$ for all positive integers $n$, then

$$\sum_{n=1}^{\infty} a_n$$

and

$$\int_1^{\infty} f(x)\,dx$$

either both converge or both diverge. Furthermore, if $\sum_{n=1}^{\infty} a_n$ converges, then the $N^{\text{th}}$ partial sum approximation $S_N$ is accurate up to an error $R_N$ where $\int_{N+1}^{\infty} f(x)\,dx < R_N < \int_N^{\infty} f(x)\,dx$.
- The $p$-series $\sum_{n=1}^{\infty} \frac{1}{n^p}$ converges if $p > 1$ and diverges if $p \leq 1$.

## Key Equations

- **Divergence Test**

  If $a_n \nrightarrow 0$ as $n \to \infty$, $\sum_{n=1}^{\infty} a_n$ diverges.
- **p-series**

  $$\sum_{n=1}^{\infty} \frac{1}{n^p} \quad \begin{cases} \text{converges, if } p > 1 \\ \text{diverges, if } p \leq 1 \end{cases}$$
- **Remainder estimate from the Integral Test**

  $$\int_{N+1}^{\infty} f(x)\,dx < R_N < \int_N^{\infty} f(x)\,dx$$

## Glossary

**Divergence Test**

if $\lim_{n\to\infty} a_n \neq 0$, then the series $\sum_{n=1}^{\infty} a_n$ diverges

**Integral Test**

for a series $\sum_{n=1}^{\infty} a_n$ with positive terms $a_n$, if there exists a continuous, decreasing function $f$ such that $f(n) = a_n$ for all positive integers $n$, then

$$\sum_{n=1}^{\infty} a_n$$

and

$$\int_1^{\infty} f(x)\,dx$$

either both converge or both diverge

***p*-series**

a series of the form $\sum_{n=1}^{\infty} 1/n^p$

**remainder estimate**

for a series $\sum_{n=}^{\infty} 1a_n$ with positive terms $a_n$ and a continuous, decreasing function $f$ such that $f(n) = a_n$ for all positive integers $n$, the remainder $R_N = \sum_{n=1}^{\infty} a_n - \sum_{n=1}^{N} a_n$ satisfies the following estimate:

$$\int_{N+1}^{\infty} f(x)\,dx < R_N < \int_{N}^{\infty} f(x)\,dx$$

# 8.4E: Exercises

## Divergence Test Problems

**Consider the sequence for each series in exercises 1 - 14, if the Divergence Test applies, either state that $\lim_{n\to\infty} a_n$ does not exist or find $\lim_{n\to\infty} a_n$. If the Divergence Test does not apply, state why.**

1) $\sum_{n=1}^{\infty} \frac{n}{n+2}$

2) $\sum_{n=1}^{\infty} \frac{n}{5n^2-3}$

**Answer**

$\lim_{n\to\infty} a_n = 0$. The Divergence Test does not apply.

3) $\sum_{n=1}^{\infty} \frac{n}{\sqrt{3n^2+2n+1}}$

4) $\sum_{n=1}^{\infty} \frac{(2n+1)(n-1)}{(n+1)^2}$

**Answer**

$\lim_{n\to\infty} a_n = 2$. So the series diverges by the $n^{\text{th}}$-Term Test for Divergence.

5) $\sum_{n=1}^{\infty} \frac{(2n+1)^{2n}}{(3n^2+1)^n}$

6) $\sum_{n=1}^{\infty} \frac{2^n}{3^{n/2}}$

**Answer**

$\lim_{n\to\infty} a_n = \infty$ (does not exist). So the series diverges by the $n^{\text{th}}$-Term Test for Divergence.

7) $\sum_{n=1}^{\infty} \frac{2^n+3^n}{10^{n/2}}$

8) $\sum_{n=1}^{\infty} e^{-2/n}$

**Answer**

$\lim_{n\to\infty} a_n = 1$. So the series diverges by the $n^{\text{th}}$-Term Test for Divergence.

9) $\sum_{n=1}^{\infty} \cos n$

10) $\sum_{n=1}^{\infty} \tan n$

**Answer**

$\lim_{n\to\infty} a_n$ does not exist. So the series diverges by the $n^{\text{th}}$-Term Test for Divergence.

11) $\sum_{n=1}^{\infty} \frac{1-\cos^2(1/n)}{\sin^2(2/n)}$

12) $\sum_{n=1}^{\infty} \left(1-\frac{1}{n}\right)^{2n}$

**Answer**

$\lim_{n\to\infty} a_n = 1/e^2$. So the series diverges by the $n^{\text{th}}$-Term Test for Divergence.

13) $\sum_{n=1}^{\infty} \frac{\ln n}{n}$

14) $\sum_{n=1}^{\infty} \frac{(\ln n)^2}{\sqrt{n}}$

**Answer**

$\lim_{n\to\infty} a_n = 0$. The Divergence Test does not apply.

## $p$-Series Problems & Integral Test Problems

**In exercises 15 - 20, state whether the given $p$-series converges.**

15) $\sum_{n=1}^{\infty} \frac{1}{\sqrt{n}}$

16) $\sum_{n=1}^{\infty} \frac{1}{n\sqrt{n}}$

**Answer**

The series converges, since $p = 3/2 > 1$.

17) $\sum_{n=1}^{\infty} \frac{1}{\sqrt[3]{n^2}}$

18) $\sum_{n=1}^{\infty} \frac{1}{\sqrt[3]{n^4}}$

**Answer**

The series converges, since $p = 4/3 > 1$.

19) $\sum_{n=1}^{\infty} \frac{n^e}{n^\pi}$

20) $\sum_{n=1}^{\infty} \frac{n^\pi}{n^{2e}}$

**Answer**

The series converges, since $p = 2e - \pi > 1$.

**In exercises 21 - 27, use the Integral Test to determine whether the following sums converge.**

21) $\sum_{n=1}^{\infty} \frac{1}{\sqrt{n+5}}$

22) $\sum_{n=1}^{\infty} \frac{1}{\sqrt[3]{n+5}}$

**Answer**

The series diverges by the Integral Test since $\int_1^{\infty} \frac{dx}{(x+5)^{1/3}}$ can be shown to diverge.

23) $\sum_{n=2}^{\infty} \frac{1}{n \ln n}$

24) $\sum_{n=1}^{\infty} \frac{n}{1+n^2}$

**Answer**

The series diverges by the Integral Test since $\int_1^{\infty} \frac{x}{1+x^2}\,dx$ can be shown to diverge.

25) $\sum_{n=1}^{\infty} \frac{e^n}{1+e^{2n}}$

26) $\sum_{n=1}^{\infty} \frac{2n}{1+n^4}$

**Answer**

The series converges by the Integral Test since $\int_1^{\infty} \frac{2x}{1+x^4}\,dx$ converges.

27) $\sum_{n=2}^{\infty} \frac{1}{n \ln^2 n}$

**Express the sums in exercises 28 - 31 as $p$-series and determine whether each converges.**

28) $\sum_{n=1}^{\infty} 2^{-\ln n}$

(Hint: $2^{-\ln n} = \frac{1}{n^{\ln 2}}$.)

**Answer**

$2^{-\ln n} = 1/n^{\ln 2}$. Since $p = \ln 2 < 1$, this series diverges by the $p$-series test.

29) $\sum_{n=1}^{\infty} 3^{-\ln n}$

(Hint: $3^{-\ln n} = \frac{1}{n^{\ln 3}}$.)

30) $\sum_{n=1}^{n} 2^{-2\ln n}$

**Answer**

$2^{-2\ln n} = 1/n^{2\ln 2}$. Since $p = 2\ln 2 - 1 < 1$, this series diverges by the $p$-series test.

31) $\sum_{n=1}^{\infty} n 3^{-2\ln n}$

**In exercises 32 - 35, use the estimate $R_N \le \int_N^{\infty} f(t)\,dt$ to find a bound for the remainder $R_N = \sum_{n=1}^{\infty} a_n - \sum_{n=1}^{N} a_n$ where $a_n = f(n)$.**

32) $\sum_{n=1}^{1000} \frac{1}{n^2}$

**Answer**

$$R_{1000} \le \int_{1000}^{\infty} \frac{dt}{t^2} = \lim_{b\to\infty} -\frac{1}{t}\Big|_{1000}^{b} = \lim_{b\to\infty} \left(-\frac{1}{b} + \frac{1}{1000}\right) = 0.001$$

33) $\sum_{n=1}^{1000} \frac{1}{n^3}$

34) $\sum_{n=1}^{1000} \frac{1}{1+n^2}$

**Answer**

$$R_{1000} \le \int_{1000}^{\infty} \frac{dt}{1+t^2} = \lim_{b\to\infty} \left(\tan^{-1} b - \tan^{-1}(1000)\right) = \pi/2 - \tan^{-1}(1000) \approx 0.000999$$

35) $\sum_{n=1}^{100} \frac{n}{2^n}$

**[Technology Required] In exercises 36 - 40, find the minimum value of $N$ such that the remainder estimate $\int_{N+1}^{\infty} f(x)\,dx < R_N < \int_N^{\infty} f(x)\,dx$ guarantees that $\sum_{n=1}^{N} a_n$ estimates $\sum_{n=1}^{\infty} a_n$, accurate to within the given error.**

36) $a_n = \frac{1}{n^2}$, error $< 10^{-4}$

**Answer**

$R_N < \int_N^\infty \frac{dx}{x^2} = 1/N$, for $N > 10^4$

37) $a_n = \frac{1}{n^{1.1}}$, error $< 10^{-4}$

38) $a_n = \frac{1}{n^{1.01}}$, error $< 10^{-4}$

**Answer**

$R_N < \int_N^\infty \frac{dx}{x^{1.01}} = 100N^{-0.01}$, for $N > 10^{600}$

39) $a_n = \frac{1}{n \ln^2 n}$, error $< 10^{-3}$

40) $a_n = \frac{1}{1+n^2}$, error $< 10^{-3}$

**Answer**

$R_N < \int_N^\infty \frac{dx}{1+x^2} = \pi/2 - \tan^{-1}(N)$, for $N > \tan(\pi/2 - 10^{-3}) \approx 1000$

**In exercises 41 - 45, find a value of $N$ such that $R_N$ is smaller than the desired error. Compute the corresponding sum $\sum_{n=1}^{N} a_n$ and compare it to the given estimate of the infinite series.**

41) $a_n = \frac{1}{n^{11}}$, error $< 10^{-4}$, $\sum_{n=1}^{\infty} \frac{1}{n^{11}} = 1.000494\ldots$

42) $a_n = \frac{1}{e^n}$, error $< 10^{-5}$, $\sum_{n=1}^{\infty} \frac{1}{e^n} = \frac{1}{e-1} = 0.581976\ldots$

**Answer**

$R_N < \int_N^\infty \frac{dx}{e^x} = e^{-N}$, for $N > 5\ln(10)$, okay if $N = 12$; $\sum_{n=1}^{12} e^{-n} = 0.581973\ldots$. Estimate agrees with $1/(e-1)$ to five decimal places.

43) $a_n = \frac{1}{e^{n^2}}$, error $< 10^{-5}$, $\sum_{n=1}^{\infty} \frac{1}{e^{n^2}} = 0.40488139857\ldots$

44) $a_n = \frac{1}{n^4}$, error $< 10^{-4}$, $\sum_{n=1}^{\infty} \frac{1}{n^4} = \frac{\pi^4}{90} = 1.08232\ldots$

**Answer**

$R_N < \int_N^\infty \frac{dx}{x^4} = 4/N^3$, for $N > (4.10^4)^{1/3}$, okay if $N = 35$; $\sum_{n=1}^{35} \frac{1}{n^4} = 1.08231\ldots$. Estimate agrees with the sum to four decimal places.

45) $a_n = \frac{1}{n^6}$, error $< 10^{-6}$, $\sum_{n=1}^{\infty} \frac{1}{n^6} = \frac{\pi^6}{945} = 1.01734306\ldots$,

46) Find the limit as $n \to \infty$ of $\frac{1}{n} + \frac{1}{n+1} + \cdots + \frac{1}{2n}$.
(Hint: Compare to $\int_n^{2n} \frac{1}{t}\, dt$.)

**Answer**

$\ln(2)$

47) Find the limit as $n \to \infty$ of $\frac{1}{n} + \frac{1}{n+1} + \cdots + \frac{1}{3n}$

The next few exercises are intended to give a sense of applications in which partial sums of the harmonic series arise.

48) In certain applications of probability, such as the so-called Watterson estimator for predicting mutation rates in population genetics, it is important to have an accurate estimate of the number $H_k = (1 + \frac{1}{2} + \frac{1}{3} + \cdots + \frac{1}{k})$. Recall that $T_k = H_k - \ln k$ is decreasing. Compute $T = \lim_{k \to \infty} T_k$ to four decimal places.

$\left(\text{Hint: } \frac{1}{k+1} < \int_k^{k+1} \frac{1}{x}\, dx.\right)$

**Answer**

$T = 0.5772...$

49) [Technology Required] Complete sampling with replacement, sometimes called the **coupon collector's problem**, is phrased as follows: Suppose you have $N$ unique items in a bin. At each step, an item is chosen at random, identified, and put back in the bin. The problem asks what is the expected number of steps $E(N)$ that it takes to draw each unique item at least once. It turns out that $E(N) = N.H_N = N\left(1 + \frac{1}{2} + \frac{1}{3} + \cdots + \frac{1}{N}\right)$. Find $E(N)$ for $N = 10, 20,$ and $50$.

50) [Technology Required] The simplest way to shuffle cards is to take the top card and insert it at a random place in the deck, called top random insertion, and then repeat. We will consider a deck to be randomly shuffled once enough top random insertions have been made that the card originally at the bottom has reached the top and then been randomly inserted. If the deck has $n$ cards, then the probability that the insertion will be below the card initially at the bottom (call this card $B$) is $1/n$. Thus the expected number of top random insertions before $B$ is no longer at the bottom is $n$. Once one card is below $B$, there are two places below $B$ and the probability that a randomly inserted card will fall below $B$ is $2/n$. The expected number of top random insertions before this happens is $n/2$. The two cards below $B$ are now in random order. Continuing this way, find a formula for the expected number of top random insertions needed to consider the deck to be randomly shuffled.

**Answer**

The expected number of random insertions to get $B$ to the top is $n + n/2 + n/3 + \cdots + n/(n-1)$. Then one more insertion puts $B$ back in at random. Thus, the expected number of shuffles to randomize the deck is $n(1 + 1/2 + \cdots + 1/n)$.

51) Suppose a scooter can travel $100$ km on a full tank of fuel. Assuming that fuel can be transferred from one scooter to another but can only be carried in the tank, present a procedure that will enable one of the scooters to travel $100H_N$ km, where $H_N = 1 + 1/2 + \cdots + 1/N$.

52) Show that for the remainder estimate to apply on $[N, \infty)$ it is sufficient that $f(x)$ be decreasing on $[N, \infty)$, but $f$ need not be decreasing on $[1, \infty)$.

**Answer**

Set $b_n = a_{n+N}$ and $g(t) = f(t + N)$ such that $f$ is decreasing on $[t, \infty)$.

53) [Technology Required] Use the remainder estimate and Integration by Parts to approximate $\sum_{n=1}^{\infty} \frac{n}{e^n}$ within an error smaller than $0.0001$.

54) Does $\sum_{n=2}^{\infty} \frac{1}{n(\ln n)^p}$ converge if $p$ is large enough? If so, for which $p$?

**Answer**

The series converges for $p > 1$ by Integral Test using change of variable.

55) [Technology Required] Suppose a computer can sum one million terms per second of the divergent series $\sum_{n=1}^{N} \frac{1}{n}$. Use the Integral Test to approximate how many seconds it will take to add up enough terms for the partial sum to exceed $100$.

56) [Technology Required] A fast computer can sum one million terms per second of the divergent series $\sum_{n=2}^{N} \frac{1}{n \ln n}$. Use the Integral Test to approximate how many seconds it will take to add up enough terms for the partial sum to exceed **100**.

**Answer**

$N = e^{e^{100}} \approx e^{10^{43}}$ terms are needed.

# 8.5: The Comparison Tests

**Learning Objectives**

- Use the Series Comparison Test to test a series for convergence.
- Use the Limit Comparison Test to determine the convergence of a series.

We have seen that the Integral Test allows us to determine the convergence or divergence of a series by comparing it to a related improper integral. In this section, we show how to use Comparison Tests to determine the convergence or divergence of a series by comparing it to a series whose convergence or divergence is known. Typically, these tests determine the convergence of series similar to geometric series or $p$-series.

## Series Comparison Test

In the preceding two sections, we discussed two large classes of series: geometric series and $p$-series. We know precisely when these series converge and when they diverge. Here, we show how to use the convergence or divergence of these series to prove convergence or divergence for other series using a method called the **Series Comparison Test**.

For example, consider the series

$$\sum_{n=1}^{\infty} \frac{1}{n^2+1}.$$

This series looks similar to the convergent series

$$\sum_{n=1}^{\infty} \frac{1}{n^2}$$

Since the terms in each of the series are positive, the sequence of partial sums for each series is monotonically increasing. Furthermore, since

$$0 < \frac{1}{n^2+1} < \frac{1}{n^2}$$

for all $n \in \mathbb{N}$, the $k^{\text{th}}$ partial sum $S_k$ of $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n^2+1}$ satisfies

$$S_k = \sum_{n=1}^{k} \frac{1}{n^2+1} < \sum_{n=1}^{k} \frac{1}{n^2} < \sum_{n=1}^{\infty} \frac{1}{n^2}.$$

(See Figure 8.5.1$a$ and Table 8.5.1 below.) Since the series on the right converges, the sequence $\{S_k\}$ is bounded above. We conclude that $\{S_k\}$ is a monotonically increasing sequence that is bounded above. Therefore, by the Monotone Convergence Theorem, $\{S_k\}$ converges. Thus,

$$\sum_{n=1}^{\infty} \frac{1}{n^2+1}$$

converges.

Similarly, consider the series

$$\sum_{n=1}^{\infty} \frac{1}{n-1/2}.$$

This series looks similar to the divergent series

$$\sum_{n=1}^{\infty} \frac{1}{n}.$$

The sequence of partial sums for each series is monotonically increasing and

$$\frac{1}{n-1/2} > \frac{1}{n} > 0$$

for every $n \in \mathbb{N}$. Therefore, the $k^{\text{th}}$ partial sum $S_k$ of

$$\sum_{n=1}^{\infty} \frac{1}{n-1/2}$$

satisfies

$$S_k = \sum_{n=1}^{k} \frac{1}{n-1/2} > \sum_{n=1}^{k} \frac{1}{n}.$$

(See Figure 8.5.1*b* and Table 8.5.2 below). Since the series $\sum_{n=1}^{\infty} \frac{1}{n}$ diverges to infinity, the sequence of partial sums $\sum_{n=1}^{k} \frac{1}{n}$ is unbounded. Consequently, $\{S_k\}$ is an unbounded sequence that diverges. We conclude that

$$\sum_{n=1}^{\infty} \frac{1}{n-1/2}$$

diverges.

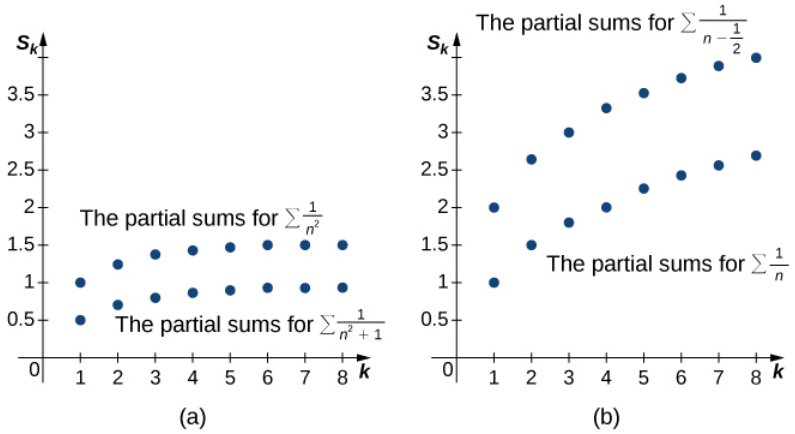

Figure 8.5.1*a*: Each of the partial sums for the given series is less than the corresponding partial sum for the converging $p-$ *series*.
Figure 8.5.1*b*: Each partial sum for the given series is greater than the corresponding partial sum for the diverging harmonic series.

### Theorem: Series Comparison Test

i. Suppose there exists an integer $N$ such that $0 \le a_n \le b_n$ for all $n \ge N$. If $\sum_{n=1}^{\infty} b_n$ converges, then $\sum_{n=1}^{\infty} a_n$ converges.

ii. Suppose there exists an integer $N$ such that $a_n \ge b_n \ge 0$ for all $n \ge N$. If $\sum_{n=1}^{\infty} b_n$ diverges, then $\sum_{n=1}^{\infty} a_n$ diverges.

**Proof**

We prove part i (the proof of part ii is the contrapositive of part i). Let $\{S_k\}$ be the sequence of partial sums associated with $\sum_{n=1}^{\infty} a_n$, and let $L = \sum_{n=1}^{\infty} b_n$. Since the terms $a_n \ge 0$,

$$S_k = a_1 + a_2 + \cdots + a_k \le a_1 + a_2 + \cdots + a_k + a_{k+1} = S_{k+1}.$$

Therefore, the sequence of partial sums is increasing. Further, since $a_n \le b_n$ for all $n \ge N$,

$$\sum_{n=N}^{k} a_n \le \sum_{n=N}^{k} b_n \le \sum_{n=1}^{\infty} b_n = L.$$

Therefore, for all $k \ge 1$,

$$S_k = (a_1 + a_2 + \cdots + a_{N-1}) + \sum_{n=N}^{k} a_n \le (a_1 + a_2 + \cdots + a_{N-1}) + L.$$

Since $a_1 + a_2 + \cdots + a_{N-1}$ is a finite number, we conclude that the sequence $S_k$ is bounded above. Therefore, $\{S_k\}$ is an increasing sequence that is bounded above. By the Monotone Convergence Theorem, we conclude that $\{S_k\}$ converges, and therefore the series $\sum_{n=1}^{\infty} a_n$ converges.

### Caution: The Terms Must be Positive

You must be sure that the terms of the original series and the series you are using to compare are *positive*! This is critical because the Series Comparison Test fails to work otherwise.

To use the Series Comparison Test (also known as the **SCT**) to determine the convergence or divergence of a series $\sum_{n=1}^{\infty} a_n$, it is necessary to find a suitable series with which to compare it. Since we know the convergence properties of geometric series and $p$-series, these series are often used. If there exists an integer $N$ such that for all $n \ge N$, each term $a_n$ is less than each corresponding term of a known convergent series, then $\sum_{n=1}^{\infty} a_n$ converges. Similarly, if there exists an integer $N$ such that for all $n \ge N$, each term $a_n$ is greater than each corresponding term of a known divergent series, then $\sum_{n=1}^{\infty} a_n$ diverges.

### Example 8.5.1: Using the Comparison Test

For each of the following series, use the Comparison Test to determine whether the series converges or diverges.

a. $\sum_{n=1}^{\infty} \frac{1}{n^3 + 3n + 1}$

b. $\sum_{n=1}^{\infty} \frac{1}{2^n + 1}$

c. $\sum_{n=2}^{\infty} \frac{1}{\ln n}$

**Solutions**

a. Compare to $\sum_{n=1}^{\infty} \frac{1}{n^3}$. Note that the terms of the original and compared series are positive. Since $\sum_{n=1}^{\infty} \frac{1}{n^3}$ is a $p$-series with $p = 3$, it converges. Further,

$$n^3+3n+1>n^3>0 \implies 0<\frac{1}{n^3+3n+1}<\frac{1}{n^3}$$

for every $n \in \mathbb{N}$. Therefore, we can conclude that $\sum_{n=1}^{\infty} \frac{1}{n^3+3n+1}$ converges.

b. Compare to $\sum_{n=1}^{\infty} \left(\frac{1}{2}\right)^n$. Again, the terms of both series are positive. Since $\sum_{n=1}^{\infty} \left(\frac{1}{2}\right)^n$ is a geometric series with $r=\frac{1}{2}$ and $\left|\frac{1}{2}\right|<1$, it converges. Also,

$$2^n+1>2^n>0 \implies 0<\frac{1}{2^n+1}<\frac{1}{2^n}$$

for every $n \in \mathbb{N}$. Therefore, we see that $\sum_{n=1}^{\infty} \frac{1}{2^n+1}$ converges.

c. Compare to $\sum_{n=2}^{\infty} \frac{1}{n}$. The terms of both series are positive.

If we let $f(x)=x$ and $g(x)=\ln(x)$, we know that $f(1)=1>0=g(1)$. Moreover, for $x \geq 1$, $f'(x)=1 \geq g'(x)=\frac{1}{x}$. Hence, by the Racetrack Principle (from Calculus I), $f(x)=x>\ln(x)=g(x)$ for $x \geq 1$. Thus,

$$0<\ln(n)<n \implies \frac{1}{\ln(n)}>\frac{1}{n}>0$$

for $n \geq 2$. Since $\sum_{n=2}^{\infty} \frac{1}{n}$ diverges, we have that $\sum_{n=2}^{\infty} \frac{1}{\ln n}$ diverges.

**Checkpoint 8.5.1**

Use the Comparison Test to determine if the series $\sum_{n=1}^{\infty} \frac{n}{n^3+n+1}$ converges or diverges.

**Answer**

The series converges.

## Limit Comparison Test

The Series Comparison Test works nicely if we can find a comparable series satisfying the hypothesis of the test. However, sometimes finding an appropriate series can be difficult. Consider the series

$$\sum_{n=2}^{\infty} \frac{1}{n^2-1}.$$

It is natural to compare this series with the convergent series

$$\sum_{n=2}^{\infty} \frac{1}{n^2}.$$

However, this series does not satisfy the hypothesis necessary to use the Series Comparison Test because

$$\frac{1}{n^2-1}>\frac{1}{n^2}$$

for all integers $n \geq 2$. Although we could look for a different series with which to compare $\sum_{n=2}^{\infty} \frac{1}{n^2-1}$, instead we show how we can use the **Limit Comparison Test** (also called the **LCT**) to compare

$$\sum_{n=2}^{\infty} \frac{1}{n^2-1}$$

and

$$\sum_{n=2}^{\infty} \frac{1}{n^2}.$$

Let us examine the idea behind the Limit Comparison Test. Consider two series $\sum_{n=1}^{\infty} a_n$ and $\sum_{n=1}^{\infty} b_n$ with *positive* terms $a_n$ and $b_n$ and evaluate

$$\lim_{n\to\infty} \frac{a_n}{b_n}.$$

If

$$\lim_{n\to\infty} \frac{a_n}{b_n} = L \neq 0,$$

then, for $n$ sufficiently large, $a_n \approx Lb_n$. Therefore, either both series converge or both series diverge. For the series $\sum_{n=2}^{\infty} \frac{1}{n^2-1}$ and $\sum_{n=2}^{\infty} \frac{1}{n^2}$, we see that

$$\lim_{n\to\infty} \frac{1/(n^2-1)}{1/n^2} = \lim_{n\to\infty} \frac{n^2}{n^2-1} = 1.$$

Since $\sum_{n=2}^{\infty} \frac{1}{n^2}$ converges, we conclude that

$$\sum_{n=2}^{\infty} \frac{1}{n^2-1}$$

converges.

The Limit Comparison Test can be used in two other cases. Suppose

$$\lim_{n\to\infty} \frac{a_n}{b_n} = 0.$$

You can conceptually think of this as saying $b_n$ will eventually be much greater than $a_n$. In this case, $\{a_n/b_n\}$ is a bounded sequence. As a result, there exists a constant $M$ such that $a_n \leq Mb_n$. Therefore, if $\sum_{n=1}^{\infty} b_n$ converges, then $\sum_{n=1}^{\infty} a_n$ converges. On the other hand, suppose

$$\lim_{n\to\infty} \frac{a_n}{b_n} = \infty.$$

Again, conceptually this tells us that $a_n$ is eventually much greater than $b_n$. In this case, $\{a_n/b_n\}$ is an unbounded sequence. Therefore, for every constant $M$ there exists an integer $N$ such that $a_n \geq Mb_n$ for all $n \geq N$. Hence, if $\sum_{n=1}^{\infty} b_n$ diverges, then $\sum_{n=1}^{\infty} a_n$ diverges as well.

We summarize these findings in the following theorem.

**Theorem: Limit Comparison Test**

Let $a_n, b_n \geq 0$ for all $n \geq 1$.

i. If $\lim_{n\to\infty} \frac{a_n}{b_n} = L \neq 0$, then $\sum_{n=1}^{\infty} a_n$ and $\sum_{n=1}^{\infty} b_n$ both converge or both diverge.

ii. If $\lim_{n\to\infty} \frac{a_n}{b_n} = 0$ and $\sum_{n=1}^{\infty} b_n$ converges, then $\sum_{n=1}^{\infty} a_n$ converges.

iii. If $\lim_{n\to\infty} \frac{a_n}{b_n} = \infty$ and $\sum_{n=1}^{\infty} b_n$ diverges, then $\sum_{n=1}^{\infty} a_n$ diverges.

Note that if $\frac{a_n}{b_n} \to 0$ and $\sum_{n=1}^{\infty} b_n$ diverges, the Limit Comparison Test gives no information. Similarly, if $\frac{a_n}{b_n} \to \infty$ and $\sum_{n=1}^{\infty} b_n$ converges, the test also provides no information.

For example, consider the two series $\sum_{n=1}^{\infty} \frac{1}{\sqrt{n}}$ and $\sum_{n=1}^{\infty} \frac{1}{n^2}$. These series are both $p$-series with $p = \frac{1}{2}$ and $p = 2$, respectively. Since $p = \frac{1}{2} < 1$, the series $\sum_{n=1}^{\infty} \frac{1}{\sqrt{n}}$ diverges. On the other hand, since $p = 2 > 1$, the series $\sum_{n=1}^{\infty} \frac{1}{n^2}$ converges. However, suppose we attempted to apply the Limit Comparison Test, using the convergent $p$–series $\sum_{n=1}^{\infty} \frac{1}{n^3}$ as our comparison series. First, we see that

$$\frac{1/\sqrt{n}}{1/n^3} = \frac{n^3}{\sqrt{n}} = n^{5/2} \to \infty \text{ as } n \to \infty.$$

Similarly, we see that

$$\frac{1/n^2}{1/n^3} = n \to \infty \text{ as } n \to \infty.$$

Therefore, if $\frac{a_n}{b_n} \to \infty$ when $\sum_{n=1}^{\infty} b_n$ converges, we do not gain any information on the convergence or divergence of $\sum_{n=1}^{\infty} a_n$.

**Caution: The Terms Must be Positive**

Just as in the Series Comparison Test, the terms of the series used for the Limit Comparison Test must be positive.

**Example 8.5.2: Using the Limit Comparison Test**

For each of the following series, use the Limit Comparison Test to determine whether the series converges or diverges. If the test does not apply, say so.

a. $\sum_{n=1}^{\infty} \frac{1}{\sqrt{n}+1}$
b. $\sum_{n=1}^{\infty} \frac{2^n+1}{3^n}$
c. $\sum_{n=1}^{\infty} \frac{\ln(n)}{n^2}$

**Solutions**

a. Compare this series to $\sum_{n=1}^{\infty} \frac{1}{\sqrt{n}}$. Note that both series have only positive terms. Calculate

$$\lim_{n\to\infty} \frac{1/(\sqrt{n}+1)}{1/\sqrt{n}} = \lim_{n\to\infty} \frac{\sqrt{n}}{\sqrt{n}+1} = \lim_{n\to\infty} \frac{1/\sqrt{n}}{1+1/\sqrt{n}} = 1.$$

By the Limit Comparison Test, since $\sum_{n=1}^{\infty} \frac{1}{\sqrt{n}}$ diverges, then $\sum_{n=1}^{\infty} \frac{1}{\sqrt{n}+1}$ diverges.

b. Compare this series to $\sum_{n=1}^{\infty} \left(\frac{2}{3}\right)^n$. Again, both series have only positive terms. We see that

$$\lim_{n\to\infty} \frac{(2^n+1)/3^n}{2^n/3^n} = \lim_{n\to\infty} \frac{2^n+1}{3^n} \cdot \frac{3^n}{2^n} = \lim_{n\to\infty} \frac{2^n+1}{2^n} = \lim_{n\to\infty} \left[1 + \left(\tfrac{1}{2}\right)^n\right] = 1.$$

Therefore,

$$\lim_{n\to\infty} \frac{(2^n+1)/3^n}{2^n/3^n} = 1.$$

Since $\sum_{n=1}^{\infty} \left(\frac{2}{3}\right)^n$ converges, we conclude that $\sum_{n=1}^{\infty} \frac{2^n+1}{3^n}$ converges.

c. Since $\ln n < n$ (see Example 8.5.1c), compare with $\sum_{n=1}^{\infty} \frac{1}{n}$. We see that

$$\lim_{n\to\infty} \frac{\ln n/n^2}{1/n} = \lim_{n\to\infty} \frac{\ln n}{n^2} \cdot \frac{n}{1} = \lim_{n\to\infty} \frac{\ln n}{n}.$$

In order to evaluate $\lim_{n\to\infty} \ln n/n$, evaluate the limit as $x \to \infty$ of the real-valued function $\ln(x)/x$. These two limits are equal, and making this change allows us to use l'Hospital's Rule.[1] We obtain

$$\lim_{x\to\infty} \frac{\ln(x)}{x} = \lim_{x\to\infty} \frac{1}{x} = 0.$$

Therefore, $\lim_{n\to\infty} \frac{\ln n}{n} = 0$, and, consequently,

$$\lim_{n\to\infty} \frac{(\ln n)/n^2}{1/n} = 0.$$

Since the limit is 0 but $\sum_{n=1}^{\infty} \frac{1}{n}$ diverges, the Limit Comparison Test does not provide any information.

Compare with $\sum_{n=1}^{\infty} \frac{1}{n^2}$ instead. In this case,

$$\lim_{n\to\infty} \frac{(\ln n)/n^2}{1/n^2} = \lim_{n\to\infty} \frac{\ln n}{n^2} \cdot \frac{n^2}{1} = \lim_{n\to\infty} \ln n = \infty.$$

Since the limit is $\infty$ but $\sum_{n=1}^{\infty} \frac{1}{n^2}$ converges, the test still does not provide any information.

So now we try a series between the two we already tried. Choosing the series $\sum_{n=1}^{\infty} \frac{1}{n^{3/2}}$, we see that

$$\lim_{n\to\infty} \frac{(\ln n)/n^2}{1/n^{3/2}} = \lim_{n\to\infty} \frac{\ln n}{n^2} \cdot \frac{n^{3/2}}{1} = \lim_{n\to\infty} \frac{\ln n}{\sqrt{n}}.$$

As above, in order to evaluate $\lim_{n\to\infty} \frac{\ln n}{\sqrt{n}}$, evaluate the limit as $x \to \infty$ of the real-valued function $\frac{\ln n}{\sqrt{n}}$. Using l'Hospital's Rule,

$$\lim_{x\to\infty} \frac{\ln x}{\sqrt{x}} = \lim_{x\to\infty} \frac{2\sqrt{x}}{x} = \lim_{x\to\infty} \frac{2}{\sqrt{x}} = 0.$$

Since the limit is 0 and $\sum_{n=1}^{\infty} \frac{1}{n^{3/2}}$ converges, we can conclude that $\sum_{n=1}^{\infty} \frac{\ln n}{n^2}$ converges.

**? Checkpoint 8.5.2**

Use the Limit Comparison Test to determine whether the series $\sum_{n=1}^{\infty} \frac{5^n}{3^n + 2}$ converges or diverges.

**Answer**

The series diverges.

## Footnotes

[1] The move to considering the limit of the real-valued function $\ln(x)/x$ is purposeful and showcases the need for rigor in Calculus. l'Hospital's Rule is only defined for *continuous* functions - not discontinuous functions like sequences. As such, we could not use l'Hospital's Rule on $\lim_{n\to\infty} \ln(n)/n$.

## Key Concepts

- The Comparison Tests determine the convergence or divergence of series with positive terms.
- When using the Comparison Tests, a series $\sum_{n=1}^{\infty} a_n$ is often compared to a geometric or $p$-series.

## Glossary

**Comparison Test**

If $0 \le a_n \le b_n$ for all $n \ge N$ and $\sum_{n=1}^{\infty} b_n$ converges, then $\sum_{n=1}^{\infty} a_n$ converges; if $a_n \ge b_n \ge 0$ for all $n \ge N$ and $\sum_{n=1}^{\infty} b_n$ diverges, then $\sum_{n=1}^{\infty} a_n$ diverges.

**Limit Comparison Test**

Suppose $a_n, b_n \ge 0$ for all $n \ge 1$. If $\lim_{n\to\infty} a_n/b_n \to L \ne 0$, then $\sum_{n=1}^{\infty} a_n$ and $\sum_{n=1}^{\infty} b_n$ both converge or both diverge; if $\lim_{n\to\infty} a_n/b_n \to 0$ and $\sum_{n=1}^{\infty} b_n$ converges, then $\sum_{n=1}^{\infty} a_n$ converges. If $\lim_{n\to\infty} a_n/b_n \to \infty$, and $\sum_{n=1}^{\infty} b_n$ diverges, then $\sum_{n=1}^{\infty} a_n$ diverges.

# 8.5E: Exercises

**Use the Series Comparison Test to determine whether each series in exercises 1 - 13 converges or diverges.**

1) $\sum_{n=1}^{\infty} a_n$ where $a_n = \dfrac{2}{n(n+1)}$

2) $\sum_{n=1}^{\infty} a_n$ where $a_n = \dfrac{1}{n(n+1/2)}$

**Answer**

Converges by comparison with $\dfrac{1}{n^2}$.

3) $\sum_{n=1}^{\infty} \dfrac{1}{2(n+1)}$

4) $\sum_{n=1}^{\infty} \dfrac{1}{2n-1}$

**Answer**

Diverges by comparison with harmonic series, since $2n-1 \geq n$.

5) $\sum_{n=2}^{\infty} \dfrac{1}{(n \ln n)^2}$

6) $\sum_{n=1}^{\infty} \dfrac{n!}{(n+2)!}$

**Answer**

$a_n = 1/(n+1)(n+2) < 1/n^2$. Converges by comparison with $p$-series, $p = 2 > 1$.

7) $\sum_{n=1}^{\infty} \dfrac{1}{n!}$

8) $\sum_{n=1}^{\infty} \dfrac{\sin(1/n)}{n}$

**Answer**

$\sin(1/n) \leq 1/n$, so converges by comparison with $p$-series, $p = 2 > 1$.

9) $\sum_{n=1}^{\infty} \dfrac{\sin^2 n}{n^2}$

10) $\sum_{n=1}^{\infty} \dfrac{\sin(1/n)}{\sqrt{n}}$

**Answer**

$\sin(1/n) \leq 1$, so converges by comparison with $p$-series, $p = 3/2 > 1$.

11) $\sum_{n=1}^{\infty} \dfrac{n^{1.2}-1}{n^{2.3}+1}$

12) $\sum_{n=1}^{\infty} \dfrac{\sqrt{n+1}-\sqrt{n}}{n}$

**Answer**

Since $\sqrt{n+1}-\sqrt{n} = 1/(\sqrt{n+1}+\sqrt{n}) \leq 2/\sqrt{n}$, series converges by comparison with $p$-series for $p = 1.5 > 1$.

13) $\sum_{n=1}^{\infty} \dfrac{\sqrt[4]{n}}{\sqrt[3]{n^4+n^2}}$

**Use the Limit Comparison Test to determine whether each series in exercises 14 - 28 converges or diverges.**

14) $\sum_{n=1}^{\infty}\left(\frac{\ln n}{n}\right)^2$

**Answer**

Converges by limit comparison with $p$-series for $p>1$.

15) $\sum_{n=1}^{\infty}\left(\frac{\ln n}{n^{0.6}}\right)^2$

16) $\sum_{n=1}^{\infty}\frac{\ln\left(1+\frac{1}{n}\right)}{n}$

**Answer**

Converges by limit comparison with $p$-series, $p=2>1$.

17) $\sum_{n=1}^{\infty}\ln\left(1+\frac{1}{n^2}\right)$

18) $\sum_{n=1}^{\infty}\frac{1}{4^n-3^n}$

**Answer**

Converges by limit comparison with $4^{-n}$.

19) $\sum_{n=1}^{\infty}\frac{1}{n^2-n\sin n}$

20) $\sum_{n=1}^{\infty}\frac{1}{e^{(1.1)n}-3^n}$

**Answer**

Converges by limit comparison with $1/e^{1.1n}$.

21) $\sum_{n=1}^{\infty}\frac{1}{e^{(1.01)n}-3^n}$

22) $\sum_{n=1}^{\infty}\frac{1}{n^{1+1/n}}$

**Answer**

Diverges by limit comparison with harmonic series.

23) $\sum_{n=1}^{\infty}\frac{1}{2^{1+1/n}}n^{1+1/n}$

24) $\sum_{n=1}^{\infty}\left(\frac{1}{n}-\sin\left(\frac{1}{n}\right)\right)$

**Answer**

Converges by limit comparison with $p$-series, $p=3>1$.

25) $\sum_{n=1}^{\infty}\left(1-\cos\left(\frac{1}{n}\right)\right)$

26) $\sum_{n=1}^{\infty}\frac{1}{n}\left(\tan^{-1}n-\frac{\pi}{2}\right)$

**Answer**

Converges by limit comparison with $p$-series, $p=3>1$.

27) $\sum_{n=1}^{\infty}\left(1-\frac{1}{n}\right)^{n.n}$ (Hint: $\left(1-\frac{1}{n}\right)^{n}\to 1/e$.)

28) $\sum_{n=1}^{\infty}\left(1-e^{-1/n}\right)$ (Hint:$1/e\approx(1-1/n)^{n}$, so $1-e^{-1/n}\approx 1/n$.)

**Answer**

Diverges by limit comparison with $1/n$.

29) Does $\sum_{n=2}^{\infty}\frac{1}{(\ln n)^{p}}$ converge if $p$ is large enough? If so, for which $p$?

30) Does $\sum_{n=1}^{\infty}\left(\frac{\ln n}{n}\right)^{p}$ converge if $p$ is large enough? If so, for which $p$?

**Answer**

Converges for $p>1$ by comparison with a $p$ series for slightly smaller $p$.

31) For which $p$ does the series $\sum_{n=1}^{\infty}2^{pn}/3^{n}$ converge?

32) For which $p>0$ does the series $\sum_{n=1}^{\infty}\frac{n^{p}}{2^{n}}$ converge?

**Answer**

Converges for all $p>0$.

33) For which $r>0$ does the series $\sum_{n=1}^{\infty}\frac{r^{n^{2}}}{2^{n}}$ converge?

34) For which $r>0$ does the series $\sum_{n=1}^{\infty}\frac{2^{n}}{r^{n^{2}}}$ converge?

**Answer**

Converges for all $r>1$. If $r>1$ then $r^{n}>4$, say, once $n>\ln(2)/\ln(r)$ and then the series converges by limit comparison with a geometric series with ratio $1/2$.

35) Find all values of $p$ and $q$ such that $\sum_{n=1}^{\infty}\frac{n^{p}}{(n!)^{q}}$ converges.

36) Does $\sum_{n=1}^{\infty}\frac{\sin^{2}(nr/2)}{n}$ converge or diverge? Explain.

**Answer**

The numerator is equal to $1$ when $n$ is odd and $0$ when $n$ is even, so the series can be rewritten $\sum_{n=1}^{\infty}\frac{1}{2n+1}$, which diverges by limit comparison with the harmonic series.

37) Explain why, for each $n$, at least one of $|\sin n|,|\sin(n+1)|,\ldots,|\sin(n+6)|$ is larger than $1/2$. Use this relation to test convergence of $\sum_{n=1}^{\infty}\frac{|\sin n|}{\sqrt{n}}$.

38) Suppose that $a_n\geq 0$ and $b_n\geq 0$ and that $\sum_{n=1}^{\infty}a_n^{2}$ and $\sum_{n=1}^{\infty}b_n^{2}$ converge. Prove that $\sum_{n=1}^{\infty}a_nb_n$ converges and $\sum_{n=1}^{\infty}a_nb_n\leq\frac{1}{2}\left(\sum_{n=1}^{\infty}a_n^{2}+\sum_{n=1}^{\infty}b_n^{2}\right)$.

**Answer**

$(a-b)^{2}=a^{2}-2ab+b^{2}$ or $a^{2}+b^{2}\geq 2ab$, so convergence follows from comparison of $2a_nb_n$ with $a_n^{2}+b_n^{2}$. Since the partial sums on the left are bounded by those on the right, the inequality holds for the infinite series.

39) Does $\sum_{n=1}^{\infty} 2^{-\ln\ln n}$ converge? (Hint: Write $2^{\ln\ln n}$ as a power of $\ln n$.)

40) Does $\sum_{n=1}^{\infty} (\ln n)^{-\ln n}$ converge? (Hint: Use $t = e^{\ln(t)}$ to compare to a $p$–series.)

**Answer**

$(\ln n)^{-\ln n} = e^{-\ln(n)\ln\ln(n)}$. If $n$ is sufficiently large, then $\ln\ln n > 2$, so $(\ln n)^{-\ln n} < 1/n^2$, and the series converges by comparison to a $p$–series.

41) Does $\sum_{n=2}^{\infty} (\ln n)^{-\ln\ln n}$ converge? (Hint: Compare $a_n$ to $1/n$.)

42) Show that if $a_n \geq 0$ and $\sum_{n=1}^{\infty} a_n$ converges, then $\sum_{n=1}^{\infty} a_n^2$ converges. If $\sum_{n=1}^{\infty} a_n^2$ converges, does $\sum_{n=1}^{\infty} a_n$ necessarily converge?

**Answer**

$a_n \to 0$, so $a_n^2 \leq |a_n|$ for large $n$. Convergence follows from limit comparison. $\sum_{n=1}^{\infty} \frac{1}{n^2}$ converges, but $\sum_{n=1}^{\infty} \frac{1}{n}$ does not, so the fact that $\sum_{n=1}^{\infty} a_n^2$ converges does not imply that $\sum_{n=1}^{\infty} a_n$ converges.

43) Suppose that $a_n > 0$ for all $n$ and that $\sum_{n=1}^{\infty} a_n$ converges. Suppose that $b_n$ is an arbitrary sequence of zeros and ones. Does $\sum_{n=1}^{\infty} a_n b_n$ necessarily converge?

44) Suppose that $a_n > 0$ for all $n$ and that $\sum_{n=1}^{\infty} a_n$ diverges. Suppose that $b_n$ is an arbitrary sequence of zeros and ones with infinitely many terms equal to one. Does $\sum_{n=1}^{\infty} a_n b_n$ necessarily diverge?

**Answer**

No. $\sum_{n=1}^{\infty} 1/n$ diverges. Let $b_k = 0$ unless $k = n^2$ for some $n$. Then $\sum_k b_k/k = \sum 1/k^2$ converges.

45) Complete the details of the following argument: If $\sum_{n=1}^{\infty} \frac{1}{n}$ converges to a finite sum $s$, then $\frac{1}{2}s = \frac{1}{2} + \frac{1}{4} + \frac{1}{6} + \cdots$ and $s - \frac{1}{2}s = 1 + \frac{1}{3} + \frac{1}{5} + \cdots$. Why does this lead to a contradiction?

46) Show that if $a_n \geq 0$ and $\sum_{n=1}^{\infty} a_n^2$ converges, then $\sum_{n=1}^{\infty} \sin^2(a_n)$ converges.

47) Suppose that $a_n/b_n \to 0$ in the Limit Comparison Test, where $a_n \geq 0$ and $b_n \geq 0$. Prove that if $\sum b_n$ converges, then $\sum a_n$ converges.

48) Let $b_n$ be an infinite sequence of zeros and ones. What is the largest possible value of $x = \sum_{n=1}^{\infty} b_n/2^n$?

**Answer**

By the Limit Comparison Test, $x = \sum_{n=1}^{\infty} b_n/2^n \leq \sum_{n=1}^{\infty} 1/2^n = 1$.

49) Let $d_n$ be an infinite sequence of digits, meaning $d_n$ takes values in $\{0, 1, \ldots, 9\}$. What is the largest possible value of $x = \sum_{n=1}^{\infty} d_n/10^n$ that converges?

50) Explain why, if $x > 1/2$, then $x$ cannot be written $x = \sum_{n=2}^{\infty} \frac{b_n}{2^n}$ $(b_n = 0 \text{ or } 1,\ b_1 = 0)$.

**Answer**

If $b_1 = 0$, then, by comparison, $x \leq \sum_{n=2}^{\infty} 1/2^n = 1/2$.

51) [Technology Required] Evelyn has a perfect balancing scale, an unlimited number of 1-kg weights, and one each of $1/2$-kg, $1/4$-kg, $1/8$-kg, and so on weights. She wishes to weigh a meteorite of unspecified origin to arbitrary precision. Assuming the scale is big enough, can she do it? What does this have to do with infinite series?

52) [Technology Required] Robert wants to know his body mass to arbitrary precision. He has a big balancing scale that works perfectly, an unlimited collection of 1-kg weights, and nine each of 0.1-kg, 0.01-kg, 0.001-kg, and so on weights. Assuming the scale is big enough, can he do this? What does this have to do with infinite series?

**Answer**

Yes. Keep adding 1-kg weights until the balance tips to the side with the weights. If it balances perfectly, with Robert standing on the other side, stop. Otherwise, remove one of the 1-kg weights, and add 0.1-kg weights one at a time. If it balances after adding some of these, stop. Otherwise if it tips to the weights, remove the last 0.1-kg weight. Start adding 0.01-kg weights. If it balances, stop. If it tips to the side with the weights, remove the last 0.01-kg weight that was added. Continue in this way for the 0.001-kg weights, and so on. After a finite number of steps, one has a finite series of the form $A + \sum_{n=1}^{N} s_n/10^n$ where $A$ is the number of full kg weights and $d_n$ is the number of $1/10^n$-kg weights that were added. If at some state this series is Robert's exact weight, the process will stop. Otherwise it represents the $N^{\text{th}}$ partial sum of an infinite series that gives Robert's exact weight, and the error of this sum is at most $1/10^N$.

53) The series $\sum_{n=1}^{\infty} \frac{1}{2n}$ is half the harmonic series and hence diverges. It is obtained from the harmonic series by deleting all terms in which $n$ is odd. Let $m > 1$ be fixed. Show, more generally, that deleting all terms $1/n$ where $n = mk$ for some integer $k$ also results in a divergent series.

54) In view of the previous exercise, it may be surprising that a subseries of the harmonic series in which about one in every five terms is deleted might converge. A depleted harmonic series is a series obtained from $\sum_{n=1}^{\infty} \frac{1}{n}$ by removing any term $1/n$ if a given digit, say 9, appears in the decimal expansion of $n$. Argue that this depleted harmonic series converges by answering the following questions.

a. How many whole numbers $n$ have $d$ digits?

b. How many $d$-digit whole numbers $h(d)$. do not contain 9 as one or more of their digits?

c. What is the smallest $d$-digit number $m(d)$?

d. Explain why the deleted harmonic series is bounded by $\sum_{d=1}^{\infty} \frac{h(d)}{m(d)}$.

e. Show that $\sum_{d=1}^{\infty} \frac{h(d)}{m(d)}$ converges.

**Answer**

a. $10^d - 10^{d-1} < 10^d$

b. $h(d) < 9^d$

c. $m(d) = 10^{d-1} + 1$

d. Group the terms in the deleted harmonic series together by number of digits. $h(d)$ bounds the number of terms, and each term is at most $\frac{1}{m(d)}$.

Then $\sum_{d=1}^{\infty} h(d)/m(d) \leq \sum_{d=1}^{\infty} 9^d/(10)^{d-1} \leq 90$. One can actually use comparison to estimate the value to smaller than 80. The actual value is smaller than 23.

55) Suppose that a sequence of numbers $a_n > 0$ has the property that $a_1 = 1$ and $a_{n+1} = \frac{1}{n+1} S_n$, where $S_n = a_1 + \cdots + a_n$. Can you determine whether $\sum_{n=1}^{\infty} a_n$ converges? (Hint: $S_n$ is monotone.)

56) Suppose that a sequence of numbers $a_n > 0$ has the property that $a_1 = 1$ and $a_{n+1} = \frac{1}{(n+1)^2} S_n$, where $S_n = a_1 + \cdots + a_n$. Can you determine whether $\sum_{n=1}^{\infty} a_n$ converges? (Hint: $S_2 = a_2 + a_1 = a_2 + S_1 = a_2 + 1 = 1 + 1/4 = (1 + 1/4)S_1, S_3 = \frac{1}{3^2} S_2 + S_2 = (1 + 1/9)S_2 = (1 + 1/9)(1 + 1/4)S_1$, etc. Look at $\ln(S_n)$, and use $\ln(1 + t) \leq t, t > 0$.)

**Answer**

Continuing the hint gives $S_N = (1 + 1/N^2)(1 + 1/(N-1)^2 \ldots (1 + 1/4))$. Then $\ln(S_N) = \ln(1 + 1/N^2) + \ln(1 + 1/(N-1)^2) + \cdots + \ln(1 + 1/4)$. Since $\ln(1 + t)$ is bounded by a constant times $t$, when $0 < t < 1$ one has $\ln(S_N) \leq C \sum_{n=1}^{N} \frac{1}{n^2}$, which converges by comparison to the $p$-series for $p = 2$.

# 8.6: The Alternating Series Test

**Learning Objectives**

- Use the Alternating Series Test to test an alternating series for convergence.
- Estimate the sum of an alternating series.
- Explain the meaning of absolute convergence and conditional convergence.

So far in this chapter, we have primarily discussed series with positive terms. In this section, we introduce alternating series, which are series whose terms alternate in sign. We will show in a later chapter that these series often arise when studying **power series**. After defining alternating series, we introduce the Alternating Series Test to determine whether such a series converges.

## The Alternating Series Test

A series whose terms alternate between positive and negative values is an **alternating series.** For example, the series

$$\sum_{n=1}^{\infty}\left(-\frac{1}{2}\right)^n = -\frac{1}{2}+\frac{1}{4}-\frac{1}{8}+\frac{1}{16}-... \tag{8.6.1}$$

and

$$\sum_{n=1}^{\infty}\frac{(-1)^{n+1}}{n} = 1-\frac{1}{2}+\frac{1}{3}-\frac{1}{4}+... \tag{8.6.2}$$

are both alternating series.

**Definition: Alternating Series**

Any series whose terms alternate between positive and negative values is called an **alternating series**. An alternating series can be written in the form

$$\sum_{n=1}^{\infty}(-1)^{n+1}b_n = b_1-b_2+b_3-b_4+... \tag{8.6.3}$$

or

$$\sum_{n-1}^{\infty}(-1)^{n}b_n = -b_1+b_2-b_3+b_4-... \tag{8.6.4}$$

Where $b_n \geq 0$ for all $n \in \mathbb{N}$.

The series shown in Equation 8.6.1 is a geometric series. Since $|r| = |-\frac{1}{2}| < 1$, the series converges. The series shown in Equation 8.6.2 is called the **alternating harmonic series**. Whereas the harmonic series diverges, the alternating harmonic series converges.

**Theorem: Convergence of the Alternating Harmonic Series**

The alternating harmonic series

$$\sum_{n=1}^{\infty}\frac{(-1)^{n+1}}{n} = 1-\frac{1}{2}+\frac{1}{3}-\frac{1}{4}+...$$

converges.

**Proof**

Consider the odd terms $S_{2k+1}$ for $k \geq 0$. Since $\frac{1}{2k+1} < \frac{1}{2k}$,

$$S_{2k+1} = S_{2k-1}-\frac{1}{2k}+\frac{1}{2k+1} < S_{2k-1}.$$

Therefore, $\{S_{2k+1}\}$ is a decreasing sequence. Also,

$$S_{2k+1} = \left(1 - \frac{1}{2}\right) + \left(\frac{1}{3} - \frac{1}{4}\right) + \ldots + \left(\frac{1}{2k-1} - \frac{1}{2k}\right) + \frac{1}{2k+1} > 0.$$

Therefore, $\{S_{2k+1}\}$ is bounded below. Since $\{S_{2k+1}\}$ is a decreasing sequence that is bounded below, by the Monotone Convergence Theorem $\{S_{2k+1}\}$ converges. Similarly, the even terms $\{S_{2k}\}$ form an increasing sequence that is bounded above because

$$S_{2k} = S_{2k-2} + \frac{1}{2k-1} - \frac{1}{2k} > S_{2k-2}$$

and

$$S_{2k} = 1 + \left(-\frac{1}{2} + \frac{1}{3}\right) + \ldots + \left(-\frac{1}{2k-2} + \frac{1}{2k-1}\right) - \frac{1}{2k} < 1.$$

Therefore, by the Monotone Convergence Theorem the sequence $\{S_{2k}\}$ also converges. Since

$$S_{2k+1} = S_{2k} + \frac{1}{2k+1},$$

we know that

$$\lim_{k\to\infty} S_{2k+1} = \lim_{k\to\infty} S_{2k} + \lim_{k\to\infty} \frac{1}{2k+1}.$$

Letting $S = \lim_{k\to\infty} S_{2k+1}$ and using the fact that $\frac{1}{2k+1} \to 0$, we conclude that $\lim_{k\to\infty} S_{2k} = S$. Since the odd and even terms in the sequence of partial sums converge to the same limit $S$, it can be shown that the sequence of partial sums converges to $S$. Therefore, the alternating harmonic series converges to $S$.

It can also be shown that the value of the alternating harmonic series is $S = \ln 2$.

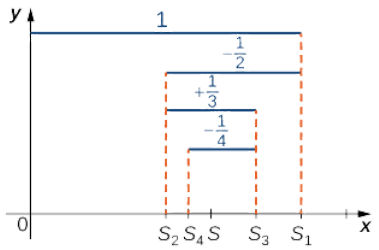

Figure 8.6.1: For the alternating harmonic series, the odd terms $S_{2k+1}$ in the sequence of partial sums are decreasing and bounded below. The even terms $S_{2k}$ are increasing and bounded above.

More generally, any alternating series having the form of either Equation 8.6.3 or Equation 8.6.4 converges as long as $b_1 \geq b_2 \geq b_3 \geq \cdots$ and $b_n \to 0$ (see Figure 8.6.2). This is called the **Alternating Series Test**. The proof is similar to the proof for the alternating harmonic series.

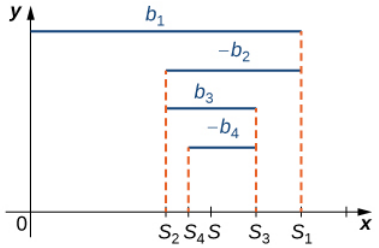

Figure 8.6.2: For an alternating series $b_1 - b_2 + b_3 - \cdots$ in which $b_1 > b_2 > b_3 > \cdots$, the odd terms $S_{2k+1}$ in the sequence of partial sums are decreasing and bounded below. The even terms $S_{2k}$ are increasing and bounded above.

**Theorem: Alternating Series Test**

An alternating series of the form

$$\sum_{n=1}^{\infty}(-1)^{n+1}b_n$$

or

$$\sum_{n=1}^{\infty}(-1)^{n}b_n$$

converges if

i. $0 \le b_{n+1} \le b_n$ for all $n \ge 1$ and
ii. $\lim\limits_{n\to\infty} b_n = 0$.

This theorem is true more generally as long as there exists some $N \in \mathbb{N}$ such that $0 \le b_{n+1} \le b_n$ for all $n \ge N$.

**Example 8.6.1: Convergence of Alternating Series**

For each alternating series, determine whether the series converges or diverges.

a. $\sum\limits_{n=1}^{\infty}\dfrac{(-1)^{n+1}}{n^2}$
b. $\sum\limits_{n=1}^{\infty}(-1)^{n+1}\dfrac{n}{n+1}$

**Solutions**

a. Since $\frac{1}{(n+1)^2} < \frac{1}{n^2}$ and $\frac{1}{n^2} \to 0$, the series converges.
b. Since $\frac{n}{n+1}$ does not approach $0$ as $n \to \infty$, we cannot apply the Alternating Series Test. Instead, we use the Divergence Test. Since $\lim\limits_{n\to\infty}\dfrac{n}{n+1} = 1 \neq 0$, the series diverges.

**Checkpoint 8.6.1**

Determine whether the series $\sum\limits_{n=1}^{\infty}(-1)^{n+1}\dfrac{n}{2^n}$ converges or diverges.

**Answer**

The series converges.

## Remainder of an Alternating Series

It is difficult to explicitly calculate the sum of most alternating series, so typically, the sum is approximated using a partial sum. When doing so, we are interested in the amount of error in our approximation.

**Theorem: Remainder Estimate from the Alternating Series Test**

Consider an alternating series of the form

$$\sum_{n=1}^{\infty}(-1)^{n+1}b_n$$

or

$$\sum_{n=1}^{\infty}(-1)^{n}b_n$$

that satisfies the hypotheses of the Alternating Series Test. Let $S$ denote the sum of the series and $S_N$ denote the $N^{\text{th}}$ partial sum. For any $N \in \mathbb{N}$, the remainder $R_N = S - S_N$ satisfies

$$|R_N| \leq b_{N+1}.$$

**Visual Justification**

A visualization of the proof can be found in Figure 8.6.2. For example, $|R_2| = |S - S_2|$; however, the distance between $S$ and $S_2$ can easily be seen to be less than $b_3$.

In other words, if the conditions of the Alternating Series Test apply, then the error in approximating the infinite series by the $N^{\text{th}}$ partial sum $S_N$ is (in magnitude) at most the size of the next term $b_{N+1}$.

### Example 8.6.2: Estimating the Remainder of an Alternating Series

Consider the alternating series

$$\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^2}.$$

Use the remainder estimate to determine a bound on the error $R_{10}$ if we approximate the sum of the series by the partial sum $S_{10}$.

**Solution**

From the theorem stated above,

$$|R_{10}| \leq b_{11} = \frac{1}{11^2} \approx 0.008265.$$

### Checkpoint 8.6.2

Find a bound for $R_{20}$ when approximating $\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n}$ by $S_{20}$.

**Answer**

0.04762

## Absolute and Conditional Convergence

Consider a series $\sum_{n=1}^{\infty} a_n$ and the related series $\sum_{n=1}^{\infty} |a_n|$. Here, we discuss possibilities for the relationship between the convergence of these two series. For example, consider the alternating harmonic series $\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n}$. The series whose terms are the absolute value of these terms is the harmonic series, since $\sum_{n=1}^{\infty} \left| \frac{(-1)^{n+1}}{n} \right| = \sum_{n=1}^{\infty} \frac{1}{n}$. Since the alternating harmonic series converges, but the harmonic series diverges, we say the alternating harmonic series exhibits **conditional convergence**.

By comparison, consider the series $\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^2}$. The series whose terms are the absolute values of the terms of this series is the series $\sum_{n=1}^{\infty} \frac{1}{n^2}$. Since both of these series converge, we say the series $\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^2}$ exhibits **absolute convergence**.

### Definition: Absolute Convergence and Conditional Convergence

A series $\sum_{n=1}^{\infty} a_n$ exhibits **absolute convergence** if $\sum_{n=1}^{\infty} |a_n|$ converges. A series $\sum_{n=1}^{\infty} a_n$ exhibits **conditional convergence** if $\sum_{n=1}^{\infty} a_n$ converges but $\sum_{n=1}^{\infty} |a_n|$ diverges.

As shown by the alternating harmonic series, a series $\sum_{n=1}^{\infty} a_n$ may converge, but $\sum_{n=1}^{\infty} |a_n|$ may diverge. In the following theorem, however, we show that if $\sum_{n=1}^{\infty} |a_n|$ converges, then $\sum_{n=1}^{\infty} a_n$ converges.

### Theorem: Absolute Convergence Implies Convergence

If $\sum_{n=1}^{\infty} |a_n|$ converges, then $\sum_{n=1}^{\infty} a_n$ converges.

**Proof**

Suppose that $\sum_{n=1}^{\infty} |a_n|$ converges. We know that $a_n = |a_n|$ or $a_n = -|a_n|$. Therefore $|a_n| + a_n = 2|a_n|$ or $|a_n| + a_n = 0$. Hence, $0 \le |a_n| + a_n \le 2|a_n|$. Consequently, by the Series Comparison Test, since $2\sum_{n=1}^{\infty} |a_n|$ converges, the series

$$\sum_{n=1}^{\infty} (|a_n| + a_n)$$

converges. By using the Algebraic Properties for Convergent Series, we conclude that

$$\sum_{n=1}^{\infty} a_n = \sum_{n=1}^{\infty} (|a_n| + a_n) - \sum_{n=1}^{\infty} |a_n|$$

converges.

### Example 8.6.3: Absolute versus Conditional Convergence

For each of the following series, determine whether the series converges absolutely, converges conditionally, or diverges.

a. $\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{3n+1}$

b. $\sum_{n=1}^{\infty} \frac{\cos(n)}{n^2}$

**Solutions**

a. We can see that

$$\sum_{n=1}^{\infty} \left| \frac{(-1)^{n+1}}{3n+1} \right| = \sum_{n=1}^{\infty} \frac{1}{3n+1}$$

diverges by using the Limit Comparison Test with the harmonic series. In fact,

$$\lim_{n\to\infty} \frac{1/(3n+1)}{1/n} = \frac{1}{3}.$$

Therefore, the series does not converge absolutely. However, since

$$3(n+1)+1 > 3n+1 \implies \frac{1}{3(n+1)+1} < \frac{1}{3n+1}, \text{ and } \frac{1}{3n+1} \to 0,$$

the series converges. We can conclude that $\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{3n+1}$ converges conditionally.

b. Noting that $|\cos n| \le 1$, to determine whether the series converges absolutely, compare

$$\sum_{n=1}^{\infty} \left| \frac{\cos n}{n^2} \right|$$

with the series $\sum_{n=1}^{\infty} \frac{1}{n^2}$. Since $\sum_{n=1}^{\infty} \frac{1}{n^2}$ converges, by the Series Comparison Test, $\sum_{n=1}^{\infty} \left| \frac{\cos n}{n^2} \right|$ converges, and therefore $\sum_{n=1}^{\infty} \frac{\cos n}{n^2}$ converges absolutely.

**? Checkpoint 8.6.3**

Determine whether the series $\sum_{n=1}^{\infty} (-1)^{n+1} \frac{n}{2n^3+1}$ converges absolutely, converges conditionally, or diverges.

**Answer**

The series converges absolutely.

To see the difference between absolute and conditional convergence, look at what happens when we *rearrange* the terms of the alternating harmonic series $\sum_{n=1}^{\infty} (-1)^{n+1} \frac{1}{n}$. We show that we can rearrange the terms so the new series diverges. Certainly, if we rearrange the terms of a finite sum, the sum will not change. However, exciting things can happen when we work with an infinite sum.

Begin by adding enough positive terms to produce a sum larger than some real number $M$. For example, let $M = 10$, and find an integer $k$ such that

$$1 + \frac{1}{3} + \frac{1}{5} + \cdots + \frac{1}{2k-1} > 10.$$

(We can do this because the series $\sum_{n=1}^{\infty} \frac{1}{2n-1}$ diverges to infinity.) Now subtract $1/2$. Then, add more positive terms until the sum reaches $100$. That is, find another integer $j > k$ such that

$$(1 + \frac{1}{3} + \cdots + \frac{1}{2k-1} - \frac{1}{2} + \frac{1}{2k+1} + \cdots + \frac{1}{2j+1} > 100.$$

After we find this value of $j$, subtract $1/4$ from the summation. Continuing in this way, we have found a way of rearranging the terms in the alternating harmonic series so that the sequence of partial sums for the rearranged series is unbounded and, therefore, diverges. That is,

$$\overbrace{\overbrace{1 + \frac{1}{3} + \frac{1}{5} + \cdots + \frac{1}{2k-1}}^{\text{slightly less than 10}} - \frac{1}{2} + \frac{1}{2k+1} + \cdots + \frac{1}{2j+1}}^{\text{slightly less than 100}} + \cdots$$

grows without bound.

The terms in the alternating harmonic series can also be rearranged so that the new series converges to a different value. In Example 8.6.4, we show how to rearrange the terms to create a new series that converges to $3\ln(2)/2$. We point out that the alternating harmonic series can be rearranged to create a series that converges to any real number $r$; however, the proof of that fact is beyond the scope of this text.

In general, any series $\sum_{n=1}^{\infty} a_n$ that converges conditionally can be rearranged so that the new series diverges or converges to a different real number. A series that converges absolutely does not have this property. For any series $\sum_{n=1}^{\infty} a_n$ that converges absolutely, the value of $\sum_{n=1}^{\infty} a_n$ is the same for any rearrangement of the terms. This result is known as the **Riemann Rearrangement Theorem**, which (again) is beyond the scope of this book.

## Example 8.6.4: Rearranging Series

Use the fact that

$$1-\frac{1}{2}+\frac{1}{3}-\frac{1}{4}+\frac{1}{5}-\cdots=\ln 2$$

to rearrange the terms in the alternating harmonic series so the sum of the rearranged series is $3\ln(2)/2$.

**Solution**

Let

$$\sum_{n=1}^{\infty}a_n=1-\frac{1}{2}+\frac{1}{3}-\frac{1}{4}+\frac{1}{5}-\frac{1}{6}+\frac{1}{7}-\frac{1}{8}+\cdots.$$

Since $\sum_{n=1}^{\infty}a_n=\ln(2)$, by the Algebraic Properties of Convergent Series,

$$\begin{aligned}\sum_{n=1}^{\infty}\frac{1}{2}a_n &= \frac{1}{2}-\frac{1}{4}+\frac{1}{6}-\frac{1}{8}+\cdots\\ &= \frac{1}{2}\sum_{n=1}^{\infty}a_n\\ &= \frac{\ln 2}{2}.\end{aligned}$$

Now introduce the series $\sum_{n=1}^{\infty}b_n$ such that for all $n\geq 1$, $b_{2n-1}=0$ and $b_{2n}=a_n/2$. Then

$$\sum_{n=1}^{\infty}b_n=0+\frac{1}{2}+0-\frac{1}{4}+0+\frac{1}{6}+0-\frac{1}{8}+\cdots=\frac{\ln 2}{2}.$$

Then using the Algebraic Properties of Convergent Series, since $\sum_{n=1}^{\infty}a_n$ and $\sum_{n=1}^{\infty}b_n$ converge, the series $\sum_{n=1}^{\infty}(a_n+b_n)$ converges and

$$\sum_{n=1}^{\infty}(a_n+b_n)=\sum_{n=1}^{\infty}a_n+\sum_{n=1}^{\infty}b_n=\ln 2+\frac{\ln 2}{2}=\frac{3\ln 2}{2}.$$

Now adding the corresponding terms, $a_n$ and $b_n$, we see that

$$\begin{aligned}\sum_{n=1}^{\infty}(a_n+b_n) &= (1+0)+\left(-\frac{1}{2}+\frac{1}{2}\right)+\left(\frac{1}{3}+0\right)+\left(-\frac{1}{4}-\frac{1}{4}\right)+\\ &\quad \left(\frac{1}{5}+0\right)+\left(-\frac{1}{6}+\frac{1}{6}\right)+\left(\frac{1}{7}+0\right)+\left(\frac{1}{8}-\frac{1}{8}\right)+\cdots\\ &= 1+\frac{1}{3}-\frac{1}{2}+\frac{1}{5}+\frac{1}{7}-\frac{1}{4}+\cdots.\end{aligned}$$

We notice that the series on the right side of the equal sign is a rearrangement of the alternating harmonic series. Since $\sum_{n=1}^{\infty}(a_n+b_n)=3\ln(2)/2$, we conclude that

$$1+\frac{1}{3}-\frac{1}{2}+\frac{1}{5}+\frac{1}{7}-\frac{1}{4}+\cdots=\frac{3\ln(2)}{2}.$$

Therefore, we have found a rearrangement of the alternating harmonic series having the desired property.

## Media

**Videos**

- Proof of the Alternating Series Test

## Key Concepts

- For an alternating series $\sum_{n=1}^{\infty}(-1)^{n+1}b_n$, if $b_{k+1} \leq b_k$ for all $k$ and $b_k \to 0$ as $k \to \infty$, the alternating series converges.
- If $\sum_{n=1}^{\infty}|a_n|$ converges, then $\sum_{n=1}^{\infty}a_n$ converges.

## Key Equations

- **Alternating series**

$$\sum_{n=1}^{\infty}(-1)^{n+1}b_n = b_1 - b_2 + b_3 - b_4 + \cdots \text{ or}$$

$$\sum_{n=1}^{\infty}(-1)^{n}b_n = -b_1 + b_2 - b_3 + b_4 - \cdots$$

## Glossary

**absolute convergence**

if the series $\sum_{n=1}^{\infty}|a_n|$ converges, the series $\sum_{n=1}^{\infty}a_n$ is said to converge absolutely

**alternating series**

a series of the form $\sum_{n=1}^{\infty}(-1)^{n+1}b_n$ or $\sum_{n=1}^{\infty}(-1)^{n}b_n$, where $b_n \geq 0$, is called an alternating series

**Alternating Series Test**

for an alternating series of either form, if $b_{n+1} \leq b_n$ for all integers $n \geq 1$ and $b_n \to 0$, then an alternating series converges

**conditional convergence**

if the series $\sum_{n=1}^{\infty}a_n$ converges, but the series $\sum_{n=1}^{\infty}|a_n|$ diverges, the series $\sum_{n=1}^{\infty}a_n$ is said to converge conditionally

# 8.6E: Exercises

**In exercises 1 - 30, state whether each of the following series converges absolutely, conditionally, or not at all.**

1) $\sum_{n=1}^{\infty}(-1)^{n+1}\frac{n}{n+3}$

2) $\sum_{n=1}^{\infty}(-1)^{n+1}\frac{\sqrt{n}+1}{\sqrt{n}+3}$

**Answer**

This series diverges by the Divergence Test. Terms do not tend to zero.

3) $\sum_{n=1}^{\infty}(-1)^{n+1}\frac{1}{\sqrt{n+3}}$

4) $\sum_{n=1}^{\infty}(-1)^{n+1}\frac{\sqrt{n+3}}{n}$

**Answer**

Converges conditionally by alternating series test, since $\sqrt{n+3}/n$ is decreasing and its limit is 0. Does not converge absolutely by comparison with $p$-series, $p=1/2$.

5) $\sum_{n=1}^{\infty}(-1)^{n+1}\frac{1}{n!}$

6) $\sum_{n=1}^{\infty}(-1)^{n+1}\frac{3^n}{n!}$

**Answer**

Converges absolutely by limit comparison to $3^n/4^n$, for example.

7) $\sum_{n=1}^{\infty}(-1)^{n+1}\left(\frac{n-1}{n}\right)^n$

8) $\sum_{n=1}^{\infty}(-1)^{n+1}\left(\frac{n+1}{n}\right)^n$

**Answer**

Diverges by Divergence Test since $\lim_{n\to\infty}|a_n|=e$ and not $0$.

9) $\sum_{n=1}^{\infty}(-1)^{n+1}\sin^2 n$

10) $\sum_{n=1}^{\infty}(-1)^{n+1}\cos^2 n$

**Answer**

Diverges by the Divergence Test, since its terms do not tend to zero. The limit of the sequence of its terms does not exist.

11) $\sum_{n=1}^{\infty}(-1)^{n+1}\sin^2(1/n)$
